Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) is the only potential curative treatment option for patients with MCL due to its potent graft-versus-lymphoma (GVL) effect. Survival following allo-SCT for MCL is variable due to high rates of non-relapse mortality (NRM). **Methods:** We retrospectively identified all patients who were treated with an allo-SCT for MCL at Loyola University Medical Center between January 1, 1999 and January 1, 2016. Probability estimates for overall survival (OS) and non-relapse mortality (NRM) at 5 years were calculated from the date of allo-SCT to the date of patient death or last known follow-up. Significance was determined using a cox proportional hazard (CPH) model. Rates of acute graft-versus-host disease (aGVHD) and relapse were also reported. **Results:** Patient characteristics (n = 29) are listed in Table. Median follow-up in surviving patients is 10 years (range 5-14 years). A majority of patients (n = 23, 79%) had 3 or more lines of treatment prior to allo-SCT. The 5 year rates of OS and NRM for all patients are 42% and 53%, respectively. Univariate analysis showed a lower risk of death in patients who received TBI-based conditioning (HR: 0.19, 95 CI: 0.04 – 0.81, p = 0.03), and those who had HLA-matched related donor (MRD) transplants (HR: 0.29, 95 CI: 0.11 – 0.79, p = 0.02). Patients who received more than 3 lines of prior treatment had a higher risk of death (HR: 2.77, 95% CI: 1.05-7.34, p = 0.04). Low rates of grade III/IV aGVHD (n = 4) and relapse (n = 4) occurred in our patient population. Two patient deaths were attributable to aGVHD, and the majority of other deaths were due to treatment-related toxicities. **Conclusions:** In an era of numerous effective non-curative salvage therapies, the optimal timing of allo-SCT for MCL needs further clarification. Our data supports early opposed to delayed allo-SCT for select high-risk patients with MCL who have a MRD.

Patient characteristics (N = 29)

	N (%)

7559 Poster Session (Board #321), Mon, 8:00 AM-11:30 AM

***MYC/BCL2/BCL6* triple hit lymphoma: A study of 33 patients who had an aggressive clinical course similar to patients with double hit lymphomas.** *First Author: Shaoying Li, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Large B cell lymphomas with *MYC, BCL2*, and *BCL6* rearrangements, designated as triple hit lymphoma (THL), are uncommon. Large series studies of THL are scant and studies comparing THL to different types of double hit lymphoma (DHL) are lacking. **Methods:** We studied the clinicopathologic features and prognosis of 33 patients with THL and compared them to 83 patients with *MYC/BCL2* DHL and 13 patients with *MYC/BCL6*DHL. **Results:** There were 21 men and 12 women, with a median age of 63 years (range, 34-85). Six patients had a history of low-grade B cell lymphoma and 27 had *de novo* lymphoma. These tumors were classified histologically as: 21 DLBCL, 10 high grade B-cell lymphoma, one concurrent DLBCL and follicular lymphoma (FL), and one concurrent DLBCL and mantle cell lymphoma. Immunohistochemical analysis showed that these tumors were positive for CD10 (94%), BCL6 (80%), BCL2 (93%), and MYC (69%, 40% as cutoff). 62% of tumors (8/13) with available data showed coexpression of MYC and BCL2. Using the Hans algorithm, 30 of 33 (91%) tumors had a germinal center B cell like (GCB) immunophenotype. All 7 cases tested by conventional cytogenetics showed a complex karyotype. Although *BCL2* was always translocated with IGH, *BCL6* translocated to *MYC* in 2of 7 cases of THL. Twenty-nine patients had treatment information available and all received immune-chemotherapy induction, including 11 with R-CHOP, 14 with R-EPOCH, 3 with R-HyperCVAD, and one with RICE (patient had a history of FL). The clinicopathological features of THL including induction chemotherapy were very similar to both the *MYC/BCL2* DHL and *MYC/BCL6* DHL (all P>0.05). There was no significant difference in median overall survival (OS) between patients with de novo lymphoma and those with a history of low-grade lymphoma (P=0.99). The OS in THL patients was 17.9 months, similar to the OS (17.2 months) of patients with *MYC/BCL6* DHL and those with *MYC/BCL2*DHL (19.9 months) (P=0.60). **Conclusions:** *MYC/BCL2/BCL6* THL is an aggressive B cell lymphoma and >90% of cases have a GCB immunophenotype. THL patients usually have an aggressive clinical course and a poor prognosis, similar to patients with double hit lymphomas.

7560 Poster Session (Board #322), Mon, 8:00 AM-11:30 AM

The outcome of high-grade B-cell lymphoma with *MYC* and *BCL2* and/or *BCL6* rearrangements or NOS compared to DLBCL patients from a single institution. *First Author: Joanna Romejko-Jarosinska, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

Background: 2016 update of the WHO 2008 classification of lymphoid neoplasms introduced new categories of highly aggressive B lymphomas (BCL): high grade B lymphoma (HGBL) with *MYC* and *BCL2* and/or *BCL6* rearrangements (HGBLR) and HGBL not otherwise specified (NOS). The prognosis for HGBL is generally considered poor, the optimal therapy is unknown. Here we evaluated outcome after first line treatment in patients with a diagnosis of HGBLR, HGBL, NOS, and DLBCL at our institution. **Methods:** Medical records of 591 consecutive patients with aggressive BCL were evaluated, archived pathology reports and samples were reviewed, diagnosis revised if necessary according to 2016 update of WHO classification. We identified 16 cases of HGBLR (3%), 26 cases of HGBL, NOS (4%), and 565 cases of DLBCL (93%). Response to first line therapy, progression free survival (PFS), and overall survival (OS) were calculated and compared between these three entities. **Results:** DLBCL patients were treated with RCHOP between 2005-2012, HGBL patients were treated between 2005-2016 with RDAEPOCH (n = 31, 5%), RCHOP or other regimens. For the first line treatment in patients with DLBCL, HGBLR and HGBL NOS, the overall response/complete response rate was 92%/75%, 81%/56%, 93%/65%, respectively (p = NS). After a median (range) follow up of 42(1-155) months, median PFS and OS for DLBCL was not reached. For both HGBLR and HGLB, NOS patients median PFS was 10 months, median OS was 16 months. The HR for risk of progression in patients with HGBLR vs DLBCL and HGBL NOS vs DLBCL was 2.4 (1.1-4.7), p = 0.01 and 2.0 (1.1-3.5), p = 0.01. The HR for risk of death, for HGBLR vs DLBCL and HGLB NOS vs DLBCL was 2.59(1.32-5.07), $p < 0.01$ and 1.8(0.9-3.3), p = 0.08. The risk of progression and the risk of death in HGBLR vs HGBL, NOS was similar, for PFS: 1.08 (0.46- 2.5), p = NS for OS: 1.2 (0.5 -3,1) p = NS. **Conclusions:** Our data confirms reports by others on poor prognosis for patients with a diagnosis of HGBL with *MYC* and *BCL2* and/or *BCL6* rearrangements as well as HGBL, NOS with an increased risk of death and risk of progression compared to DLBCL patients. There was no difference in outcome between HGBL-R and HGBL, NOS patients in our series.

7561 Poster Session (Board #323), Mon, 8:00 AM-11:30 AM

Development of a clinical trial immunohistochemistry (IHC) assay using a novel antibody to CD38. *First Author: Karen Wakamiya, Agilent Technologies, Carpinteria, CA*

Background: CD38 is a type II transmembrane glycoprotein expressed on normal lymphoid and myeloid cells and can be highly expressed in hematologic malignancies. An IHC prototype assay was developed to detect CD38 expression in formalin-fixed, paraffin-embedded (FFPE) tissue specimens from three relapsed or refractory non-Hodgkin's lymphoma (NHL) subtypes: diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL) and mantle cell lymphoma (MCL) for selection of patients for treatment with daratumumab in a Phase 2 clinical trial (NCT02413489). **Methods:** This assay is based on EnVision FLEX IHC technology using CD38, clone DAK-CD38, primary antibody that has been developed and manufactured by Agilent Technologies. The assay staining protocol was developed for Dako PT Link and Autostainer Link 48. Specificity of DAK-CD38 staining was demonstrated by Western blot analysis of cancer cell lysates, as well as IHC on both normal and cancer tissue. Assay precision and robustness were evaluated using commercially procured FFPE DLBCL, FL and MCL specimens. **Results:** CD38 IHC DAK-CD38 detected a broad range of CD38 expression in DLBCL, FL, and MCL specimens. FFPE specimens derived from cancer cell lines exhibited a range of IHC staining intensity and confirmed the reported expression of CD38 in the scientific literature. All precision and robustness results met acceptance criteria for both IHC intensity and percent positive cells staining. **Conclusions:** Our studies demonstrate that the Dako CD38 IHC DAK-CD38 assay is sensitive, specific, precise, and robust for the detection of CD38 expression in DLBCL, FL and MCL. This assay may also have the potential to be used for the detection of CD38 in additional tumor types.

7562 Poster Session (Board #324), Mon, 8:00 AM-11:30 AM

Patterns of use of CNS prophylaxis in DLBCL in a large health system. *First Author: Michael A. Thompson, Aurora Advanced Healthcare, Milwaukee, WI*

Background: Diffuse large B-cell lymphoma (DLBCL) patients (pts) with risk factors based on the R-IPI (Sehn et al. 2007 http://ow.ly/k4Xu308hsBM) and CNS IPI (Schmitz et al. 2016http://ow.ly/dZIb301YyQ4) may relapse in the central nervous system (CNS). NCCN Guidelines (v2.2016) rec lumbar puncture (LP) if 4-6 risk factors present or HIV, testicular, breast, or double expresser and notes optimal management is uncertain. We wished to evaluate the use of CNS px in a large community health system. **Methods:** The Aurora Health Care cancer registry was searched for DLBCL from 1/1/16 to 12/31/16. Pts with CNS px were selected for more detailed analysis for stage, Myc, R-IPI, CNS IPI and cost of px. CNS px was categorized as: 1) intravenous (IV) high dose methotrexate (HD MTX), 2) IT chemo via Ommaya, or 3) IT via LP. Outcomes were CNS px utilization, survival, and costs. **Results:** 146 DLBCL pts were treated (5 R-CHOP, 2 DA-R-EPOCH). CNS px was given in 7/146 (4.8%). Pts were 5 males, 2 females. Median age was 58, (range: 38-76). Median R-IPI was 2.4 (range: 0-5). Median CNS IPI was 2.7 (range: 0-5). HD MTX was used in 3 pts. IT was used in 4 pts, with 0 by Ommaya and 4 by LP. Except for one death, there was no CNS or other recurrences yet. Costs per cycle were (drug + administration): 1) HD MTX: $587+ 3166 (hospitalization and leucovorin) = $3753, 2) IT Ommaya: $20 + 921 = $941 (not including Ommaya surgery), 3) IT LP: $20 + 2460 (includes interventional radiology) = $2480. **Conclusions:** CNS px rate was low across a range of stages and risk scores, which potentially reflects lack of recognition of risk as well as uncertainly about the value including utility (risk reduction) vs cost ($ and pt toxicity). Evaluating for improved utility is necessary, such as lenalidomide (a small molecule with CNS penetration) in R2CHOP (Ayed et al. 2016 http://ow.ly/6s5d308G4I4). If that 6 fold risk reduction holds, the value may be high for lenalidomide added to high risk CNS IPI DLBCL pts therapy.

Treatment	N	Stage	R-IPI	CNS IPI	MYC	Cost ($)/cycle
HD MTX	3	III or IV, IAE, IVAE	0, 2, 3	0, 3, 3	neg, neg, neg	3166
IT Ommaya	0	NA	NA	NA	NA	941
IT LP	4	IAE, IVAE, IIIAE, IVEB	1, 2, 4, 5	1, 2, 5, 5	pos, neg, pos, neg	2480
Lenalidomide 25mg d1-10 q21	0	NA	NA	NA	NA	4514

NA= not applicable

7563 Poster Session (Board #325), Mon, 8:00 AM-11:30 AM

Treatment patterns among elderly follicular lymphoma patients diagnosed between 2000 and 2011: An analysis of linked SEER-Medicare data. *First Author: Ebere Onukwugha, University of Maryland, Baltimore, MD*

Background: There are multiple treatment regimens approved for the management of follicular lymphoma (FL). However, there is limited information available to describe the course of therapy (COT) that patients receive following FL diagnosis. **Methods:** Using the linked Surveillance, Epidemiology, and End Results (SEER) registry & Medicare claims dataset, we analyzed patients 66 years and older diagnosed with FL from 2000 to 2011. In order to characterize FL treatments, we identified first, second and subsequent-lines of therapy listed in the National Comprehensive Cancer Network guidelines 2.2016. We identified the first COT (COT1) as the first regimen that a patient receives after diagnosis. We identified the second and third COT (COT2 and COT3) as new treatment received following/interrupting COT1 or COT2, respectively. Using visual analytics software, we investigated and reported the proportion of patients receiving each COT, the top three regimens within each COT, and the median time to starting a COT from diagnosis or end of a previous COT. **Results:** 10,836 FL patients were identified after applying the inclusion/exclusion criteria. Sixty-two percent (N=6,756) of the patients received FL-directed treatment. Among patients receiving COT1, 65% received COT2. Among patients receiving COT2, 79% received COT3. The table below provides additional information on the COT received. **Conclusions:** Analysis of real-world data indicates that almost 4 out of 10 elderly FL patients do not receive the listed FL-directed treatments. In contrast to rituximab, there was limited use of RCHOP and RCVP after COT1 during the study period. Additional research is needed to understand the differences across demographic groups and associated health outcomes.

Top 3 regimens	Proportion among each COT (%)	Median time to initiation from diagnosis or end of a previous regimen (days)
1st course	-	77
Rituximab	47%	95
RCHOP*	26%	57
RCVP**	19%	62
2nd course	-	77
Rituximab	50%	84
RCVP**	5%	36
RCHOP*	4%	45
3rd course	-	101
Rituximab	53%	103
RCHOP*	2%	59
RCVP**	2%	99

* RCHOP = rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone ** RCVP = rituximab, cyclophosphamide, vincristine, prednisone

7564 Poster Session (Board #326), Mon, 8:00 AM-11:30 AM

Phase 1 trial evaluating MRG-106, a synthetic inhibitor of microRNA-155, in patients with cutaneous t-cell lymphoma (CTCL). *First Author: Francine M. Foss, Yale Cancer Center, Woodbridge, CT*

Background: MRG-106 is an oligonucleotide inhibitor of miR-155, a microRNA with a strong mechanistic link to CTCL, selected based on its activity in mycosis fungoides (MF) cell lines. The objective of this first-in-human study is to evaluate the safety, tolerability, maximum tolerated dose (MTD), pharmacokinetics (PK), and preliminary efficacy of MRG-106 in MF patients. **Methods:** This Phase 1 trial employs a dose-escalation design to evaluate either intratumoral (IT, 75 mg/dose) or subcutaneous (SC, $\leq$ 900 mg/dose) administration of MRG-106. Patients were required to have biopsy-proven stage I-III MF and plaque- or tumor-stage lesions. **Results:** Fifteen patients (12M/3F, median age 59 years) have been dosed over 1-4 weeks. All patients tolerated the IT or SC administrations well with only minor local injection reactions in 8 patients. Thirteen of 15 patients completed dosing as scheduled. There were no clinically significant MRG-106 related adverse events with the exception of one grade 3 pruritus. The MTD has not yet been reached. In the IT cohort, a reduction of $\geq$50% in the baseline Composite Assessment of Index Lesion Severity (CAILS) score was observed in the MRG-106 treated lesions in all 4 evaluable patients who completed dosing; such responses were maintained to the End of Study visit (Day 28 or 35). Histological examination of pre- and post-treatment biopsies of the MRG-106-injected lesion from most patients revealed a trend in reduction in neoplastic cell density and depth; 1 patient had a complete loss of the neoplastic infiltrate. Gene expression analysis of the pre- and post-treatment biopsies showed reduction of the PI3K/AKT, JAK/STAT, and NFkB survival pathways and increased cell death consistent with the expected MRG-106 mechanism of action. In the SC cohorts, 3/8 patients had a maximal decrease in their modified Severity-Weighted Assessment Tool (mSWAT) of $>$ 39% indicative of a significant response. One patient at the 900 mg SC dose level had a possible flare of their disease after 3 doses that resolved after 3 weeks. **Conclusions:** Based on favorable clinical safety, efficacy and PK data, additional patients are being accrued. Updated results will be presented as available. Clinical trial information: NCT02580552.

7565 Poster Session (Board #327), Mon, 8:00 AM-11:30 AM

Results of a phase II trial of efficacy and safety of entospletinib (ENTO) in patients with lymphoplasmacytoid lymphoma/Waldenstrom's macroglubulinemia (LPL/WM). *First Author: Sarit E. Assouline, Sir Mortimer B. Davis-Jewish General Hospital, Montreal, QC, Canada*

Background: ENTO is an orally bioavailable, selective inhibitor of spleen tyrosine kinase (Syk, a mediator of B-cell receptor [BCR] signaling). Targeting the BCR-signaling pathway has been a focus in B-cell related hematological malignancies including LPL/WM. **Methods:** This reports the LPL cohort in a phase 2 trial that more broadly evaluated efficacy and safety of ENTO (800 mg BID) in patients with relapsed and refractory (R/R) B-cell malignancies. Tumor response was assessed at weeks 8, 16, 24, and then every 12 weeks. The primary endpoint was PFS at week 24. **Results:** 17 LPL patients (median age 72 years [range: 47–89], 65% male, and median of 3 prior regimens [range: 1–8]) were enrolled. Prior therapies included anti-CD20 antibodies (100%), alkylating agents (71%; bendamustine 24%), purine analogues (24%), and vinca alkaloid (41%). No patient had prior ibrutinib. Median treatment duration was 16 weeks (range: 1-84), with 3 patients continuing on treatment. The most common treatment-emergent AEs (any grade/$\geq$grade 3, independent of causality) were fatigue (53%, 6%), constipation (47%, 0%), nausea (47%, 6%), diarrhea (29%, 6%), insomnia (29%, 0%) and lab abnormalities including neutropenia (53%, 12%), increased creatinine (53%, 0%), increased ALT (41%, 6%) and decreased WBC (41%, 6%). One death due to progressive disease (PD) was reported within 30 days from last dose. 12 (71%) patients were evaluable for tumor response. 5 patients (29%) discontinued prior to initial tumor assessment: PD (n = 2), withdrawal consent (n = 2) and AE (n = 1). ORR was 24% (90% CI: 9%, 46%), with 1 (6%) patient achieving PR, 3 with minor response (18%) and 7 (41%) maintaining stable disease. Reductions of IgM from baseline were greatest in the patient with PR. PFS rate at week 24 was 82% (95% CI: 44%, 95%). Median time to treatment failure and median time to response were 3.7m and 1.9 m respectively. Median duration of response has not been reached. **Conclusions:** ENTO was well tolerated and demonstrated limited activity in patients with R/R LPL. Further development of ENTO in LPL will focus on its role in combination therapies. Clinical trial information: NCT01799889.

TPS7566 Poster Session (Board #328a), Mon, 8:00 AM-11:30 AM

Ironclad: A randomized phase III study of ibrutinib (Ibr) or no consolidation following autologous hematopoietic stem cell transplantation (AutoHCT) for relapsed/refractory activated-B-cell (ABC) subtype diffuse large B-cell lymphoma (DLBCL). *First Author: Charalambos Andreadis, University of California, San Francisco, San Francisco, CA*

Background: Relapsed DLBCL in the rituximab era portends a poor prognosis with only about 25% of patients achieving long-term disease control following 2ndline therapy and AutoHCT. Patients with the ABC subtype have an inferior prognosis at diagnosis than those with GC and are overrepresented at relapse. In order to improve outcomes in ABC-DLBCL, we designed a study targeting disease pathobiology at the time of AutoHCT. Ibr has a safety profile allowing combination with cytotoxic chemotherapy and has single-agent activity with a 37% response rate in patients with relapsed/refractory ABC-DLBCL. **Methods:** This is an intergroup, randomized, placebo-controlled phase III study combining Ibr or placebo with high-dose chemotherapy during conditioning with AutoHCT and for 12 months following AutoHCT. Pts with relapsed or refractory DLBCL have tissue submitted centrally for real-time review and subtype assignment by GEP (Frederick Laboratory). Key eligibility criteria include no more than 3 prior regimens, no active CNS involvement, no need for long-term anticoagulation, and no progression on prior Ibr. Pts with chemosensitive ABC-DLBCL are randomized to Ibr 560 mg or placebo with BEAM or CBV chemotherapy until day 0. After engraftment, pts receive Ibr 560 mg daily or placebo for 12 additional cycles. Pts with progressive disease on placebo can cross over to Ibr monotherapy. An initial safety cohort of 6 pts is being enrolled to evaluate the tolerability of Ibr with concurrent BEAM and CBV therapy. The primary endpoint is superior 2-year PFS (Ha/H0: 67% vs 50%). Secondary endpoints include time to count recovery, post-transplant response rates, OS, PFS, and incidence of 2^{ary}malignancies. In correlative studies, we will assess the prognostic and predictive role of pre-transplant FDG-PET in the setting of Ibr or placebo therapy, the role of emergent BCR pathway mutations, double hit genetics, and pharmacogenetic determinants on treatment outcome and toxicities. We expect to accrue 296 patients over 4 years. An Alliance/BMT-CTN study: NCT02443077 Clinical trial information: NCT02443077.

TPS7567 Poster Session (Board #328b), Mon, 8:00 AM-11:30 AM

COSMOS: MOR208 plus idelalisib or venetoclax in patients with relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL) or small lymphocytic lymphoma (SLL) previously treated with a Bruton's tyrosine kinase inhibitor (BTKi)—A two-cohort phase II study. *First Author: Clemens-Martin Wendtner, Klinikum Schwabing, Department I of Medicine, Academic Teaching Hospital of University of Munich, Munich, Germany*

Background: Patients (pts) with R/R CLL who discontinue treatment with the BTKi ibrutinib due to progression have a particularly dismal prognosis. A phase I study showed that the Fc-enhanced, humanized, CD19 antibody MOR208 was well tolerated with encouraging single-agent activity in pts with R/R CLL/SLL. In preclinical models, MOR208 showed synergy with idelalisib (an inhibitor of PI3K delta) and venetoclax (an inhibitor of BCL-2), both approved for the treatment of CLL. **Methods:** This two-cohort, phase II study will investigate MOR208 combined with idelalisib (cohort A) or venetoclax (cohort B) in pts with R/R CLL or R/R SLL and includes a safety run-in phase for each cohort, to be evaluated by an Independent Data Monitoring Committee. Key inclusion criteria: aged $\geq$18 years, R/R CLL/SLL while receiving a BTKi therapy or intolerance of such therapy, BTKi administered as a single-agent or in combination for at least 1 month as the most recent prior anticancer therapy, ECOG performance status of 0–2, and adequate organ function. Key exclusion criteria: transformed CLL/SLL or Richter's syndrome, BTKi treatment within 5 days prior to study drug dosing, prior treatment with a CD19-targeted therapy, a PI3K inhibitor (cohort A) or a BCL-2 inhibitor (cohort B). Pts will be treated for a maximum of 24 (28-day) cycles or until disease progression. Treatment will be MOR208 12 mg/kg IV (weekly for the first 3 months, every second week for the next 3 months, and monthly thereafter) in combination with oral idelalisib 150 mg twice-daily or venetoclax administered on a weekly ramp-up dosing schedule to the recommended daily dose of 400 mg. Primary endpoint: overall response rate based on independent review; secondary and exploratory endpoints include: progression-free and overall survival, duration of response, safety, pharmacokinetics, MOR208 immunogenicity, quality of life and minimal residual disease negativity. 120 pts per cohort are planned. Clinical trial information: 2015-002915-14.

TPS7568 Poster Session (Board #329a), Mon, 8:00 AM-11:30 AM

A phase I trial of CD19-targeted EGFRt/19-28z/4-1BBL armored chimeric antigen receptor (CAR) modified T cells in patients with relapsed or refractory chronic lymphocytic leukemia. *First Author: Jae Hong Park, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite the recent progress in the therapy of CLL with BTK, PI3Kδ, and BCL2 inhibitors, CLL remains incurable and patients with high-risk disease features (i.e. del17p, complex karyotype) and patients whose disease progress after treatment with the above targeted agents continue to have extremely poor prognosis. CD19-specific chimeric antigen receptor (CAR) T cell therapy with various 2nd generation CARs (19-28z or 19-41BBz) have demonstrated anti-tumor efficacy in CLL but the complete response (CR) rates in CLL have been suboptimal (20-45%) compared to CR rates in ALL (80-90%). The suboptimal activity of the current 2nd generation CAR T cells can be due to the inhibitory tumor microenvironment (TM) of CLL. We believe one approach to over the hostile TM is through the use of CD19-CAR T cells further modified to express a second costimulatory ligand, 4-1BBL. A binding of 4-1BBL to its cognate receptor enhances T cell proliferation, IL-2 secretion, and survival and cytolytic activity of the T cells compared to 19-28z. 19-41BBz and 1928BBz (Zhao Z et al. Cancer Cell 2015;28: 415-428). **Methods:** This phase I dose escalating trial is a single-center clinical trial (MSKCC) to study the safety and efficacy of autologous EGFRt/19-28z/4-1BBL$^+$ CAR T cells in patients with relapsed CLL. Given the concern for potential systemic toxicity the vector includes a "safety switch" in the form of a gene for the expression of truncated form of human epidermal growth factor receptor (EGFRt). Patients with relapsed CLL are eligible for the trial. Patients will receive conditioning chemotherapy of cyclophosphamide followed by escalating doses of CAR T cells ($1x10^5$ – $3x10^6$ CAR T cells/kg). The primary endpoint is safety and maximum tolerated doses of the CAR T ells. Secondary objectives include response assessment by iwCLL criteria. The comprehensive treatment algorithms for CRS and neurotoxicity are based on our CAR T cell experience in other studies. The study will begin enrollment in February 2017 and enroll up to 30 patients. Clinical trial information: Pending.

TPS7569 Poster Session (Board #329b), Mon, 8:00 AM-11:30 AM

KI intolerance study: A phase 2 study to assess the safety and efficacy of TGR-1202 in pts with chronic lymphocytic leukemia (CLL) who are intolerant to prior BTK or PI3K-delta inhibitor therapy. *First Author: Colleen Dorsey, Abramson Cancer Center, Philadelphia, PA*

Background: Although kinase inhibitor (KI) therapies, such as ibrutinib, are generally well tolerated, intolerance is the most common reason for discontinuation (d/c) in practice (~50%, Mato et al, Blood 2016). Additionally KI interruptions (≥ 8 days) can shorten OS (Barr et al, ASCO 2015). Fortunately, data suggest that KIs have non-overlapping toxicity profiles. Therefore, pts who d/c KI due to intolerance, with ongoing CLL response, represent an unmet need. TGR-1202 is a next generation, highly-specific PI3K-delta inhibitor with nanomolar inhibitory potency. TGR-1202 is well-tolerated with a d/c rate due to AEs of 8% as demonstrated in an integrated safety analysis of 165 treated pts (Burris et al, ASCO 2016). **Methods:** A phase 2 investigator initiated study is being conducted to assess the safety and activity of TGR-1202 in CLL pts who are KI intolerant. KI Intolerance is defined as ≥ 1 Gr 3 or ≥ 2 Gr 2 non-heme toxicities, ≥ 1 Gr 3 neutropenia with infection or fever, and/or ≥ 1 Gr 4 heme toxicity leading to KI (BTK and/or PI3K inhibitor) d/c (Table). Toxicities must resolve to ≤ Gr 1 prior to TGR-1202 dosing. Prior KI must be d/c for ≥ 14 days without progression (PD). All eligible pts are treated with TGR-1202 (800mg oral daily) until PD, toxicity or study conclusion. Primary study endpoint is PFS. Secondary endpoints include ORR, duration of response, time to treatment failure and TGR-1202 safety profile. Peripheral blood samples are collected prior to TGR-1202, after 28 days and at PD for correlative analyses to identify markers associated with KI intolerance. The trial commenced 10/1/2016. 55 eligible pts will be enrolled in approximately 12 months with 24 months follow-up. As of 1/2017, 10 study sites are enrolling pts with 10 more to be activated. To date, 10 pts have been enrolled and treated with TGR-1202. Clinical trial information: NCT02742090.

Intolerance stratified by KI class.

BTK toxicities	PI3K toxicities
A-fib	Pneumonitis
HTN	Transaminitis
Bleeding	Rash
Arthralgia	Colitis
Rash	Infection
Diarrhea	
Infection	
Pneumonitis	

Any additional grade ≥ 2 non-heme toxicity not listed will be evaluated by the study chair

TPS7570 Poster Session (Board #330a), Mon, 8:00 AM-11:30 AM

A phase Ia/Ib study of a novel BTK inhibitor, DTRMWXHS-12 (DTRM-12), and combination products, with everolimus and pomalidomide, in pts with CLL or other B-cell lymphomas. *First Author: Jennifer Gill, Abramson Cancer Center, Philadelphia, PA*

Background: Synthetic lethality (SL) relies on the chemical inhibition of two aberrant genes to selectively kill malignant cells. SL is now a clinical reality in an era of multiple targeted agents and advanced genetic testing. We investigated small molecule combinations for SL through in vitro and in vivo screening and optimization studies (Table, US patent 20160324878) and demonstrated the potential of SL through best-in-class combinations of targeted agents, immune modulation and low-dose combinations. We hypothesize that BTK and mTOR inhibition combined with an IMiD target multiple key signaling pathways, improve selective cell kill and address acquired drug-resistance. DTRM-555 is an optimized mechanism-based combination of the novel BTK inhibitor DTRM-12, with everolimus (E) and pomalidomide (P). In xenograft tumor models, DTRM-555 has shown superior efficacy over single agents at lower combined doses (1/18 of DTRM-12, 1/6 of E, and 1/6 of P). **Methods:** We are conducting a phase I, first-in-human multicenter trial exploring DTRM-555 in pts with CLL and B-cell NHL. Phase Ia consists of escalating DTRM-12 monotherapy doses. Phase Ib will explore doublet combination of DTRM-12 plus everolimus, and DTRM-555, the novel triplet combination. Safety is the primary study endpoint. Secondary endpoints include anti-tumor activity and pharmacokinetic studies. Eligible pts are > / = 18 years / ECOG < / = 1 with CLL or B-cell NHL with no available therapies. Treatment is administered for 21 consecutive days of a 28-day cycle, until disease progression or unacceptable toxicity. The trial commenced on 9/27/16. Phase 1a (single subject, 50/100mg respectively) has enrolled 5 pts without DLT and is currently at the 200 mg dose level. Up to 50 pts will be enrolled. Five additional sites are planned to open in the near future across the US. Clinical trial information: NCT02900716.

Viability inhibition of human lymphoma cells by the compounds (%).

TMD-8 cells

	DTRMWXHS-12 concentration		
Treatment	1 μM	0.1 μM	0.01 μM
	61.66	59.59	46.07
Doublet Combination E at 0.1 μM	65.94	67.20	66.17
Double Combination P at 0.1 μM	53.25	49.26	30.27

TPS7571 Poster Session (Board #330b), Mon, 8:00 AM-11:30 AM

B-MIND: MOR208 plus bendamustine (BEN) versus rituximab (RTX) plus BEN in patients with relapsed or refractory (R-R) diffuse large B-cell lymphoma (DLBCL): An open-label, randomized phase II/III trial. *First Author: Grzegorz S. Nowakowski, Mayo Clinic, Rochester, MN*

Background: Patients ineligible for stem cell transplantation (SCT) or who relapse after SCT, and those who fail to respond to second-line or salvage chemotherapy, represent an unmet medical need for which new therapeutic strategies are required. MOR208 is a novel Fc-enhanced, humanized, monoclonal antibody directed against CD19. Significant single-agent activity of MOR208 in patients with R-R DLBCL (Jurczak et al., J Clin Oncol 34, 2016 [suppl; abstr 7545]) and enhancement of MOR208-mediated cytotoxicity by BEN in preclinical studies, provide a strong rationale to study MOR208 + BEN in patients with R-R DLBCL. **Methods:** B-MIND is a randomized (1:1), two-arm, multicenter, open-label, adaptive design, phase II/III study of MOR208 + BEN vs RTX + BEN in adult patients with histologically confirmed DLBCL who have relapsed after or are refractory to 1 to 3 prior lines of therapy and who are not candidates for high-dose chemotherapy and autologous SCT. At least 1 prior therapy line must have included a CD20-targeted therapy. Other key inclusion criteria: age ≥18 years; measurable disease; availability of tumor tissue for central pathology review; ECOG 0–2, and adequate major organ systems function. Key exclusion criteria: primary refractory DLBCL; central nervous system involvement, and known double/triple hit DLBCL genetics. The safety of the combination will be assessed in an initial phase II evaluation. Treatment will comprise 6 cycles of MOR208 (12 mg/kg IV) + BEN (90 mg/m^2 IV) or RTX 375 mg/m^2 IV + BEN. Patients achieving a response after cycle 6 will continue to receive antibody treatment for up to 18 additional cycles. Primary endpoint: progression-free survival (PFS); secondary endpoints include: best overall response, overall survival, safety, quality of life, immunogenicity and pharmacokinetics. Enrollment of 330 patients is anticipated in Europe, US and Asia-Pacific countries. Fourteen patients have been randomized to date. Clinical trial information: NCT02763319.

TPS7572 Poster Session (Board #331a), Mon, 8:00 AM-11:30 AM

Zuma-6: Phase 1-2 multicenter study evaluating safety and efficacy of axicabtagene ciloleucel (axi-cel; KTE-C19) in combination with atezolizumab in patients with refractory diffuse large b-cell lymphoma (DLBCL). *First Author: Frederick Lundry Locke, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Approximately 1/3 of patients with DLBCL, the most common type of B-cell lymphoma, will become refractory to standard combination chemotherapy and have uniformly poor clinical outcomes (Crump, ASCO 2016). Axi-cel (autologous anti-CD19 chimeric antigen receptor [CAR] T cell therapy) has shown promising response rates in patients with refractory DLBCL compared with standard approaches, although some patients do not respond or progress after an initial response (Locke, *Mol Ther* 2016). Expression of PD-L1 on DLBCL cells and activation-dependent expression of PD-1 on CAR T cells after infusion led to the hypothesis that PD-1 pathway blockade may augment the activity of axi-cel and result in improved clinical outcomes. This study will evaluate safety and efficacy of axi-cel when given with atezolizumab (anti–PD-L1 antibody), delivered sequentially, in patients with refractory DLBCL. **Methods:** Phase 1 will enroll ~3-9 patients to estimate the incidence of dose-limiting toxicities. Phase 2 will enroll ~22 patients to evaluate safety and efficacy, with a primary endpoint of complete response (CR) rate (Cheson 2007). Secondary endpoints include key efficacy outcomes such as objective response rate (CR+partial response [PR]), duration of response, progression-free and overall survival, and safety and biomarker outcomes. Eligible adult patients will have received prior adequate therapy (including anti-CD20 monoclonal antibody and an anthracycline-based regimen) and have an ECOG PS of 0-1 and adequate bone marrow and organ function. Patients with a history of Richter transformation, transformed follicular lymphoma, CNS disease, or active infection are not eligible. Patients will receive fludarabine 30 mg/m^2/d and cyclophosphamide 500 mg/m^2/d $\times$ 3 d, followed by a single infusion of axi-cel (target dose, 2 $\times$ 10^{6}anti-CD19 CAR T cells/kg) followed by atezolizumab 1200 mg given every 21 d for 4 doses (phase 1, first dose to occur 21, 14, and 1 d after axi-cel infusion in cohorts 1, 2, and 3, respectively). The study opened to accrual in September 2016. Clinical trial information: NCT02926833.

TPS7573 Poster Session (Board #331b), Mon, 8:00 AM-11:30 AM

Phase II study of durvalumab (anti-PD-L1 antibody) in combination with R-CHOP or lenalidomide plus R-CHOP in previously untreated, high-risk diffuse large B-cell lymphoma. *First Author: Grzegorz S. Nowakowski, Mayo Clinic, Rochester, MN*

Background: The PD-1/PD-L1 pathway is an important immune checkpoint used by tumor cells and may provide an effective target for enhancing anticancer immune response. In DLBCL, high PD-L1 expression has been identified as a negative prognostic factor for overall survival. Durvalumab (MEDI4736) is a high-affinity human IgG1 monoclonal Ab that selectively blocks PD-L1 binding to PD-1 and CD80, and preliminary preclinical and clinical activity support the study of durvalumab in high-risk DLBCL subtypes. The primary study objective is to explore the clinical activity of durvalumab with R-CHOP in non-activated B-cell–like (non-ABC) and durvalumab with lenalidomide + R-CHOP (R^2-CHOP) in ABC previously untreated DLBCL; secondary objectives are to evaluate safety and identify biomarkers predictive of clinical response. **Methods:** This is a phase II, two-arm, open-label, global, multicenter study of durvalumab combinations in patients with previously untreated, high-risk DLBCL (MEDI4736-DLBCL-001; EUDRA CT 2015-005173-20; NCT03003520). High risk was defined as Ann Arbor stage III/IV or II with bulky disease ($\geq$7.0 cm), along with intermediate-high/high IPI $\geq$3 or NCCN-IPI $\geq$4; patients must also have CD20+ DLBCL, ECOG PS 0-2, and no prior antilymphoma therapy. All patients receive durvalumab + R-CHOP21 in induction cycle 1 simultaneous to cell-of-origin (COO) analysis by gene expression profiling with NanoString technology. Beginning with cycle 2, Arm A (non-ABC) receives durvalumab 1125 mg IV on day 1 with 6 or 8 cycles of R-CHOP21; Arm B (ABC) receives the same durvalumab + R-CHOP21 doses with oral lenalidomide 15 mg/day on days 1-14. Both arms receive durvalumab consolidation 1500 mg IV on day 1 q28d for $\leq$12 months from induction cycle 1, day 1. The primary endpoint is 2-y progression-free survival (PFS); secondary endpoints include clinical response to treatment in biomarker-defined subpopulations (tumor and peripheral blood) and safety as assessed per NCI CTCAE v4.03 criteria. Exploratory endpoints include PFS at 12 mo, complete response, and PK/PD. Recruitment is ongoing, with a target enrollment of 120 patients. Clinical trial information: NCT03003520.

TPS7574 Poster Session (Board #332a), Mon, 8:00 AM-11:30 AM

Phase I/II study of durvalumab (anti–PD-L1 antibody) as monotherapy and in combination in patients with lymphoma or chronic lymphocytic leukemia. *First Author: Thomas E. Witzig, Mayo Clinic, Rochester, MN*

Background: The PD-1/PD-L1 pathway is an important immune checkpoint used by tumor cells to evade immune cell detection and inhibit antitumor responses. PD-1/PD-L1 expression in multiple hematologic malignancies may provide an effective target for enhancing anticancer immune response. Durvalumab (MEDI4736) is a high-affinity human IgG1 monoclonal Ab that selectively blocks PD-L1 binding to PD-1 and CD80, and has shown preliminary evidence of antitumor activity across multiple tumor types. Study objectives are to evaluate durvalumab monotherapy and combinations to determine dose and safety, as well as identify histologies and combinations that show the best complementary antitumor signals for future study. **Methods:** This is a phase I/II open-label, global, multicenter study of durvalumab as a monotherapy and in combination in relapsed/refractory B-cell lymphoma or CLL (MEDI4736-NHL-001; EUDRA CT 2015-003516-21; NCT02733042). Patients must have histologically-confirmed FL, MCL, splenic or nodal MZL, T-cell/histiocyte rich BCL, PMBCL, ALK+ large BCL, transformed large BCL, Richter's transformation, DLBCL (NOS), CLL/SLL, or classical HL during the dose-finding part. Inclusion criteria are ECOG PS 0-2, and $\geq$1 prior antilymphoma therapy. Up to 253 patients may enroll in 4 treatment arms, which include fixed-dose durvalumab 1500 mg Q4W monotherapy or combinations with lenalidomide/rituximab, ibrutinib, or bendamustine/rituximab. The study has 3 parts: dose finding, dose confirmation, and dose expansion. The monotherapy arm does not have a dose finding or expansion part; upon progression, patients may receive combination therapy or involved-field radiation to a single nodal site (evaluating for systemic abscopal antitumor effect). Primary endpoints are safety, identification of recommended phase II dose (phase I, 3+3 design), and overall response rate (ORR; phase II); secondary endpoints include DOR, PFS, and PK/PD. ORR is measured by 2014 IWG criteria for lymphoma or modified 2008 iwCLL criteria for CLL; safety is assessed per NCI CTCAE v4.03 criteria. Recruitment is ongoing, with a target enrollment of 253 patients across 60-80 centers globally. Clinical trial information: NCT02733042.

TPS7575 Poster Session (Board #332b), Mon, 8:00 AM-11:30 AM

Phase 1b/3 study of avelumab-based combination regimens in patients with relapsed or refractory diffuse large B-cell lymphoma (R/R DLBCL). *First Author: Robert W. Chen, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Approximately 50% of patients (pts) with advanced DLBCL are refractory to or relapse following first line R-CHOP therapy. Pts with R/R DLBCL have limited treatment options and a poor prognosis. This study assesses immunotherapy-based regimens containing avelumab (a fully human IgG1 anti–PD-L1 antibody) in combination with utomilumab (a novel 4-1BB agonist), azacitidine, rituximab, and/or conventional chemotherapy (CT; bendamustine) in pts with R/R DLBCL. **Methods:** JAVELIN DLBCL (NCT02951156) is a global, multicenter, randomized, open-label, 2-component(phase 1b followed by phase 3) study of avelumab-based combination regimens in R/R DLBCL. In phase 1b, up to 84 pts will be randomized 1:1:1 to receive avelumab/rituximab/utomilumab, or avelumab/azacitidine/utomilumab, or avelumab/rituximab/bendamustine. The primary phase 1b objectives are preliminary assessments of dose-limiting toxicities (n = 6 per arm) and efficacy (objective response [OR]; n = 28 per arm). One regimen from phase 1b will be selected for phase 3 evaluation in 220 additional pts randomized 1:1 to the chosen regimen or investigator's choice CT (rituximab/bendamustine or rituximab/gemcitabine/oxaliplatin). The primary phase 3 objective is to demonstrate progression-free survival (PFS) superiority of the avelumab-based regimen over CT. Overall survival is a key secondary endpoint. Eligible pts have completed up to 4 lines of prior rituximab/multiagent CT, and/or have failed autologous stem cell transplantation (ASCT), or are not eligible for intensive CT or ASCT. Other eligibility criteria include ECOG PS $\leq$1 and no prior therapy with a checkpoint inhibitor. Treatment with avelumab, utomilumab, and azacitidine will be continued until the pt no longer receives clinical benefit; rituximab and bendamustine are limited to 8 and 6 cycles, respectively. OR and PFS will be assessed per Lugano disease classification criteria. Other secondary efficacy endpoints include disease control, duration of response, time to response, and minimal residual disease burden. Safety, PK, immunogenicity, pt-reported outcomes, and biomarkers will also be evaluated. Clinical trial information: NCT02951156.

TPS7576 Poster Session (Board #333a), Mon, 8:00 AM-11:30 AM

A multicenter, randomized, double-blind, placebo-controlled phase III study of the Bruton's tyrosine kinase (BTK) inhibitor, ibrutinib, in combination with rituximab versus placebo in combination with rituximab in patients with treatment-naive follicular lymphoma (PERSPECTIVE). *First Author: Nathan Hale Fowler, Stanford University, Stanford, CA*

Background: Follicular lymphoma (FL) is the most common subtype of indolent non-Hodgkin lymphoma. A limited number of chemotherapy-free options exist for patients with treatment-naïve (TN) FL who are older or who have comorbidities. Single-agent rituximab is considered a treatment option for elderly or infirm patients. In a phase 2 study, frontline treatment with ibrutinib in combination with rituximab for 4 weekly doses without maintenance resulted in an ORR of 85% (CR, 35%) with a median follow-up of 22 months and an 18-month PFS rate of 87% (Fowler Blood 2016). The phase 2 study serves as the basis for the randomized, double-blind, placebo-controlled phase 3 PERSPECTIVE (PCYC-1141-CA) trial. PERSPECTIVE will be conducted in two parts and will uniquely test (1) whether frontline treatment with ibrutinib in combination with rituximab results in prolongation of PFS compared to rituximab alone, and (2) whether continuous versus finite treatment with ibrutinib affects PFS outcomes. **Methods:** In the ongoing PERSPECTIVE trial, approximately 440 patients with TN FL meeting at least one Groupe d'Etude des Lymphomes Folliculaires (GELF) criterion will be randomized if they also meet one of the following criteria: age ≥70 years or age 60 to 69 with one or more comorbidities (creatinine clearance 30-59 mL/min or ECOG performance status of 2). Patients will be randomized to receive either ibrutinib or oral placebo once daily. All patients will be given rituximab for 4 weekly doses followed by maintenance. After at least 2 years of treatment in Part 1, patients randomized to ibrutinib who still remain on ibrutinib will be re-randomized in Part 2 to continue ibrutinib or switch to placebo. Key exclusion criteria include any prior treatment for FL, evidence of CNS involvement, or transformation. Analyses will be conducted in two distinct parts, both with a primary endpoint of PFS. The study is open for enrollment with sites planned in the US, EU, and Asia Pacific. Clinical trial information: NCT02947347.

TPS7577 Poster Session (Board #333b), Mon, 8:00 AM-11:30 AM

CheckMate 436: A phase 1-2 study to evaluate safety and efficacy of nivolumab plus brentuximab vedotin in patients with CD30-expressing relapsed/refractory non-Hodgkin lymphomas. *First Author: Paul M. Barr, University of Rochester Medical Center, Rochester, NY*

Background: Nivolumab (nivo) is a PD-1 immune checkpoint inhibitor that augments T-cell activation and host anti-tumor responses. PD-1 blockade has shown promise in B- and T-cell non-Hodgkin lymphoma (NHL),[1] but many patients (pts) with NHL do not respond or progress after response. Combination therapy using anti-tumor agents with complementary mechanisms of action and low immunosuppressive impact may result in more frequent and durable responses. Brentuximab vedotin (BV) is an anti-CD30 antibodydrug conjugate that induces cell cycle arrest and apoptosis, with activity in a range of NHL tumors.[2,3] Tumor cells undergoing BV-induced apoptosis have shown subsequent immune-mediated anti-tumor cytotoxicity.[4] Therefore, nivo and BV may synergize if combined for relapsed/refractory (RR) NHL. **Methods:** CheckMate 436 (NCT02581631) is a phase 12, open-label, international, single-arm study evaluating nivo + BV for CD30-expressing RR NHL (study start: Dec 2015) in pts with RR diffuse large B-cell lymphoma, peripheral T-cell lymphoma (excluding anaplastic large cell lymphoma), and cutaneous T-cell lymphoma (mycosis fungoides/Sézary syndrome); cohorts with primary mediastinal B-cell lymphoma (PMBL) and mediastinal gray zone lymphoma were made eligible in Sept 2016. Pts with PMBL must be aged ≥15 y (≥18 y for other histologies). All pts must have CD30-expressing disease, defined by CD30 on ≥1% of tumor cells or tumor-infiltrating lymphocytes by immunohistochemistry. In the phase 1 component, 6 pts will receive nivo and BV until disease progression or unacceptable toxicity. In the phase 2 component, ~130 more pts across the 5 histologies will be enrolled and treated at the recommended dose. Primary endpoints: safety, tolerability, and investigator-assessed objective response rate; secondary endpoints: duration of response and complete response (CR), CR rate, and progression-free and overall survival. Accrual is ongoing. References: 1. Lesokhin A et al. *JCO* 2016;34:2698704 2. Jacobsen E et al. *Blood* 2015;125:1394402 3. Horwitz S et al. *Blood* 2014;123:3095100 4. Gardai S et al. *Cancer Res* 2015;75(15 Suppl):2469 [abstract]. Clinical trial information: NCT02581631.

TPS7578 Poster Session (Board #334a), Mon, 8:00 AM-11:30 AM

Phase 1 study of the safety and efficacy of INCB050465 combined with obinutuzumab and bendamustine for relapsed or refractory (R/R) follicular lymphoma (FL) (CITADEL-102). *First Author: Morton Coleman, New York-Presbyterian Hospital, Weill Cornell Medicine, New York, NY*

Background: Aberrant PI3Kδ activation is implicated in B-cell non-Hodgkin lymphomas (NHL) including FL, the most common indolent subtype. INCB050465, a selective PI3Kδ inhibitor, is being evaluated in an ongoing phase 1/2 study as monotherapy for r/r B-cell NHL, including FL (ASH 2016; Abstract 4195). Obinutuzumab plus bendamustine is approved for patients (pts) with rituximab-refractory FL. This phase 1 cohort expansion study will assess the safety, efficacy, and pharmacokinetics of INCB050465 combined with obinutuzumab and bendamustine in pts with r/r FL (NCT03039114). **Methods:** Eligible adults will have documented CD20+ FL r/r to 1–4 prior treatments (must include rituximab), ≥1 measurable lesion (> 1.5 cm in ≥1 dimension), ECOG PS ≤2, and adequate hematologic, hepatic and renal function. Exclusion criteria will include: transformation of FL to aggressive lymphoma or receipt of allogeneic stem cell transplant (SCT) ≤6 months (or having graft-versus-host-disease after allogeneic or autologous SCT ≤3 months) before study start; receipt of any PI3K inhibitor, obinutuzumab, or bendamustine ≤12 months, or rituximab ≤1 month prior to study. Part 1 (safety run-in) will use a 3+3 design. Pts will receive INCB050465 PO at a dose of 20 mg QD continuously for 2 cycles (1 cycle = 4 wks) followed by 20 mg QW. Up to 2 dose reductions will be allowed. Pts will receive obinutuzumab 1000 mg IV (cycle 1: days 1, 8, and 15; cycles 2–6: day 1) and bendamustine 90 mg/m^2 IV (cycles 1–6: days 1 and 2). In part 2 (expansion), the safety and efficacy of INCB050465 (maximum tolerated dose) plus obinutuzumab and bendamustine will be evaluated in 30 pts, including pts treated in part 1 at the dose level deemed safe and tolerated. In both parts 1 and 2, pts not progressing after 6 cycles will be maintained on INCB050465 at the dose deemed safe and tolerated, and will continue on obinutuzumab 1000 mg IV administered on Day 1 of every second cycle for an additional 24 cycles or until disease progression. Response will be assessed using Lugano criteria (FDG-PET; CT/MRI) every 12 wks until cycle 12 and every 16 wks thereafter. The trial is open for enrollment. Clinical trial information: NCT03039114.

TPS7579 Poster Session (Board #334b), Mon, 8:00 AM-11:30 AM

Phase 2 study of the safety and efficacy of INCB050465 in patients with relapsed or refractory (R/R) diffuse large b-cell lymphoma (DLBCL) (CITADEL-202). *First Author: Morton Coleman, New York-Presbyterian Hospital, Weill Cornell Medicine, New York, NY*

Background: Aberrant activation of PI3Kδ is implicated in B-cell malignancies. INCB050465, a highly selective PI3Kδ inhibitor, is demonstrating preliminary efficacy in an ongoing phase 1/2 dose-escalation and expansion study as monotherapy for r/r DLBCL as well as for other r/r B-cell malignancies (ASH 2016; Abstract 4195). This phase 2 study will further evaluate the efficacy and safety of single-agent INCB050465 in pts with r/r DLBCL. **Methods:** In this phase 2, multicenter, open-label study (NCT02998476), eligible adults will have r/r DLBCL diagnosis, defined as receiving 1–5 prior treatments and be ineligible for high-dose chemotherapy or autologous stem-cell transplant (SCT). Pts will also have ≥1 measurable lesion (nodal ≥2 cm or extranodal > 1 cm in longest dimension); Eastern Cooperative Oncology Group performance status ≤2; adequate hematologic, hepatic, and renal function; no mediastinal large B-cell lymphoma or CNS metastases; no allogeneic SCT ≤6 months, or graft-versus-host-disease after allogeneic SCT, or autologous SCT ≤3 months, before first dose; and no prior treatment with PI3K inhibitors. Pts will be enrolled into 2 groups according to prior treatment with a Bruton's tyrosine kinase (BTK) inhibitor (Group A [n = 100, no BTK inhibitor] or B [n≤20, received BTK inhibitor]). Both groups will receive INCB050465 20 mg orally QD for 8 wks; then 20 mg QW until disease progression, death, unacceptable toxicity, or consent withdrawal. The primary endpoint is the objective response rate in Group A (complete/partial response per independent review committee based on Lugano criteria). Secondary endpoints will include duration of response, progression-free survival, overall survival, and safety in Group A (these endpoints will be exploratory in Group B). Other exploratory assessments will include pharmacokinetics and association between genetic characteristics and treatment response in both groups. In a planned interim futility analysis of Group A, the study will be terminated if ≤13 of the first 40 treated pts respond (no futility analysis of Group B will be conducted). The study is currently recruiting (estimated completion date, March 2020). Clinical trial information: NCT02998476.

8000 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Daratumumab (DARA) in combination with carfilzomib, lenalidomide, and dexamethasone (KRd) in patients (pts) with newly diagnosed multiple myeloma (MMY1001): An open-label, phase 1b study. *First Author: Andrzej J. Jakubowiak, University of Chicago Medical Center, Chicago, IL*

Background: DARA in combination with established standard of care regimens prolongs PFS, deepens responses, and demonstrates a favorable safety profile in relapsed or refractory multiple myeloma (MM). The tolerability and efficacy of DARA-KRd in newly diagnosed MM pts was examined. **Methods:** Newly diagnosed pts regardless of transplantation eligibility were enrolled. Pts received DARA 16 mg/kg QW for Cycles 1-2, Q2W for Cycles 3-6, and Q4W thereafter. All pts received the 1st dose of DARA split over 2 days. Carfilzomib (K) was administered on Days 1, 8 and 15 of each 28-day cycle (20 mg/m^2 on C1D1, 36 or 70 mg/m^2 subsequently based on tolerability of first dose) for ≤13 cycles or elective discontinuation for ASCT. Lenalidomide 25 mg was given on Days 1-21 and dexamethasone 20-40 mg per week. The primary endpoint was tolerability. **Results:** Twenty-two pts (median [range] age, 60 [34-74] y) were enrolled and received a median of 8 (1-10) treatment cycles. Nineteen pts escalated K dose to 70 mg/m^2 by C1D15. Median (range) duration of follow-up was 7.4 (4.0-9.3) months. Six (27%) pts discontinued treatment (1 AE [pulmonary embolism]; 1 PD; 4 other [ASCT]). Serious AEs occurred in 46% of pts, and 14% were possibly related to DARA; 18 (82%) experienced a grade 3/4 TEAE. The most common grade 3/4 TEAEs (>10%) were lymphopenia (50%) and neutropenia (23%); 1 (5%) cardiac grade 3 TEAE was observed (congestive heart failure) which resolved; pt quickly resumed study treatment with reduced K dose. No grade 5 TEAE was reported. All DARA-associated infusion reactions (27% of pts) were grade ≤2. Treatment with DARA-KRd yielded an ORR (≥partial response) of 100% (5% complete response, 86% ≥very good partial response) in 21 response-evaluable pts. The 6-month PFS rate was 100%. **Conclusions:** The addition of DARA to KRd was well tolerated; the overall safety profile was consistent with that previously reported for KRd, with no additional toxicity observed with the addition of DARA. Deep and durable responses were observed. These data support further investigation of DARA-KRd as a frontline treatment regimen. Updated data will be presented based on longer follow up. Clinical trial information: NCT01998971.

8001 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Lenalidomide, doxorubicin hydrochloride and dexamethasone versus bortezomib, lenalidomide, and dexamethasone prior to scheduled stem cell transplant in newly diagnosed myeloma. *First Author: Stefan Knop, Medizinische Klinik und Poliklinik II, Julius Maximilians Universität Würzburg, Würzburg, Germany*

Background: In younger, medically fit patients (pts) with newly diagnosed (ND) multiple myeloma (MM), autologous stem cell transplant (SCT) remains a standard of care. Prior to SCT, induction triplets with at least one of the newer compounds are recommended. Bortezomib (V), lenalidomide (R) and dexamethasone (D; VRD) ranks amongst the most effective treatments. VRD + SCT proved superior over VRD alone in a randomized, controlled trial (RCT). We found encouraging efficacy and low toxicity with RAD (RD and adriamycin) + SCT and decided to compare RAD versus VRD induction in an RCT. **Methods:** The DSMM XIV study was set up according to a double 2x2-factorial design to enroll NDMM pts up to 65 years (yrs). Post-induction (PI) CR rate was the efficacy endpoint for the initial study phase. We hypothesized CR rate with RAD would be non-inferior to an estimated 20% CR with VRD. The study was powered to confirm non-inferiority of RAD at a 10% margin with a one-sided α level of .05. Minimal residual disease (MRD) was analyzed by eight-color flow cytometry (EuroFlow standards) on marrow samples. **Results:** 476 pts were randomized between 05/2012 and 06/2016, 469 of whom (median age 55 (range, 32–65) yrs) received at least one dose of study drug. 18.3% of pts had ISS stage III MM and 17.2%, elevated LDH. 11.3% of pts had del17p; 11.1% had t(4;14); and 4% had t(14;16). 232 pts were randomized to 3 four-week RAD cycles and 237 to 3 three-week VRD cycles, respectively. 89.7% of RAD versus 93.2% of VRD pts completed all induction cycles. PI CR rate was 11.8% (90% CI, 7.9%-16.3%) with RAD versus 13.0% (90% CI, 8.9-18.0) with VRD, (P = .697). 72/317 pts (22.7%) with paired baseline/PI samples achieved negative MRD at a median sensitivity level of $6.73x10^{-6}$. 47 (20.3%) RAD versus 35 (14.8%) VRD pts experienced treatment-emergent SAEs (P = .144). Treatment-related induction mortality was 0% in either arm. **Conclusions:** To the best of our knowledge, this is the first RCT to compare two lenalidomide-based triplets prior to SCT. The endpoint was met with comparable PI CR rates for RAD and VRD, respectively. Tolerability was encouraging in both arms. Follow-up data is needed to analyze time-dependent endpoints. Clinical trial information: NCT01685814.

8002 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

An open-label, single arm, phase IIa study of bortezomib, lenalidomide, dexamethasone, and elotuzumab in newly diagnosed multiple myeloma. *First Author: Jacob Laubach, Dana-Farber Cancer Institute, Boston, MA*

Background: Elotuzumab (elo) is approved for use in combination with lenalidomide (len) and dexamethasone (dex) for relapsed and refractory multiple myeloma (MM). This phase 2a study evaluated the efficacy and safety of elo in combination with len, subcutaneous bortezomib (bortez), and dex. **Methods:** The primary objective of this study was to determine the response rate of newly diagnosed, transplant-eligible MM patients (pts) after four cycles of therapy with elo plus len, bortez, and dex. Pts were newly diagnosed with MM by the revised IMWG criteria. Elo was administered days 1, 8, and 15 of the first two 28 day cycles and days 1 and 11 in cycles 3 and 4. Following cycle 4, pts underwent stem cell mobilization and could then proceed with either autologous stem cell transplant (ASCT) or defer transplant and receive four more cycles of induction therapy with elo plus len, bortez, and dex. Following either ASCT or 8 cycles of induction chemotherapy, pts transitioned to risk-adapted maintenance with elo, len, and dex plus every other week bortez (pts with high-risk cytogenetics, ISS stage II or III) or elo, len, dex (all others). Responses were assessed by the modified Uniform Response Criteria and toxicities graded based on NCI-CTCAE V4. **Results:** 41 patients with a median age of 60 were enrolled and this analysis encompasses response data from 29 patients. The overall response rate (ORR) after four cycles was 100%, with 24% achieving a complete response (CR), 47% achieving a very good partial response (VGPR), and 29% a partial response (PR). The rate of VGPR or better was 71%. The median number of CD34+ stem cells collected was 10.3 x 10^6. The most frequent grade 3 or higher toxicities included thrombocytopenia (15%) and hypophosphatemia (12%). The rate of grade 3 or higher peripheral neuropathy was 2%. Two pts died while on study, one due to complications of septicemia and the other due to respiratory failure. **Conclusions:** The combination of elo plus len, bortez, and dex was effective in newly diagnosed, ASCT-eligible patients. The rate of high-grade toxicities was low, although there were two grade 5 events (septicemia and respiratory failure). Clinical trial information: NCT02375555.

8003 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Carfilzomib-lenalidomide-dexamethasone (KRd) vs carfilzomib-cyclophosphamide-dexamethasone (KCd) induction: Planned interim analysis of the randomized FORTE trial in newly diagnosed multiple myeloma (NDMM). *First Author: Francesca Maria Gay, Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy*

Background: Phase I/II studies showed the safety and efficacy of KRd and KCd in NDMM pts (Jakubowiak Blood 2012, Bringhen Blood 2014). **Methods:** NDMM pts ≤65 yrs were randomized (1:1:1; stratification ISS and age) to: 4 28-day KCd cycles (carfilzomib:20/36 mg/m^2 IV d 1,2,8,9,15,16; cyclophosphamide 300 mg/m^2 d 1,8,15; dexamethasone:20 mg d 1,2,8,9,15,16) followed by MEL200-ASCT and consolidation with 4 KCd cycles; or 4 28-day KRd cycles (carfilzomib and dexamethasone as above; lenalidomide:25 mg d 1-21) followed by MEL200-ASCT and 4 KRd cycles; or 12 KRd cycles. After the 4th induction cycle, all pts received Cyclophosphamide 2 g/m^2, followed by PBSC collection. We report results of the first planned safety interim analysis on induction and mobilization and preliminary efficacy data. We pooled the 2 KRd groups since treatment was the same until mobilization. Data cut-off was October 30, 2016. **Results:** 281 pts were evaluated (KCd, n=94; KRd, n=187). The most frequent grade 3-4 AEs plus SAEs in both arms were hematological (mainly neutropenia) and infections (mainly pneumonia/fever); increased AST/ALT/GGT (mainly reversible) and dermatological (rash) AEs were higher in KRd; cardiac AEs were 2% (atrial fibrillation[1%]/ischemic heart disease[1%]) in KRd vs 1% (atrial fibrillation) in KCd. In KCd, 1 pt died of infection (not treatment-related) vs 3 in the KRd (2 cardiac arrest [1 not treatment-related],1 infection not treatment-related). In the KCd vs KRd arms, 99% vs 95% (P=0.44) of pts mobilized stem cells (median number of PBSC collected:9 vs 6x10^6CD34/Kg with KCd vs KRd); 10% vs 24% (P=0.01) required Plerixafor. Rate of ≥VGPR was 61% with KCd vs 74% with KRd (P=0.05). **Conclusions:** Safety profile was acceptable; more pts required plerixafor in KRd. Rate of VGPR was higher with KRd. Updated data on more patients will be presented at the meeting. Clinicaltrials.gov NCT02203643.

Grade 3-4 AEs/SAEs	KCd	KRd
Hematological	13%	9%
Cardiac	1%	2%
Hypertension	0%	2%
Thromboembolism	0%	1%
Gastrointestinal	0%	3%

8004 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Carfilzomib weekly-melphalan-prednisone in untreated elderly multiple myeloma: IFM2012-03. *First Author: Xavier Leleu, CHU, Poitiers, France*

Background: Melphalan-prednisone-bortezomib (MPV) is a standard of care upfront for newly diagnosed elderly myeloma (eNDMM). Despite significant improvements on MPV's safety profile, toxicity issues remain. Carfilzomib (K) is a novel generation proteasome inhibitor with a different safety profile from Bortezomib. Carmysap phase I/II study (twice a week Carfilzomib+MP) demonstrated K at 36mg/m² safe and active in eNDMM. We thought to study the K weekly-MP combination in eNDMM. **Methods:** IFM2012-03 is a multicenter phase I/II study in eNDMM (65 and older) aimed to determine the maximum tolerated dose (MTD) of K weekly. 4 cohorts of 6 patients each were recruited at K 36, 45, 56 and 70 mg/m^2 on days 1, 8, 15, 22 IV of 35-days cycles, with oral Melphalan and Prednisone from days 1 to 4 at usual doses. Patients received a 9-cycles induction followed by a K monotherapy maintenance at 36 mg/m^2 IV every 2 weeks for 1 year. 3 dose-limiting toxicities (DLTs) defined MTD at the lower N-1 dose. **Results:** 24 patients were included at K 36, 45, 56 and 70 mg/m². One DLT occurred at 36 mg/m² (grade 4 lymphopenia), one at 45 mg/m² (tumor lysis syndrome with grade 4 renal insufficiency), two at 56 mg/m² (grade 3 cardiac insufficiency and grade 3 febrile neutropenia) and two at 70 mg/m² (grade 3 nausea/vomiting and grade 3 hepatic cytolysis). One patient died from cardiac dysfunction considered related to K at 56 mg/m². 3 patients stopped therapy and 3 others required dose reduction of K. Following DSMB's request a second 6-patients cohort was recruited at 70 mg/m², with increased attention around hyper-hydration and monitoring HTA. We observed no DLT and no grade 3/4 adverse event in this cohort. Median age was 75 years, 56% patients were R-ISS 2 or 3. For the whole cohort (N=30), the overall response rate was 87% including 67% very good partial responses and 44% complete responses. **Conclusions:** The MTD of weekly K in the KMP combination is 70 mg/m² upfront for eNDMM, but it seems reasonable to recommend 56mg/m² after 75 years-old for safety reasons. KMP offers high response rates and possibly greater CR rate. However, since the CLARION study (VMP vs KMP) will not allow KMP's approval in eNDMM in Europe, IFM decided to stop IFM2012-03 after phase I without performing phase II. Clinical trial information: NCT02302495.

8005 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Impact of denosumab (DMB) compared with zoledronic acid (ZA) on renal function in the treatment of myeloma bone disease. *First Author: Noopur S. Raje, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Osteolytic bone disease and renal dysfunction are complications of multiple myeloma. ZA, used for the prevention and treatment of bone complications, can be nephrotoxic. DMB inhibits RANKL and thereby osteoclast function, and is not renally cleared. This international, phase III, randomized, double blind study evaluates the efficacy and safety of DMB compared with ZA in newly diagnosed myeloma patients (pts). **Methods:** Eligible pts were randomized 1:1 to DMB 120mg SC Q4W or ZA 4mg (renally adjusted) IV Q4W along with anti-myeloma therapy. Pts with baseline CrCl<30mL/min were excluded due to ZA dosing restrictions. The primary endpoint was non-inferiority of DMB to ZA with respect to time to first on-study SRE. Overall survival (OS) was a secondary endpoint; progression-free survival (PFS) was an exploratory endpoint. Renal toxicity and safety were assessed. **Results:** 1718 pts were randomized, 859 to each arm. Baseline renal insufficiency (CrCl ≤ 60mL/min) was reported in 26.7% of pts. DMB was non-inferior to ZA ($P = 0.01$) in delaying time to first on-study SRE. Fewer AEs potentially related to renal toxicity were reported with DMB compared to ZA overall (10.0% vs 17.1%, $P < 0.001$) in those with baseline CrCl > 60mL/min (8.8% vs 14.2%) and particularly in those with baseline CrCl ≤ 60mL/min (12.9% vs 26.4%). 12.5% of pts on DMB experienced an increase in creatinine, compared to 20.8% of those on ZA. Median cumulative exposure (Q1, Q3) to DMB was 15.75 months (8.18, 25.79) compared to 14.78 months (7.46, 24.87) for ZA. PFS yielded a HR (95%CI) of 0.82 (0.68, 0.99); descriptive $P = 0.036$. OS HR (95%CI) between DMB and ZA was 0.9 ([0.70, 1.16]; $P = 0.41$), with fewer deaths in DMB (121 [14.1%]) than in ZA (129 [15.0%]). **Conclusions:** DMB achieved the primary endpoint of non-inferiority to ZA in delaying time to first on study SRE in pts with newly diagnosed MM. Pts on DMB had a significantly lower rate of renal AEs compared to ZA; more importantly this rate was 2-fold lower in pts with renal insufficiency (CrCl≤60mL/min). The bone specific benefits in combination with the renal function results and possible prolongation of PFS with DMB therapy is promising. Clinical trial information: NCT01345019.

8006 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Efficacy of daratumumab in combination with lenalidomide plus dexamethasone (DRd) or bortezomib plus dexamethasone (DVd) in relapsed or refractory multiple myeloma (RRMM) based on cytogenetic risk status. *First Author: Katja C. Weisel, Universitaetsklinikum Tuebingen der Eberhard-Karls-Universitaet, Abteilung fuer Innere Medizin II, Tuebingen, Germany*

Background: In 2 randomized phase 3 trials of RRMM patients (pts), DRd (POLLUX) or DVd (CASTOR) significantly improved PFS and deepened responses compared with Rd or Vd alone, respectively. The novel mechanism of action of daratumumab (D) may improve the poor prognosis associated with high-risk cytogenetic abnormalities in RRMM. Therefore, we examined the efficacy of DRd and DVd among RRMM pts with standard (std) or high cytogenetic risk status. **Methods:** Bone marrow aspirates were collected at screening and assessed centrally via next generation sequencing (NGS). Pts with high-risk cytogenetics included those who had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; std-risk pts were defined as those confirmed negative for these abnormalities. Efficacy analyses included PFS and ORR. **Results:** Samples from 311/569 pts in POLLUX and 353/498 pts in CASTOR were assessed via NGS. In POLLUX, the median duration of follow-up was 17.3 months. Significantly longer median PFS and numerically higher ORR were observed with DRd vs Rd among high-risk patients, and significant improvements in these outcomes were observed in std-risk patients (Table). In CASTOR, the median duration of follow-up was 13.0 months. Significantly longer median PFS and higher ORR were observed with DVd vs Vd among both high- and std-risk pts (Table). Concordance rates for t(4;14), t(14;16), and del17p were high (88%-98%) between NGS and FISH. Updated data, including subgroup analyses, will be presented. **Conclusions:** In RRMM pts, the addition of D to standard-of-care regimens improved outcomes regardless of cytogenetic risk status. Targeting CD38 by combining D with Rd or Vd appears to improve the poor outcomes associated with high-risk cytogenetic status. See table. Clinical trial information: NCT02136134 and NCT02076009.

8007 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

A phase Ib study of isatuximab in combination with pomalidomide (Pom) and dexamethasone (Dex) in relapsed/refractory multiple myeloma (RRMM). *First Author: Joseph Mikhael, Mayo Clinic, Phoenix, AZ*

Background: Isatuximab (ISA) is an anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase Ib study of ISA plus Pom/Dex in pts with RRMM (NCT02283775). **Methods:** Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10 or 20 mg/kg (4 weekly doses, then every 2 wks until disease progression or intolerable toxicity) with Pom 4 mg (Days 1–21) and Dex 40 mg (Days 1, 8, 15, and 22; 20 mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10 mg/kg (plus Pom/Dex) based on preliminary safety, efficacy and PK data. Primary objective: determine maximum tolerated dose (MTD). **Results:** 26 pts were analyzed (5 mg/kg [n = 8]; 10 mg/kg [n = 12]; 20 mg/kg [n = 6]), median age 65 (42–80) yrs. Median 4.0 (2–11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks, and 16 pts remained on treatment. 2 pts at 10 mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). DLTs reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusional state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (35%), and dyspnea (31%). Most frequent Gr 3/4 hematologic abnormality (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%). Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts. 16 (62%) pts achieved at least PR (5, 8 and 3 pts at 5, 10 and 20 mg/kg), including 1 CR, 8 VGPR, and 7 PR. Clinical benefit rate (≥ MR) was 73%. Median time to 1st response, 4.2 wks; median duration of response, 25.6 wks. The PK parameters of ISA were not affected by co-administration with Pom/Dex. **Conclusions:** The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination is ongoing. Clinical trial information: NCT02283775.

8008 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Phase I/II dose expansion of a trial investigating bendamustine and pomalidomide with dexamethasone (BPd) in patients with relapsed/refractory multiple myeloma. *First Author: Dharshan Sivaraj, Duke University, Durham, NC*

Background: The combination of bendamustine, pomalidomide, and dexamethasone (BPd) displays promising activity in heavily pretreated RRMM. In the Phase I portion, MTD was 120 mg/m^{2}bendamustine/3mg pomalidomide/40mg dexamethasone. We report our combined findings from the additional phase II expansion cohort for the first phase I/II trial of BPd in patients with RRMM (NCT01754402). **Methods:** All patients had to be refractory to prior lenalidomide as well as be pomalidomide naïve, and must have relapsed or have been refractory to their most recent therapy. Treatment consisted of oral pomalidomide PO QD on days 1-21, intravenous (IV) bendamustine given over 30 minutes on day 1, and dexamethasone 40mg on days 1, 8, 15, and 22 of a 28-day cycle. Bendamustine was administered at 120 mg/m^2 for cycle 1, day 1. **Results:** A total study population of 38 patients was enrolled, with 34 evaluable for toxicity and 32 for efficacy, with 7 patients still receiving treatment. Data cut-off was January 18, 2017. The median age was 67 years, median number of prior regimens was 5, median time from diagnosis was 3.6 years, and median follow-up was 11.7 months. 82% of patients had a prior stem cell transplant, 100% had prior bortezomib, 32% had prior carfilzomib, and all were lenalidomide refractory. Cytogenetic abnormalities included 6 patients with del(17p), 4 with t(4;14), 7 with del(13), and 7 with t(11;14). Patients received a median of 4 cycles of therapy. Best response assessments in 32 evaluable patients showed 3 sCR, 3 VGPR, 17 PR, 7 SD, and 2 PD for an ORR of 72%. The median PFS and OS were 9.6 months and 21.3 months respectively for the entire cohort, with 16 of 32 still alive at follow-up. Grade ≥3 drug-related AEs included fatigue (8%), neutropenia (45%), anemia (26%), thrombocytopenia (24%), and diarrhea (8%). 71% of patients experienced grade ≥3 AEs including neutropenia, anemia, and diarrhea. **Conclusions:** The BPd regimen is relatively tolerable and achieves a promising overall response rate (ORR of 72%) and durable responses in a heavily pretreated lenalidomide–refractory population with prior bortezomib exposure, and a median of 5 lines of prior therapy. Clinical trial information: NCT01754402.

8009 Poster Discussion Session; Displayed in Poster Session (Board #335), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Lenalidomide induction and maintenance therapy for transplant eligible myeloma patients: Results of the Myeloma XI study. *First Author: Graham H. Jackson, Department of Haematology, University of Newcastle, Newcastle-upon-Tyne, United Kingdom*

Background: Immunomodulatory (IMiD) agents are effective therapies for multiple myeloma (MM), with Lenalidomide (Len) having fewer side effects than Thalidomide (Thal), enabling long-term treatment. The optimum IMiD induction and maintenance regimen are unknown. We therefore compared triplet induction regimens of Len vs Thal and examined the role of maintenance Len vs observation, enabling us to explore the interaction of Len induction with Len maintenance. **Methods:** Myeloma XI is a multicenter, randomized controlled trial for newly diagnosed MM, with pathways for transplant eligible (TE) and non-eligible patients. For TE patients the induction question compared Len or Thal plus cyclophosphamide and dexamethasone (CRD vs CTD) continued for a minimum of 4 cycles and to max. response. For patients with a suboptimal response there was a subsequent randomization to a proteasome inhibitor containing triplet or no further therapy prior to ASCT. A maintenance randomization at 3 months post ASCT compared Len till disease progression vs observation. 2042 TE patients underwent the induction randomization (CRD 1021, CTD 1021). After a median follow up of 36.3 months, 965 PFS and 415 OS primary endpoint events had occurred. Secondary endpoints included response and toxicity. **Results:** In TE patients, CRD induction was associated with deeper responses than CTD: ≥VGPR CRD 60% vs CTD 53%. This was associated with a significantly improved median PFS (HR 0.85, 95%CI 0.75, 0.96, CRD 35.9 months vs CTD 32.9, p=0.0116) and 3 year OS: 82.9% vs 77.0% (HR 0.77, 95%CI 0.63, 0.93, p=0.0072). Maintenance therapy with Len was associated with a significantly longer median PFS compared to observation (HR 0.47, 95%CI 0.38, 0.60) across all subgroups including patients with high-risk disease. Exploratory analysis across the TE pathway suggested that CRD induction with Len maintenance was optimum: 60 month PFS CRD-R 50.2%, CTD-R 39.1%, CRD-obs 18.5%, CTD-obs 23.4%. **Conclusions:** CRD was associated with deeper responses than CTD, and with a PFS and OS benefit. The best outcomes were associated with Len induction plus Len maintenance. Our findings support continuing Len therapy through induction until disease progression. Clinical trial information: NCT01554852.

8010 Poster Discussion Session; Displayed in Poster Session (Board #336), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Response status as predictor of survival after autologous hematopoietic cell transplant (AHCT), without or with consolidation (with bortezomib, lenalidomide (Len) and dexamethasone) and len maintenance (AM vs. ACM) versus tandem AHCT and len maintenance (TAM) for up-front treatment of patients (pts) with multiple myeloma (MM): BMT CTN0702-stamina (NCT01109004). *First Author: George Somlo, City of Hope, Duarte, CA*

Background: The Stamina trial primarily aimed to identify the best strategy among AM, ACM, and TAM, leading to longer PFS (LBA-1, ASH, 2016). Here we report on interim, exploratory results of the association between PFS and overall survival (OS) and baseline MM response, risk category, and treatments (Rx). **Methods:** Pts with MM, < 71 years, < 12 mos from diagnosis were randomized to melphalan 200mg/m^2(mel) and AHCT (AM), tandem mel AHCT (TAM), or mel AHCT and 4 cycles of RVD ((ACM). Pts received Len till progression. Pts were stratified by high risk vs. standard (del13q, del17q, t(4;14), t(14;16), t(14;20) and hypodyploid; high β2 microglobulin). Kaplan Meier estimates of PFS and OS were performed as a function of Rx and ≥ very good partial response (VPGR including CRs) vs. < VGPR. Cox proportional hazard models explored associations between PFS or OS and risk category, Rx, and ≥ VPGR vs. < VGPR. **Results:** Between 6/2010-11/2013, 758 pts (AM, N = 257; ACM, N = 254; TAM, N = 247) aged 20-70 years (median 57y) were enrolled (24% high-risk). Baseline ≥VGPR responses were 45.5- 49.8%. PFS at 38 months was similar. For < VGPR, 38-mos PFS with TAM:55.8% (95%CI: 45.8%, 64.7%); ACM: 54.0% (44.7%, 62.5%); AM: 50.1% (40.6%, 58.9%); For ≥VGPR, 38-mos PFS with TAM: 57.1% (46.8%, 66.1%); ACM: 60.1% (50.1%, 68.7%); AM: 55.1% (45.1%, 64.0%). Analyzing response, risk category, and Rx revealed no association between baseline response and PFS (Baseline response < VGPR, hazard ratio (HR): 1.21,95% CI: 0.97-1.52) or OS (baseline response < VGPR, HR 1.02, 95%CI:0.70-1.48). High risk category had an adverse association for PFS (HR 1.62, 95% CI: 1.27-2.07) and OS (HR 1.51 (95% CI:1.01-2.26). **Conclusions:** In this analysis < VGPR at baseline was not associated with PFS or OS. High-risk had an adverse association. Whether accomplishment of CR/minimal residual disease after AM, ACM,or TAM predicts for longer PFS and OS is the subject of ongoing analysis. Clinical trial information: NCT01109004.

Minimal residual disease (MRD) monitoring by multiparameter flow cytometry (MFC) in newly diagnosed transplant eligible multiple myeloma (MM) patients: Results from the EMN02/HO95 phase 3 trial. *First Author: Stefania Oliva, Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy*

Background: MRD detection is a sensitive tool to measure response in MM. We assessed MRD by MFC in newly diagnosed MM patients (pts) enrolled in the EMN02/HO95 phase 3 trial. **Methods:** Pts were ≤65 years old and received Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, intensification with Bortezomib-Melphalan-Prednisone (VMP) vs High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD analysis was performed in pts achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10^{-5}. Quality checks were performed to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D *ASH* 2016 abstract 2072). **Results:** 316 pts were evaluable before maintenance: median age was 57 years, 18% (57/316) pts had ISS III and 22% (70/316) had high risk cytogenetic (HR-C) defined as having at least one among del17, t(4;14) or t(14;16); 63% (199/316) had received HDM and 37% (117/316) VMP; thereafter 51% (160/316) had received VRD. 76% (239/316) were MRD negative (MRD-) of whom 64% (153/239) received HDM vs 36% (86/239) VMP, with a median follow-up time of 30 months from MRD enrolment. 3-year PFS was 50% in MRD positive (MRD+) vs 77% in MRD- pts (HR: 2.87, p < 0.001). Subgroup analyses were performed to evaluate the risk factors for MRD+ according to baseline characteristics and therapies: HR-C was the most important risk factor (HR 9.87, interaction-p = 0.001). Finally, 48% of MRD+ pts at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-. **Conclusions:** MRD by MFC is a strong prognostic factor in MM pts receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; HR-C is the most important prognostic factor in MRD+ pts. Clinical trial information: NCT01208766.

Bendamustine with ixazomib and dexamethasone (BID) for double refractory relapsed multiple myeloma (RRMM): Phase I safety and dosing results. *First Author: Binod Dhakal, Medical College of Wisconsin, Milwaukee, WI*

Background: Bendamustine has promising activity in RRMM. This phase I (NCT02477215) study assessed the overall safety and activity of the combination of bendamustine with ixazomib & dexamethasone in pts. with MM pts. refractory to proteasome inhibitors and IMIDs. **Methods:** Design: Open label dose escalation (3+ 3 design) Doses: Bendamustine at escalating doses of 70, 80 and 90 mg/m^2 on days 1,2 of each cycle with weekly ixazomib (4mg) and dexamethasone (40 mg) on days 1,8, 15 in 28-day cycles for up to 8 cycles in responders and 4 cycles if no anti-MM response. Primary end point was safety, maximum tolerated dose (MTD) and the recommended phase II (RP2D) dose. **Results:** As of Jan 2017, the phase I portion is complete (N= 15). The median age was 67 years with 5 (range: 2-10) median number of prior therapies. Prior therapies included bortezomib (100%), lenalidomide (100%), carfilzomib (47%), oprozomib (7%), thalidomide (7%), pomalidomide (7%) and 87% autotransplant. Five (33%) pts. completed their planned courses of therapy (4 or 8 cycles) and 3 (20%) continued on active therapy. Seven (47%) pts. discontinued study treatment (6 related to disease progression). Grade 3/ 4 adverse events were: lymphopenia (67%), neutropenia (27%), thrombocytopenia (33%), decreased WBC counts (13%), hematuria (7%), diarrhea (7%), anemia (7%), lung infection (7%), and skin ulceration (7%). Three (20%) pts. died of myeloma progression. In dose cohort 3 (bendamustine 90 mg/m2), 2 /6 pts. developed hematologic DLTs (neutropenia and thrombocytopenia) meeting MTD; RP2D was determined to be 80 mg/m2. The table below shows responses among pts receiving at least 2 cycles. The median duration of response was not reached at median follow up of 8 months (range, 4-13+) in responders. **Conclusions:** BID has an acceptable safety profile and a promising ORR of 45% and CBR of 73% in pts. with advanced double refractory MM. Clinical trial information: NCT02477215.

Response in 3 cohorts.

Dosing cohort	N	Evaluable (>=2 cycles)	Response
70mg/m2	3	3	1 SD, 2PD
80mg/m2	6	5	2 VGPR, 2PR, 1PD
90 mg/m2	6	3	1PR, 2SD
Total	15	11	ORR -45% (5/11) CBR-73% (8/11)

SD: stable disease; VGPR: very good partial response, PR; partial response, PD: Progressive disease ORR: VGPR+ PR; CBR: VGPR+PR+SD

Replacement of ixazomib for relapsed/refractory multiple myeloma patients refractory to a bortezomib or carfilzomib-containing combination therapy. *First Author: James R. Berenson, Institute for Myeloma and Bone Cancer Research, Los Angeles, CA*

Background: The proteasome inhibitor (PI) ixazomib (Ixz) is the first orally administered PI approved for treating multiple myeloma (MM). It has shown clinical activity as a single agent and when used in other combinations. In this phase 1/2 trial, we evaluated Ixz as a replacement therapy for bortezomib or carfilzomib for MM patients who were refractory to a bortezomib- or carfilzomib-containing combination regimen. **Methods:** This was a phase 1/2, intra-patient, multicenter, open-label trial evaluating the replacement of ixazomib for bortezomib or carfilzomib for MM patients who were refractory in combination with the other agents that the patients had received and failed. Patients received Ixz on days 1, 8 and 15 on a 28-day schedule and the other drugs were administered using the same doses and schedules as they were receiving during their prior regimen. If the Ixz maximum tolerated dose (MTD) for a particular combination regimen was previously determined, then patients were enrolled directly into Phase 2 (PhII). If not, MTD was determined during the Phase 1 (PhI) portion of the trial. **Results:** To date, a total of 40 patients have been enrolled; 37 patients (21 were enrolled in PhI and 16 in PhII) had completed at least one cycle of this treatment. Patients received a median of 5 prior treatments (range, 1-22). The median follow-up time for all patients was 1.6 months (range, 0.1-10.7 months), whereas that of PhII was 2.2 months (range, 0.2-10.7 months). There was no clinical benefit (CBR; 0%) nor any overall response rate (ORR; 0%) for patients receiving Ixz 3 mg (PhI). Nine patients (43%) showed stable disease (SD) while 12 (57%) exhibited disease progression (PD). In PhII (4mg Ixz) portion of the trial, ORR and CBR were both 18.7% with 16 (43.2%) patients showing SD, and 18 (48.6%) patients displaying PD. Common ≥ Gr3 adverse events were anemia (11%), thrombocytopenia (5.4%), hyponatremia (5.4%), dehydration (5.4%) and neutropenia (2.7%). **Conclusions:** Replacement of bortezomib or carfilzomib with Ixz infrequently leads to responses among RRMM patient who have progressed while on proteasome inhibitor -containing combination regimens. Clinical trial information: NCT02206425.

Natural history of t(11;14) multiple myeloma (MM). *First Author: Arjun Lakshman, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: t(11;14) is a standard risk cytogenetic marker in MM. **Methods:** We reviewed 366 patients with MM who had t(11;14) by FISH and 732 age and period-matched controls without t(11;14), seen at our institution from 2004 to 2014 and outcomes were analyzed using time to first progression or death (PFS1) and overall survival (OS). **Results:** For the t(11;14) group at diagnosis, the median age was 63.7 yr (range, 22.1-95.4) with 64.5% of patients being male. Eighty nine (24.3%) patients were above 70 yr of age at diagnosis. 33.8%, 40.3% and 25.9% patients belonged to ISS 1, II and III stages respectively. 13% patients had elevated LDH. Monosomy 17 or del 17p were identified in 10.6% patients. The median follow up period was 56.9 months (m) (95% CI: 54.6-62.2) and 209 (57.1%) patients were alive at last follow-up. Among patients receiving proteasome inhibitor (PI)-based, immunomodulator (IMiD)-based, PI+IMiD based or other agent based induction therapy, 71.2%, 70.3%, 90.4% and 37.5% patients respectively attained ≥PR as best response to induction ($p < 0.01$). During their course, 223 (60.9%) patients underwent stem cell transplant. Median PFS1 and OS were 23.1 (CI: 20.8-27.9) and 78.6 (CI: 66.7-105.9) m respectively. Among the controls, high risk cytogenetics (HRC) was present in 142 (19.4%), and the median OS was 83.8 m (CI: 70.8-97.0) being comparable to t(11;14) group ($p = 0.8$). For all 1098 patients, using a Cox-proportional hazards model with age > 70 years, induction therapy (novel agent-based vs others), cytogenetics [HRC vs t(11;14) without HRC vs no HRC or t(11;14)], and ISS stage III vs II/I as predictors, age > 70 years [HR-2.2 (CI: 1.8-2.8) and $p < 0.01$], ISS III vs ISS II/I [HR-1.4 (CI: 1.1-1.8) and $p < 0.01$] and HRC [HR of 2.1 (CI: 1.6-2.8) vs no HRC or t(11;14) ($p < 0.01$) and 1.9 (CI = 1.4-2.6) for t(11;14) without HRC ($p < 0.01$)were associated with reduced OS. The risk for reduced OS did not differ between t(11;14) without HRC, and those without t(11;14) or HRC [HR-1.1 (CI: 0.9-1.4), $p = 0.4$]. **Conclusions:** Our study characterizes the outcomes of a large cohort of MM patients with t(11;14) at diagnosis. Advanced age, HRC and advanced stage at diagnosis were associated with worse OS in our cohort. t(11;14) MM without HRC does not differ in outcome compared to non-t(11;14) MM without HRC.

Pembrolizumab (Pembro) plus lenalidomide (Len) and low-dose dexamethasone (Dex) for relapsed/refractory multiple myeloma (RRMM): Efficacy and biomarker analyses. *First Author: Enrique M. Ocio, Complejo Asistencial Universitario de Salamanca/IBSAL, Salamanca, Spain*

Background: The PD-1 inhibitor pembro blocks interaction of PD-1 with its ligands PD-L1/PD-L2, activating antitumor immunity. Combination of pembro, len, and dex may provide synergistic antitumor activity in RRMM. **Methods:** Theopen-label, phase 1 KEYNOTE-023 (NCT02036502) study of pembro + len + low-dose dex enrolled patients (pts) with RRMM treated with ≥2 prior therapies (tx). Pts received pembro 200 mg IV Q2W, len 25 mg PO on d1-21, and dex 40 mg PO weekly on each 28-d cycle. Primary end point was safety. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included flow cytometry (FC) (PD-L1, PD-L2 on CD38$^+$CD138$^+$ cells) at screening or predose cycle 1, d 1 bone marrow (BM) aspirate. Absolute and/or relative numbers of circulating immune cells (by FC) and gene expression profile (GEP) (by Nanostring) were evaluated in predose cycle 1, d1 and cycle 2, d1 blood. **Results:** Median age was 61 y; median (range) prior lines of tx was 4 (1-10); 38 (75%) pts were len-refractory and 27 (53%) pts were double refractory. Most common grade ≥3 tx-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 (4%) pts died (hepatic failure, ischemic stroke) because of TRAEs. Immune-related AEs occurred in 5 (10%) pts. No pneumonitis was reported. For response-evaluable pts, ORR was 50% (20/40; 1 sCR, 14 PR, 5 VGPR); 1 had PD. ORR was 38% (11/29) for len-refractory pts. In 16/32 pts with FC-evaluable BM aspirate with >100 CD38$^+$CD138$^+$ cells, all were PD-L1$^+$, while PD-L2 expression was variable. At cycle 2, d1, frequency of circulating HLA-DR$^+$, central (CD45RO$^+$CCR7$^-$), and effector memory (CD45O$^+$CCR7$^+$) CD8$^+$ T cells significantly increased and naive (CD45RA$^+$) CD8$^+$ T cells significantly decreased; all with multiplicity adjusted P values ≤ 0.01. **Conclusions:** Pembro + len + low-dose dex has an acceptable safety profile and antitumor activity in pts with RRMM, including len-refractory pts. PD-L1 was expressed in all pts evaluated by FC, whereas PD-L2 expression was variable. Among the pool of circulating T cells in peripheral blood, HLA-DR$^+$ and memory T-cell subset fractions increased after treatment. Clinical trial information: NCT02036502.

WT1 heteroclitic epitope immunization following autologous stem cell transplantation in patients with high-risk multiple myeloma (MM). *First Author: Guenther Koehne, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Host T-cells mount immune responses (IR's) against Wilms tumor 1 (WT1) in A*0201^{+}MM pts through formation of WT1 peptide fragment (RMFPNAPYL)/HLA-A*0201 complex. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT. **Methods:** 16 MM pts underwent autoSCT with melphalan conditioning followed by (f/b) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. GPS was administered with montanide s.c. starting 2 wks post-SCT and q.2 wks thereafter x 6 initial doses f/b boosters q.4 wks x 6 additional doses. GM-CSF was given on days -2 and 0 of each cycle. GPS consisted of 4 peptides: WT1-A1: Y*MFPNAPYL; 427-L (long): RSDELVRHHNMHQRNMTKL; 331-L: PGCNKRYFKLSHLQMHSRKHTG, and 122A1-L: SGQAY*MFPNAPYLPSCLES. 2 of the 4 peptides were mutated at a single residue (*) to induce stronger HLA-binding/reduce tolerance. WT1-specific IR's were assessed by intracellular IFN-g analyses post-challenge with PBMC's pulsed with a 'total pool' of overlapping 15mers along the entire WT1 protein; or each of the 4 WT1 peptides in GPS; or the non-mutated (native) WT1 peptides corresponding to the 2 heteroclitic sequences. **Results:** 16 pts; median follow-up: 18 mos (range: 5-31 mos) for survivors; median age: 61.6 y. Overall survival (OS) and progression-free survival (PFS) (95% CI) at 18 mos: 0.88 (0.73-0.99) and 0.62 (0.42-0.97) respectively. Current median PFS: 23.6 mos (15.2 - not reached). No >G2 systemic side effects were observed, however, all pts developed local nodularity at the site of injections which resolved over 2 – 6 wks. Both CD8+ and CD4+ IR's could be detected at various levels and were induced not only against the heteroclitic peptides (within GPS), but also against the corresponding native WT1 peptide sequences as well as the 'total pool' of WT1-derived overlapping peptides. **Conclusions:** Administration of the novel WT1 heteroclitic peptide immunizer GPS post auto SCT demonstrates favorable safety profile along with encouraging mPFS of currently 23.6 mos in this high-risk MM population. Clinical trial information: NCT01827137.

Development of a fully human T cell engaging bispecific antibody for the treatment of multiple myeloma. *First Author: Ben Buelow, TeneoBio, Inc., Menlo Park, CA*

Background: Although BCMA is a plasma cell specific surface molecule attractive as an antibody target in multiple myeloma, its scarcity on the cell surface may limit the efficacy of a conventional antibody. T-cell engaging bispecific antibody approaches are highly efficacious and are particularly well suited for a membrane target with limited expression, such as BCMA. Teneobio has developed a multivalent antibody platform based on modular human VH domains, which allowed us to build T cell engaging bispecific antibodies with low and high T cell agonistic activities. **Methods:** UniRats were immunized with either CD3 or BCMA antigens and antigen-specific UniAbs were identified by antibody repertoire sequencing and high-throughput gene assembly, expression, and screening. High affinity binding VH sequences were selected using recombinant proteins and cells. In vitro efficacy studies included T-cell activation by cytokine- and tumor cell kill by calcein-release assays. In vivo efficacy of the molecules was evaluated in NSG mice harboring myeloma cells and human PBMCs. **Results:** BCMA-specific UniAbs bound plasma cells with high affinities (100-700pM) and cross-reacted with cynomolgus plasma cells. Strong and weak T cell agonists were identified that bound human T cells with high and low affinities respectively and cross-reacted with cynomolgus T cells. T cell engaging bispecifics with a strong (H929 cytotoxicity:EC_{50}=27pM) and a weak T cell activating arm (H929 cytotoxicity: EC_{50}=1170pM) demonstrated T-cell activation and tumor-cell cytotoxicity in vitro; bispecifics with a weak CD3 engaging arm showed markedly reduced cytokine production even at doses saturating for cytotoxicity. In vivo, BCMAxCD3 bispecific antibodies reduced tumor load and increased survival when co-administered with human PBMCs as compared to controls. **Conclusions:** Our results suggest that T cell engaging bispecifics with low-affinity anti-CD3 arms could be preferred for the treatment of Multiple Myeloma.

Carfilzomib-associated cardiovascular adverse events: A systematic review and meta-analysis. *First Author: Adam Justin Waxman, Abramson Cancer Center, Philadelphia, PA*

Background: The incidence and nature of cardiovascular adverse events (CVAEs) with carfilzomib (CFZ) in multiple myeloma (MM) remain incompletely defined. We performed the first systematic review and meta-analysis of CFZ CVAEs. **Methods:** PubMed was queried for the keywords "carfilzomib," "Kyprolis," and "PX-171." Phase 1-3 clinical trials of carfilzomib in MM with evaluable toxicity data were included. CVAEs were defined as heart failure, hypertension, ischemia, and arrhythmia. All-grade and grade ≥3 CVAEs and study characteristics were recorded. Summary incidence rates and relative risks (for randomized trials) with 95% confidence intervals were calculated using the logistic-normal random-effects model. Subgroup analyses were performed using study level covariates. **Results:** 514 studies were reviewed. 2623 MM patients from 25 eligible studies were included. Incidence rates are summarized in the table. All grade and grade ≥3 CVAEs were seen in 16.8% and 7.6 %, respectively. Phase 2 or 3 studies, carfilzomib doses ≥45mg/m^2, and longer infusion length were study characteristics associated with high-grade cardiac AEs ($p<0.05$). Median age >65, prior MM therapies, and concurrent MM therapies were not associated with CVAEs ($p>.05$). For the three randomized trials, the relative risk of all-grade and grade ≥3 CVAEs were 1.75 and 2.25, respectively ($p<0.001$). **Conclusions:** CFZ is associated with a significant incidence of CVAEs, including heart failure, hypertension, ischemia, and arrhythmia. Phase I studies may be underdetecting CVAEs. Future studies are needed to: identify patients at high-risk for CVAEs, develop optimal monitoring strategies, and explore therapies to mitigate these risks.

Adverse Event	All-Grade Incidence % (95% CI)	p-value	Grade ≥3 Incidence % (95% CI)	p-value
Any Cardiac	16.8 (11.9-22.3)	<0.001	7.6 (5.4-10.1)	<0.001
Heart Failure	4.1 (2.3-6.3)	<0.001	2.6 (1.5-3.8)	<0.001
Hypertension	12.2 (9.7-14.9)	<0.001	4.3 (2.6-6.4)	<0.001

Evaluation of an oral direct anti-Xa anticoagulant, apixaban, for the prevention of venous thromboembolism in patients with myeloma treated with IMiD* compounds: A pilot study (MYELAXAT). *First Author: Brigitte Pegourie, University Hospital Grenoble-Alpes, Grenoble, France*

Background: The risk of venous thromboembolism (VTE) is higher in myeloma patients recieving IMiD* compounds (IMiD*: registered). A VTE prophylaxis using low-molecular-weight heparin or aspirin is proposed. Apixaban is an oral direct anti-Xa. Several studies have shown the efficiency and safety of apixaban in VTE prophylaxis compared to enoxaparin. The objective of this prospective pilot study was to assess the risk of VTE and bleeding in patients with myeloma treated with IMiD* compounds, using apixaban in a preventive scheme. **Methods:** Myeloma patients requiring Melphalan-Prednisone-Thalidomide in first line, or Lenalidomide-Dexamethasone in relapse, asymptomatic regarding VTE at inclusion, were enrolled between 2014 - 2016. All patients recieved apixaban, 2.5 mg x 2/day for 6 months, and were monthly monitored. Venous (pulmonary embolism – PE, or symptomatic proximal or distal deep vein thrombosis - DVT, or all proximal asymptomatic events detected by systematic proximal bilateral compression ultrasound) or arterial thrombotic events, and bleeding events (ISTH 2005) were registered. Based on meta-analysis of Carrier regarding VTE recurrence, and results from the ADOPT study in medical conditions regarding hemorrhages, < 13 symptomatic VTE events, < 3 severe and < 14 clinically relevant non major (CRNM) bleeding were expected on the treatment period. **Results:** 104 patients were enrolled (mean age 69.8 +/- 7.8yrs), 11 in first line, 93 in relapse. No PE or arterial cardiovascular events were reported. Two venous thrombotic events were registered, i.e an asymptomatic proximal DVT (patient in relapse) and a symptomatic distal DVT, although apixaban was stopped 14 days before, due to Lenalidomide-induced thrombopenia. Only one major and 11 CRNM hemorrhages were reported. **Conclusions:** Referring to the incidence of thromboembolic events in Carrier's meta-analysis, and to hemorrhagic events in medical patients recieving apixaban in primary VTE prophylaxis, apixaban used in a preventive scheme seems to be efficient and safe in preventing VTE in myeloma patients treated with IMiD* compounds. Clinical trial information: NCT02066454.

Prognostic impact of kinetics of circulating plasma cells before and after induction therapy in newly diagnosed multiple myeloma patients undergoing early transplantation. *First Author: Rajshekhar Chakraborty, Mayo Clinic, Department of Hematology, Rochester, MN*

Background: Circulating plasma cells (CPCs) at diagnosis, prior to transplant and at relapse have a negative prognostic impact on survival in multiple myeloma (MM). However, the impact of changes in CPCs along the course of illness has not been defined. **Methods:** We evaluated 247 patients with newly diagnosed MM (NDMM) undergoing early autologous stem cell transplantation (ASCT) in the era of novel agents (2007 to 2015), who had serial evaluation of CPCs at diagnosis and pre-ASCT by 6-color flow cytometry. **Results:** The median age at transplant was 62 years. A total of 117 (47%) patients had no detectable CPCs at both time points (CPC-/-), 82 (33%) had CPCs at diagnosis followed by complete eradication after induction therapy (CPC+/-) and 48 (19%) had detectable clonal CPCs at transplant, with persistence of cells (CPC+/+; n=45) or emergence of new CPCs (CPC-/+; n=3) after induction. The incidence of t(11;14) by iFISH was lower in the CPC-/- group (19%) compared to CPC+/- (29%) and CPC +/+ or -/+ (39%) groups (p=0.033). Conversely, the incidence of hyperdiploidy was significantly higher in patients with CPC-/-, compared to those with CPC+/- and CPC+/+ or -/+ (64%, 44% and 39% respectively; p=0.005). The rate of post-ASCT stringent complete response was 32% in the CPC-/- group, 30% in CPC+/- group and 12% in CPC+/+ or -/+ group (p=0.018). At a median follow-up of 58 months from ASCT, the median progression-free survival (PFS) from transplant in the 3 respective groups was 30, 24 and 14 months and the 5-year overall survival (OS) rates were 83%, 70% and 43% (p<0.001 for both comparisons). On a multivariate analysis, using CPC-/- group as the comparator, PFS and OS was significantly inferior in CPC+/- (RR 1.6; p=0.020 and RR 2.7; p=0.008 for PFS and OS respectively) and CPC +/+ or -/+ groups (RR 2.9; p<0.001 and RR 5.8; p<0.001 for PFS and OS respectively). **Conclusions:** Clonal CPCs are detectable in more than 50% of newly diagnosed MM patients undergoing upfront ASCT. Monitoring for CPCs before initiation of induction therapy and before ASCT by 6-color flow cytometry is highly predictive of outcome in NDMM and should be incorporated into prospective clinical trials.

8021 Poster Session (Board #347), Mon, 8:00 AM-11:30 AM

Acupuncture for symptom reduction in myeloma patients undergoing hematopoietic stem cell transplantation: A randomized, sham-controlled trial. *First Author: Gary E. Deng, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Hematopoietic stem cell transplantation (HCT) is a potentially curative treatment for a number of hematologic malignancies, but is associated with a high symptom burden for patients. We conducted a randomized sham-controlled trial to evaluate the preliminary efficacy and safety of acupuncture as an integrative treatment for managing common symptoms during HCT. **Methods:** Adult patients with multiple myeloma undergoing high dose melphalan followed by autologous peripheral blood HCT were randomized to receive either true or sham acupuncture once daily for five days starting on the day after chemotherapy. Symptom burden was assessed with the MD Anderson Symptom Inventory (MDASI) at baseline, during transplantation, and at 15 and 30 days after transplantation. **Results:** Among 60 participants, symptoms that are significantly reduced by true acupuncture more than sham acupuncture at 15 days include the following: nausea, lack of appetite, and drowsiness (p = 0.042, 0.025, and 0.010, respectively). Patients receiving sham acupuncture were more likely to increase use of pain medication post-transplantation (odds ratio 5.31, p = 0.017). Acupuncture was well tolerated with few attributable adverse events. **Conclusions:** True acupuncture may prevent escalation of symptoms including nausea, lack of appetite, and drowsiness experienced by patients undergoing autologous HCT, and to reduce the use of pain medications. These findings need to be confirmed in a future definitive study. Clinical trial information: NCT01811862.

8022 Poster Session (Board #348), Mon, 8:00 AM-11:30 AM

Autologous stem cell transplant (ASCT) for newly diagnosed multiple myeloma (MM) in the era of novel agents: A meta-analysis of phase III randomized controlled trials. *First Author: Binod Dhakal, Medical College of Wisconsin, Milwaukee, WI*

Background: Given the unprecedented deep response rates with the novel agent induction, the role of high dose therapy (HDT) followed by ASCT in MM pts. has been questioned, and was re-evaluated in a number of randomized clinical trials (RCTs). Although, the results of most studies suggest the continued benefit of HDT/ASCT, some RCTs suggest no overall survival (OS) benefit. We undertook a systematic review and meta-analysis of phase III randomized RCTs evaluating the role of HDT compared to standard therapy (SDT) in the context of novel agent induction **Methods:** We searched the PubMed, Scopus and Cochrane Collection of Controlled Trial databases using the term *myeloma* combined with *autologous* or *transplant* or *myeloablative* or *stem cell* from 2000-2016. A total of 2480 articles identified, of which 4 large phase III RCTs compared upfront HDT with SDT with novel agents use. Two individuals independently extracted the data. Reported hazard ratio (HR) and survival data were pooled using random effects models (STATA v14, College Station, Tx). Heterogeneity was assessed using I^2. **Results:** Four studies comprising 2421 patients were included (Table 1). One study did not report the HR for death and hence OS analysis was limited to 3 studies. The combined hazard for progression with HDT was 0.55 (95% CI 0.40-0.71) (p < 0.005). The combined hazard for death with HDT was 0.65 (95% CI 0.29-1.0) (p = 0.007). Sensitivity and sub-group analysis showed no difference in PFS (p = 0.06) and OS (p = 0.22) with HDT. Significant heterogeneity was demonstrated by I^2 of 71.4% for PFS (p = 0.01) and 68.4% for OS (p = 0.04). **Conclusions:** Based on our analysis, even in the novel agent era, HDT appears to be beneficial and should be considered standard of care for all transplant eligible MM pts.

8023 Poster Session (Board #349), Mon, 8:00 AM-11:30 AM

Impact of t(11;14) on outcomes in African American (AA) and non-AA (NAA) patients (Pts) with newly diagnosed multiple myeloma (NDMM): Connect MM registry. *First Author: Cristina Gasparetto, Duke University Medical Center, Durham, NC*

Background: t(11;14) is a common cytogenetic abnormality historically associated with standard-risk and generally favorable MM outcomes, but has shown poor prognosis in some retrospective analyses. Connect MM is a prospective, US, observational, multicenter registry that collects data on management and natural history of NDMM pts in clinical practice. The impact of t(11;14) on survival outcomes was assessed in AA and NAA pts. **Methods:** Adult NDMM pts who completed induction and were tested for t(11;14) by FISH/cytogenetics were grouped by race (AA vs NAA). Endpoints were PFS and OS. Kaplan-Meier analyses were adjusted for differences in cohort, age, ISS stage, transplant intent, t(4;14), hemoglobin, platelets, calcium, creatinine, and diabetes history. Data cutoff was Jul 7, 2016. **Results:** 3011 pts were enrolled in 2 cohorts (Cohort 1: n = 1493, Sep 2009–Dec 2011, median follow-up = 39.3 mos; Cohort 2: n = 1518, Dec 2012–Apr 2016, median follow-up = 16.4 mos). Of 1539 (52%) pts tested for t(11;14), 363 (24%) were t(11;14)-positive, including 53 (26%) of 205 AA and 310 (23%) of 1334 NAA pts. First-line bortezomib exposure was similar across groups. A trend of shorter PFS was observed in AA pts with t(11;14) vs AA without t(11;14) (Table). AA pts with t(11;14) had significantly higher risk of death compared to those without t(11;14) and higher rate of early mortality than NAA pts. No differences in PFS or OS were noted in NAA pts with or without t(11;14). For OS, the interaction between race and t(11;14) status was statistically significant (P= 0.004). **Conclusions:** In Connect MM, the effect of t(11;14) on OS was significantly different between AA and NAA pts. t(11;14) was associated with poorer survival outcomes in AA pts, and thus, may be a risk factor for poor prognosis. Additional analyses will be conducted to elucidate the role of induction treatment, transplant and maintenance in AA and non-AA pts with t(11;14). Clinical trial information: NCT01081028.

8024 Poster Session (Board #350), Mon, 8:00 AM-11:30 AM

MOR202 with low-dose dexamethasone (Dex) and in combination with pomalidomide/dex and lenalidomide/dex in relapsed or refractory multiple myeloma (RRMM): Interim analysis of a phase I/IIa dose-escalation study. *First Author: Marc Raab, Department of Medicine V, University Hospital Heidelberg and National Center for Tumor Diseases, Heidelberg, Germany*

Background: CD38 is a type II transmembrane glycoprotein expressed by MM cells. MOR202, a human IgG1 CD38 monoclonal antibody, has shown high single-agent activity in preclinical models of MM and synergy in combination with immunomodulatory drugs (IMiDs), lenalidomide (LEN) and pomalidomide (POM). **Methods:** This interim analysis of a multicenter phase I/IIa study reports safety and efficacy data from RRMM patient (pt) cohorts treated with clinically relevant doses of MOR202 (2-hour IV infusion; 4, 8 and 16 mg/kg q1w) + Dex (≤40 mg), or at 8 or 16 mg/kg q1w with an IMiD/Dex. Primary objectives were to evaluate the safety, maximum tolerated dose (MTD) and recommended phase II dose of MOR202. **Results:** As of January 2017, 79 pts had been treated, including 44 in clinically relevant cohorts: 18 received MOR202 + Dex, 15 MOR202 + LEN/Dex and 11 MOR202 + POM/Dex. Pts had received a median of 3, 2 and 3 prior treatment lines, respectively. The MTD of MOR202 was not reached. Combinations were generally well tolerated, with grade ≥3 adverse events (AEs) mainly hematological; 2 pts discontinued due to a MOR202-related AE (one grade 4 thrombocytopenia; one grade 3 acute kidney failure). Infusion-related reactions (all grade 1 or 2) were seen in only 3/44 (7%) pts, and mainly occurred during the first infusion. In the MOR202 + Dex cohort, 5/17 (29%) evaluable pts (receiving at least 1 cycle of treatment) had a response, including 3 with partial responses (PRs) and 2 with very good PRs (VGPRs). Responses were also seen in 11/13 (85%, 8 PRs, 3 VGPRs) evaluable pts in the MOR202 + LEN/Dex cohort and 5/9 (56%, 2 complete responses, 3 PRs) in the MOR202 + POM/Dex cohort. Longest response duration was 17 months (MOR202/Dex). Preliminary analysis showed preservation of high CD38 levels on MM cells under MOR202 therapy. **Conclusions:** In heavily pretreated pts with RRMM, a 2-hour infusion of MOR202 administered at up to 16 mg/kg with Dex or in combination with an IMiD/Dex, showed a favorable safety profile, including excellent infusion tolerability. Promising preliminary efficacy and long-lasting tumor control was seen. Clinical trial information: NCT01421186.

8025 Poster Session (Board #351), Mon, 8:00 AM-11:30 AM

Daratumumab, lenalidomide, and dexamethasone (DRd) vs lenalidomide and dexamethasone (Rd) in relapsed or refractory multiple myeloma (RRMM): Efficacy and safety update (POLLUX). *First Author: Nizar J. Bahlis, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: Daratumumab (D) is a human CD38-targeting mAb that significantly prolongs progression-free survival (PFS) when added to standard-of-care regimens in patients (pts) with RRMM. We examined updated efficacy and safety data from POLLUX (NCT02076009), a randomized phase 3 study of DRd vs Rd in RRMM. **Methods:** Pts with ≥1 prior line of therapy (LOT) received Rd (25 mg PO lenalidomide on days 1-21 of each q4w cycle; 40 mg dexamethasone weekly) ± D (16 mg/kg IV qw for cycles 1 and 2, q2w for cycles 3-6, then q4w until disease progression). Pts refractory to lenalidomide were ineligible. Minimal residual disease (MRD) was assessed on bone marrow samples at time of suspected complete response (CR) and at 3 and 6 months post-suspected CR at sensitivities of 10^{-4}, 10^{-5}, and 10^{-6} via next-generation sequencing (Adaptive Biotechnologies, Seattle, WA). **Results:** Pts received a median (range) of 1 (1-11) prior LOT. 55% received prior IMiDs (18% lenalidomide). Based on previous median follow-up of 17.3 months, DRd significantly prolonged PFS (median: not reached vs 17.5 months; HR, 0.37; 95% CI, 0.28-0.50; $P < 0.0001$) and significantly improved overall response rate (ORR; 93% vs 76%, $P < 0.0001$) vs Rd. DRd induced higher rates of deep responses vs Rd (≥very good partial response [VGPR]: 78% vs 45%; ≥CR: 46% vs 20%; all $P < 0.0001$) and included MRD negativity, which was > 3-fold higher across all 3 sensitivity thresholds for DRd vs Rd (25% vs 6% at the 10^{-5} threshold). MRD-negative pts demonstrated longer PFS vs MRD-positive pts. Follow up for overall survival (OS) is ongoing (OS events: 40 [14%] in DRd and 56 [20%] in Rd). No new safety signals were identified with longer follow up. Updated efficacy and safety data based on approximately 25-months follow up will be presented at the meeting. **Conclusions:** DRd provided significant benefits vs Rd in terms of PFS, ORR, and MRD negativity, and the favorable safety profile of DRd was maintained with longer follow up. These data further validate the use of DRd in RRMM pts who received ≥1 prior therapy. Clinical trial information: NCT02076009.

8026 Poster Session (Board #352), Mon, 8:00 AM-11:30 AM

Loss of heterozygosity in multiple myeloma: A role for PARP inhibition? *First Author: Charlotte Pawlyn, The Institute of Cancer Research, London, United Kingdom*

Background: PARP inhibitors can induce synthetic lethality in tumors characterized by homologous recombination deficiency (HRD). Two PARP inhibitors are approved for the treatment of *BRCA* mutated ovarian cancer. HRD can be detected by evaluating genome-wide loss of heterozygosity (LOH), which is associated with response to PARP inhibition. Myeloma (MM) is a genetically unstable tumor and we hypothesized that LOH could be detected in patient samples, supporting a potential role for PARP inhibition in MM. **Methods:** We analyzed 406 cases at all disease stages: MGUS (n = 7), smoldering MM (SMM, n = 30) newly diagnosed MM (NDMM, n = 71), treated MM (TRMM, n = 64) and relapsed MM (RLMM, n = 234). CD138+ plasma cell DNA underwent targeted next generation sequencing (FoundationOne Heme) interrogating 405 cancer related genes and 3543 single nucleotide polymorphisms (SNPs) across the genome. An algorithm using the minor allele frequencies of the examined SNPs and copy number profile across the 22 autosomal chromosomes identified LOH segments. Events unlikely to be caused by HRD, e.g. whole chromosome or chromosome-arm loss, were excluded. The percentage of genomic LOH for each sample was calculated as the sum of the lengths of included LOH segments divided by the length of the interrogated genome. **Results:** We found evidence of HRD detected by LOH with higher LOH selecting for patients with poor outcome. LOH increases with advancing disease stage from a median of 0.3% in MGUS to 3.1% in RLMM. LOH was highest in the PR and MMSET molecular subgroups and correlated significantly with the gene expression defined risk score GEP70 (R = 0.4, $p < 0.001$) and proliferation index (R = 0.4, $p < 0.001$). Outcome of RLMM patients, the biggest clinical group, was analyzed and patients with LOH above the 3rdquartile (≥5%LOH) had significantly worse overall survival than those with lower levels ($p < 0.001$). LOH correlates and overlaps with other metrics of poor prognosis, suggesting it may be a prognostic marker itself. **Conclusions:** We demonstrated LOH in MM samples, increasing as disease progresses and associated with poor prognosis. These data support the further evaluation of PARP inhibitors in MM patients, particularly in the relapsed setting with a high unmet need for new treatments.

8027 Poster Session (Board #353), Mon, 8:00 AM-11:30 AM

Pomalidomide (POM) + low-dose dexamethasone (LoDEX) after lenalidomide (LEN)-based second-line (2L) treatment (Tx) in patients (Pts) with relapsed/refractory multiple myeloma (RRMM): Analysis of progression-free survival (PFS) by level of disease control. *First Author: David Siegel, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ*

Background: Recent trials of triple therapy in 2L and third-line (3L) Tx excluded pts refractory to LEN. This is not reflective of standard of care in first line and 2L where LEN is given until progressive disease (PD). MM-014 enrolled pts with RRMM and 2L LEN-based Tx failure. Here we report results only from cohort A of pts receiving POM + LoDEX. Cohort B will investigate POM + LoDEX + daratumumab. **Methods:** Adult pts with MM, 2 prior Tx lines, and PD after ≥ 2 cycles of 2L LEN-based Tx received POM + LoDEX. The primary endpoint was overall response rate (ORR). Other endpoints included time to response (TTR), PFS, second primary malignancies (SPMs), and biomarkers. **Results:** Of 51 pts in cohort A, 39 (76.5%) discontinued Tx. Most pts (88.2%) were refractory to their last LEN Tx, (median Tx duration 24.6 mos) and 72.5% had prior bortezomib. At a median follow-up of 13.6 mos, ORR was 29.4% (2.0% complete response, 9.8% very good partial response, and 17.6% partial response [PR]) and median TTR was 1.9 mos; 66% of pts had ongoing response at 1 yr. Minimal response [MR] was reached in 15.7%. Median PFS was 13.8 mos. Pts with ≥ MR had similar Tx durations as those achieving ≥ PR. Additional results in Table. Post-Tx T-cell populations were significantly higher vs baseline ($CD3^+$, 72.6% vs 67.8%; $CD3^+/CD8^+$, 36.9% vs 32.1%). Relative changes from baseline were significantly greater in pts with response vs pts with no response ($CD3^+$, 10.4 vs −0.8; $CD3^+/CD4^+$, 4.2 vs −3.5). **Conclusions:** This update confirms the safety and efficacy of POM + LoDEX following 2L LEN-based Tx failure in pts with RRMM. Hematologic adverse event (AE) rates improved and median PFS was longer with 3L use than previously reported with POM + LoDEX use in later Tx lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR. Clinical trial information: NCT01946477.

8028 Poster Session (Board #354), Mon, 8:00 AM-11:30 AM

Phase 3 ELOQUENT-2 study: Extended four year follow-up (FU) of elotuzumab plus lenalidomide/dexamethasone (ELd) vs Ld in relapsed/refractory multiple myeloma (RRMM). *First Author: Sagar Lonial, Winship Cancer Institute, Atlanta, GA*

Background: Elotuzumab, an immunostimulatory monoclonal antibody, has a dual mechanism of action: directly activating NK cells and tagging myeloma cells for recognition/death via antibody-dependent cell-mediated cytotoxicity. In a 3-y FU, ELOQUENT-2 (NCT01239797) showed a sustained 27% reduction in risk of disease progression/death for ELd vs Ld and OS trend in favor of ELd (Dimopoulos et al, ASH 2015). Here we present extended 4-y FU data (median FU 46 mo). **Methods:** RRMM patients (pts) were randomized 1:1 to ELd or Ld in 28-d cycles until disease progression/unacceptable toxicity. Coprimary endpoints: PFS, ORR. Secondary endpoint: OS. **Results:** Of 646 RRMM pts, 321 were randomized to ELd, 325 to Ld; ~ twice as many pts remain on therapy in ELd vs Ld (17 vs 9%) at data cut-off (Oct 18, 2016). Discontinuation was mainly due to disease progression (both arms 54%). At 4-y FU, ELd had 29% reduction in risk of progression/death vs Ld (HR 0.71, 95% CI 0.59–0.86) and relative improvement of 50% in PFS (21 vs 14%). Pts with ≥VGPR (ELd 112 [35%], Ld 95 [29%]) had greatest reduction in risk of progression/death (HR 0.65, 95% CI 0.46–0.94). ORR was 79% (ELd) vs 66% (Ld). OS will be presented. G3–4 AEs in ≥5% of pts included second primary malignancies (SPMs), vascular diseases, cardiac disorders and infections (ELd vs Ld: 9 vs 6%, 10 vs 8%, 5 vs 8%, 33 vs 26%). Overall rate (any grade) of infection and SPMs was 84 vs 75% and 17 vs 11% for ELd vs Ld. However, pts had longer exposure to ELd vs Ld (median [Q1, Q3] treatment cycles (19 [9, 42] vs 14 [6, 25]). There were fewer deaths with ELd vs Ld (165 vs 186), mainly due to disease progression and infection in both arms. **Conclusions:** Elotuzumab in combination with Ld consistently met its efficacy objectives at 4-y FU. ELd showed durable, clinically relevant improvement in PFS, with 29% reduction in risk of progression/death, consistent with 2-y (30%) and 3-y FU (27%). Safety, including rate of SPMs, was consistent with previous findings, with minimal incremental AEs with addition of elotuzumab to Ld. These data represent the longest median FU of an immuno-oncology agent in MM. Study funding: BMS. Writing support: C Tomas, Caudex, funded by BMS. Clinical trial information: NCT01239797.

8029 Poster Session (Board #355), Mon, 8:00 AM-11:30 AM

HDAC11 as a candidate therapeutic target in multiple myeloma. *First Author: Allison Distler, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: Histone deacetylase (HDAC) inhibitors (HDI) have a therapeutic niche in multiple myeloma (MM) due to their ability to salvage proteasome inhibitor and immunomodulatory drug responsiveness in refractory patients, thus raising interest in this therapeutic class. Selective HDI may further improve therapeutic efficacy. **Methods:** B cell lymphopoiesis was evaluated using Tg-HDAC11-eGFP mice expressing eGFP regulated by the HDAC11 promoter and congenic mouse strains deficient in HDAC11 expression globally (B6.HDAC11$^{-/-}$) or targeted to the B cell lineage (CD19Cre.HDAC11$^{-/-}$). Molecular and pharmacologic means were used to impair HDAC11 in established MM cell lines. Viability was measured by activated caspase-3, Annexin/PI (A/PI) staining, and CCK-8 viability assay. Subcellular localization changes induced by HDI and identification of the novel binding partner IRF4 were assessed by proximity ligation assay (PLA). **Results:** Profound eGFP increases in PC of Tg-HDAC11-eGFP mice suggest HDAC11 influences late stage B cell development. In addition, HDAC11 deficiency results in dramatically reduced PC in the bone marrow and periphery. PC depletion in CD19Cre.HDAC11$^{-/-}$mice suggests activity inherent in B cells rather than via externally derived signals. Quisinostat (QS), an HDI with enhanced HDAC11 selectivity, showed dose-dependent cytotoxicity in 10 MM cell lines (EC50 1-10nM). This activity was synergistic with bortezomib (BTZ) and carfilzomib (CFZ) in RPMI-8226 cells, while synergism was amplified in the BTZ-resistant RPMI-8226-B25 cell line. Exposure of RPMI-8226 cells to QS decreased detection of nuclear, but not cytosolic, HDAC11. Targeted siRNA–mediated silencing of HDAC11 in RPMI-8226 cells activated caspase-3 and reduced viability by A/PI staining. PLA of MM cell lines showed a novel interaction between HDAC11 and IRF4, an essential regulator of PC differentiation and MM survival, unmasking a potential mechanism for HDAC11-induced cytotoxicity in MM. This interaction was disrupted by QS. **Conclusions:** We show that HDAC11 inhibition reduces MM cell survival in vitro. Furthermore, we identify IRF4 as a binding partner for HDAC11 and propose this interaction as a candidate mechanism regulating PC maturation and MM survival.

8030 Poster Session (Board #356), Mon, 8:00 AM-11:30 AM

Cost effectiveness of carfilzomib (CAR), ixazomib (IXA), elotuzumab (ELO), or daratumumab (DAR) with lenalidomide and dexamethasone (LEN+DEX) vs LEN+DEX in relapsed/refractory multiple myeloma (R/R MM). *First Author: Nimer Alsaid, Center for Health Outcomes and PharmacoEconomic Research, College of Pharmacy, University of Arizona, Tucson, AZ*

Background: CAR, IXA, ELO, and DAR in triplet combination with LEN+DEX have shown superior efficacy over LEN+DEX in R/R MM, but their comparative efficacy and cost effectiveness has not been estimated. **Methods:** Network meta-analysis [NMA] and Bücher method were used to indirectly estimate comparative progression-free survival (PFS) efficacy. A 2-state Markov model (progression-free, progressed or death) was specified. Inputs included: cost of chemotherapy, administration, adverse events (AE) management, disease monitoring; utilities for health states; and disutilities for AEs. Incremental cost effectiveness (ICER) and cost utility ratios (ICUR) were calculated for resp. PFS life years (PFS LY) and quality adjusted life years (PFS QALY) gained in base case and probabilistic sensitivity analyses (PSA). **Results:** NMA and Bücher indirect comparison methods yielded similar PFS hazard ratios (HR), revealing superiority of DAR+LEN+DEX over other triplets in terms of PFS (Table). Using the exponential distribution to fit PFS data, our cost effectiveness analysis indicated that all 4 triplet regimens were associated with additional PFS LY and QALY gained over LEN+DEX at additional cost. DAR+LEN+DEX was associated with the greatest PFS LY and QALY gained at the lowest relative cost, yielding superior ICER and ICUR estimates compared to other triplet regimens. **Conclusions:** The superior PFS efficacy of DAR+LEN+DEX is associated with positive cost effectiveness and cost utility in the setting of R/R MM.

Network meta-analysis hazard ratios	CAR+LEN+DEX 0.99 (0.75-1.30) 1.87 (1.28-2.73) 0.69 (0.57-0.83)	IXA+LEN+DEX 0.93 (0.69-1.26) 1.96 (1.34-3.00) 0.74 (0.59-0.93)	ELO+LEN+DEX 1.05 (0.78-1.49) 1.85 (1.29-2.70) 0.70 (0.57-0.86)	DAR+LEN+DEX 0.37 (0.27-0.52)	LEN+DEX

8031 Poster Session (Board #357), Mon, 8:00 AM-11:30 AM

Risk stratification of smoldering multiple myeloma (SMM): Predictive value of free light chains and group-based trajectory modeling (GBTM). *First Author: Ajai Chari, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: A serum free light chain ratio (FLCR) ≥ 100 and bone marrow plasma cell (BMPC) ≥ 60% have recently been classified as myeloma defining events to identify a group of SMM patients at high risk (ie. > 50% risk at 2 years) of organ damage. However rates of progression for FLCr range from 30% to 98%. Reasons for the discrepancy include selection/referral bias, patient heterogeneity, and lack of consideration of disease evolution. The objective of this study was to determine the predictive value of baseline FLCR > 100 and BMPC > 60% in our patient population and also to determine the significance of m spike and FLC evolution using GBTM. **Methods:** We retrospectively investigated the predictive value of these events, including involved–uninvolved FLC (dFLC), in 273 consecutive SMM patients seen at our institution between 2010 and 2015. GBTM uses the outcomes of groups of individuals with similar trajectories over time (vs apriori assumptions of % change) to model population trajectories. **Results:** In patients with FLCR ≥ 100 at diagnosis, the median time to progression was 23 mos with 2-year progression of 52%. In patients with BMPC ≥ 60% at diagnosis, median time to progression was 25 months with 2-year progression of 47%. For 111 patients available for analysis, GBTM two distinct trajectories in dFLC during the 1st year. 18% of patients fell into a high risk group experiencing a 171% increase in dFLC at 1 year vs the remaining patients only had a 16% increase. The high risk group had a median TTP of 13.7 mos versus not reached for the remaining (log-rank p = 0.0063). Similarly the 25% of patients who had a 62% increase in mean m spike within 1 year had TTP of 27 mos versus the remaining 75% who had no increase had a median TTP of 84 mos (log rank p = 0.0943). **Conclusions:** Our results not only confirm a more modest 52% 2 year risk of PD with an FLCR > 100 and dFLC > 100, but also suggest that a high risk dFLC trajectory evolution may help identify a SMM high risk group, with a median TTP of only 13.7 mos. Results of multivariate analysis and sensitivity/specificity comparisons of baseline as well as evolving biomarkers will be presented at the meeting.

8032 Poster Session (Board #358), Mon, 8:00 AM-11:30 AM

The impact of body mass index on the risk of early progression of smoldering multiple myeloma to symptomatic myeloma. *First Author: Wilson I. Gonsalves, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Human adipocytes can contribute directly to the *in vitro* growth and progression of multiple myeloma (MM) cell lines. Clinically, an elevated body mass index (BMI) has been associated with an increased risk of MGUS and a shorter time to progression (TTP) of MGUS to MM. However, the impact of BMI on the risk of early progression to MM from a more advanced plasma cell disorder such as smoldering MM (SMM) remains unknown. **Methods:** This study included patients (pts) with a known or new diagnosis of SMM evaluated at the Mayo Clinic, Rochester from January 2000-December 2010. Pts were classified based on their BMI as: normal (< 25) and elevated (>/= 25) BMI. Progression to symptomatic MM was defined by the development of hypercalcemia, renal insufficiency, anemia or lytic bone lesions. **Results:** There were 306 pts with a diagnosis of SMM who were included in this analysis. The median follow up was 106 months. There were 203 (66%) pts who progressed to symptomatic MM at last follow up. The median BMI of the group was 27.5 (Range: 17.2 – 56.4). There were 228 (75%) pts with an elevated BMI. There were 76 (28%) pts who had myeloma defining events (MDEs) such as a serum free light chain ratio > 100 or > 60% clonal bone marrow plasma cells at initial evaluation. MDEs were present in 17% and 33% of pts with a normal and elevated BMI respectively (P = 0.011). The median TTP of SMM to MM in pts with a normal and elevated BMI was 64 and 36 months respectively (P = 0.0006). The 2-year progression rate of SMM to symptomatic MM in pts with a normal and elevated BMI was 16% and 42% respectively (P < 0.0001). Upon limiting the analysis to only SMM pts without MDEs at initial evaluation (N =187), the 2-year progression rate to symptomatic MM with a normal and elevated BMI was 15% and 33% respectively (P = 0.013). In a multivariable model, only elevated BMI (P = 0.004) and increasing clonal bone marrow plasma cells (P = 0.001) was statistically significant in predicting for a 2-year progression to MM. **Conclusions:** SMM pts with an elevated BMI appear to have a higher risk of early progression to MM than those with a normal BMI. This study provides evidence of a potentially modifiable risk factor for the progression of SMM to MM and warrants confirmation in larger studies.

8033 Poster Session (Board #359), Mon, 8:00 AM-11:30 AM

Safety and efficacy of daratumumab-based regimens in elderly (≥75 y) patients (Pts) with relapsed or refractory multiple myeloma (RRMM): Subgroup analysis of POLLUX and CASTOR. *First Author: Maria-Victoria Mateos, University of Salamanca Hospital, Salamanca, Spain*

Background: Daratumumab (D) plus lenalidomide and dexamethasone (Rd; POLLUX) or with bortezomib and dexamethasone (Vd; CASTOR) demonstrated prolonged PFS and tolerability compared with Rd and Vd alone, respectively, in RRMM pts. We examined the safety and efficacy profiles of DRd and DVd in elderly (≥75 y) pts from these phase 3 studies. **Methods:** Pts with ≥1 prior line of therapy were enrolled. All pts in POLLUX were treated until progression; CASTOR pts received 8 cycles of Vd ± daratumumab. Different D (16 mg/kg) dosing schedules were used in POLLUX (qw for cycles 1-2, q2w for cycles 3-6, and q4w thereafter) and CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, and q4w thereafter). Elderly pts received a reduced dexamethasone dose (20 mg once weekly). **Results:** In POLLUX, 29/286 (DRd) and 35/283 (Rd) were ≥75 y, with 86% and 91% having ECOG status ≤1, respectively. With 17.3 months of median follow up, 10% in DRd and 11% in Rd discontinued due to treatment-emergent adverse events (TEAEs). Common (>10%) grade 3/4 TEAEs for DRd included neutropenia and hypokalemia (Table). Twelve (41%) DRd pts experienced infusion-related reactions (IRR) and 4 (14%) experienced grade 3/4 IRR; none discontinued due to IRR. Median PFS was not reached (NR) in DRd vs 11.4 months in Rd (HR 0.19; 95% CI, 0.06-0.55; *P*=0.0007), and ≥CR % was significantly higher with DRd vs Rd (52% vs 9%; P=0.0002). In CASTOR, 23/251 (DVd) and 35/247 (Vd) were ≥75 y, with 100% and 94% having ECOG status ≤1, respectively. With 13.0 months of median follow up, rates of discontinuation due to TEAEs were similar (15% vs 20%). Thrombocytopenia, fatigue, and pneumonia were common grade 3/4 TEAEs for DVd (Table). Thirteen (65%) pts reported IRR (10% grade 3/4) and no pts discontinued due to IRR. Median PFS was NR in DVd vs 8.1 months in Vd (HR 0.27; 95% CI, 0.12-0.61; *P*=0.0007), and significantly higher ≥CR % was observed in DVd vs Vd (25% vs 3%; *P*=0.0154). **Conclusions:** The safety and efficacy profiles in elderly pts were generally comparable with the overall population in each study. Clinical trial information: NCT02136134 and NCT02076009.

% Grade 3/4 TEAEs	DRd	Rd	DVd	Vd
Neutropenia	45	31	0	3
Hypokalemia	14	3	0	0
Pneumonia	10	11	15	17
Thrombocytopenia	7	14	45	37
Anemia	3	20	10	11
Fatigue	3	3	15	11

8034 Poster Session (Board #360), Mon, 8:00 AM-11:30 AM

Impact of metformin use in the outcomes of multiple myeloma patients post stem cell transplant. *First Author: Narjust Duma, Mayo Clinic, Rochester, MN*

Background: Multiple myeloma (MM), a monoclonal plasma cell disorder, is one of the most common hematologic malignancies in the US. In preclinical studies, metformin demonstrated plasma cells cytotoxicity. However, there is lack of studies translating the effect of metformin into the clinical setting. Therefore, we assessed the clinical effect of metformin in patients (pts) with MM. **Methods:** All MM pts who underwent stem cell transplant (SCT) at the Mayo Clinic Rochester from 2007 to 2012 were reviewed. Patients were grouped based on metformin use. Initial diagnosis at our institution and ≥12 months of follow up were required. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis. **Results:** Out of 687 pts, 78 (11.4%) were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin (Mt) and no-metformin (NMt) groups were similar (Table). Median (M) metformin dose was 2000 mg daily and m duration of metformin use from MM diagnosis was 22 months. Pts on the Mt group achieved higher rates of CR after SCT (41% vs. 29%, p<0.02). Median PFS after SCT was longer in the Mt group, 31.3 months (95% CI: 10.4-52.2) vs. 16.6 months in the NMt group (95%CI: 14.5-18.7) p<0.04. There was a trend towards longer OS in the Mt group, but it was not statistically significant (170 vs. 106 months, p<0.10). In a multivariate analysis of metformin use, age, ISS, LDH, and cytogenetics/FISH, the former was an independent predictor of PFS after SCT (OR: 0.38, 95%CI: 0.20-0.68, p<0.001). **Conclusions:** Metformin use was associated with a better PFS and higher CR after SCT in our MM cohort. A trend towards better OS was also noted in the Mt group. Larger studies are needed to enhance our understanding of the clinic effect of metformin on MM.

Characteristics	Mt No./% (n=78)	NMt No./% (n=609)
Age (M)	61	61
Male	46/59	355/58
Creatinine (M)	0.9	0.9
International Staging System (ISS)		
I	22/28	135/22
II	19/24	175/29
III	15/19	107/18
Unknown	22/28	195/31
Plasma cells circulating index (M)	0.9	0.8
% Bone marrow plasma cells (M)	29	40
LDH (M)	185	184
FISH (normal karyotype)	68/88	533/88
Treatment with cyclophosphamide	16/21	125/21

8035 Poster Session (Board #361), Mon, 8:00 AM-11:30 AM

Synergism of gambogenic acid with bortezomib induce apoptosis of multiple myeloma. *First Author: Runzhe Chen, Department of Hematology and Oncology, Zhongda Hospital, Medical School, Southeast University, Nanjing, China*

Background: Multiple myeloma (MM) is one of the most common primary tumors of the bone marrow that accounts for approximately 10% of all hematological cancer. Gambogenic acid (GNA) is one of the natural compound isolated from gamboge and has demonstrated advantages such as a more potent anticancer effect and less systemic toxicity according to early investigations. In this study, we hypothesized that GNA could synergistically potentiate BTZ-induced apoptosis of MM cells and that combining BTZ and GNA may provide a more effective approach to treat MM. **Methods:** CCK-8 assay, CI isobologram, flow cytometry, western blot, xenograft tumour models, TUNEL and immunochemistry were used in this study to detect to possible mechanisms of apoptosis led by GNA and BTZ *in vitro* and *in vivo*. **Results:** The percentage of MM.1S in G2/M phase after 48h of 4.0nM BTZ, 0.90μM GNA and combination treatment were 31.09±2.16%, 26.68±1.96% and 19.88±1.89% respectively. The percentage of MM.1S in G2/M phase of control group was 17.23±1.65%. The apoptosis rates of MM.1S cells for 48h were 6.57±0.15% in control group, 89.67±5.15% after treatment with 4.0nM BTZ, 97.80±0.81% after treatment with 0.90μM GNA, and 98.9±3.86% after treatment with 4.0nM BTZ plus 0.9μM GNA respectively. All the treatment groups showed a more significant apoptosis rate compared to that of the control group ($p<0.01$). MM.1S tumors were implanted in BALB/Ca nu/nu male mice. The tumor weights of GNA and BTZ plus GNA groups decreased significantly when compared with those of control group ($p<0.01$ and $p<0.001$, respectively) and the tumor weight of combination group was significantly less than that of BTZ or GNA group ($p<0.001$). When mice were treated with BTZ combined with GNA, the tumor inhibition rate was 41.94%, whereas those of mice treated with BTZ or GNA alone were 9.68% and 19.35%, respectively. We also found that the combined treatment could induce more markedly increased apoptosis of MM.1S cells via the activation of PARP cleavage, P53, Caspase-3 cleavage and Bax and inhibition of Bcl-2 expression. **Conclusions:** Our data support that a synergistic antitumor activity exists between BTZ and GNA, and provide a rationale for successful utilization of dual BTZ and GNA in MM chemotherapy in the future.

8036 Poster Session (Board #362), Mon, 8:00 AM-11:30 AM

Daratumumab, bortezomib and dexamethasone (DVd) vs bortezomib and dexamethasone (Vd) in relapsed or refractory multiple myeloma (RRMM): Efficacy and safety update (CASTOR). *First Author: Suzanne Lentzsch, Division of Hematology/Oncology, Columbia University, New York, NY*

Background: Daratumumab (D), a human, CD38-targeting mAb, is well tolerated and induces deep and durable responses in patients (pts) with RRMM. We provide an update of CASTOR (NCT02136134), a multicenter, phase 3, randomized study of DVd vs Vd in RRMM. **Methods:** All pts received ≥1 prior line of therapy (LOT) and were administered 8 cycles (Q3W) of Vd (1.3 mg/m^2 SC bortezomib on days 1, 4, 8, and 11; 20 mg PO/IV dexamethasone on days 1-2, 4-5, 8-9, and 11-12) ± D (16 mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Bortezomib-refractory pts were ineligible. Minimal residual disease (MRD) was assessed upon suspected CR and at 6 and 12 months following the first dose at sensitivities of 10^{-4}, 10^{-5}, and 10^{-6}using the ClonoSEQ assay (Adaptive Biotechnologies, Seattle, WA). **Results:** Pts received a median (range) of 2 (1-10) prior LOTs. 66% were previously treated with bortezomib and 21% were refractory to lenalidomide in their last prior LOT. After a median follow-up of 13.0 months, PFS was significantly prolonged with DVd vs Vd (median: not reached vs 7.1 months; HR, 0.33; 95% CI, 0.26-0.43; $P<$ 0.0001). This PFS benefit was seen regardless of number of prior LOTs received, with greatest benefit observed in 1 prior line pts (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; $P<$ 0.0001). ORR was also significantly higher for DVd vs Vd (84% vs 63%), along with ≥VGPR (62% vs 29%) and ≥CR (26% vs 10%; $P<$ 0.0001 for all). MRD-negative rates were ≥4-fold higher at all three sensitivity thresholds with DVd vs Vd (10% vs 2% at 10^{-5} threshold). Pts who achieved MRD negativity demonstrated prolonged PFS compared with MRD-positive pts. 37 (15%) and 58 (24%) deaths were observed in DVd vs Vd, respectively, and follow up is ongoing. The most common grade 3/4 TEAE was thrombocytopenia (45% vs 33%). Updated efficacy and safety data will be presented. **Conclusions:** DVd provided significant benefits with respect to PFS, ORR, depth of response, and MRD-negative rate vs Vd. No new safety signals were reported. These data continue to support the use of DVd in RRMM pts and indicate that pts with 1 prior LOT will derive the most benefit. Clinical trial information: NCT02136134.

8037 Poster Session (Board #363), Mon, 8:00 AM-11:30 AM

CALGB/ECOG 100104 (Alliance) study: Lenalidomide (LEN) vs placebo (PBO) maintenance (maint) after stem cell transplant (SCT) for patients (pts) with multiple myeloma—Overall survival (OS) and progression-free survival (PFS) adjusted for treatment (tx) crossover (XO). *First Author: Philip L. McCarthy, Roswell Park Cancer Institute, Buffalo, NY*

Background: At a prespecified interim analysis (Dec 2009), the phase 3 CALGB study results surpassed the prespecified superiority boundary (significantly improved PFS for LEN maint vs PBO after SCT) and the majority of PBO arm pts without progressive disease (PD) crossed over to LEN maint. An updated analysis (cutoff Mar 2015), showed significantly longer OS with LEN maint (HR, 0.56; 95% CI, 0.42-0.76). We examined the effect of LEN vs PBO on OS and PFS from randomization, adjusting for XO effects. **Methods:** The rank-preserving structural failure time model (RPSFTM; Robins, *Commun Stat Theory Methods*, 1991) was used for XO adjustment; the iterative parameter estimation (IPE; Branson, *Stat Med*, 2002) algorithm was used as validation. Survival was portioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for pts who remained on Tx. **Results:** Pts were randomized to LEN maint (n = 231) and PBO (n = 229) (intent-to-treat [ITT] population); 76 pts without PD crossed over from PBO to LEN. Median time from randomization to XO was 11.5 mos. The relative Tx effect for OS and PFS increased for LEN vs PBO when adjusting for XO using RPSFTM and IPE (Table). The landmark analysis at the Dec 2009 interim (PBO XO, n = 76; No XO, n = 34) showed the Tx effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. **Conclusions:** Adjusting for the potential diluting effects of XO reduced median OS and PFS with PBO, and improved the Tx effect in the ITT analyses for OS and PFS for LEN vs PBO maint after SCT. The statistical significance of the ITT analyses was maintained throughout. Support: U10CA180821, U10CA180882, CA180820. Clinical trial information: NCT00114101.

	OS[a]	PFS[a]
	LEN (n = 231) vs PBO (n = 229)	
ITT, Unadjusted	NR vs 79.0 0.56 (0.42-0.76)	58.4 vs 28.9 0.58 (0.46-0.73)
RPSFTM	NR vs 70.9 0.48 (0.34-0.69)[b]	58.4 vs 25.8 0.50 (0.39-0.63)[b]
IPE	NR vs 70.9 0.48 (0.33-0.68)[b]	58.4 vs 25.8 0.48 (0.36-0.63)[b]

8038 Poster Session (Board #364), Mon, 8:00 AM-11:30 AM

Daratumumab-based combination therapies (DCT) in heavily-pretreated patients (pts) with relapsed and/or refractory multiple myeloma (RRMM). *First Author: Arjun Lakshman, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Daratumumab-based Combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) showed exceptional activity in RRMM in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited. **Methods:** RRMM pts seen at Mayo Clinic, MN from 12/2015 -12/2016 were reviewed. Pts who received ≥ 1cycle of DCT were included. Time-to-event analyses were done from date of starting DCT. Common terminology criteria for adverse events v4.0 were used to grade toxicities. **Results:** Of 130 pts, 59% were males and median age at DCT initiation was 67 (43-93) years, ECOG performance score was ≥2 in 29%. Pts were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months (m), and median number of prior therapies was 4 (1-14). 14% of pts were refractory to prior D monotherapy. Fifty-three (41%), 34 (26%) and 25 (19%) received DPd, DRd and DVd respectively. Eighteen (14%) pts received 'other' DCT. Median time to first response (≥ PR) was 3.1 m (95% CI 2.1-4.6). Overall response rate was 46%, [CR-2%, VGPR-18%, PR-26%]. Minimal response was seen in 17%, with clinical benefit rate of 62%. Median estimated follow up from initiation of DCT was 5.5 m (CI 4.2-6.1). The median duration of response was 6.1 m [CI 5.1- not reached (NR)]. Median progression free survival (PFS) was 5.5 m (CI 4.1-7.8) and median time to next therapy (TTNT) was 5.9 m (CI 4.6-9.4). Median PFS for DPd, DRd, DVd and other DCTs were 4.6 (CI 2.7-NR), 7.8 (CI 5-NR), 3.9 (CI 2.1-NR) and 3.9 (CI 2.8-8.2) m, respectively (p = 0.3). Median PFS for quadruple refractory (n = 28) MM was 2.8 m (CI 2.2-5.3) vs 5.9 m (CI 4.9-NR) for the rest ($p < 0.01$). Median overall survival (OS) from DCT was NR (CI 11.4-NR). Grade 3 or higher hematological toxicities were seen in 42% of pts. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%). **Conclusions:** DCT are effective in RRMM, but the PFS remains short particularly in quadruple refractory pts, reflecting the challenges encountered in managing heavily-pretreated, and often less fit patients, in routine practice.

8039 Poster Session (Board #365), Mon, 8:00 AM-11:30 AM

Semaphorin 4D to suppress bone formation in multiple myeloma. *First Author: Konstantinos Lontos, University of Pittsburgh Medical Center Department of Medicine, Pittsburgh, PA*

Background: Myeloma bone disease is characterized by osteoclast activation and long-term osteoblast suppression. We investigated if Semaphorin 4D (Sema4D; CD100) plays a role in these processes. Sema4D has been shown to be a potent osteoblast inhibitor (Negishi-Koga T et al, Nat Med. 2011). A study recently identified that the breast cancer cell line MDA-MB-231 utilizes Sema4D to create osteolysis (Yang Y et al, PLOS One 2016). There have been previous data that Sema4D is increased in the serum of myeloma patients (Terpos et al, Blood 2012) and that co-culturing myeloma cell lines with osteocytes increases the expression of Sema4D mRNA in both (Suvannasankha et al, Blood 2016). We sought to investigate if myeloma cells are using Sema4D to suppress bone formation and if they affect the levels of Sema4D produced by osteoclasts. **Methods:** We used lentivirus carrying shRNA for Sema4D or control (Scr) to knock down the level of the protein in the 5TGM1 murine myeloma cell line. Knockdown was verified by qPCR and Western Blot. We subsequently co-cultured the 5TGM1 cells with the MC3T3-subclone M4 (MC4) murine stromal cell line for 2 days, removed the myeloma cells and then differentiated the MC4 cells using ascorbic acid and β-glycerolphosphate. At day 5, we analyzed the cells for Runx2 (a critical gene for the differentiation of stromal cells into osteoblasts) expression utilizing qPCR. Also, we performed qPCR in primary osteoclast (OCL) mouse cells differentiating into OCL with RANKL with or without pre-treatment with myeloma-conditioned media for 3 days before the addition of RANKL. **Results:** When 5TGM1-Scr were co-cultured with MC4 cells the expression of Runx2 on day 5 was decreased (p=0.02). Strikingly, the 5TGM1-shSema4D cells when co-cultured with MC4s did not have the same effect and allowed the upregulation of Runx2 expression on day 5 (p=0.01). Myeloma-conditioned media increased Sema4D expression by OCL throughout the 5 days of differentiation 2 to 3-fold (p=0.01 for day 5). **Conclusions:** The myeloma cells seem to be utilizing Sema4D both directly and indirectly to inhibit bone formation. Targeted therapy against Sema4D may improve outcomes and fracture-free survival for multiple myeloma patients.

8040 Poster Session (Board #366), Mon, 8:00 AM-11:30 AM

Impact of post-autologous stem cell transplant (ASCT) maintenance therapy on outcomes in patients (Pts) with newly diagnosed multiple myeloma (NDMM) using the large prospective community-based Connect MM registry. *First Author: Sundar Jagannath, Mount Sinai Medical Center, New York, NY*

Background: Maintenance therapy (MT) improved progression-free survival (PFS) and overall survival (OS) in MM clinical trials. The observational Connect MM registry, which is largely community based, was used to assess impact of MT on outcomes in ASCT-eligible NDMM pts. **Methods:** Adult NDMM pts ≤60 days from diagnosis were eligible for enrollment. Pts receiving induction and ASCT were included and analyzed by 4 MT regimens: No MT, lenalidomide-based (LEN), bortezomib-based (BORT), and LEN+BORT MT. Duration was from 100 days post-ASCT (no MT group) or start of MT until progressive disease, death, discontinuation, or data cutoff. End points were PFS, 2nd PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics was performed. **Results:** Of 1493 enrolled pts (Cohort 1; Sep 2009 – Dec 2011), 1450 were treated; 81% (n=1173) were in a community setting. A total of 432 (29%) met analysis criteria. Data cutoff was Jan 7, 2016 (median follow-up of 39.3 mo). Median age was 60 y (range, 24-78 y); 60%, men; and 86%, white. 165 pts did not receive MT. Of 267 pts receiving MT, 213 (80%) received LEN; 30 (11%), BORT; and 16 (6%), LEN+BORT. Only LEN MT is presented, as interpretation of other MT data was limited by small sample sizes. Median treatment duration for LEN MT vs No MT was 35.2 vs 26.1 mo, respectively. PFS and OS significantly increased with LEN MT vs No MT (Table); 2nd PFS was similar for both. Exploratory analyses showed generally similar PFS and OS improvements across subgroups (age, ECOG status, ISS stage, risk group, and induction regimen). No new safety signals were observed. **Conclusions:** In ASCT-eligible NDMM pts, PFS and OS improved with LEN MT vs No MT and appeared to be independent of induction regimen. Preliminary analysis of 2nd PFS suggests no impact on the efficacy of 2nd line therapy. These data from a largely community-based setting confirm results from randomized phase III trials. Clinical trial information: NCT01081028.

	LEN (n = 213)	No MT (n = 165)	Hazard Ratio (95% CI)
Median PFS, mo	50.3	30.8	0.62 (0.46, 0.82) *P*= .0009
3-yr PFS	56%	42%

8041 Poster Session (Board #367), Mon, 8:00 AM-11:30 AM

Rates of peripheral neuropathy (PN) in patients (Pts) with relapsed and refractory multiple myeloma (RRMM) treated with carfilzomib vs comparators in pivotal phase III trials. *First Author: Ruben Niesvizky, Center for Myeloma, New York Presbyterian Hospital-Weill Cornell Medical Center, New York, NY*

Background: PN is a dose-limiting toxicity for some anti-MM agents, such as the proteasome inhibitor (PI) bortezomib (V). Carfilzomib (K), a novel irreversible PI associated with low PN, was evaluated in 2 recent phase 3 studies in RRMM pts. **Methods:** This analysis evaluated PN rates in ASPIRE (K [27 mg/m^2]-lenalidomide [R]-dexamethasone[d] [KRd] vs Rd in relapsed MM; Stewart 2015) and ENDEAVOR (Kd [K 56 mg/m^2] vs Vd in RRMM; Dimopoulos 2016). We evaluated grade ≥2 PN during treatment, patient-reported outcomes (PROs; QLQ-C30 pain, FACT/GOG-neurotoxicity subscales), and progression-free survival (PFS) in pts with BL history of PN. **Results:** In ASPIRE, grade ≥2 PN rate was low (8.9% [KRd] vs 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with KRd vs Rd for pts with BL grade ≥2 PN. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Vd (6.0% vs 32.0%; Table). Pts had significantly improved pain and neurotoxicity subscale scores with Kd vs Vd. PFS improved with Kd vs Vd in pts with BL history of grade ≥2 PN (Table). **Conclusions:** In ENDEAVOR, Kd resulted in less PN vs Vd; in ASPIRE, PN rate was similar for KRd vs Rd. PFS was longer with KRd and Kd vs Rd and Vd, respectively, including in pts with BL grade ≥2 PN. Improved pain and neurotoxicity outcomes with K may be attributed to better disease control and/or lower PN rates. Clinical trial information: NCT01568866, NCT01080391.

Comparative efficacy of multiple myeloma therapies for treatment of first relapse: A systematic literature review and network meta-analysis. *First Author: Eric M Maiese, Janssen Scientific Affairs, LLC, Horsham, PA*

Background: Treatment for multiple myeloma (MM) in the US has undergone significant advances, with several new therapies recently FDA approved for relapse/refractory MM (RRMM), including carfilzomib+lenalidomide+dex (KRd), carfilzomib+dex (Kd), daratumumab+lenalidomide+dex (DRd), daratumumab+bortezomib+dex (DVd), ixaxomib+lenalidomide+dex (IRd), and elotuzumab+lenalidomide+dex (ERd). These new therapies have shown improvements in clinical outcomes in randomized controlled trials (RCTs). However, with few head-to-head RCTs, there is little comparative evidence to determine the most effective treatment for specific patients. A systematic literature review (SLR) and network meta-analysis (NMA) was conducted to determine the comparative efficacy (progression free survival (PFS)) of MM therapies for treating first relapse. **Methods:** The SLR searched MEDLINE, Embase, and the Cochrane Library for RCTs investigating the efficacy of treatments for RRMM (to August 2016). NMA was conducted on the PFS hazard ratios (HR), where available in RCTs for patients with one prior line of treatment, using Bayesian fixed effects mixed treatment comparisons. **Results:** Data formed two evidence networks. Network 1: RCTs with Rd; Network 2: RCTs with Vd. Analyses found DRd and DVd had the highest probability of being the best treatment (0.96 and 0.89, respectively). Compared to other MM therapies, DRd and DVd had the lowest risk of progression or death (PFS HR <1.0) (Table 1). For example, compared to KRd, DRd had a 41% (PFS HR 0.59) reduced risk of progression or death. **Conclusions:** This analysis provides comparative evidence among treatments where head-to-head RCTs have not been conducted. For treating first relapse, compared to other MM treatments, this analysis found that DRd and DVd had the highest probability of providing the longest progression free survival.

NMA results.

Treatment	PFS HR (95% Credible Interval)
Network 1 - DRd Compared to:	
KRd	0.59 (0.35, 1.01)
ERd	0.55 (0.31, 0.95)
IRd	0.49 (0.29, 0.84)
Rd	0.41 (0.26, 0.65)
Network 2 - DVd Compared to:	
Kd	0.69 (0.37, 1.25)
Vd	0.31 (0.18, 0.52)

Outcomes of secondary cancers among myeloma survivors. *First Author: Jorge J. Castillo, Dana-Farber Cancer Institute, Boston, MA*

Background: With increasing survival, myeloma patients (pts) experience second cancers. We analyzed receipt of surgery and cancer-specific survival (CSS) among myeloma survivors with common solid tumors, in comparison with pts without myeloma. **Methods:** We extracted Surveillance, Epidemiology, and End Results (SEER) data on pts diagnosed with common cancers in 2004-2013. Among them, we identified myeloma survivors, and we matched each to 50 randomly sampled controls with the same cancer by age, sex, race, and year of diagnosis. We then compared CSS, cumulative incidence function (CIF) for death from the index cancer (but not from myeloma), and receipt of surgery (for non-metastastic, stage-matched tumors only) using a Cox (for hazard ratio, HR), Fine-Gray (for subhazard ratio, SHR), and conditional logistic models, respectively. **Results:** Myeloma survivors were significantly older (*P*<.001), and more often black (except in bladder cancer) than pts with respective cancers from the general population. In the case-control analysis, breast (*P*=.002) and lung cancers (*P*=.003) were more often diagnosed at an early stage among myeloma survivors. Receipt of surgery did not significantly differ, except for lower use of prostatectomy in myeloma survivors (odds ratio, 0.59, 95%CI, 0.44-0.81). CSS significantly differed only in lung cancer, and was better among myeloma survivors even when stratified by stage. CIF of cancer death was significantly lower for myeloma cases with lung and colorectal cancer. **Conclusions:** Despite additional competing mortality from recurrent myeloma, myeloma survivors have similar CSS and CIF of death after common cancers compared with other pts. This highlights the need to treat them similarly to other pts, without assuming a poor prognosis. Better outcomes in lung cancer are not fully explained by earlier detection, suggesting a biological difference.

Racial differences in abnormalities by FISH in minorities with multiple myeloma: A single-center experience. *First Author: Miguel Gonzalez Velez, Rutgers New Jersey Medical School, Newark, NJ*

Background: Racial disparities of FISH abnormalities in multiple myeloma (MM) have been well described in whites (W) but partially described in minorities (M) (Paulus et al, ASH 2016, 4432). We aimed to explore racial-based differences of FISH abnormalities using the largest cohort of m to date. **Methods:** CD-138 selected FISH was done on 799 consecutive patients (pts). Pts without symptomatic MM, and biopsy >6 months after diagnosis were excluded. The abnormalities evaluated included standard and intermediate risk: IGH rearrangements (IGH r), t(4;14), t(11;14), and high risk: t(14;20), t(14;16), del13q, del 17p, 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all m (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis. **Results:** 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (3%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 26% ISS stage 3. There were no were no statistically significant differences in FISH abnormalities between the m (Table1). Overall W had more abnormalities in IGH r, t(4;14), t(11;14), t(14:20), 1q21 gain compared to M. Most notably W had more IGH r (39% vs 28%; p=0.019) and t(11;14) (20% vs 12%; p=0.024). There were no statistically significant differences between W and m in the high risk FISH abnormalities. **Conclusions:** We had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

AFM26 is a novel, highly potent BCMA/CD16A-directed bispecific antibody for high affinity NK-cell engagement in multiple myeloma. *First Author: Thorsten Gantke, Affimed GmbH, Heidelberg, Germany*

Background: Despite recent advances in the treatment of multiple myeloma (MM), novel therapies are needed to achieve long-lasting remissions in a greater number of patients. Natural killer (NK) cells play a key role in the immune response to MM and have been implicated in the clinical efficacy of current standard of care interventions, including IMiDs, proteasome inhibitors, recently approved immunotherapies and autologous stem cell transplantation (ASCT). Numerous strategies are being developed to enhance the natural NK-cell cytotoxicity against myeloma cells, which is frequently dysregulated in MM. Approaches include modulation of activity, through cytokine stimulation or immune checkpoint targeting, and adoptive transfer of culture expanded NK-cells in ASCT-eligible MM. While highly attractive, these approaches are non-targeted, as they rely on the natural cytotoxicity of NK-cells, and may benefit from antigen-specific retargeting and effector activation. AFM26 is a novel tetravalent, bispecific antibody designed to specifically enhance NK-cell anti-MM activity by redirecting NK-cell lysis to BCMA, an antigen expressed on MM cells. **Methods:** NK-cell engagement and cytotoxicity of AFM26 towards MM cell lines and freshly isolated tumor cells from MM patients was characterized *in vitro* and compared with classical antibody formats. **Results:** AFM26 engages NK-cells with superior avidity (K_D: 1-2nM) through bivalent interaction with CD16A (FcγRIIIa) and demonstrates extended cell surface retention that is not affected by high level IgG, as is particularly relevant in MM. Importantly, AFM26 does not induce NK-cell depletion but selectively induces potent and efficacious lysis of MM cells *in vitro*. **Conclusions:** In summary, AFM26 is a promising candidate to enhance NK-cell activity and confer tumor-specificity to NK-cells in MM. Differentiation of AFM26 from classical antibody formats and its potential for combination with cellular NK-cell therapies is highlighted.

Trends in survival and costs among US multiple myeloma patients. *First Author: Eric M Maiese, Janssen Scientific Affairs, LLC, Horsham, PA*

Background: Survival among multiple myeloma (MM) patients has improved over time, but little is known about concurrent changes in healthcare costs. This study examined trends in both survival and healthcare costs over the same time periods in US MM patients. **Methods:** The MarketScan Commercial and Medicare claims dataset was used to identify 5199 adult patients diagnosed with MM from Jan. 2006 to Dec. 2014. Patients had no prior evidence of cancer, were continuously enrolled for >12 months prior to MM diagnosis, and were followed through the earliest event (death, end of enrollment, or end of the study period (9/30/2015)). Multivariate GLM and Cox proportional hazards models estimated healthcare costs and survival probabilities, respectively, for two time periods during which patients were diagnosed with MM (2006-2010 vs 2011-2014) while controlling for demographic and clinical characteristics. The recycled prediction method was used to calculate the incremental cost estimates between the time periods. **Results:** Patients diagnosed in 2011-2014 had a 35% lower risk of death compared to those diagnosed in 2006-2010 (HR [95% CI] = 0.65 [0.57-0.74]. Patients diagnosed in 2011-2014 had 18% (95% CI: 6-31%) higher all cause and 26% (95% CI: 6-50%) higher MM-related per patient per month costs compared to those diagnosed in 2006-2010 (Table). **Conclusions:** Among MM patients, survival has improved at a greater rate than the increase in healthcare costs. In addition to improvements in MM treatment, changes in overall disease management may have contributed to both the increased expenditures and survival improvements observed in this study.

Healthcare costs, by time period of diagnosis.

	2006-2010 (N=2597)	2011-2014 (N=2602)	Cost Ratio
Adjusted* all-cause healthcare costs,** mean (SD)	$13,960 ($5213)	$16,449 ($6142)	1.18^
Adjusted* MM-specific healthcare costs, ** mean (SD)	$7,476 ($5524)	$9,422 ($1438)	1.26^

*Adjusted for age, sex, insurance provider, geographic region, MM treatments, pre-index healthcare costs, baseline comorbidity index, and baseline number of comorbid diagnoses. **Costs per patient per month. ^p<0.01 for time periods 2011-2014 vs 2006-2010.

Risk stratification by detection of clonal circulating plasma cells (CPCs) by multi-parametric flow cytometry (MFC) in light chain amyloidosis (AL). *First Author: Surbhi Sidana, Mayo Clinic, Rochester, MN*

Background: Presence of CPCs by six color MFC is associated with worse outcomes in multiple myeloma (MM). Using a slide based immunofluorescence assay, CPCs are associated with worse prognosis in AL, but outcomes with MFC are not known. **Methods:** We retrospectively analyzed 154 patients (pts) from Jan 2008 – Dec 2015 with AL who had CPCs analyzed by MFC at diagnosis. **Results:** CPCs were present in 42% pts (n = 64, median = 88 per 150,000 events, range 6-17844). Table 1 lists baseline characteristics, treatment and response. In univariate analysis, bone marrow (BM) plasma cells > 15% (p<0.0001), dFLC > 60 mg/dL (p=0.02) and presence of active MM (p=0.0004) were associated with detectable CPCs. In multivariate (MV) model, only BM plasma cells > 15% predicted for presence of CPCs (p=0.02). There was no difference in hematologic or organ response in the 2 groups. Median follow up was 43 months (m). Pts with detectable CPCs had worse survival than those without detectable CPCs (90 m vs. 98 m, p=0.0004). In MV analysis model with Mayo Stage and detectable CPCs, presence of CPCs at diagnosis was independently associated with poor survival (CPCs p= 0.02, Mayo Stage p < 0.0001). **Conclusions:** Presence of detectable CPCs is an independent adverse prognostic factor for survival in AL. Comparatively fewer pts with detectable CPCs underwent early ASCT, which may reflect a more aggressive disease presentation.

Factors predicting organ response in light chain amyloidosis (AL). *First Author: Surbhi Sidana, Mayo Clinic, Rochester, MN*

Background: Organ response (OR) in AL is often delayed and difficult to predict early. **Methods:** We retrospectively analyzed 1308 patients (pts) with newly diagnosed AL from 2006 – 2015 to determine factors which could predict for OR. **Results:** Median age was 64 years (yr) and Mayo Stage was: 1 (22%); 2 (23%); 3 (25%); 4 (31%). Organ involvement was: cardiac (74%, n=932); renal (59%, n=738), liver (16%, n=205); gut (24%, n=310) and autonomic (12%, n=152). 59% (n=765) had > 1 organ involved, including 43% (n=567) with > 1 critical organ (heart, kidney, liver) involved. Treatment was: ASCT based (28%, n=330, N=1186), bortezomib based (24%, n=281), alkylator based (33%, n=392), others (5%, n=54) and none (10%). In evaluable pts, VGPR or better rates were: 53% at 6 months (m) (N=625), 72% at 12 m (N=465) and 57% overall (N=688). Table 1 lists OR at various time points. Complete OR in all involved critical organs was seen in: 51% (n=308, N=600), partial response (at least 1 OR when >1 organ involved) in 12% (n=73) and none in 37% (n=219). Complete OR was associated with better overall survival (OS) than partial or no OR (median OS: not reached vs 42 m vs 29 m; P <0.0001). In multivariate model the following variables at baseline or 1 yr mark were predictive of complete OR: lower Mayo Stage (p=0.01), fewer critical organs involved (p=0.007), higher baseline GFR (p=0.03), female sex (Complete OR 60% vs 47%; p=0.04) and VGPR at 1 yr (Complete OR 70% vs. 36%; p <0.0001). Other factors included in the model were age (p=0.9), bilirubin (p=0.1) and transplant (p=0.2). All aforementioned factors were significant in univariate analysis. **Conclusions:** Achievement of response in all involved critical organs is associated with better survival in AL pts than partial or no OR. Various baseline factors and VGPR at 1 yr can predict for achieving complete OR, with 70% pts who achieve VGPR at 1 yr having a complete OR.

Outcomes according to involved free light chain (FLC) levels in patients with normal FLC ratio after initial therapy in light chain amyloidosis (AL). *First Author: Nidhi Tandon, Mayo Clinic, Rochester, MN*

Background: Complete response in AL is defined as normal FLC ratio with negative serum and urine immunofixation. It is not clear if high involved serum FLC (hIFLC) in a patient with normal ratio may contribute to ongoing amyloid formation and hence affect outcomes. **Methods:** Data of 1308 patients (pts) with systemic AL seen within 90 days of diagnosis, at Mayo Clinic between 2006-2015, was analyzed retrospectively. Among these, 369 pts had 2 consecutive normal FLC ratio values after 1st line treatment and form the study population. Log rank test was used to estimate survival differences. **Results:** Among these 369 pts, pts with hIFLC at 1st reading of normal FLC ratio (hIFLC1; n=170; 46.1%) were compared to those who did not (n=199; 53.9%). At diagnosis, the median age [61.5 vs 60.8 years (y); p=0.2], proportion of males (62.4 vs 58.3%; p=0.4), percentage of pts with renal involvement (73.5 vs 64.8%; p=0.07), in mayo stage I / II / III / IV (32.9% / 23%/ 27.3% / 16.8% vs 43.6 %/ 22.9% / 18.1% / 15.4%; p=0.1), with bone marrow plasma cells >10% (24.2 vs 30%; p=0.2) and with presence of t(11; 14)(48.4 vs 60; p=0.08) was similar, while cardiac (67.5 vs 53.3%; p=0.006) and hepatic (18.2 vs 9.1%; p=0.01) involvement was higher in hIFLC1 group. The median follow-up from diagnosis was 6.1 y (95% CI; 5.6, 6.8). The median progression free survival (PFS) in pts who had hIFLC1 was lower than for those who did not; 2.6 y (95% CI; 1.9, 4.5) vs 5.2 y (95% CI; 4.6, 6.4), p<0.0001, as was the median overall survival [OS; 6.7 y (95% CI; 4.5, 8.3) vs not reached (NR), p<0.0001]. We performed a more stringent comparison for pts with 2 consecutive hIFLC values (hIFLC2; n=112; 30.4%) versus not (n=257; 69.6%). The median PFS (3.2 y; 95% CI; 2.2, 4.5 vs 5.6 y; 95% CI; 4.7, 7.1; p<0.0001) and OS (7.8 y; 95% CI; 6.4, NR vs NR; 95%CI; 9.5, NR; p<0.0001) were significantly reduced in pts with hIFLC2 versus not as well. A multivariate analysis confirmed an impact of hIFLC1 and hIFLC2 on PFS/OS independent of serum creatinine. **Conclusions:** In pts with systemic AL, persistent elevation of the involved FLC predicts for poor prognosis (independent of serum creatinine) even among those who achieved normal FLC ratio after 1st line treatment.

Treatment approaches and outcomes in extramedullary plasmacytomas. *First Author: Gaurav Goyal, Creighton University Medical Center, Omaha, NE*

Background: There is a lack of contemporary studies analyzing the optimum radiation dose and prognostic factors for outcomes of extramedullary plasmacytomas. In this study, we aim to answer these questions by utilizing the National Cancer Data Base (NCDB). **Methods:** This is a retrospective study of patients with histologically confirmed diagnosis of plasmacytoma from 2000-2011 using NCDB. Patients who had bone marrow involvement were excluded from the analysis. Hazard ratios were calculated using the Cox-proportional hazard method. In addition, we utilized survival trees as a novel tool for assessing prognostic effect of factors among four age quartiles (Q): Q1: 18-52, Q2:52-62, Q3:62-72, and Q4: ≥72 years. **Results:** A total of 5,056 patients were included in the study (median age 62 years; range, 52-72 years). Of these, 63% were males. Radiation therapy was received by 3,905 patients, with a median radiation dose of 45 Gy. A radiation dose of ≥40 Gy was associated with improved overall survival (OS) as compared to <40 Gy. Factors associated with worse OS included older age (≥65 years) and bone disease (Table). In survival tree analysis, radiation dose ≥44.5 Gy was associated with better OS in Q1 as compared to lower dose. For Q2 and Q3, disease location played a major role, with improved survival seen in upper aero-digestive and lymph node disease as compared to bone and soft tissue. In Q3, among the bone and soft tissue disease, radiation dose ≥ 43.5 Gy was associated with the better survival as compared to ≤43.5 Gy. In Q4, soft tissue and upper aerodigestive plasmacytomas had better outcomes as compared to bone and lymph node disease. Among the latter group, a radiation dose ≥30.3 Gy was associated with improved OS as compared to lower dose. **Conclusions:** This is the largest study of extramedullary plasmacytomas in the United States. This study shows that dose of radiation has a significant impact on outcomes, in addition to disease location and age.

Factors affecting survival in extramedullary plasmacytoma.

Prognostic variable	Hazard ratio	95% CI
Age ≥65 vs. younger	3.41	2.95, 3.93
Plasmacytoma bone vs. other	1.59	1.35, 1.87
Radiation dose ≥40 Gy vs. <40 Gy	0.21	0.07, 0.65

TPS8051 Poster Session (Board #377a), Mon, 8:00 AM-11:30 AM

Phase 1 study to evaluate the safety and efficacy of immunotherapy with tremelimumab and durvalumab in multiple myeloma patients receiving high dose chemotherapy and autologous stem cell transplant (HDT/ASCT) + peripheral blood lymphocyte (PBL) reinfusion. *First Author: Alexander M. Lesokhin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Multiple myeloma (MM) remains an incurable hematologic malignancy despite the advent of new classes of drugs, including immunomodulatory agents, proteasome inhibitors, and monoclonal antibodies. The success and synergistic activity of immunotherapy (IMT) in solid tumors and hematologic malignancies has fueled their investigation in MM. HDT/ASCT as consolidation or as treatment for relapse remains a cornerstone for improving overall survival. HDT/ASCT transiently eliminates immune-suppressive cell populations and provides a viable IMT platform. Reinfusion of PBLs harvested pre-HDT induces immune responses, supporting its inclusion in IMT combinations. This study evaluates the effect of IMT, using tremelimumab (T), an anti-CTLA-4 monoclonal antibody, and durvalumab (D), an anti-PD-L1 monoclonal antibody, together with autologous PBL reinfusion and starting T ± D at Day 100 and earlier (Day 30) post-ASCT. **Methods:** This ongoing Phase 1, open-label, multicenter study (NCT02716805) evaluates the safety and preliminary efficacy of T and D administered on 2 schedules in MM patients at high risk for relapse as outlined below. Cohort initiation requires dose-limiting toxicity in < 2/6 patients in the previous cohort. The primary endpoint is safety. Secondary endpoints are objective response rate per IMWG, minimal residual disease, progression free and overall survival, and 100-day ASCT-related mortality. Exploratory endpoints include immunological effects and immune response. Enrollment opened 18 Nov 2016. As of 31 Dec 2016, 1 patient is enrolled in Cohort 1; enrollment is ongoing. Clinical trial information: NCT02716805.

Cohort (n=6)	Day -31	Treatment (Day)	Cycle 1*		Cycle 2		Cycles 3-8
1	T	LEU (-10)	Day 100	T	Day 100 +4 weeks	T	D
2	T	HDT (-2)	Day 30	T	Day 100	T	every
3	T + D	ASCT (0)	Day 100	T + D	Day 100 +4 weeks	T + D	4 weeks
4	T + D	PBL reinfusion +T (3)	Day 30	T + D	Day 100	T + D	

Doses: T = tremelimumab 75 mg; D = durvalumab 1500 mg; HDT = melphalan 200 mg/m^{2}IV LEU = leukapheresis
*T ± D starting at either 100 or 30 days post-HDT/ASCT + PBL

TPS8052 Poster Session (Board #377b), Mon, 8:00 AM-11:30 AM

CheckMate 602: An open-label, randomized, phase 3 trial of combinations of nivolumab, elotuzumab, pomalidomide and dexamethasone in relapsed/refractory multiple myeloma. *First Author: Sagar Lonial, Winship Cancer Institute, Atlanta, GA*

Background: Multiple myeloma (MM) cells may evade immune surveillance by suppressing immune responses through the PD-1 pathway, via upregulation of PD-L1.[1]Nivolumab (nivo), a PD-1 immune checkpoint inhibitor that blocks PD-L1 interaction and disrupts MM-mediated PD-1 signaling, demonstrated modest activity as monotherapy in patients (pts) with relapsed/refractory multiple myeloma (RRMM) in a phase 1b study.[2] Pomalidomide, an immunomodulatory drug (IMiD), may sensitize MM cells to PD-1 blockade, and has shown efficacy with dexamethasone (Pd) for RRMM. Elotuzumab (elo), an anti-SLAMF7 monoclonal antibody, directly activates natural killer cells and facilitates antibody-dependent cell-mediated cytotoxicity. Preclinical work suggests PD-1 blockade may enhance elo efficacy[3]; thus nivo + Pd + elo may increase clinical benefit. **Methods:** CheckMate 602 (NCT02726581) is a phase 3, open-label, randomized study of efficacy and safety of nivo + Pd (N-Pd) vs Pd in pts with RRMM. Nivo combined with elo + Pd (NE-Pd) will be evaluated in an exploratory arm. Eligible pts must have measurable MM after ≥2 prior lines of therapy (LoTs) that included an IMiD and proteasome inhibitor, each for ≥2 consecutive cycles, alone or combined, and be refractory to their last LoT. Pts with prior elo are eligible. A planned 406 pts will be randomized 3:3:1 to N-Pd, Pd and NE-Pd, stratified by LoT (2 vs 3+) and International Staging System disease stage (I–II vs III). Pts in the Pd arm may cross over to the NE-Pd arm at disease progression. Pts are enrolled at 119 sites in 13 countries. Coprimary endpoints (N-Pd and Pd arms): objective response rate (ORR) and progression-free survival (PFS), assessed by an independent review committee. Secondary endpoints (N-Pd and Pd arms): time to response, duration of response, investigator-assessed ORR and PFS. Exploratory endpoints include ORR and PFS (NE-Pd arm), and safety/tolerability and minimal residual disease status (all arms). 1. Liu et al. *Blood* 2007;110: 296–304 2. Lesokhin et al. *JCO* 2016;34:2698–704 3. Bezman et al. *Haematologica* 2016;101:161–2 [S450] Study support: BMS. Writing support: A Gill, Caudex, funded by BMS. Clinical trial information: NCT02726581.

TPS8053 Poster Session (Board #378a), Mon, 8:00 AM-11:30 AM

A phase Ib study of atezolizumab (atezo) alone or in combination with lenalidomide or pomalidomide and/or daratumumab in patients (pts) with multiple myeloma (MM). *First Author: Hearn J. Cho, Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The advent of proteasome inhibitors and immunomodulatory drugs (IMiDs) have significantly improved outcomes in MM, and the first monoclonal antibodies for MM have been recently approved (daratumumab, elotuzumab). Despite novel therapies and improved disease management, MM is still considered incurable and most pts relapse, confirming the need for additional treatment options. MM cells express PD-L1, with higher levels observed after relapse and with advanced disease. Additionally, PD-L1–expressing immune cells in the microenvironment promote MM cell survival and potential immune escape. However, anti–PD-1 monotherapy did not result in objective responses in the MM cohort of a Ph I study, suggesting that MM pts need combination therapy. Daratumumab has activity as a single agent, as well as in combination with IMiDs plus dexamethasone and bortezomib plus dexamethasone in R/R MM. Immunomodulatory activity for daratumumab has also been reported. Thus, disruption of the PD-L1/PD-1 pathway may be additive or synergistic. The safety and efficacy of atezo (anti–PD-L1) alone or with lenalidomide or pomalidomide and/or daratumumab will be evaluated in a Ph Ib study of MM pts. NCT02431208. **Methods:** R/R MM pts with ≤ 3 prior therapies will be enrolled in Cohorts A (atezo), B (atezo + lenalidomide), D (atezo + daratumumab) and E (atezo + daratumumab + lenalidomide); MM pts with measurable disease after ASCT (Cohort C: atezo) or ≥ 3 prior therapies (Cohort F: atezo + daratumumab + pomalidomide) will also be enrolled. Cohorts B, D, E and F include a safety run-in (D) or dose escalation phase (B, E, F) and an expansion. Lenalidomide and pomalidomide will be dose escalated and the MTD evaluated in expansion phases. Atezo will be given at 1200 mg IV (A, B, C) or 840 mg IV (D, E, F); pts will get daratumumab at 16 mg/kg IV (D, E, F). All pts will be ECOG PS ≤ 2. Primary endpoints are ORR and the RP2D of lenalidomide and pomalidomide with atezo and daratumumab and the RP2D of lenalidomide with atezo. DOR and PFS are secondary endpoints; safety, PK and the relationship between biomarkers and other endpoints, including efficacy, will be assessed. Pts will be enrolled at 19 US sites. Clinical trial information: NCT02431208.

TPS8054 Poster Session (Board #378b), Mon, 8:00 AM-11:30 AM

Durvalumab (DURVA) plus daratumumab (DARA) in patients (pts) with relapsed and refractory multiple myeloma (RRMM). *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: DARA, a monoclonal antibody (mAb) against CD38, is approved for RRMM. Combination treatment (Tx) with DARA + DURVA, a mAb against programmed death ligand-1 (PD-L1), may enhance host anti-MM immunity and response. DARA and PD-L1 mAbs have each demonstrated clinical activity in combination with pomalidomide (POM) + low-dose dexamethasone (LoDEX) in MM. Thus, the phase 2 MEDI4736-MM-003 trial is evaluating DURVA + DARA in RRMM, and, in an exploratory analysis, the addition of POM + LoDEX to DARA + DURVA either upon progressive disease (PD) with DARA + DURVA or as up-front Tx will be assessed. **Methods:** ≈ 144 pts with RRMM are being enrolled. Pts with measurable MM who received ≥ 3 prior anti-MM Txs, including a protease inhibitor and an immunomodulatory agent, or are double-refractory to these 2 agents will be included. Exclusion criteria include allogeneic stem cell transplant (SCT), autologous SCT ≤ 12 weeks, and prior DARA or other CD38 antibody therapies. Primary endpoints are overall response rate (ORR) and safety. Secondary endpoints are time to response, duration of response, progression-free survival, and pharmacokinetics. The study includes a 3 + 3 safety run-in phase to confirm the tolerability of the recommended phase 2 doses (RP2Ds) of DURVA and DARA. Dose-limiting toxicities will be evaluated during the first Tx cycle. Safety and efficacy will be assessed by a Simon 2-stage design (Table). POM + LoDEX may be added to DARA + DURVA in pts who received ≥ 2 cycles of DARA + DURVA and had confirmed PD. Based on preliminary safety and efficacy, the 4-drug regimen may be explored as up-front Tx. Tx with either the 2- or 4-drug regimens will continue until PD or unacceptable toxicity. Pts treated with POM will be followed for second primary malignancies every 6 mos until the end of the trial. To date, 6 pts have enrolled in the run-in phase. Clinical trial information: NCT02807454.

Study Drug in 28-d Cycles	Safety Run-In	Stage 1 (RP2D)	Stage 2[a]	Exploratory	Expansion
DURVA		1500 mg (can be de-escalated to 750 mg) C1 D2; C2+ D1 or D2			
DARA		16 mg/kg C1-2 D1, 8, 15, 22; C3-6 D1, 15; C7+ D1			
POM		—		4 mg/day D1-21	
LoDEX		—		40 mg (20 mg if > 75 yrs old) D1, 8, 15, 22	

C, cycle. [a] If minimum ORR threshold met in Stage 1

TPS8055 Poster Session (Board #379a), Mon, 8:00 AM-11:30 AM

A phase 1/2 study of durvalumab (DURVA) in combination with lenalidomide (LEN) with or without dexamethasone (DEX) in patients (pts) with newly diagnosed multiple myeloma (NDMM). *First Author: Sagar Lonial, Winship Cancer Institute, Atlanta, GA*

Background: LEN + DEX (Rd) is approved for pts with newly diagnosed MM, including those who are transplant non-eligible (TNE). DURVA is a monoclonal antibody to programmed death ligand 1 (PD-L1) that blocks PD-L1 binding to programmed death-1 (PD-1). Preclinical studies showed anti-MM immune responses with PD-1/PD-L1 blockade that were enhanced with LEN (Görgün et al, 2015). Here, we present a phase 1/2, multicenter, open-label trial in progress (MEDI4736-MM-002) designed to evaluate DURVA in combination with LEN ± DEX in a target population of pts who are TNE and/or with high-risk NDMM. **Methods:** Enrollment of up to 138 pts from the US, Canada, and Europe is planned to determine the recommended dose of DURVA (primary endpoint) with LEN ± DEX for the treatment (Tx) of NDMM. Key secondary endpoints include safety, response outcomes, pharmacokinetics, progression-free survival, and overall survival. Pts with previously untreated MM with ≥ 1 of the following will be included: 1 of the CRAB criteria or clonal bone marrow plasma cells ≥ 60% and an Eastern Cooperative Oncology Group performance status of ≤ 2. Pts with a history of primary immunodeficiency will be excluded. Each independent cohort (A, B, C) will enroll 6 pts in parallel in the dose-finding phase (Table). Dose-limiting toxicities will be evaluated during the first cycle of Tx. The optimal regimen will be determined from the dose-finding phase and a parallel dose-expansion phase of up to 40 pts per cohort. Tx will continue until progressive disease or unacceptable toxicity. To date, 15 pts have enrolled. Clinical trial information: NCT02685826.

	28-d Cycle		
Study Drug	**Cohort A TNE and High Risk[a]**	**Cohort B TNE and ≥ 65 Yrs Old**	**Cohort C Post-Transplant and High Risk[a]**
DURVA[b]	1500 mg on D1		
LEN[c]	25 mg		10 mg
DEX	40 mg (20 mg if > 75 yrs old) on D1, 8, 15, 22		Not applicable

[a] Pts with ≥ 1 feature: t(4;14), del(17p), 1q rearrangement, and/or t(14;16); International Staging System stage III disease; or lactate dehydrogenase levels > 2 × upper limit of normal. [b] Can be de-escalated to 750 mg. [c] D1-21; adjustable per creatinine clearance value.

TPS8056 Poster Session (Board #379b), Mon, 8:00 AM-11:30 AM

Phase 2, open-label study of venetoclax in combination with carfilzomib and dexamethasone in patients with relapsed/refractory multiple myeloma. *First Author: Orlando Bueno, AbbVie Inc., Chicago, IL*

Background: A significant unmet need for multiple myeloma (MM) therapy remains as many patients eventually relapse after or become refractory to current treatment options. Investigation of novel agents and combinations in relapsed/refractory (R/R) patients are therefore critical to advance therapy and improve patient outcomes. Venetoclax is a potent, selective, orally bioavailable inhibitor of BCL-2. Combination of venetoclax with dexamethasone and bortezomib, a proteasome inhibitor that can inhibit MCL-1 indirectly via stabilizing the MCL-1-neutralizing protein NOXA, showed high rates of clinical response in a Phase 1 study. The mechanism of MCL-1 inhibition is thought to be a class effect of proteasome inhibitors. Given the clinical data supporting the combination of venetoclax with a proteasome inhibitor, this study will evaluate whether venetoclax combined with carfilzomib and dexamethasone can provide a well-tolerated and efficacious treatment option for R/R MM patients. **Methods:** This Phase 2, open-label study will assess the combination of venetoclax, carfilzomib, and dexamethasone in patients with R/R MM (NCT02899052). Primary objectives are to assess the safety and tolerability of this combination. Secondary objectives include evaluation of the pharmacokinetics of venetoclax and carfilzomib, preliminary efficacy of the combination (including overall response rate, very good partial response or better rate, progression-free survival, time to progression, and duration of response), and minimal residual disease (MRD) in bone marrow by next generation sequencing. Exploratory objectives will assess pharmacodynamic and predictive biomarkers, MRD by PET, pharmacogenetics, and patient-reported outcomes. Safety and pharmacokinetic profiles of the combination will be evaluated in initial dose escalation cohorts to determine appropriate doses of venetoclax and carfilzomib to be used with dexamethasone; a dose expansion phase will evaluate the safety and efficacy profiles of the combination based on selected doses. Study recruitment began in January 2017, with target enrollment of ~40 patients from 10–15 sites in the United States. Clinical trial information: NCT02899052.

TPS8057 Poster Session (Board #380a), Mon, 8:00 AM-11:30 AM

A phase III, randomized, open-label study of isatuximab (SAR650984) plus pomalidomide (Pom) and dexamethasone (Dex) versus Pom and Dex in relapsed/refractory multiple myeloma. *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: Treatment for refractory or relapsed and refractory multiple myeloma (MM) remains an unmet need. Isatuximab (ISA), an anti-CD38 monoclonal antibody with multiple mechanisms of tumor killing, has shown efficacy and an acceptable tolerability profile in Phase 1/2 studies in patients with refractory or relapsed and refractory MM (RRMM) (Richter et al. ASCO 2016; Vij et al. ASCO 2016). **Methods:** This Phase III, prospective, multicenter, randomized, open-label study (NCT02990338; ICARIA-MM) is being conducted to evaluate the clinical benefit of ISA in combination with Pom and low-dose Dex (Pom/Dex) versus Pom/Dex for the treatment of adult patients with RRMM and demonstrated disease progression within 60 days of the last therapy, and who have received at least 2 prior lines of therapy, including lenalidomide and a proteasome inhibitor (bortezomib, carfilzomib, or ixazomib) alone or in combination. Patients will be randomly assigned in a 1:1 ratio to either ISA (10 mg/kg IV on Days 1, 8, 15, and 22 in the 1st cycle; Days 1 and 15 in subsequent cycles) plus Pom (4 mg on Days 1–21) and Dex (40 mg for patients $<$ 75 years of age and 20 mg for patients $\geq$75 years of age, on Days 1, 8, 15, and 22) or Pom and Dex. Treatment cycles will be 28 days each. Patients will continue therapy until disease progression, occurrence of unacceptable adverse events (AEs), or their decision to discontinue the study, whichever comes first. The primary endpoint is progression-free survival (PFS), i.e. time from randomization to progressive disease or death from any cause. Response will be determined by IMWG criteria (2016). Key secondary endpoints include overall response rate and overall survival (OS). Safety evaluations include treatment-emergent AEs/serious AEs (including infusion-associated reactions), laboratory parameters, vital signs and assessment of physical examination. Statistical analyses will be conducted according to a pre-specified plan; approximately 300 patients (150 in each arm) are expected to be enrolled in this study. The first patient was recruited in January 2017. Study funding: Sanofi. Clinical trial information: NCT02990338.

TPS8058 Poster Session (Board #380b), Mon, 8:00 AM-11:30 AM

Novel phase 1a/1b dose-finding study design of CWP232291 (CWP291) in relapsed or refractory myeloma (MM). *First Author: Sung-Soo Yoon, Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea*

Background: CWP291, a novel peptidomimetic small molecule, has potent, selective inhibitory activity on a Wnt gene reporter, decreasing expression of β-catenin target genes, cyclin D1 and survivin. With broad anti-cancer efficacy in vitro, it significantly outperforms lenalidomide as a single agent combination in MM bone marrow engraftment models. **Methods:** This Phase 1a/1b study (NCT #02426723) was designed to define a well-tolerated dose of CWP291 as a single agent in subjects with R/R MM. CWP291 was administered IV over $\geq$30 minutes 2x weekly for 3 weeks out of a 4-week cycle, with standard 3+3 dose escalation design. But an important objective in terms of patient benefit and further clinical development was to explore activity of a combination regimen with lenalidomide. Thus, a novel study design allowed initiation of the Phase 1b as soon as CWP291 achieved a well-tolerated dose as a single agent. Combination therapy would start at one dose level lower. Enrollment of patients onto each arm was guided by Safety Review Committee assessments, including baseline laboratory values, performance status, extent of prior therapy, or prior adverse events related to lenalidomide. **Results:** Initiated September 2015, the starting dose was based on a prior Phase 1 study in AML, 198 mg/m^2. There were 4 sites involved, and 11 patients enrolled over 12 months. Approval of the new design by regulatory authorities and IRBs was completed by November 2016. A well-tolerated single agent dose (297 mg/m^2) was identified, allowing initiation of the Phase 1b at a dose of 198 mg/m^2(one dose level lower) combined with lenalidomide. Four subjects were enrolled in ~2 months to the Phase 1b. Enrollment to both arms is continuing and the status of this study will be updated at presentation. **Conclusions:** The ability to consider combination therapy with a novel drug is clearly a motivation for patient participation in clinical trials; especially true in MM, as multiple new therapies are available. This trial design was approved and allowed based on assessment of individual patient safety and potential benefit. Rapid enrollment in the combination therapy arm may significantly foster development of novel agents with this study design. Clinical trial information: NCT #02426723.

8500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Gefitinib (G) versus vinorelbine+cisplatin (VP) as adjuvant treatment in stage II-IIIA (N1-N2) non-small-cell lung cancer (NSCLC) with *EGFR*-activating mutation (ADJUVANT): A randomized, Phase III trial (CTONG 1104). *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Cisplatin-based adjuvant chemotherapy is standard of care for patients (pts) with stage II-IIIA non-small cell lung cancer (NSCLC). Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors have shown no benefits in the adjuvant setting for pts with unselected resected NSCLC in the BR19 and RADIANT trials. ADJUVANT (NCT01405079) is the first randomized trial to compare gefitinib (G) with vinorelbine+cisplatin (VP) in completely resected pathological stage II-IIIA (N1-N2) NSCLC with *EGFR*-activating mutation. **Methods:** Completely resected stage II-IIIA (N1-N2) NSCLC pts with *EGFR*-activating mutation were randomized 1:1 to receive G (250 mg once daily) for 24 months or vinorelbine (25 mg/m^2 Day 1 and Day 8) plus cisplatin (75 mg/m^2 Day 1) every 3 weeks for 4 cycles. Stratification factors were lymph node status (pN1/N2) and *EGFR*mutation status. The primary endpoint was disease-free survival (DFS) in the intent-to-treat population. **Results:** A total of 222 pts were randomly assigned (Sep 19 2011 to Apr 24 2014). Baseline characteristics were balanced. At the time of data cutoff, the median duration of treatment was 21.9 months in the G arm, and 4 cycles in the VP arm. The median follow-up period was 36.5 months (range 0.1 to 62.8). G had significantly longer median DFS (28.7 months, 95% confidence interval [CI] 24.9 to 32.5) than VP (18.0 months, 95% CI 13.6 to 22.3; hazard ratio 0.60; 95% CI 0.42 to 0.87; p= 0.005). 3-year DFS was significantly better with G (34.0% vs 27.0%; p= 0.013). The number of overall survival events was 76 (34.2%). In the subgroup analysis of patients treated with G, lymph node status (pN1/N2) demonstrated significant correlation with DFS ($p<$ 0.05). Grade 3 or higher adverse events were less common with G than with VP (12.3% vs 48.3%; $p<$ 0.001). No interstitial lung disease was observed with G. **Conclusions:** Adjuvant G significantly prolonged DFS compared with VP in pts with resected stage II-IIIA (N1-N2) NSCLC with *EGFR*-activating mutation. Adjuvant gefitinib should be considered as an important option for stage II-IIIA lung cancer pts with *EGFR* mutation. Clinical trial information: NCT01405079.

8501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Salvage guideline for local-regional failure after stereotactic ablative radiotherapy for early-stage non-small cell lung cancer. *First Author: Eric Brooks, MD Anderson Cancer Center, Houston, TX*

Background: Up to 1 in 7 patients receiving stereotactic ablative radiotherapy (SABR) for early-stage non-small cell lung cancer (NSCLC) will develop local-regional recurrence. While SABR is the pillar of treatment for medically inoperable patients, little is known about outcomes and management for this potentially curable, local-regionally recurrent patient group. **Methods:** We present the first long-term results for the largest group of salvaged patients with local-regional recurrence after SABR. 772 patients with clinically early-stage I-II NSCLC were treated with SABR (50 Gy in 4 or 70 Gy in 10 fractions) between 2004-2014 at our center. Patients with isolated local recurrence (LR, n = 34) or regional recurrence (RR, n = 41) were analyzed and compared to patients with no recurrence (NR, n = 569). **Results:** Median time to LR or RR after SABR was 14 months. Salvage was performed in 79.4% of LR and 92.7% of RR patients. Salvage consisted of surgery (20% LR, 2% RR), re-irradiation (24% LR, 17% RR), radiofrequency ablation (15% LR), chemotherapy (15% LR, 26% RR), and chemoradiation (6% LR, 44% RR) based on a standard multi-disciplinary decision approach (Figure 1). 5-year OS was 37.1% for LR and 39.1% for RR patients. Of LR and RR patients, those receiving salvage had significantly better 5-year OS compared to those not receiving salvage (45.2% LR, 42.9% RR, 0% no salvage; p = 0.009). 5-year OS for salvaged patients was not statistically different from patients with NR (53.5% NR, p = 0.466). 5-year lung-cancer specific survival was 51% for LR and 55.1% for RR patients. Subsequent DM occurred in 20.5% of LR and 29.3% of RR patients at a median of 8.4-10.3 months. No salvaged patient experienced grade 5 toxicity. **Conclusions:** Patients with local or regional recurrence after SABR have excellent outcomes with salvage therapy, with no statistical difference in 5- year OS between LR and RR patients salvaged after SABR, and patients with no recurrence. Because a standard multidisciplinary approach was applied to any LR or RR patient after SABR, a novel treatment algorithm is generated. We offer a much needed management guide for thoracic oncologists treating patients who local-regionally recur after SABR.

8502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Prophylactic cranial irradiation (PCI) versus observation in radically treated stage III non-small cell lung cancer (NSCLC): A randomized phase III NVALT11 study. *First Author: Harry J.M. Groen, University of Groningen, University Medical Center Groningen, Groningen, Netherlands*

Background: Brain metastases are one of the major sites of tumor failure in patients (pts) with radically treated stage III NSCLC. The value of PCI in these pts remains unsettled. This study is designed to investigate whether PCI reduces the incidence of symptomatic brain metastases (sBM). **Methods:** Pts were randomized between observation and PCI after concurrent or sequential chemo-RT with or without surgery. PCI dose was left to the physician(36 Gy/18F, 30 Gy/12F, 30 Gy/10F). Pts were registered before randomization, those progressing after chemo-RT were not randomized. Pts were followed for sBM (defined as increased intracranial pressure, headache, nausea, vomiting, cognitive, affective disturbances, seizures, focal neurological symptoms andMRI/CT), side effects, survival, quality of life (QLQ-C30, EuroQol 5D). The primary endpoint is the proportion of patients developing sBM. Randomizing 300 pts the study has 90% (2-sided p = 0.05) power to detect 17% decrease in pts developing sBM at 24 months (mo). **Results:** Between 2009 and 2015, 195 pts were registered, 175 were randomized, 87 received PCI and 88 pts were in the observation arm. In 2013 due to slow accrual, it was decided to reduce the number of randomized pts to 175 pts. With 75 events a 2-sided log-rank test would have 80% power to detect HR 0.52 and alpha 0.05. One pt in PCI arm was withdrawn after randomization. Pts characteristics were male (n = 114, 66%); adeno/squa/other 72 (41%), 62 (36%), 40 (23%); PS 0/1/2 66 (38%), 99 (57%), 9 (5%); stage IIIA/B 93 (53%), 80 (46%), unknown 1 (1%). Median follow up was 48.5 mo (95% CI, 39 - 54). Proportion of pts with sBM was 4/86 (4.6%) in PCI and 25/88 (28.4 %) in observation (p < 0.00001). Seven (8.1%) pts in PCI and 26 (29.7%) pts in observation arm had BM on imaging (p < 0.001). Median time to sBM was not reached in either arm. Median OS was 24.2 mo in PCI and 21.9 mo in observation arm (p = 0.52). Global QoL at 3 mo was worse in PCI arm (p = 0.02) but not afterwards. **Conclusions:** PCI significantly decreases the proportion of patients developing both symptomatic BM without influencing overall survival. PCI decreases 3 months global quality of life measures but not beyond. Clinical trial information: NTR 1601.

8503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Nivolumab (nivo) ± ipilimumab (ipi) in advanced small-cell lung cancer (SCLC): First report of a randomized expansion cohort from CheckMate 032. *First Author: Matthew David Hellmann, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with advanced SCLC after first-line platinum-based chemotherapy (PLT-CT) have a poor prognosis and limited treatment options. CheckMate 032 is a phase I/II trial evaluating multiple regimens of nivo ± ipi in solid tumors, including advanced SCLC. Tolerability and efficacy of nivo ± ipi were demonstrated in early results from the initial treatment arms (Antonia, *Lancet Oncol* 2016), prompting long-term follow-up and the addition of a randomized expansion cohort to further evaluate nivo ± ipi in advanced SCLC. **Methods:** In the initial treatment arms, pts with advanced SCLC and disease progression after prior PLT-CT were assigned to nivo (3 mg/kg Q2W; n = 98) or nivo 1 + ipi 3 (1 mg/kg and 3 mg/kg Q3W x 4, then nivo 3 Q2W; n = 61); safety/efficacy was assessed with a follow-up of ~18 mo. In the subsequent SCLC expansion cohort, pts were randomized 3:2 to nivo vs nivo 1 + ipi 3 and stratified by number of prior therapies. The primary endpoint was objective response rate (ORR). **Results:** Updated efficacy/safety results from the initial (non-randomized) nivo and nivo 1 + ipi 3 arms are summarized in the table. Responses were durable and occurred regardless of PD-L1 expression or PLT-sensitivity; safety was consistent with prior nivo ± ipi studies. In the expansion cohort, 247 pts were randomized to nivo or nivo 1 + ipi 3. The presentation will contain the first report of efficacy/safety results and subgroup analyses from this randomized expansion cohort. **Conclusions:** Durable responses are observed with nivo and nivo + ipi in pts with previously treated SCLC. The expansion cohort represents the first randomized evaluation of combined immune checkpoint blockade in SCLC. Clinical trial information: NCT01928394.

Updated results from initial CheckMate 032 SCLC treatment arms.

8504 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Phase II study of maintenance pembrolizumab (pembro) in extensive stage small cell lung cancer (ES-SCLC) patients (pts). *First Author: Shirish M. Gadgeel, Karmanos Cancer Institute, Detroit, MI*

Background: The median progression free survival (PFS) and overall survival (OS) following initial chemotherapy in ES-SCLC pts are 2 and 7 months, respectively (Ready N, J Clin Oncol 2015). We evaluated the benefits of maintenance pembro in ES-SCLC pts who had response/stable disease after 4-6 cycles of platinum/etoposide. **Methods:** Pts were required to begin pembro within 8 weeks of completion of chemotherapy, with restaging scans no more than 3 weeks prior to start of pembro. Prophylactic cranial radiation was permitted. Pts were treated with pembro 200 mg I.V. every 3 weeks for a maximum of 2 years. Disease assessment was done every 2 cycles for the first 6 cycles and then as per investigator discretion. Primary end point of the study was PFS. PFS according to immune related response criteria (irPFS) and OS were also assessed. Tumor tissue was analyzed for PD-L1 expression by the DAKO 22C3 antibody. Any level of expression was considered as positive for PDL1. Blood for circulating tumor cells (CTCs) was collected prior to first, second and third cycle of pembro. **Results:** Of the 45 pts enrolled, 55% were males and 22% had brain metastases. Median age was 66 years. The median time from end of chemotherapy to start of pembro was 5 weeks. Median number of pembro cycles was 4 (1-20 cycles). 35 pts had measurable disease at study entry. The disease control rate with pembro was 42% (1 CR, 3 PR, 15 SD). At a median follow up of 6 months, the median PFS was 1.4 months (90% CI-1.3-4.0) and the irPFS was 4.7 months (90% CI- 1.8-6.7). The median OS was 9.2 months (90% CI-6.1-15.2). 11 pts are still on therapy (3-20 cycles). The median CTC prior to pembro was 1 (0-256, n=37 pts). Each unit increase in baseline CTC correlated with worse PFS ($p = 0.052$; adjusted for brain mets, age and sex). PDL1 could be assessed in 35 pts and was positive in 1 pt. Most common adverse events were fatigue, nausea, cough and dyspnea. One pt developed atrio-ventricular conduction block and 1 pt type 1 diabetes. **Conclusions:** Maintenance pembro did not improve PFS in these patients but favorable OS suggests that some SCLC patients can benefit from maintenance pembro. Biomarkers to identify patients most likely to benefit from pembro need to be defined. Clinical trial information: NCT02359019.

Randomized trial of cisplatin and etoposide in combination with veliparib or placebo for extensive stage small cell lung cancer: ECOG-ACRIN 2511 study. *First Author: Taofeek Kunle Owonikoko, Emory University, Atlanta, GA*

Background: Veliparib, a potent inhibitor of Poly (ADP) ribose polymerase (PARP) enzyme potentiates standard chemotherapy against small cell lung cancer (SCLC) in preclinical studies. We evaluated the combination of veliparib (V) with cisplatin/etoposide (CE) doublet for first-line therapy of extensive stage SCLC (ES-SCLC). **Methods:** Patients with ES-SCLC stratified by gender and serum LDH levels, were randomized to receive four 3-wk cycles of CE (75mg/m^2 and 100 mg/m^2) along with V (100mg bid on d1-7) or placebo (P). The primary endpoint was progression-free survival (PFS); secondary endpoints included overall survival (OS). Using an overall one-sided 0.10 level logrank test, this study had 88% power to detect a 37.5% reduction in the PFS hazard rate. **Results:** 128 eligible pts were enrolled across 33 US sites. Median age, 66 yrs; men, 52%; PS 0/1 (29%/71%). The estimated median PFS was 6.1 m vs. 5.5 m [unstratified HR: 0.75; 1-sided $p = 0.06$) favoring CE+V. The median OS was 10.3 m vs. 8.9 m respectively for CE+V and CE+P [stratified HR: 0.83 (80% CI 0.64-1.07); 1-sided $p = 0.17$]. There was a significant treatment by strata interaction in PFS: male pts with high LDH derived benefit [PFS HR of 0.34 (80% CI: 0.22-0.51)]; among pts not in this strata: PFS HR = 0.81 (80% CI: 0.60-1.09). The best objective response rate was 71.9% vs. 65.6% (2-sided $p = 0.57$). Salient grade ≥3 adverse events occurring in 5% of patients are summarized in the table below. Analysis of tumor samples for predictive biomarkers is planned. **Conclusions:** The addition of veliparib to doublet chemotherapy was associated with improved PFS in patients with extensive stage SCLC. Clinical trial information: NCT01642251.

8506 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Mature overall survival (OS) results from the LUME-Meso study of nintedanib (N) + pemetrexed/cisplatin (PEM/CIS) vs placebo (P) + PEM/CIS in chemo-naïve patients (pts) with malignant pleural mesothelioma (MPM). *First Author: Anna K. Nowak, School of Medicine, Faculty of Medicine and Health Sciences, University of Western Australia, Crawley, Australia*

Background: LUME-Meso is a Phase (Ph) II/III, double-blind, randomized study. N targets MPM by inhibiting VEGFR 1–3, PDGFR α/β, FGFR 1–3, Src and Abl kinases. Primary analysis of the Ph II data demonstrated improved progression-free survival (PFS; hazard ratio [HR]=0.56; 95% confidence interval [CI] 0.34–0.91; p=0.017). Mature Ph 2 OS and updated PFS results are reported here. **Methods:** Pts with unresectable MPM (ECOG PS 0–1) were stratified by histology (epithelioid/biphasic) and randomized 1:1 to receive ≤6 cycles PEM (500 mg/m^2)/CIS (75 mg/m^2) Day 1 + N or P (200 mg bid, Days 2–21), followed by N or P monotherapy until progression or toxicity. The primary endpoint was PFS. The primary OS analysis and updated PFS analysis were performed as predefined. **Results:** 87 pts were randomly assigned (N=44, P=43). OS benefit favored N over P treatment (HR=0.77; 95% CI 0.46–1.29; p=0.319; 62 [71%] OS events) and was greatest in epithelioid pts (HR=0.70; 95% CI 0.40–1.21; p=0.197) with a median (m) OS gain of 5.4 months (mOS [95% CI]: 20.6 [16.2–28.8] N vs 15.2 [12.2–23.6] P). Updated PFS results (HR=0.54; 95% CI 0.33–0.87; p=0.010) also showed greatest benefit for epithelioid pts (HR=0.49; 95% CI 0.30–0.82; p=0.006) with a mPFS gain of 4.0 months (mPFS [95% CI]: 9.7 [7.2–12.4] N vs 5.7 [5.5–7.0] P). Improved forced vital capacity, objective response rates and duration of response were also observed with N treatment. Drug-related adverse events (AEs) in N- vs P-treated pts were 97.7% vs 97.6%. Grade ≥3 AEs of note included neutropenia (27.3% vs 4.9%), ALT (11.4% vs 0) and GGT (6.8% vs 0) elevations, and diarrhea (6.8% vs 0). AEs led to trial discontinuation in only 3 (6.8%) N vs 7 (17.1%) P pts. **Conclusions:** Mature Ph II OS data show that adding N to standard 1st-line treatment gives a strong signal towards improved OS. Updated PFS confirmed the primary analysis; AEs were manageable. The greatest clinical benefit was observed in pts with epithelioid histology. Median survival of 20.6 months in epithelioid pts treated with N is unprecedented in advanced MPM trials. Ph III is actively recruiting in this pt population. Clinical trial information: NCT01907100.

Second- or third-line nivolumab (Nivo) versus nivo plus ipilimumab (Ipi) in malignant pleural mesothelioma (MPM) patients: Results of the IFCT-1501 MAPS2 randomized phase II trial. *First Author: Arnaud Scherpereel, University Hospital of Lille, Lille, France*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Monday, June 5, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

8508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Neoadjuvant nivolumab in early-stage, resectable non-small cell lung cancers. *First Author: Jamie E. Chaft, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Anti-PD-1 therapy produces objective and often durable responses in ~20% of unselected patients (pts) with metastatic non-small cell lung cancer (NSCLC). However, the role of PD-1 blockade in treating resectable NSCLC is unknown. This is the first study to test nivolumab in the neoadjuvant setting. This trial design provides an opportunity to examine anti-PD-1 mechanism of action and immunologic correlates of outcomes. **Methods:** Patients with Stage IB - IIIA NSCLC received 2 doses of nivolumab 3mg/kg over 4 weeks before surgery. The primary endpoint was safety in 20 patients with resected NSCLC. Efficacy was explored using objective pathologic response criteria. Correlative studies of the tumor immune microenvironment, tumor mutation and predicted neoantigen loads, and changes in T cell receptor (TCR) clonality in tumor and blood pre and post treatment were conducted. **Results:** 22 pts were treated. Nivolumab was well-tolerated and no surgeries were delayed. 1 pt withdrew from study preop without progression or toxicity. Among the 21 attempted resections, 1 tumor was unresectable. 9/21 (43%, 95% CI 24-63%) had a major pathologic response ($<$ 10% viable tumor cells in resection specimen). With a median postop follow-up of 9 months, 18 pts (86%) remain alive and recurrence free. Pre-treatment tumor exome sequencing showed a correlation between both tumor mutation and predicted neoantigen loads with pathologic response. Multiplex immunohistochemistry of pre- and post-treatment tumors showed an influx of PD-1+CD8+ T cells into responding tumors. TCR sequencing demonstrated that expanded peripheral T cell clones after treatment match clones found in the tumor. **Conclusions:** Neoadjuvant nivolumab in resectable NSCLC did not delay surgery. Major pathologic response rate was encouraging and compares favorably to outcomes with cisplatin-based neoadjuvant chemotherapy. Genomic analyses suggest that higher mutational and neoantigen burden could result in deeper pathologic response. Immunologic analyses support the detection of intra-tumoral T cell clones in the blood after treatment with nivolumab and may provide further insight into the molecular and immunologic features of response and non-response to PD-1 blockade. Clinical trial information: NCT02259621.

8513 Poster Discussion Session; Displayed in Poster Session (Board #249), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Trabectedin (T) as second line treatment option for patients with epithelioid malignant pleural mesothelioma (MPM) in progression following pemetrexed/platin-derivates chemotherapy: ATREUS trial. *First Author: Diego Luigi Cortinovis, Azienda Ospedaliera San Gerardo, Monza, Italy*

Background: Systemic chemotherapy in MPM is inevitably followed by relapse, and response rates to second line treatment are limited. T is an antineoplastic agent targeting both the malignant cells and the tumor microenvironment with demonstrated activity against a range of tumors. We aimed to study the activity and safety of T in advanced MPM. **Methods:** ATREUS, an Italian multicenter single arm phase II trial, assessed the activity T in MPM evaluating the proportion of patients responding to treatment and achieving progression free survival for 12 weeks (PFS12w). Pre-treated epithelioid and naive or pre-treated biphasic/sarcomatoid pts were treated until progression or unacceptable toxicity. Initial dose was 1.3 mg/m^2, over 3 hours every 21 days, later reduced to 1.1 mg/m^{2}to improve tolerability. In the epithelioid cohort, sample size was based on a Simon's Optimal Two-Stage Design. The study was set to reject, at an alpha error of 10% the hypothesis that PFS12w was $\leq$25% and to demonstrate, with a power of 85% the hypothesis that PFS12w was $\geq$40%. At least 20 out of 62 pts with assessed disease, no major protocol violations, either receiving $\geq$12 weeks of treatment or interrupting before for progression or death (per protocol – PP analysis) were to reach PFS12w in order to consider T effective. **Results:** 71 pts were enrolled and evaluable. Average age was 65.8 $\pm$ 8.75 years. 71.8% were male and 82.5% presented stage III or IV disease. 42.4% (25/59) of pts included in the PP analysis obtained PFS12w (95% CI: 29.6% - 55.9%). In a second, more conservative analysis, including pts withdrawn prematurely for toxicity or intercurrent illness as failures, PFS12w rate reached 38.5% (25/65 pts). The most frequent grade $\geq$3 treatment-related toxicities werehepatic toxicity (60.5%), non-febrile neutropenia (21.1%), and fatigue (6.6%). Five pts (7%) interrupted treatment for toxicities (2 liver, 1 multi-organ failure, 1 thrombocytopenia, 1 T intolerance). **Conclusions:** In pts with advanced epithelioid MPM, second line treatment with T showed an elevated rate of disease stabilization. Safety data is promising but require further evaluation. Clinical trial information: NCT02194231.

Outcomes of anti-PD-1 therapy in mesothelioma and correlation with PD-L1 expression. *First Author: Gareth Rivalland, Olivia Newton-John Cancer Wellness and Research Centre, Melbourne, Australia*

Background: Early phase trials of anti-programmed death 1 (PD-1) antibodies have demonstrated important responses in malignant mesothelioma (MM). Expression of the ligand, PD-L1, is a potential biomarker for PD-1 directed therapy use and is expressed in a significant proportion of MM. We present results for a cohort treated with PD-1 inhibitory antibodies and assessed for PD-L1 expression. **Methods:** Patients (pts) with unresectable pleural or peritoneal mm treated with anti-PD-1 antibodies were included. Data was collected retrospectively. Radiological response was assessed using RECIST 1.1. Overall survival (OS) and progression-free survival (PFS) were evaluated. PD-L1 expression was assessed with IHC clone E1L3N (Cell Signaling Technology). PD-L1 positivity was defined as membranous expression on tumour cells: $>$ 5% for PD-L1+ and $>$ 50% for PD-L1^{hi}. **Results:** Forty-six pts were treated between July 2015 and January 2017. Median age was 66.5 years, ECOG PS was 0/1 in 3/46 (7%) and 35/46 (76%) respectively. Most were male (83%), and 43/46 (93%) had $\geq$1 prior therapy, with a median of 2 (range 0 - 5). The predominant histology was epithelioid (n = 32/46; 70%). Pembrolizumab was used in 45/46 and BGB-A317 (a PD-L1 antibody) in 1 pt. Of the 46 pts, the overall response rate (ORR) was 15% (7 PR) with 15/46 (33%) achieving stable disease, giving a DCR of 44%. Progression was seen in 24/46 (52%). Median OS for the entire cohort was 8.0 months (95% CI: 2.3 – 11.9). Median duration of response was not yet reached (range 1.5 -19.8). PD-L1 testing was performed in 14 samples, with PD-L1+ in 5 (36%) and PD-L1^{hi} in 4 (29%). The ORR was 40% (2 PR, 3 SD) with PD-L1+, 50% (2 PR, 2 SD) with PD-L1^{hi} and 22% (2/9 patients) with negative expression. PFS and OS were greater with both PD-L1+ (PFS HR: 0.26, 95% CI 0.05 – 1.32, p = 0.10) and PD-L1^{hi} (PFS HR: 0.17, 95% CI 0.02 – 1.47, p = 0.11). PD-L1+ positivity remained a borderline predictor of improved survival on multivariate analysis (p = 0.06). Complete PD-L1 analysis will be presented at the meeting. **Conclusions:** PD-1 targeted therapy demonstrated a clinically significant response rate in this cohort of mm patients. Initial analysis suggests PD-L1 expression is correlated with improved response and survival.

8515 Poster Discussion Session; Displayed in Poster Session (Board #251), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Immune microenvironment in mesothelioma: Looking beyond PD-L1. *First Author: Bibhusal Thapa, Olivia Newton-John Cancer Research Institute, Melbourne, Australia*

Background: Studies using immune checkpoint inhibitors in mesothelioma (MM) have shown promise. Differences in response to PD-L1 and PD-1 inhibitors (10% vs 25%) have been reported. Also, expression of PD-L1 alone appears to be a limited predictor. As the roles of the multiple check point receptors and their ligands become defined, an understanding of their expression and interplay in the mm tumour microenvironment, which could affect suitability for checkpoint inhibition therapy, has become necessary. **Methods:** Tissue microarrays were constructed and stained with PD-L2, LAG3 and TIM3 antibodies. Tumour infiltrating lymphocytes (TILs) were assessed in the stroma and expressed as a % of stromal area within invasive tumour. These data were combined with PD-L1 expression, CD4+ and CD8+ infiltration in the same cohort reported previously. To quantify the immunosuppressive milieu, we combined our assessment of PD-L1, PD-L2 and TIM3 expression to derive an "Immune checkpoint score (ICS)" and explored its correlation with the tumour microenvironment and clinicopathological covariates. We are also exploring its predictive value in an independent cohort of mm patients who have received anti-PD-1 treatment. **Results:** Amongst 329 patients evaluated, PD-L1 was positive (+) in 41.7% and PD-L2+ in 24.5%. TIM3+ lymphocytes were found in 99.4% but LAG3+ lymphocytes in only 0.2%. 28/173 (16%) of PD-L1- patients were PD-L2+ and 31/136 (22%) PD-L1 and PD-L2 negative patients had high infiltration with TIM3+ lymphocytes. High ICS was associated with non-epithelioid histology, increased TILs and poorer survival. On multivariate analysis, high TILs, non-epithelioid histology and poor physiological status remained significantly associated with poorer survival. Data on the predictive role of ICS score will also be reported. **Conclusions:** While co-expression of PD-L1, PD-L2 and TIM3 can occur, their expression is mutually exclusive in a large proportion of patients. The expression of PD-L2 may explain differences in responses seen between PD-1 compared to PD-L1 inhibitors. A comprehensive assessment of these multiple immunosuppressive pathways may be necessary to truly gauge the immunosuppressive environment and tailor immunotherapy for individual cases.

8516 Poster Discussion Session; Displayed in Poster Session (Board #252), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Prevalence and clinical correlation of programmed cell death 1 ligand (PD-L1) expression in patients with resected non-small cell lung cancer (NSCLC): Results from the European Thoracic Oncology Platform (ETOP) Lungscape cohort. *First Author: Keith Kerr, Aberdeen Royal Infirmary, Aberdeen, United Kingdom*

Background: Conflicting data exists on the potential prognostic impact of PD-L1 expression in NSCLC. The Lungscape project, a fully annotated large biobank of resected stage I-III NSCLC, allows detailed analysis of this issue. **Methods:** Prevalence of PD-L1 positivity and its association with clinicopathological characteristics and patient outcome - Relapse-free Survival (RFS), Time-to-Relapse (TTR) and Overall Survival (OS) - was explored in the ETOP Lungscape cohort. PD-L1 expression was assessed on tissue microarrays (TMAs) using the DAKO 28-8 immunohistochemistry assay. Positivity cut-off points of ≥1%, 5% and 50% for neoplastic cell membrane staining were considered. **Results:** PD-L1 data were available for 2182 patients, from 15 ETOP centers, with median follow-up 4.8 years; 1191 patients still alive; median age 66 years; 64% male, 32/54/11% for current/former/never smokers; 49/29/22% for stages I/II/III; 51/42/4/3% adenocarcinomas (AC)/squamous cell (SCC) /large cell and sarcomatoid (LCS)/other. Median RFS/TTR/OS were 53/99/69 months (AC: 52/84/72, SCC: 54/not reached/64; and LSC 52/103/74). PD-L1 prevalence with 1% cut-off was, overall: 43%, 95% confidence interval (95%CI): 41-46; (AC: 42%, 95%CI: 39-46; SCC: 44%, 95%CI: 40-47; and LCS: 53%, 95%CI: 42-65), while for 5% threshold, prevalence was 34%, 95%CI: 32-36. PD-L1 1% positivity was a significant predictor only for AC: $HR_{RFS: + vs -} = 0.82$; 95%CI: 0.69-0.97, $HR_{TTR: + vs -} = 0.83$; 95%CI: 0.68-1.01, $HR_{OS: + vs -} = 0.83$; 95%CI: 0.69-1.01 (adjusted p = 0.024, 0.064, 0.063 respectively). This effect is found also for the 5% cut-off, and preserved in the overall model including all histologies. Using the 50% cut-off, PD-L1 positivity was detected in 17% of patients; 95%CI: 15-18, but was no longer a significant predictor of outcome, overall and by histology type. **Conclusions:** PD-L1 positivity (1% and 5% cut-offs) was present in more than one third of resected NSCLC and was associated with a better prognosis for AC patients.

8517 Poster Discussion Session; Displayed in Poster Session (Board #253), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Genomic alterations (GA) and tumor mutational burden (TMB) in large cell neuroendocrine carcinoma of lung (L-LCNEC) as compared to small cell lung carcinoma (SCLC) as assessed via comprehensive genomic profiling (CGP). *First Author: Young Kwang Chae, Northwestern Medicine Developmental Therapeutics Institute, Chicago, IL*

Background: SCLC and L-LCNEC are aggressive neoplasms that are both associated with smoking history and are thought to overlap in clinical, histogenetic, and genomic features. We reviewed the genomic profiles of >1187 patients to assess the genomic similarities of these diseases. **Methods:** Comprehensive genomic profiling (CGP) of tumors from 300 L-LCNEC and 887 SCLC patients in the course of clinical care was performed to suggest pathways to benefit from therapy. **Results:** Commonly altered genes in both diseases included *TP53, RB1, MYC/MYCL1, MLL2, LRP1B* and *PTEN;* alterations in other genes occurred at somewhat differing frequencies (table). For both diseases, *RB1* mutation significantly co-occurred with *TP53* mutations (p<0.001), but occurred in a mutually exclusive fashion to *STK11* and *CDKN2A* (p<0.001). *RB1* was mutually exclusive with *KRAS* for L-LCNEC but not for SCLC. The interquartile range for SCLC and L-LCNEC TMB is 7.9 and 12.6 with the 75% quartile being 14.4 and 17.1 respectively. Cases of both diseases will be presented with radiographic response to genomically matched targeted therapy and immunotherapy, particularly in cases of high TMB. **Conclusions:** Given the similar overall genomic profiles and clinical behavior of a subset of these diseases, they could be conceived of as a single disease to be further classified by genomically defined classes such as SCLC-type (*TP53*/*RB1*mutated) and NSCLC-like (wild type for one or both). By analogy to NSLC and melanoma, benefit from immunotherapy appears most likely for only the upper quartile of cases in TMB.

Gene	L-LCNEC Frequency (% altered)	SCLC
TP53	72.3	90.9
RB1	37.7	69.5
CDKN2A	15.0	3.3

A nationwide genomic screening project for small cell lung cancer in Japan (LC-SCRUM-Japan). *First Author: Haruyasu Murakami, Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Recent genomic studies of small-cell lung cancer (SCLC) have identified promising therapeutic strategies for this highly lethal form of cancer. Thus, we established a nationwide lung cancer genomic screening project in Japan (LC-SCRUM-Japan) to identify SCLC patients harboring targetable genomic alterations for the development of novel targeted therapies. **Methods:** The samples were subjected to a next-generation sequencing (NGS) system, Oncomine™ Comprehensive Assay, enabling the simultaneous analysis of 143 cancer-related genes. **Results:** As of December 2016, 133 institutions were participating and 295 patients had been enrolled. The median age was 69 years (range, 14-90 years). Two hundred seventeen (74%) were male and most patients (93%) were smokers. Among 268 samples completed analysis, we identified high prevalence of inactivating TP53/RB1 mutations in 198 (74%) /82 (31) of cases, respectively. MYC/MYCL1/MYCN amplifications were detected in 10 (4%) /13 (5) /4 (1) of cases, respectively. The NGS analysis also showed that 62 (23%) of cases had at least one targetable genomic alterations, including 7 EGFR activating mutations (3%), 6 KRAS activating mutations (2%), and 8 FGFR1 copy number gains (3%). No case was positive for ALK or ROS1 fusions. Never-smokers (71% vs. 5%, p<0.001) were significantly frequent in the EGFR type compared to the others. The KRAS type showed significantly poor progression free survival (PFS) of the first-line chemotherapy compared to the others (median PFS 1.2 vs. 6.1 months, respectively; p<0.001). Mutations in the PI3K/AKT/mTOR pathway were detected in 22 (8%) of the tumors: 10 PIK3CA mutations (4%), 9 PTEN inactivating mutations (3%) and 3 TSC2 inactivating mutations (1%). Among them, a case with PTEN mutation was enrolled in the investigator initiated phase II study of gedatolisib named "EAGLE-PAT" (UMIN 000020585). **Conclusions:** We identified a series of targetable genomic alterations in SCLC. This nationwide screening system is helpful for identifying targetable genomic alterations and their clinical features, contributing to the development of novel targeted therapies for this disease. Updated screening results will be presented at the 2017 ASCO Annual Meeting.

Analysis of circulating tumor DNA in localized lung cancer for detection of molecular residual disease and personalization of adjuvant strategies. *First Author: Aadel Chaudhuri, Stanford Cancer Institute, Stanford, CA*

Background: Identifying localized non-small cell lung cancer (NSCLC) patients with residual disease following curative intent therapy is difficult due to normal tissue changes caused by surgery or radiation and an inability to detect microscopic disease. Analysis of circulating tumor DNA (ctDNA) might enable identification of molecular residual disease (MRD) and personalization of adjuvant treatment approaches but has not been explored in lung cancer. **Methods:** We applied CAPP-Seq, an ultra-sensitive next-generation sequencing based ctDNA quantitation method, to pre- and post-treatment blood samples from a cohort of 41 patients treated with chemoradiation, radiotherapy or surgery for stage I-III primary lung cancer. Detection of ctDNA at a single MRD time-point within 4 months of treatment completion was compared with surveillance by cross-sectional imaging. Furthermore, we developed an approach for identification of tumor mutation burden based on mutations detected in plasma, leveraging whole exome sequencing data from 1,177 NSCLCs sequenced by TCGA. **Results:** Median follow-up time was 35 months. Pre-treatment ctDNA was detected in 38 (93%) patients and 19 (46%) had detectable post-treatment ctDNA MRD. MRD+ patients displayed significantly inferior 3-year freedom from progression (0% vs. 92%; HR 38; P < 0.0001) and 3-year overall survival (8% vs. 75%; HR 12; P < 0.0001) than MRD- patients. Detection of ctDNA MRD had positive and negative predictive values for disease progression of 100% and 93%, respectively. Furthermore, we non-invasively identified activating EGFR mutations or high mutational burden (≥5 CAPP-Seq non-synonymous mutations, corresponding to > 200 non-synonymous mutations per exome or > 4 single nucleotide variants per megabase of exome) in 47% of patients with detectable ctDNA MRD, suggesting potentially favorable responses to TKIs and immune checkpoint inhibitors, respectively. **Conclusions:** Our results indicate that ctDNA analysis accurately detects MRD in localized lung cancer patients and could facilitate personalized adjuvant treatment at early time-points when disease burden is minimal.

Molecular analysis of thymic epithelial tumors (TETs): A report by The Cancer Genome Atlas (TCGA) research network. *First Author: Patrick J. Loehrer, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Thymoma (T) and thymic carcinoma (TC) are the most common malignancies of the anterior mediastinum. Additionally, thymoma has an unique association with autoimmune disorders, notably myasthenia gravis (MG). Histologic classification of TETs has been largely based on the gross description of the epithelial cell appearance and the relative abundance of associated lymphocytes. A comprehensive molecular analysis of TETs has not heretofore been conducted. **Methods:** The TCGA Research Network conducted multi-platform analyses of 117 TETs (T = 105; TC = 10 and micronodular T = 2), which included whole-exome, transcriptome, methylome and targeted proteome analysis. Patient characteristics: median age = 60 years (range 17-84); M:F (%) = 52:48; Masaoka Stage (I-36, IIA-39, IIB-19; III-15; IVA-1; IVB-5); mg was present in 32 patients. No patient had prior therapy for metastatic disease, but 14 had prior chemotherapy and 39 had prior radiation therapy in adjuvant setting. WHO histologic classification (blinded review) revealed A = 10; A/B = 48, B1 = 12, B2 = 25, B3 = 10, micronodular T = 2 and TC = 10. **Results:** T has one of the lowest mutational loads of any tumor in the TCGA. A unique transcription factor, GTF2I, was the most commonly observed mutation in WHO Types A and A/B. All GTF2I mutations were exclusively at the amino acid 424 locus. This is the only tumor with this specific mutation within the entire TCGA database. HRAS, NRAS and TP53 mutations were less commonly noted among all TETs. Four distinct molecular-driven subtypes of TETs were identified that strongly correlated with the current WHO histologic classification. Increased aneuploidy and overexpression of muscle autoantigens were associated with mg phenotype. **Conclusions:** Based on molecular analysis, four clusters were identified that correlated strongly with the current WHO Histologic Classification. Also identified was a unique mutation in GTF2I, which was associated with WHO Type A and A/B thymoma. This international effort represents the largest and most comprehensive molecular analysis of TETs conducted to date is expected to have important clinical and translational implications for this rare disease.

A phase II study of pembrolizumab for patients with previously treated advanced thymic epithelial tumor. *First Author: Jinhyun Cho, Inha University Hospital, Incheon, Republic of Korea*

Background: No standard treatment exists for patients with thymic epithelial tumor (TET) who progress after platinum-containing chemotherapy. We conducted a phase II study of pembrolizumab in patients with TET to evaluate the efficacy and safety. **Methods:** Between March 2016 and December 2016, patients with histologically confirmed TET who progressed after platinum-containing chemotherapy were eligible. Patients were excluded if they had an active autoimmune disease requiring systemic treatment within the past one year. Patients received 200mg of pembrolizumab intravenously every 3 weeks until tumor progression or unacceptable toxicity. The trial was registered with ClinicalTrials.gov, number NCT02607631. **Results:** 33 patients were enrolled, 26 with thymic carcinoma (TC) and 7 with thymoma (T). 19 (57.3%) patients received ≥ 2 prior lines of systemic chemotherapy. Median number of cycles was 8 (ranges, 1-13) and median follow up was 6.3 months (ranges, 1.4-9.9). Of 33 patients, 8 (24.2%) achieved partial responses, 17 (51.5%) stable disease, and 8 (24.2%) progressive disease as best response, resulting in overall response rate of 24.2% (7 confirmed PR). The median progression-free survival was not reached for 7 T and 6.2 months for 26 TC. The most common adverse events of any grade include dyspnea (33.3%), chest wall pain (30.3%), anorexia (21.2%) and fatigue (21.2%). Treatment-related adverse events ≥ grade 3 associated with immune related adverse events (irAE) include hepatitis (12.1%), myocarditis (9.1%), myasthenia gravis (6.1%), thyroiditis (3.0%), ANCA-associated rapidly progressive glomerulonephritis (3.0%), colitis (3.0%), and subacute myoclonus (3.0%) except anemia (3.0%). 8 (24.2%) patients (5 T, 3 TC) discontinued study treatment due to irAE, which were manageable with immediate administration of high dose corticosteroid and other immunosuppressive agents in most of patients (87.5%). **Conclusions:** Pembrolizumab showed promising antitumor activity in refractory or relapsed TET. Given the relatively high incidence of irAEs, early detection and management of autoimmune toxicity is essential to ensure feasibility of pembrolizumab treatment in patients with TET. Clinical trial information: NCT02607631.

Treatment of lung cancer patients in multidisciplinary (MDC) and serial care (SC) clinics. *First Author: Meredith Ray, University of Memphis, Memphis, TN*

Background: MDC may improve the quality of care for complex diseases. We compared the use of stage-appropriate treatment for lung cancer patients in a co-located MDC to serially-referred (SC) patients within the same healthcare system. **Methods:** Prospective cohort study of newly-diagnosed lung cancer patients enrolled before onset of treatment from MDC or the standard clinics (SC). Eligible pts had ECOG PS 0-2. Stage-appropriate treatment selection was determined using National Comprehensive Cancer Network (NCCN) guidelines based on clinical stage just before treatment onset. Differences in stage-based treatment rates were calculated using Chi-squared tests. **Results:** 162 had MDC and 317 SC. Compared to serial care patients, MDC patients were more likely black (37% v 30%) female (51% vs 48%), older (median 69 vs median 66) and less likely commercially insured (36% v 43%). Surgical resection was more frequently used for early stage patients in MDC: 72% v 58% for stage IA/IB (p = 0.2259); 58% v 31% for stage IIA/B and IIIA (T3N1M0) (p = 0.0375). MDC patients also had trends towards higher rates of recommended concurrent chemoradiation therapy for stage IIIA (T4N0-1M0) (75% vs 53%) (p = 0.5835), IIIB (T1-3N3, T4N2) (78% v 68%), but equal rates of concurrent chemoradiation therapy for stage IIIA (T1-3N2M0) (68% vs 68%). Stage IV patientss were more likely to receive chemotherapy or targeted therapy in MDC v SC (87% vs 80%) (p = 0.3795). **Conclusions:** Lung cancer patients in the MDC model are more likely to receive recommended stage-appropriate treatment than those in the usual serial care model, despite relatively adverse demographic characteristics. Clinical trial information: NCT02123797.

Safety and feasibility of consolidation pembrolizumab following concurrent chemoradiation for unresectable stage III non-small cell lung cancer: Hoosier Cancer Research Network LUN14-179. *First Author: Greg Andrew Durm, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: The standard of care for unresectable stage III NSCLC is concurrent chemorad. Following treatment, the risk of radiation pneumonitis is greatest at 1-3 mo. Pneumonitis risk increases with consolidation chemotherapy. A previous trial by our group (Hanna et al, JCO 2008) of consolidation docetaxel showed 80.8% completed 3 planned cycles of chemo with a grade 3-5 pneumonitis rate of 9.6% and 1 death. PD-1 inhibitors are also associated with an increased risk of pneumonitis in the metastatic setting. We conducted a phase II trial of consolidation pembro initiated 1-2 mo after concurrent chemorad, a period during which pts are at high risk of developing pneumonitis. **Methods:** Pts with stage III NSCLC who completed chemorad with either carbo/paclitaxel, cis/etop, or cis/pemetrexed plus 59-66.6 Gy of radiation and had no PD received pembro 200mg IV q3wk for up to 1 yr. Primary endpoint is time to metastatic disease. The objective of the study is to evaluate both safety and efficacy, and here we report preliminary safety and feasibility results. Evaluable pts for this analysis had ≥3 mo of f/u or went off study due to PD, toxicity, or death < 3 mos after initiation of pembro. **Results:** 93 pts enrolled. Median age 67 (range 46-84), 59 (63.4%) were male. 87 (93.5%) were former or current smokers. 68 (73.1%) received carbo/pac, 24 (25.8%) received cis/etop, and 1 received cis/pemetrexed. SqCC (n = 41), non-SqCC (n = 43), NSCLC NOS (n = 8), mixed (n = 1). IIIA (n = 56), IIIB (n = 37). At the time of analysis, 83 of 93 pts were evaluable. 66 of 83 (79.5%) received ≥ 3 mo of pembro. 17 (20.5%) pts developed any grade pneumonitis with 14 of 17 occurring in the first 12 wks (median 9 wks). Only 3 (3.6%) pts developed grade 3-5 pneumonitis related to pembro. There was 1 pneumonitis-related death and a second death from respiratory failure possibly related to pembro. **Conclusions:** This early report indicates that most patients can safely receive consolidation pembro within 1-2 mo of completing chemorad. The incidence of serious pneumonitis during the first 3 mo of treatment appears low. Updated safety data on all 93 pts will be presented at the ASCO meeting. Clinical trial information: NCT02343952.

8524 Poster Discussion Session; Displayed in Poster Session (Board #260), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Temporal trend in the use of surgery in the management of stage IIIa non-small cell lung cancer (NSCLC) between 2000-2013: A SEER analysis. *First Author: Veena Iyer, University Of Toledo, Toledo, OH*

Background: The optimal treatment of patients with Stage IIIA NSCLC, a heterogeneous group comprised of T1-T4, N0-N2 disease, is controversial. Lack of clear data and guidelines allows several options for treatment, and hence there has been significant variability in clinical practice. The purpose of this study was to evaluate the nationwide trends in rates of surgery for Stage IIIA lung cancer diagnosed between 2000-2013. **Methods:** The study included patients with Stage IIIA NSCLC, 18 years and older diagnosed between 2000 and 2013. We used Z-tests in SEER*Stat to compare relative survival rates for patients diagnosed between 2000-2010. **Results:** Among the 27,697 patients with Stage IIIA NSCLC, 45% were females and median age was 67. 35% were treated with surgery. Multivariate analysis demonstrated that year of diagnosis, race, marital status, geographic region, tumor size, tumor grade, nodal status all were significantly associated with the use of surgery. Relative survival at 24 months (RS_{24}) was 62% for patients who had surgery and 29% for patients without surgery (z = -47.3). The proportion of patients receiving surgery decreased from 55.6% in 2000 to 32.6% in 2010 and 29.7 in 2013 ($p < 0.0001$) while the relative survival at 24 months (RS_{24}) from 2000 to 2010 rose from 34.7% to 43.2% (z = -4.89). The RS_{24} for patients who received surgery rose from 55.3% in 2000 to 77.6 % in 2010 (z = -3.58). Change in RS_{24} for patients who did not have surgery also improved from 19.6% to 31.2%. The median RS of the surgical cohort changed from 28 m to 44 m. **Conclusions:** Based upon reporting within the SEER database, the proportion of stage IIIA NSCLC patients undergoing surgery has decreased over the study time period. However, the relative survival rates have improved significantly for both the overall group and those having surgery, suggesting that significant strides have been made both in selecting the group of patients who would benefit from surgical resection and in the overall management of this group of patients.

8525 Poster Session (Board #261), Sat, 8:00 AM-11:30 AM

Survival benefit of systemic chemotherapy given as adjuvant (ACT) after thoracic surgery for N0-1 non-small cell lung cancer (NSCLC) patients (pts) with synchronous brain metastasis (SBM). *First Author: Sarah Shin, University at Buffalo, Buffalo, NY*

Background: Pts with solitary SBM and otherwise early-stage NSCLC demonstrate prolonged survival with surgical resection of both primary and metastatic disease. The role of "ACT" after thoracic surgery in this circumstance is not well-defined. We seek to determine the effect on overall survival(OS) of ACT after resection of primary tumor in pts with surgically resectable primary NSCLC and SBM. **Methods:** The National Cancer Database (NCDB) was queried to identify pts who underwent resection of NSCLC as the primary cancer (without other malignancies) from years 2010-2014 (n = 90,518). We then focused on pts who also were diagnosed with SBM (n = 807). Only patients with pathologically confirmed N stage 0 (n = 419) or 1 (n = 101) status were included in the final analysis. Patients who received platinum-based ACT within 3 months after surgery were considered to have received ACT. Associations between treatment groups were analyzed using the Chi-square test for categorical variables and Wilcoxon Rank Sum test for continuous variables. Univariate and multivariate proportional hazards modeling results were used to assess the effect of treatment and the confounding variables on OS. Relative prognosis was summarized using estimates and 95% confidence interval(CI) for the hazard ratio (HR). Unadjusted differences in OS between the treatments are shown using Kaplan-Meier methods. All analyses were performed using SAS version 9.4. **Results:** There is no imbalance in terms of gender, race, income, nodal status, histology between groups. Non-ACT pts were older (n = 181, median 64 vs 58 years in ACT group, $p < 0.001$). Age, nodal status, ACT, and histology were associated with OS in both univariate and multivariate analysis, with OS HR 0.51 (95% CI 0.39-0.66) in favor of ACT (n = 339). One- and 5-year survival in ACT group versus non-ACT group was 83% (95% CI 78%-87%) and 33% (25%-40%), versus 57%(95% CI 48%-65%) and 18% (95% CI 11%-26%), respectively. **Conclusions:** ACT after thoracic surgery for N0-1 NSCLC with SBM is associated with improved OS in this analysis.

8526 Poster Session (Board #262), Sat, 8:00 AM-11:30 AM

The role of adjuvant chemotherapy in stage IB non-small cell lung cancer: A decision, effectiveness, and cost-effectiveness analysis. *First Author: Jessica Lynn Hudson, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Despite complete surgical resection (SR), half of stage I non-small cell lung cancer (NSCLC) patients die from systemic relapse. An independent risk factor for systemic progression is pathologic stage IB subtype (T2aN0M0, AJCC 7). The role of adjuvant chemotherapy (AC) in stage IB NSCLC is controversial. We studied the effectiveness and cost-effectiveness of AC after SR in stage IB NSCLC. **Methods:** Propensity score matching was performed on the National Cancer Database (2004-2011). The Kaplan-Meier method generated conditional probabilistic incremental 1- to 5-year survival after SR stratified by receipt of AC. Medicare allowable charges for SR, AC, and their respective complications were used. Decision analysis modeling and microsimulation were performed to account for proportions of chemotherapeutic agents administered in real-world settings. The incremental cost-effectiveness ratio (ICER) was calculated over a 5-year horizon. Probabilistic and two-way sensitivity analyses were performed. **Results:** 3662 of 18709 patient (19.6%) who met inclusion criteria received AC for SR stage IB NSCLC, with usage ranging from 15-27% annually. After propensity score matching, an overall survival benefit of AC was conferred over SR alone (at 5 years: 68.9% vs 60.4%, $p < 0.001$). The incremental cost of AC over SR alone was $11,541. The incremental effectiveness of AC was 0.28 life-years, with an ICER of $41,218. In two-way sensitivity analysis, AC plus SR dominated for the entire range of cost and survival estimates. In probabilistic sensitivity analysis, AC plus SR dominated the model above a willing-to-pay threshold of $16,000. AC costs could nearly double and the ICER remained under conventional thresholds. However, only 3 of the 4 common AC regimens were cost effective. **Conclusions:** In stage IB NSCLC, surgery is insufficient to render a cure. The addition of AC to SR extends life-expectancy and is cost-effective compared to SR alone. These conclusions are valid over a range of clinically meaningful variations in cost and treatment outcomes, though a cost-conscious approach is needed when selecting an AC regimen. This represents a novel change in the treatment of stage IB NSCLC.

8527 Poster Session (Board #263), Sat, 8:00 AM-11:30 AM

Early experience with IBM Watson for Oncology (WFO) cognitive computing system for lung and colorectal cancer treatment. *First Author: S.P. Somashekhar, Manipal Comprehensive Cancer Center, Bangalore, India*

Background: IBM Watson for Oncology is an artificial intelligence cognitive computing system that provides confidence-ranked, evidence-based treatment recommendations for cancer. In the present study, we examine the level of agreement for lung and colorectal cancer therapy between the multidisciplinary tumour board from Manipal Comprehensive Cancer Centre in Bangalore, India, and Watson for Oncology. **Methods:** Watson for Oncology is a Memorial Sloan Kettering Cancer Center (New York, USA) trained cognitive computing system that uses natural language processing and machine learning to provide treatment recommendations. It processes structured and unstructured data from medical literature, treatment guidelines, medical records, imaging, lab and pathology reports, and the expertise of Memorial Sloan Kettering experts to formulate therapeutic recommendations. Treatment recommendations are provided in three categories: recommended, for consideration and not recommended. In this report we provide the results of the independent and blinded evaluation by the multidisciplinary tumour board and Watson for Oncology of 362 total cancer cases comprised of 112 lung, 126 colon and 124 rectal cancers seen at the Centre within the last three years. The recommendations of the two agents were compared for agreement and considered concordant when the tumour board recommendation was included in the recommended or for consideration categories of the treatment advisor. **Results:** Overall, treatment recommendations were concordant in 96.4% of lung, 81.0% of colon and 92.7% of rectal cancer cases. By tumour stage, treatment recommendations were concordant in 88.9% of localized and 97.9% of metastatic lung cancer, 85.5% of localized and 76.6% of metastatic colon cancer, and 96.8% of localized and 80.6% of metastatic rectal cancer. **Conclusions:** Treatment recommendations made by the Manipal multidisciplinary tumour board and Watson for Oncology were highly concordant in the cancers examined. This cognitive computing technology holds much promise in helping oncologists make information intensive, evidence based treatment decisions.

8528 Poster Session (Board #264), Sat, 8:00 AM-11:30 AM

Typical bronchial NETs as a misleading biology. *First Author: Dalvinder Mandair, Royal Free Hospital Neuroendocrine Tumour Unit, London, United Kingdom*

Background: Bronchial Neuroendocrine tumours (NETs) are rare with an incidence of between 0.2 – 2 per 100,000 population. There has been an increase in prevalence due to increased awareness, enhanced immunohistochemistry and greater use of Computed tomography (CT). Bronchial NETs are classified according to the WHO guidelines developed in 2004 where they are graded by histological classification into 'typical', 'atypical' NETs or small and large neuroendocrine carcinoma's (NECs). Typical NETs are regarded as being low-grade malignant however metastatic disease can still develop. Aims: We sought to determine the incidence of metastatic typical bronchial NETs, their survival and investigate the imaging and treatment used in their management. **Methods:** We performed a retrospective analysis of all bronchial NETs managed at our centre from 2001 to 2016. From those identified as typical NETs, we analysed clinical records in those with advanced disease (Stage IV). **Results:** From a total of 251 bronchial NETs, there were 147 'Typical' NETs, 30(20%) of whom had advanced disease compared to 82 'Atypical' bronchial NETs of whom 55 had advanced disease (67%). The median age at diagnosis was 58 (range 24-77). In the 'Typical' NETs, 24/30 had liver metastases, 19/30 skeletal metastases, and 16 had carcinoid syndrome (CS). Functional imaging with FDG PET scan was positive in 7/10 patients and somatostatin receptor scintigraphy (SRS) positive in 16/20 and in 4/11 there was avidity with both. 20 patients were treated with somatostatin analogues predominantly for CS symptoms. 11 patients treated with peptide radiolabelled receptor targeted therapy (PRRT) with a median Time-To-Progression (TTP) of 27 months. 11 patients received chemotherapy with median TTP of 16 months with 4 patients demonstrating partial response. **Conclusions:** Typical bronchial NETs can lead to advanced disease in up to 20% of patients. Their behavior can be aggressive and is not predictable by histology alone. Functional imaging with both FDG and SRS may help determine the most appropriate treatment. Both PRRT and chemotherapy can be considered in progressive disease.

8529 Poster Session (Board #265), Sat, 8:00 AM-11:30 AM

The role of adjuvant therapy in the management of resected large cell neuroendocrine carcinoma (LCNEC) of the lung: A National Cancer Database (NCDB) analysis. *First Author: Lara Ann Kujtan, University of Missouri at Kansas City Medical School, Kansas City, MO*

Background: Large cell neuroendocrine carcinoma (LCNEC) is characterized by aggressive behavior and poor outcomes compared with other non-small cell lung cancers (ONSCLC). **Methods:** The National Cancer Database (NCDB) was used to identify patients diagnosed with early stage NSCLC (pathologic stage I, II, IIIA) from 2004-2012 who underwent surgical resection. Patients were divided into two groups: LCNEC and ONSCLC. One-way ANOVA was used to compare continuous variables, and chi-squared testing was used to compare categorical variables. Multivariate logistic regression analyses were used to obtain hazard ratios. **Results:** We identified 1672 patients with resected LCNEC and 134139 with resected ONSCLC. A higher proportion of patients with ONSCLC had a Charlson-Deyo co-morbidity score of 0 compared to LCNEC patients (50.6% vs. 43.8%; $p < 0.001$). No other significant differences in clinical and demographic characteristics were identified. Overall survival was lower for LCNEC patients across all stages when compared to patients with resected ONSCLC (46 months versus 74 months; 5-year survival 45% versus 57%; $p < 0.001$). Multivariate analysis confirmed the survival benefit for adjuvant chemotherapy in resected LCNEC across all stages, including stage IA, although it did not reach statistical significance (hazard ratio 0.72 (0.51-1.02), $p = 0.64$; Table). **Conclusions:** Adjuvant chemotherapy significantly improves survival for stage IB, II and IIIA LCNEC compared to surgery alone. Patients with stage IA LCNEC appear to benefit from adjuvant chemotherapy although it did not reach statistical significance. The overall magnitude of benefit from adjuvant chemotherapy appears to be higher for patients with LCNEC compared to ONSCLC.

Pathologic Stage	5-Year Survival		*p*-value	Adjusted HR	Adjusted *p*-value
	Surgical resection	Surgical resection + chemotherapy			
IA	49%	58%	0.009	0.72 (0.51,1.02)	0.064
IB	42%	67%	<0.001	0.47 (0.34,0.66)	<0.001
IIA	31%	52%	0.019	0.52 (0.29,0.96)	0.036
IIB	30%	50%	<0.001	0.57 (0.35,0.92)	0.021
IIIA	12%	28%	<0.001	0.41 (0.25,0.67)	<0.001

8530 Poster Session (Board #266), Sat, 8:00 AM-11:30 AM

Phase 1/2 study of veliparib (V) combined with carboplatin (Cb) and etoposide (E) in patients (pts) with extensive-stage disease (ED) small cell lung cancer (SCLC) and other solid tumors: Phase 1 results. *First Author: Florence Atrafi, Erasmus Medisch Centrum, Rotterdam, Netherlands*

Background: The majority of SCLC cases are diagnosed as ED, for which there is a poor prognosis and no curative treatment (Tx). V, a potent PARP inhibitor, has been shown in preclinical studies to enhance the antitumor activity of platinum-based agents and E against SCLC. The presented phase 1 dose-escalation (NCT02289690) evaluated V combined with Cb/E. **Methods:** Pts (≥18 years) with ED SCLC or other advanced/metastatic solid tumors with ≤1 line of prior cytotoxic therapy and ECOG performance score 0/1 were included. This study followed a 3+3 design. V starting dose and schedule were 80 mg BID PO administered on days (D) –2 to 5 in combination with Cb AUC 5 mg/mL • min administered on D 1 and E 100 mg/m^2 administered on D 1 to 3 via intravenous infusion in 21-D cycles. V schedules of D –2 to 12 and continuous dosing were also explored. Primary objectives were to establish the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) for V combined with Cb/E, and to evaluate the pharmacokinetic (PK) interaction between V and E. **Results:** Thirty-nine pts (n = 24 ED SCLC; n = 15 other solid tumors) with median age of 62 years (range 43–79) received study Tx. Most common adverse events (AEs; ≥40%) were nausea (54%), fatigue (51%), alopecia (46%), and anemia (44%); grade 3/4 AEs (≥30%) were decreased neutrophil count, neutropenia (31% each), and anemia (26%). Dose-limiting toxicity occurred in 1 pt (n = 1 grade 3 fatigue) at V 240 mg BID D –2 to 5. The MTD was not reached; RP2D for V was set at 240 mg BID on D –2 to 12 based on long-term tolerability. Continuous dosing of V 240 mg BID with Cb/E resulted in unacceptable Cb/E dose delays due to hematologic toxicity. Coadministration of V (80 to 240 mg BID) with Cb/E exhibited dose-proportional kinetics with no impact on the E PK. Confirmed responses: ED SCLC 63% (15/24 pts) across all dose levels and in 83% (5/6) at RP2D; other tumor types: 13% (2/15) across all dose levels. **Conclusions:** V + Cb/E had an acceptable safety profile in pts with ED SCLC, with an RP2D of 240 mg BID D –2 to 12. Coadministration of V with Cb/E had no effect on E PK. Responses were seen across all dose levels. A phase 2 study of V with Cb/E in ED SCLC is ongoing. Clinical trial information: NCT02289690.

8531 Poster Session (Board #267), Sat, 8:00 AM-11:30 AM

A multicenter, randomized, open-label, phase II trial of erlotinib versus etoposide plus cisplatin with concurrent radiotherapy in unresectable stage III non-small cell lung cancer (NSCLC) with epidermal growth factor receptor (EGFR) activating mutation. *First Author: Ligang Xing, Shandong Cancer Hospital, Jinan, China*

Background: Concurrent chemoradiotherapy is the standard treatment for patients(pts) with unresectable stage IIIA/IIIB NSCLC. In EGFR mutant pts, tyrosine kinase inhibitor(TKI) exhibits clinical benefits over chemotherapy regimens in terms of efficacy and safety as well as specific enhancement of radiation effects. This multicenter, randomized, open-label, phase II trial aimed to compare the erlotinib and etoposide/cisplatin with concurrent radiotherapy (RT) in pts with EGFR-mutant. **Methods:** Histopathology/cytology confirmed stage IIIA/B unresectable NSCLC pts (age 18-75) with ECOG PS 0-1 and EGFR exon 19 or 21 mutation were included and randomized (1:1) into two arms: erlotinib (E) and etoposide/cisplatin (EP). E arm was treated with oral erlotinib (150mg/day for 2 years or till either disease progression or intolerable toxicities) and RT (200cGy/day, 5 days/week for 6 weeks from first day erlotinib). EP arm was treated with sequential etoposide (50 mg/m^2 IV days 1-5, 29-33) and cisplatin (50mg/m^{2}IV day 1,8, 29,36) and RT (from first day drug). Primary endpoint is progress free survival (PFS). Secondary endpoints are objective response rate(ORR), local control rate(LCR), overall survival(OS), quality of life(QoL) and safety. **Results:** 252 pts were screened, and 41 were enrolled into E(n=20) and EP (n=21) arms. Characteristics of age, sex, histologic type, N2, EGFR 19 and 21 mutation were well balanced in each arm. Comparing with EP, median PFS of E arm was significantly improved (27.86 vs 6.41 months; HR 0.053, 95% CI: 0.006-0.463; $P<0.001$). ORR and DCR were 60.0% vs. 38.1% ($P=0.217$), and 65% vs. 47.6%($P=0.350$), respectively. Two arms had same incidence of adverse effects (CTCAE Grade≥1, 86.7%[13/15]), and most common sAE(Grade≥3) was rash (20%, 3/15) and hematological toxicity(26.7%, 4/15), respectively. **Conclusions:** In unresectable stage III EGFR mutant NSCLC pts, concurrent erlotinib/RT provides a statistically significant PFS improvement with well tolerability. These results warrant a phase III study to confirm. (RECEL, NCT01714908). Clinical trial information: NCT01714908.

8532 Poster Session (Board #268), Sat, 8:00 AM-11:30 AM

Randomized trial of thoracic radiotherapy with or without concurrent daily low-dose carboplatin in elderly patients with locally advanced non-small cell lung cancer (NSCLC): Long-term follow-up of Japan Clinical Oncology Group (JCOG) Study JCOG0301. *First Author: Shinji Atagi, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan*

Background: In the phase III JCOG0301 trial, concurrent chemoradiotherapy (CRT) was compared with radiotherapy (RT), demonstrating clinically significant survival benefits in elderly patients with locally advanced NSCLC after a median follow-up of 19.4 months. However, the long-term patterns and cumulative incidences of toxicity associated with CRT and RT are poorly understood for elderly patients. We report long-term survival data and late toxicities after a minimum follow-up of 6.4 years. **Methods:** Eligible patients were older than 70 years and had unresectable stage III NSCLC. They were randomly assigned to RT alone (RT arm: irradiation with 60 Gy in 30 fractions) or CRT (CRT arm: the same RT with additional concurrent use of carboplatin 30 mg/m^2 per fraction up to the first 20 fractions). The primary endpoint was overall survival (OS). Prognosis and adverse events data were collected beyond those in the initial report of this trial. Kaplan-Meier survival curves and 3- and 5-year survival proportions were calculated. Late toxicities were defined as occurring later than 90 days after RT initiation. **Results:** From September 2003 to May 2010, 200 patients (RT arm, n = 100; CRT arm, n = 100) were enrolled. Consistent with the initial report, the CRT arm had better OS than the RT arm (HR = 0.743, 95% CI = 0.552 – 0.998, one-sided p = 0.0239 by stratified log-rank test). In the RT and CRT arms, median OS was 16.5 and 21.7 months, 3-year survival was 16.3% and 34.3%, and 5-year survival was 9.2% and 15.2%, respectively. %Grade 3/4 late toxicities were 7.4% (heart 2.1%, lung 5.3%) in the RT arm (n = 94) and 7.5% (esophagus 1.1%, lung 6.5%) in the CRT arm (n = 93). No additional cases of late toxicity (Grade 3/4) were seen since the initial report. There were 7 treatment-related deaths, all of which were recorded in the initial report: 4 (4.0%) in the RT arm and 3 (3.0%) in the CRT arm. **Conclusions:** Long-term follow-up confirms the survival benefits of CRT for elderly patients with locally advanced NSCLC. There was no observed increase in late toxicity with CRT, as compared with RT alone. Clinical trial information: 00132665.

8533 Poster Session (Board #269), Sat, 8:00 AM-11:30 AM

Impact of adjuvant chemotherapy in non-metastatic node positive bronchial neuroendocrine tumors (BNET). *First Author: Gustavo Figueiredo Marcondes Westin, Mayo Clinic, Rochester, MN*

Background: BNET are a rare and frequently indolent group of neoplasms. Lobectomy is frequently done for patients with non-metastatic disease, and the role of adjuvant chemotherapy for patients with node positive disease (N+) is debated. **Methods:** Utilizing the National Cancer Database from 2004-2012 we identified 1682 patients with N+ non-metastatic BNET. All patients underwent primary resection, had pathologically confirmed diagnosis, complete follow up data, and were alive > 30 days following surgery. Overall survival (OS) was analyzed utilizing Kaplan-Meier curves, and log-rank tests were used to compare 2 groups of patients that differed based on receiving or not adjuvant chemotherapy. Subgroup analyses were performed based on histologic subtypes. Cox proportional hazards was performed to control for age, sex, race, grade, surgical margins, type of surgery, year of diagnosis, Charlson/Deyo Score, insurance, facility type, and location. **Results:** 651 patients with typical carcinoid (CT), 239 atypical carcinoid (ACT), 426 large cell neuroendocrine carcinoma (LCNEC), and 366 neuroendocrine carcinoma (NEC) were analyzed. The cohort median age was 61, and the female:male ratio was 1.8 for CT, ACT and NEC, and 1 for LCNEC 90% of patients were White and there were no significant differences amongst histologic subtypes. 6% of patients with CT received ADJ-CT, compared to 40% ACT, 42% NEC, and 70% LCNEC. In a multivariate analysis, only increasing age was associated with worse prognosis across all histologic subtypes, and non-academic facility for CT, and male sex for NEC. ADJ-CT was not associated with OS benefit for patients with ACT (HR 1.1; 95% CI 0.68-1.78; p:0.6), was associated with inferior OS in CT (HR: 3.8 (95% CI 1.9-7.0; p = 0.004) and NEC (HR: 2.15; 95% CI 1.5-3.0; p < 0.001), and may provide benefit for LCNEC (HR: 0.67; 95% CI 0.5-0.9; p = 0.009). **Conclusions:** Adjuvant chemotherapy was not associated with survival benefit for patients with node positive and non-metastatic BNET except for LCNEC, and may be harmful for patients with CT and NEC.

8534 Poster Session (Board #270), Sat, 8:00 AM-11:30 AM

Randomized phase II trial of S-1 plus cisplatin or docetaxel plus cisplatin with concurrent thoracic radiotherapy for inoperable stage III non-small cell lung cancer (TORG1018). *First Author: Kaoru Kubota, Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan*

Background: Concurrent chemoradiotherapy (CCRT) is standard of care in patients with inoperable stage III non-small cell lung cancer (NSCLC), however the best chemotherapy regimen has not been identified. The study was conducted to evaluate cisplatin plus S-1 (SP) or cisplatin plus docetaxel (DP) both with concurrent thoracic radiotherapy in patients with inoperable stage III NSCLC. **Methods:** Patients with inoperable stage III NSCLC were randomized to SP (S-1 40 mg/m^2 twice a day on days 1-14 and 29-42 plus cisplatin 60 mg/m^2 on days 1 and 29) or DP (docetaxel 50 mg/m^2 and cisplatin 80 mg/m^2 on days 1 and 29), stratified by institution, gender, histology, and stage. In both arms, concurrent radiotherapy began on day 1 (60 Gy/30 fr). After CCRT, patients in each group received two additional cycles of the consolidation chemotherapy. Primary endpoint was 2-year overall survival (OS), and secondary endpoints were OS, progression-free survival (PFS), toxicity profile, dose intensity and objective response rate (ORR). **Results:** From May 2011 to August 2014, 110 patients were enrolled from 19 institutions. Four patients (one in SP and 3 in DP) were ineligible, and 106 patients (53 in each arm) were evaluable for efficacy and safety. Patient characteristics were: male/female 83/23; median age 65 (range 42-74); performance status 0/1 59/47; IIIA/IIIB 59/47. With a median follow-up of 39.3 months, 2-year survival and median OS were 79% (95% CI: 66-88%) and 55.2 months in the SP arm and 69% (95% CI: 55-80%) and 50.8 months in the DP arm, respectively. ORR and median PFS in SP arm were 71.7% and 11.6 months, and ones in the DP arm were 67.9% and 19.9 months. Grade 3/4 leukopenia (62.3/34.0%) and neutropenia (56.6/28.3%) were significantly more frequent in DP arm than SP arm. Incidences of non-hematological toxicities including febrile neutropenia, anorexia, nausea, diarrhea, radiation pneumonitis and esophagitis tended to be higher in DP arm. No treatment-related death occurred. **Conclusions:** The 2-year OS favored for SP arm with less toxicity. We choose SP with concurrent thoracic radiotherapy as a future reference regimen. Clinical trial information: UMIN000005993.

8535 Poster Session (Board #271), Sat, 8:00 AM-11:30 AM

Feasibility of endobronchial ultrasound fine-needle aspiration for massively parallel next-generation sequencing in cancer patients. *First Author: Simon R. Turner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Next generation sequencing (NGS) is an important emerging tool in precision oncology, allowing identification of a growing number of clinically validated and investigational therapeutic molecular targets. A potential limitation is that some NGS assays require more DNA input than more limited molecular assays. Endobronchial ultrasound fine-needle aspiration (EBUS-FNA) is a minimally invasive procedure for sampling mediastinal and pulmonary lesions, but it is unknown if it provides adequate material for NGS. **Methods:** An IRB approved, retrospective review was performed of patients undergoing EBUS-FNA by thoracic surgeons at our institution 3/1/14 - 9/28/16. NGS was performed using an assay developed at our institution that detects mutations in up to 410 genes (MSK-IMPACT). Samples diagnostic for malignancy and with MSK-IMPACT requested were identified. Pathology and clinical data were drawn from the medical record and MSK-IMPACT results were examined. **Results:** 784 EBUS-FNA were done in the study period. MSK-IMPACT was requested on 115 positive samples. MSK-IMPACT was successful in 99 samples (86.1%), identifying an average of 12.7 mutations at a mean coverage depth of 806X. In 17 (17.2%) samples, tumor content was suboptimal (< 20% of nucleated cells), with fewer identified mutations than in cases with higher tumor content (6.8 vs 13.9, p = 0.01). NGS was performed on paraffin-embedded cell blocks in 93 cases (93.9%), and in 6 cases DNA extraction was performed from residual cytological material isolated from supernatant including cell-free DNA. Failures were attributable to low cell content (7), high contamination by benign cells (4) or both (1) and processing issues (4). No difference in surgical or radiologic parameters were identified for failed or suboptimal samples. **Conclusions:** In our practice, EBUS-FNA has a high rate of success for obtaining adequate tissue for NGS. Ability to utilize cell-free DNA for molecular studies – a new process in our lab – allows increased success of molecular testing in scant samples. Further studies may identify factors contributing to NGS failure and to improving success for samples with minimal cellularity.

8536 Poster Session (Board #272), Sat, 8:00 AM-11:30 AM

Retrospective analysis of clinical outcomes of early stage ALK-positive (ALK+) non-small cell lung cancer (NSCLC). *First Author: Ibiayi Dagogo-Jack, Massachusetts General Hospital, Boston, MA*

Background: ALK rearrangements are important oncogenic drivers in NSCLC. However, the prognostic implications of these rearrangements are unclear due to 1) conflicting results from small series of patients (pts) with early-stage ALK+ NSCLC, and 2) use of highly effective ALK tyrosine kinase inhibitors (TKI) in the metastatic setting. To assess the prognostic significance of ALK rearrangements in resected NSCLC, we performed a retrospective analysis of survival outcomes among pts with resected ALK+, EGFR+, or KRAS+ NSCLC treated at two institutions. **Methods:** We reviewed charts of pts that underwent resection for stage 1-3 NSCLC at Massachusetts General Hospital or Memorial Sloan Kettering Cancer Center between 1/2009 and 12/2012. Recurrence-free survival (RFS) was estimated for each genotype. **Results:** Among 764 pts (480 KRAS+, 255 EGFR+, 29 ALK+), we identified 555 (73%), 101 (13%), and 108 (14%) pts with stage I, 2, and 3 NSCLC, respectively. ALK+ pts were distributed across all stages: 10 (34%) stage I, 6 (21%) stage 2, and 13 (45%) stage 3 NSCLCs. Chemotherapy was administered to 14 ALK+ (0% stage 1, 67% stage 2, 77% stage 3), 45 EGFR+ (3% stage 1, 44% stage 2, 81% stage 3), and 96 KRAS+ pts (4% stage 1, 56% stage 2, 71% stage 3), respectively, for early-stage NSCLC. Thirteen (7%) stage 1 EGFR+ patients received adjuvant EGFR TKI. Although median RFS was not reached for EGFR+ pts, it was 24.3 months (95%CI 11.4 to 65.3) for ALK+ pts and 72.9 months (95%CI 59.7 to undefined) for KRAS+ pts. RFS for ALK+ NSCLC was significantly shorter than the other groups (HR 2.9, 95%CI: 1.75-4.89 vs. EGFR and HR 1.8, 95%CI: 1.12-2.93 vs. KRAS). When adjusted for stage, ALK+ NSCLC remained associated with worse RFS compared to EGFR+ NSCLC (HR 1.8, 95%CI: 1.09-3.12), but not when compared to KRAS+ NSCLC (HR 1.30, 95%CI: 0.79-2.12). **Conclusions:** Early stage ALK+ NSCLC is associated with shorter RFS than EGFR+ NSCLC. The propensity for relapse and the significant anti-tumor activity of ALK TKIs in pts with metastatic NSCLC suggest that enrollment of patients on trials of adjuvant ALK TKIs should be prioritized.

8537 Poster Session (Board #273), Sat, 8:00 AM-11:30 AM

Multi-modality therapy for stage IIIa N2 non-small cell lung cancer: Does the answer lie in the components? *First Author: Jonathan David Spicer, McGill University Health Centre, Montréal, QC, Canada*

Background: Neoadjuvant chemoradiation prior to surgery offers excellent locoregional control, while neoadjuvant chemotherapy I meant to offer improved systemic therapy in stage IIIA N2 non-small cell lung cancer (NSCLC). Data are lacking to select the optimal regimen. We compared oncologic outcomes for stage IIIA N2 NSCLC utilizing granular data from three experienced lung cancer treatment centers. **Methods:** This collaborative retrospective study unites 3 major thoracic centers with differing approaches to IIIA N2 NSCLC. Patients undergoing surgical resection post-neoadjuvant chemotherapy (CxT) or concurrent chemoradiation (CxRT) were included. Primary outcomes were overall and disease- free survival (OS and DFS). **Results:** Demographic data and outcome data are in Table 1. There were no differences in 5-year OS (CxT 40% vs CxRT 42%, p=0.265) nor in DFS (CxT 30% vs 31%, p=0.275). Recurrence rates (CxT47%vsCxRT48%,p=0.799) and patterns were identical (Local: CxT 10% vs CxRT 8%; and Distant: CxT 30% vsCxRT29%,p=0.764). There was no difference in peri-operative mortality. To address potential bias from differing staging strategies, we excluded patients without invasive mediastinal staging and there were still no differences in OS (CxT 40% vs CxRT 42%, p=0.364) and DFS (CxT 30% vs CxRT 31%, p=0.332) Multivariable analysis identified pnemonectomy (HR1.66,p<0.001) and ypN2 (HR1.84, p<0.001) to be associated with overall survival. **Conclusions:** Both treatment strategies produce equivalent and better than expected outcomes compared to historical controls for IIIA N2 NSCLC.

Demographic and outcome data.

	Preoperative chemotherapy only (N=662)	Preoperative chemo-radiation (N=109)	P value
Age, years; Mean(Range)	64(31-86)	62(43-80)	0.050

8538 Poster Session (Board #274), Sat, 8:00 AM-11:30 AM

Interplay between immune infiltration and tumor progression and survival in non-small cell lung cancer: An analysis of institutional and public data. *First Author: Ali Jalali, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In many types of cancer, infiltration of tumor by immune cells, as a reflection of the immune response against the tumor, is thought to play a critical role in clinical outcome. Tumors, however, tend to evade the immune response as they progress. In this study, we characterize the interplay between immune infiltration and tumor progression and survival in non-small cell lung cancer (NSCLC). **Methods:** We performed histologic immune profiling and microarray expression analysis on primary tumor specimens from 275 NSCLC patients (PR: PROSPECT trial) as well as RNA-Seq expression analysis on biopsy specimens from 50 patients with advanced NSCLC (B2: BATTLE-2 trial). RNA-Seq data from the TCGA lung cancer project was also analyzed. Immune Infiltration Score (IIS) was computed from the expression data using the Estimate package in R. Immune Suppression Score (ISS) was defined as the difference between the mean of CD3, CD4, CD8, FOXP3, and PD1 counts in the periphery and core of the tumor. **Results:** Tumor IIS is correlated (all $p < 0.0005$) with tumor immune infiltration as measured by inflammatory cell count on frozen tumor or several immune marker counts in tumor core. IIS is positively associated with survival ($p = 0.04$) independently of age ($p = 0.008$) and stage ($p = 8e\text{-}10$). IIS in the top half is associated with higher median survival vs. bottom half (10.2 vs 2.2 months, $p < 0.0001$) in B2. In TCGA lung adenocarcinoma samples, IIS is higher in stage I/II disease vs stage III/IV ($p = 0.003$). For all immune markers in PR samples, periphery of the tumor on average has higher counts vs tumor core ($p < 0.0011$), and this difference (suppression score) is higher in stage III/IV samples vs stage I/II for CD3, CD4, and CD8 (all $p < 0.04$) and for FOXP3 and PD1 ($p < 0.1$). ISS is negatively associated with survival ($p = 0.02$) independently of age ($p = 0.06$) and stage ($p < 0.0001$). **Conclusions:** As NSCLC tumors progress, immune infiltration in the periphery of the tumor increases while infiltration in the core decreases, reflecting increasing immune suppression. Tumor immune infiltration and suppression, as measured by IIS and ISS, are significant predictors of survival, independently of age and stage.

8539 Poster Session (Board #275), Sat, 8:00 AM-11:30 AM

Risk factors associated with brain metastases in ECOG-ACRIN E1505, a phase III randomized trial of adjuvant chemotherapy with or without bevacizumab for patients with completely resected stage IB (>/= 4 cm) - IIIA non-small cell lung cancer (NSCLC). *First Author: John M. Varlotto, University of Massachusetts Memorial Medical Center, Worcester, MA*

Background: ECOG-ACRIN E1505 was a phase III randomized trial of adjuvant chemotherapy with or without bevacizumab for patients with completely-resected Stage IB (>4CM) – IIIA non-small cell lung cancer. Prior studies have shown that the risk of brain recurrence in patients after definitive surgical resection is approximately 10%; however, covariates associated with development of brain recurrence have varied across these studies. We sought to estimate the incidence of and risk factors for brain recurrence. **Methods:** Among the 1501 patients enrolled to ECOG-ACRIN E1505, 121 patients developed brain metastases as their first site of recurrence and are the subject of this investigation. All 1501 patients underwent a pneumonectomy (N = 192) or (bi) lobectomy and had an R0 resection. The cumulative incidence of brain recurrence was estimated after adjusting for recurrence at other sites and death as competing events. A multivariable regression model was fitted using the methodology of Fine and Gray to evaluate the effect of covariates on the subdistribution of brain recurrence. **Results:** With a median follow-up of 50.3 months, a total of 121 brain metastases had been reported as the first site of recurrence. The incidence of brain recurrence at 12 months post-randomization was 3.7% (95% CI: 2.8% – 4.7%), and it increased to 8.5% (95% CI: 7.0% - 10.0%) at 3 years, and to 9.9% (95% CI: 8.0% - 11.7%) at 6 years. Risk factors for brain metastases included pneumonectomy (HR=1.8; p=0.01), and nonsquamous histology(HR=2.04; p=0.003), but bevacizumab(HR=0.64; p=0.02) was associated with potentially protective effect. **Conclusions:** The cumulative incidence of brain recurrence increased over time to 9.9% at 6 years in this population of patients with surgically-resected non-small cell lung cancer. Treatment, tumor histology, and type of resection appear to be associated with the risk of brain recurrence. Clinical trial information: NCT00324805.

8540 Poster Session (Board #276), Sat, 8:00 AM-11:30 AM

A nomogram for predicting post-operative cancer specific survival in AJCC 8th edition stage I NSCLC patients. *First Author: Wenhua Liang, Department of Thoracic Surgery/Oncology, the First Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory and National Clinical Research Center for Respiratory Disease, Guangzhou, China*

Background: The AJCC 8th edition staging system has moved 4-5 cm 7th edition stage Ib NSCLC to current stage IIa, thus theoretically all current stage I patients are not considered candidates for adjuvant therapy (ad-Tx). This study was to develop a clinical nomogram for predicting cancer specific survival (CSS) of the current stage I resected NSCLC to identify those with higher risk for cancer-related deaths and potentially benefiting from ad-Tx. **Methods:** NSCLC cases between 1998 and 2013 was extracted from the SEER database and were randomly divided into training (n = 23,496) and validation (n = 7,915) cohorts. We identified and integrated the recurrence-associated factors to build a nomogram. The model was subjected to bootstrap internal validation and independent validation. The predictive accuracy and discriminative ability were illustrated by calibration plots and concordance index (C-index). We determined the cut-off for high-risk group by matching the nomogram-predicted 5-year CSS with that of the current 4-5 cm stage IIa cases. **Results:** In multivariate analysis, independent factors for CSS were examined lymph node count (< 16 vs. $>= 16$), tumor size, resection scope (lobectomy/segmentectomy/wedge resection), differentiation grade, histology (squamous vs. non-squamous vs. former BAC with majority being AIS/MIA) and visceral pleural invasion, which were then integrated into the model (sex and age were not included due to lack of direction to ad-Tx selection). The calibration curves showed excellent agreement between nomogram prediction and actual observation. The C-index of the nomogram was higher than that of staging system (Ia1, Ia2, Ia3, Ib) (training set, 0.60 vs. 0.56, $P < 0.01$; validation set, 0.60 vs. 0.57, $P < 0.01$). Specifically, 21.5% stage Ib patients (8.8% of all stage I) were categorized into high risk group (score > 29.5) and had inferior CSS compared with 4-5 cm stage IIa patients. **Conclusions:** We established a nomogram that can individually predict CSS for 8th edition stage I NSCLC. By this model, we identified a subset of patients with relatively high risk for recurrence. Further study to determine the impact of postoperative ad-Tx on these high risk patients is undergoing.

8541 Poster Session (Board #277), Sat, 8:00 AM-11:30 AM

Comprehensive molecular and immune profiling of non-small cell lung cancer and matched distant metastases to suggest distinct molecular mechanisms underlying metastasis. *First Author: Won-Chul Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite complete resection, many non-small cell lung cancer (NSCLC) patients still develop and succumb to distant metastases. Previous studies suggested distant metastasis may be due to genomic evolution and/or suppressed immune surveillance. However, the relationship between specific genomic alterations and immune surveillance has not been systemically studied. **Methods:** We performed whole exome sequencing, RNA-Seq, methylation microarray, immunohistochemistry using multiple immune markers, and T cell receptor sequencing on 7 pairs of NSCLC primary tumors and matched metastases including 6 metachronous brain and 1 synchronous liver metastases. **Results:** On average, 84% of all somatic mutations (54% to 97%) and all 28 canonical cancer gene mutations were shared between primary tumors and paired distant metastases. Metastases also resembled paired primary tumors closely in regard to somatic copy number aberration profiles, methylation profiles. Subclonal analysis showed almost identical clonal architectures in 4 of 7 pairs of primary tumor and metastasis comparable to the similarity observed between different regions within the same tumors. The other 3 pairs, however, displayed clear evidence of clonal evolution. We validated these findings in a published dataset consisting of 38 pairs of primary NSCLC tumors and matched distant metastases. The RNA-Seq data showed that 25 of the top 35 significantly down-regulated signaling pathways in metastases relative to primary tumors were related to immune activation, which was validated in an independent cohort of 41 primary NSCLC tumors and distant metastases using NanoString's PanCancer Immune Profiling Panel. **Conclusions:** Our data suggest that molecular mechanisms underlying postsurgical distant metastasis may be variable among NSCLC patients. While genomic evolution may play a role in development of metastasis in some patients, distant metastasis may be early event during carcinogenesis without further genomic evolution in a substantial proportion of NSCLC patients. Furthermore, immune suppression may be a characteristic of cancer cells of metastatic capacity.

8542 Poster Session (Board #278), Sat, 8:00 AM-11:30 AM

Results of stereotactic body radiation therapy (SBRT) for T2 lung cancer: Outcomes of longer term follow-up. *First Author: Stephen Shamp, University Hospitals, Cleveland, OH*

Background: SBRT is a well-established, highly efficacious treatment for T1N0 non-small cell lung carcinoma (NSCLC). Its efficacy in T2N0 cancers is less clear. This is a review of our institutional experience with long-term follow-up. **Methods:** 45 patients with medically inoperable T2 N0/Nx M0 NSCLC who were treated with definitive SBRT between 2009 and 2013 were analyzed retrospectively. All patients underwent PET/CT staging and fiducial marker placement for image guided therapy with the Cyberknife platform. Radiation dose was 50 Gray in 5 fractions (N = 24), 50 Gray in 4 fractions (N = 11) or 54-60 Gray in 3 fractions (N = 10) delivered over 7 to 14 days. We analyzed overall survival from the date of start of SBRT, and we performed analyses actuarially using Cox regression analysis and Kaplan-Meier survival analysis for comparisons of hazard ratio (HR) among subgroups. **Results:** 45 patients were studied (median age 74). The 5-year actuarial overall survival was 18.7% (39.3% at 2 years), with most patients dying from lung cancer recurrence/progression outside of the treatment field. Subgroup analyses showed no statistically significant differences with respect to age, gender, histology, nominal radiation prescription dose, tumor diameter or PTV target volume (median PTV 87cc). There was statistically significantly better survival associated with increased maximum biologically effective dose (BED10) of radiation at the center of the tumor ($p = 0.03$). **Conclusions:** Unlike the outcomes for T1 NSCLC, our results in T2 NSCLC were disappointing, with a high rate of out-of-field failure and death from lung cancer. We stress the importance of diagnosis and treatment of NSCLC at the T1N0 stage. We suggest that patients with T2N0/Nx NSCLC be considered for SBRT dose intensification and/or combined modality therapy protocols.

8543 Poster Session (Board #279), Sat, 8:00 AM-11:30 AM

Detailed pathologic evaluation of low dose CT (LDCT) detected stage I/0 lung adenocarcinomas (ADCA). *First Author: Eric Burks, Lahey Hospital and Medical Center, Burlington, MA*

Background: Although LDCT lung screening improves survival, some worry that indolent BAC-like ADCA may be over-detected/treated. Comprehensive histologic subtyping has recently been adopted to improve grading and thus risk stratification in lung ADCA. We report a detailed pathologic comparison of stage I/0 lung ADCAs detected by LDCT screening vs. incidentally discovered ADCAs stratified by NCCN risk criteria. **Methods:** We performed comprehensive histologic subtyping on 35 consecutive stage I/0 LDCT screen detected ADCAs in patients meeting NCCN group 1/2 high risk (HR) criteria and compared to incidentally detected stage I/0 ADCAs meeting HR (n = 41) or low-risk (LR, n = 28) criteria. **Results:** Screen detected and incidentally detected ADCAs from HR groups show an equally low-rate of indolent, non-invasive/minimally invasive ADCAs (9%) compared to LR patients (36%). Aggressive solid predominant ADCAs were equally more frequent in HR patients from screen and incidentally detected patients (19%) compared to LR patients (6%). The rate of angiolymphatic invasion (59%) and air space invasion (32-34%) were similarly elevated in HR screen and incidental patients compared to LR patients (39% & 17% respectively). A collection of lepidic predominant (BAC-like) ADCAs associated with aggressive non-predominant cribriform and/or solid patterns, elevated mitotic rates, and high proportion of lymphatic invasion were uniquely observed in the screen-detected group (12%). Subgroup analysis of screen detected NCCN group 1 vs. 2 shows group 2 tumors exhibit histologic features which are at least as aggressive as group 1 tumors, albeit at smaller invasive sizes (1.2 cm vs. 1.5 cm) and lower stage (IA 75% vs. 61%). **Conclusions:** This is the first detailed pathologic comparison of LDCT screen detected vs incidentally discovered stage I/0 ADCA. Tumors from HR patients are pathologically more aggressive than LR tumors. Not all BAC-like tumors in LDCT screen detected patients should be presumed indolent given that approximately half of these bear histologic features of aggressive ADCAs while still in a lepidic predominant phase. NCCN group 2 tumors are similar to group 1 and should be further studied.

8544 Poster Session (Board #280), Sat, 8:00 AM-11:30 AM

Short- and long-term outcomes of early stage non-small cell lung cancer (NSCLC) surgery. *First Author: Michael J. Kelley, Durham VA Medical Center, Durham, NC*

Background: The goal of this study was to determine patient factors associated with short- vs long-term survival after surgery for stage I/II NSCLC and assess the distribution of causes of death over time. **Methods:** Using the VA Central Cancer Registry, we identified patients diagnosed 2001-2005 with stage I/II NSCLC who had surgery and survived 30 days after resection. We used multivariate logistic regression models to determine the impact of patient characteristics on 1 year (1Y), 5 year (5Y), and 10 year (10Y) mortality. We compared causes of death at 1Y versus 5Y after diagnosis. **Results:** The analysis included 4,693 patients. Among these patients, the 1Y, 5Y, and 10Y overall survival (OS) rates were 87%, 45%, and 22%, respectively. 50% of patients alive at 5 year survived to 10 years. For each survival time period, highest survival rates were among patients who were younger ($\leq$65), had stage I disease, had lobectomy, and had fewer comorbidities (all $p < 0.0001$). Significant differences in 1Y and 10Y OS were noted for histology, with highest 1Y OS among adenocarcinoma (88%) and squamous cell (87%) and highest 10Y OS among large cell (28%) and adenocarcinoma (25%). Racial differences were only observed in 10Y OS (whites 22%, blacks 26%, $p = 0.01$). In multivariate analyses, age $>$ 65, stage II disease, surgery other than lobectomy, and $\geq$3 comorbidities were associated with increased likelihood of 1Y, 5Y, and 10Y mortality. Large cell and other histology were the only additional significant predictors of 1Y mortality [OR: 1.94 (1.33-2.84) and OR:1.36 (1.05-1.77), respectively], and squamous cell histology was a significant predictor of 10Y mortality [OR: 1.19 (1.02-1.40)] relative to adenocarcinoma. Among patients who died within 1 year of diagnosis (n = 616), the primary causes of death were lung cancer (63%), cardiovascular disease (10%), other cancer (8%), respiratory disease (3%), and other causes (15). The contribution of these causes of 5Y mortality (n = 2602) were 60%, 11%, 10%, 4%, and 12%, respectively. **Conclusions:** Half of patients alive at 5Y after resection of stage I/II NSCLC were alive at 10Y. 10Y survival is associated with younger age, earlier stage, non-squamous histology, lobectomy, and fewer comorbidities, but not race.

8545 Poster Session (Board #281), Sat, 8:00 AM-11:30 AM

Intratumor heterogeneity of stage IA lung adenocarcinoma by multiregion whole exome sequencing and association with survival. *First Author: Kelly Quek, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Our previous study has suggested that complex genomic intratumor heterogeneity (gITH) was associated with an increased risk of relapse in patients with localized lung adenocarcinomas (LUAD). We have launched a study to investigate molecular and immune profile ITH of Stage IA NSCLC (a patient population with no optimal biomarker to guide postsurgical therapy) to understand the molecular evolution during early carcinogenesis and to identify biomarkers for early detection and intervention. Here, we report the preliminary analysis on gITH. **Methods:** We performed multiregion whole exome sequencing on 30 Stage IA LUAD and matched normal lung tissue to a median sequencing depth of 494x. 15 patients have relapsed within 3 years postsurgery (cases) and 15 patients have not relapsed with a minimum of 5-year postsurgical follow up (controls). Cases and controls are 1:1 matched for the key prognostic factors including tumor size, smoking status, age, gender, ethnicity and lobectomy or wedge resection. Shannon diversity index (SDI) was used to quantify ITH in each individual tumor. Kaplan-Meier method was used to evaluate the relationship between ITH and disease-free survival (DFS) as well as overall survival (OS). **Results:** Consistent with our previous study, 108 of 110 (98.2%) canonical cancer gene mutations were shared events by all regions of individual tumor. Compared to non-relapsed controls, tumors from relapsed cases demonstrated significantly higher degree of ITH (SDI of 1.78 in cases vs 1.58 for controls, $p = 0.016$). Higher degree of gITH was associated with shorter DFS ($p = 0.008$) and shorter OS ($p = 0.0153$). Significantly higher mutation burden was observed in tumors from relapsed patients (median of 10.86 mutations per MB in cases vs 7.45 mutations per MB in controls, $p = 0.03$). Analysis of gITH on a larger cohort and on predicted neoantigen, methylation, gene expression and immune profiles are in progress. **Conclusions:** Majority of cancer gene mutations are clonal events during early carcinogenesis of LUAD. Complex gITH may be associated with more aggressive biology and inferior clinical outcome in patients with Stage IA LUAD, therefore, may be evaluated as a potential biomarker.

8546 Poster Session (Board #282), Sat, 8:00 AM-11:30 AM

Tolerability of veliparib (V) in combination with carboplatin (C)/paclitaxel (P): Based chemoradiotherapy (CRT) in subjects with stage III non-small cell lung cancer (NSCLC). *First Author: David E. Kozono, Dana-Farber Cancer Institute, Boston, MA*

Background: CRT is a standard for patients with Stage III NSCLC. V is a potent, orally bioavailable PARP1/2 inhibitor that can delay DNA repair following chemotherapy or radiation induced damage. A Phase 2 study indicated favorable efficacy of V vs placebo when added to C/P in advanced NSCLC (Ramalingam et al. *Clin Cancer Res.* 2016). Based on these results, a Phase 1/2 trial was initiated to study the safety and efficacy of V/C/P-based CRT in the treatment of Stage III NSCLC. **Methods:** Subjects without prior NSCLC therapy suitable for definitive CRT received V plus C AUC 2 + P 45 mg/m^2 weekly + 60 Gy over 6-9 weeks. V was escalated from 60 mg BID to a maximum planned dose based on prior studies of 240 mg BID via 3+3 design with allowed over-enrollment followed by consolidation therapy of V 120 mg BID + C AUC 6 + P 200 mg/m^2 for up to two 21-day cycles. **Results:** Thirty-one subjects (median age 64; 10 male) have been enrolled to date into dosing cohorts at 60 mg (7), 80 mg (9), 120 mg (7) and 200 mg (8). PK of V was dose proportional. CRT or V required dose reduction for 0 or 1 subject, respectively. Four (13%) subjects discontinued study during CRT. No DLTs have been observed and an MTD has not yet been identified. The most common any grade AEs were fatigue (16), esophagitis (15), nausea (13), neutropenia (12), thrombocytopenia (12), constipation (10) and decreased appetite (10). 21 SAEs were observed including 8 with reasonable attribution to V but outside the DLT window including G3/4 febrile neutropenia (2), G3 dehydration (1), G3 vomiting (1), G3 radiation esophagitis (1), G3 esophageal stricture (1), G3 intractable N/V (1) and G5 sepsis during consolidation (1). Of 21 subjects evaluable for tumor assessment, best response was CR (1), PR (11), SD (6), and PD (3). **Conclusions:** V/C/P-based CRT followed by V/C/P consolidation therapy is a tractable regimen for the treatment of Stage III NSCLC. A randomized placebo-controlled Phase 2 extension of this study is planned. Clinical trial information: NCT02412371.

8547 Poster Session (Board #283), Sat, 8:00 AM-11:30 AM

Phase Ib study of tepotinib in EGFR-mutant/c-Met-positive NSCLC: Final data and long-term responders. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Patients (pts) with NSCLC that is initially responsive to EGFR tyrosine kinase inhibitors (EGFR TKI) typically develop resistance, often associated with aberrant c-Met activity. Dual inhibition of EGFR and c-Met is therefore a rational option to treat c-Met+ EGFR TKI-resistant NSCLC. Tepotinib is a highly selective c-Met inhibitor with good tolerability and promising activity against solid tumors. We report final data from a phase Ib trial of tepotinib + gefitinib in pts with c-Met+/EGFR-mutant NSCLC conducted in Asia. **Methods:** Eligible pts were adults with locally advanced/metastatic NSCLC and ECOG PS 0–1. Tumors had to express EGFR with an activating mutation be resistant to EGFR TKI therapy and be c-Met+ by IHC. Pts received tepotinib 300 or 500 mg QD combined with gefitinib 250 mg QD (T300G250 or T500G250). The primary objective was to determine the recommended phase II dose (RP2D) of tepotinib in combination with gefitinib; secondary objectives included pharmacokinetics (PK), safety, and antitumor activity. **Results:** 18 pts were enrolled (median age 65 [41–78]; 8 male); 6 received T300G250, 12 T500G250. No dose-limiting toxicities were observed, and tepotinib 500 mg QD was confirmed as the RP2D. 17 pts experienced treatment-related treatment-emergent adverse events (TRTEAEs), mostly grade $\leq$2 and most commonly diarrhea (12), rash (8), and amylase increase (6). Grade $\geq$3 TRTEAEs were increased amylase (n = 4), increased lipase (3), neutropenia (1), and hyperglycemia (1). The best overall response was partial response in 6 pts; 4/7 pts with IHC 3+ tumors responded (all treated with T500G250) vs 2/11 with IHC 2+ tumors. Response durations of pts with PR were 4.2–12.5 months. 4/18 pts (IHC 2+, n = 3) had stable disease. 8 pts experienced progression free survival $>$ 5 months, 3 pts $>$ 10 months. PK were as expected from previous studies. **Conclusions:** Tepotinib in combination with gefitinib was well tolerated. The RP2D of tepotinib for use in combination with gefitinib in NSCLC is 500 mg QD. T500G250 showed signs of activity against c-Met+ tumors. A phase II trial is randomizing $\approx$156 pts with c-Met+/T790M– tumors who have failed first-line EFGR TKI 2:1 to tepotinib + gefitinib or pemetrexed + cisplatin/carboplatin. Clinical trial information: NCT02864992.

8548 Poster Session (Board #284), Sat, 8:00 AM-11:30 AM

Prognostic impact of PD-L1 expression in correlation with HLA class I expression status in stage I adenocarcinoma of the lung. *First Author: Kazue Yoneda, University of Occupational and Environmental Health, Kitakyushu, Japan*

Background: Programmed death-ligand 1 (PD-L1) and human leukocyte antigen (HLA) class-I, expressed on tumor cells (TCs), are important regulators in cancer immunity. The current study was conducted to assess prognostic impact of PD-L1 status in correlation with HLA class-I status in lung adenocarcinoma. **Methods:** A total of 94 patients with completely resected pathologic stage I lung adenocarcinoma were retrospectively reviewed. PD-L1 expression on TCs was evaluated with immunohistochemistry, in correlation with several clinicopathological and molecular features including HLA class-I expression on tumor TCs. **Results:** Seventeen patients (18.1%) had tumor with positive PD-L1 expression (percentage of TCs expressing PD-L1, $\geq$ 5%), and the incidence was higher in smokers with higher smoking index and in poorly differentiated tumor. There was no significant correlation between HLA class-I expression and PD-L1 expression. PD-L1-positivity was a significant factor to predict a poor survival (5-year survival rate, 66.7% versus 85.9%; P = 0.048), which was enhanced in tumor with normal HLA class-I expression (p = 0.029) but disappeared in tumor with reduced HLA class-I expression. **Conclusions:** The prognostic impact of PD-L1 expression on TCs in early-stage resectable lung adenocarcinoma was distinct according to HLA class-I expression on TCs.

8549 Poster Session (Board #285), Sat, 8:00 AM-11:30 AM

Lobectomy with mediastinal nodal dissection versus partial lobectomy in patients with bronchial carcinoid tumors: A NCDB analysis. *First Author: Gustavo Figueiredo Marcondes Westin, Mayo Clinic, Rochester, MN*

Background: Bronchial carcinoid tumors are a rare group of neoplasms that usually have an indolent clinical behavior. Surgical resection is the main treatment modality for patients with early stage disease, however it is unclear if lobectomy with mediastinal lymph node dissection (L) is superior compared to partial lobectomy (PL). **Methods:** Utilizing the National Cancer Database from 2004-2012, 1551 patients diagnosed with T1N0 or T2N0 typical carcinoid tumors (CT), and 167 atypical carcinoid tumors (ACT), who underwent L or PL (segmental or wedge resection) as initial treatment strategy, and did not receive chemotherapy or radiation were identified. All patients had pathologically confirmed diagnosis, negative surgical margins, and complete follow up data. Overall survival (OS) was analyzed utilizing Kaplan-Meier curves, and log-rank tests were used for statistical comparisons. Cox proportional hazards were performed to control for age, sex, race, grade, year of diagnosis, Charlson/Deyo Score, insurance, income, and facility type. T-test was used to compare post-surgical hospital stay. **Results:** The entire cohort median age was 61 years (range 18-90), and male to female ratio was 0.43. 75% of patients with CT and 78% of ATC underwent L. The 90 day mortality following surgery was $<$ 1 % in both surgical groups. Patients who underwent L had longer post-operative hospitalization stay (mean 5.3 vs. 4.3 days; $p < 0.001$). The 5 year survival for patients with CT was 95% in the L versus 93% in the PL group (p = 0.62), and for ACT 89% in the L versus 81% PL group (p = 0.28). In a multivariate analysis increasing age was the only prognostic factor, and was associated with inferior survival. The HR for death comparing PL to L was 1.09 (95% CI: 0.65-1.78; p = 0.71) for CT and 1.25 (95% CI: 0.45-3.23; p = 0.65) for ACT. **Conclusions:** Patients with localized node-negative CT and ACT have excellent 5 year survival. Performing a lobectomy with mediastinal node dissection may not provide additional benefit compared to partial lobectomy, but this may increase the length of hospital stay.

8550 Poster Session (Board #286), Sat, 8:00 AM-11:30 AM

The correlation between mutation burden and disease free survival in patients with lung adenocarcinomas. *First Author: Changzheng Wang, BGI Education Center, University of Chinese Academy of Sciences, Shenzhen, China*

Background: Lung cancer is one of the leading causes of cancerous deaths globally. High mutation burden is a special character in lung adenocarcinoma patients. Mutation burden is usually based on the number of non-synonymous mutations implying the instability of genome. We hypothesize genome-wide mutation burden indicates mutation degree and is correlated with prognostic in lung adenocarcinoma. **Methods:** Whole-exome sequencing was performed on 98 Chinese lung adenocarcinoma patients with tumor and normal tissue to a mean depth of 49.6x. The total number of non-synonymous somatic mutations was calculated from the sequencing data of each patient. Patients were divided into high mutation burden and low mutation burden groups in accordance with the mean mutation burden and Kaplan-Meier analysis was performed for survival analysis between these two groups. The association between mutation burden and age or smoking status was analyzed by Wilcoxon rank-sum test. **Results:** Among these 98 patients, the values of mutation burden varied from 5 to 1121 with mean value 161.8, 36 (36.7%) patients with smoking history and 34 (34.7%) patients were older than 65 years; the numbers of patients in I, II, III stage were 19 (19.4%), 16 (16.3%) and 63 (64.3%) respectively. 32 patients were classified into high mutation burden group, the other 66 patients classified into low mutation burden group. Survival analysis showed a significantly longer disease free survival (DFS) in low mutation burden group (p-value = 0.0133).Mutation burden was significantly associated with age ($<$ 65 vs $\geq$65, p-value = 0.0208) and smoking status (p-value = 8.67×10^{-4}). **Conclusions:** The association between mutation burden and age or smoking status suggested the high risk for mutation burden accumulation. The significant difference of DFS between high mutation burden and low mutation burden groups reveals the potential of mutation burden as one of the prognostic factors in patients with lung adenocarcinomas.

8551 Poster Session (Board #287), Sat, 8:00 AM-11:30 AM

Differential expression of immune inhibitory markers in association with HLA class I and the immune microenvironment in resected lung adenocarcinomas. *First Author: Mingjuan Lisa Zhang, Massachusetts General Hospital, Boston, MA*

Background: Similar to programed death ligand 1 (PD-L1), indoleamine 2,3-Dioxygenase 1 (IDO1) is known to exert immunosuppressive effects and be variably expressed in human lung cancer. However, IDO1 expression has not been well-studied in lung adenocarcinoma (ADC). **Methods:** PD-L1 and IDO1 expression were evaluated in 261 resected ADC using tissue microarrays and H-scores (cutoff 5). We compared IDO1 with PD-L1 expression in association with clinical features, tumor-infiltrating lymphocytes (TILs), HLA class I (β-2 microglobulin; B2M) expression, molecular alterations, and patient outcomes. **Results:** There was expression of PD-L1 in 89 (34.1%) and IDO1 in 74 (28.5%) cases, with co-expression in 49 (18.8%). Both PD-L1 and IDO1 were significantly associated with smoking, aggressive pathologic features, and abundant CD8+ and T-bet+ (Th1 marker) TILs. PD-L1 expression and abundant CD8+ were inversely associated with a loss of B2M membranous expression (p = 0.0019 and $p < 0.001$, respectively). Compared to PD-L1+/IDO1+ and PD-L1+ only cases, significantly fewer IDO1+ only cases had abundant CD8+ and T-bet+ TILs ($p < 0.001$, respectively). PD-L1 expression was significantly associated with *EGFR* wild-type ($p < 0.001$) and *KRAS* mutants (p = 0.021), whereas there was no difference in IDO1 expression between different molecular alterations. As for survival, PD-L1 was significantly associated with decreased progression-free (PFS) and overall survival (OS), while IDO1 was associated only with decreased OS. Interestingly, there was a significant difference in the 5-year PFS and OS (p = 0.004 and 0.038, respectively), where cases without PD-L1 or IDO1 expression had the longest survival, and those with PD-L1 alone had the shortest survival. **Conclusions:** While PD-L1 +/- IDO1 expression is observed in association with B2M expression, CTL/Th1 microenvironments, *EGFR* wild-type, and *KRAS* mutations, isolated IDO1 expression does not demonstrate these associations, suggesting that IDO1 may serve a distinct immunosuppressive role in ADC. Thus, blockade of IDO1 may represent an alternative and/or complementary therapeutic strategy to reactivate anti-tumor immunity.

8553 Poster Session (Board #289), Sat, 8:00 AM-11:30 AM

Expansion study of ADI-PEG 20, pemetrexed and cisplatin in patients with ASS1-deficient malignant pleural mesothelioma (TRAP). *First Author: Melissa Phillips, St Bartholomew's Hospital, London, United Kingdom*

Background: Argininosuccinate synthetase 1 (ASS1)-deficient malignant pleural mesothelioma (MPM) cells are sensitive to arginine deprivation with pegylated arginine deiminase (ADI-PEG20), which also potentiates the cytotoxic effect of pemetrexed (PEM). In the phase I dose-escalation TRAP study (NCT02029690) we showed that ADI-PEG20 with first-line PEM and cisplatin (CIS) chemotherapy (ADIPEMCIS) produced a 100% disease control rate (DCR) in patients (pts; n = 9) with ASS1-deficient thoracic cancers, with no additional toxicity (Beddowes et al 2017). Here, we present the TRAP expansion cohort experience in MPM. **Methods:** Good performance (ECOG 0-1) MPM pts with non-resectable disease and measurable by modified RECIST, were enrolled in a phase I TRAP expansion cohort at the maximum tolerated dose (MTD) of ADIPEMCIS, using tumoral ASS1 loss as a selection biomarker. PEM (500mg/m2) and CIS (75mg/m2) were given every 3 weeks with weekly IM ADI-PEG20 (36mg/m2) for a maximum of 6 cycles with maintenance ADI-PEG20 in responding pts. Primary endpoint was tumor response rate (modified RECIST), with secondary endpoints including progression-free survival (PFS), overall survival (OS), and toxicity. We measured plasma arginine and citrulline concentrations, ADI-PEG20 antibodies, and biopsied patients on progression to explore resistance mechanisms. **Results:** 31 ASS1-deficient MPM pts (median age 67) were enrolled (11 epithelioid, 10 biphasic and 10 sarcomatoid) out of 92 screened pts. Plasma arginine decreased with a reciprocal increase in plasma citrulline. The partial response rate was 35.5% (95% CI 19.2%-54.6%) with a DCR of 93.5% (95% CI 78.6%-99.2%). Median PFS was 5.6 months (95% CI 4-6) and median OS was 10.1 months (95% CI 6.7-17.7). 10/31 pts (32.3%) experienced grade 3/4 treatment-related toxicities, the most common being neutropenia (16.1%). Upregulation of ASS1 expression was observed in 2/3 biopsies on progression. **Conclusions:** The ADIPEMCIS regimen is active in ASS1-deficient MPM pts, including non-epithelioid disease. Based on these data the ATOMIC-meso phase 2/3 trial has opened comparing ADIPEMCIS versus PEMCISPlacebo, focusing on pts with non-epithelioid MPM. Clinical trial information: NCT02029690.

8554 Poster Session (Board #290), Sat, 8:00 AM-11:30 AM

Patterns of comorbidity, treatment, resource utilization, and referral in malignant pleural mesothelioma patients in the US. *First Author: Marjorie Glass Zauderer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Malignant pleural mesothelioma (MPM) is a rare but aggressive cancer, which may be challenging to diagnose. The standard of care for MPM is cisplatin plus pemetrexed. In the recent phase III MAPS trial, addition of bevacizumab provided a significant survival benefit. There is limited data on real-world MPM treatment patterns to provide context to trial results. Consequently, the present study was conducted to evaluate treatment and referral patterns, co-morbidities and resource use in patients with MPM in the U.S. **Methods:** Patients ≥18 years old with a diagnosis of MPM between Jan 2004 and September 2015 were identified from the MarketScan claims database. Patients were required to have data for 12 months prior, and at least 3 months post, the diagnosis index date. Patients with other (non-MPM) cancers, malignant mesothelioma of non-pleural origin and those enrolled in clinical trials were excluded from the analysis. Treatment and resource utilization were identified by their corresponding HCPCS and DRG codes. Referral patterns were estimated starting from the first lung-related visit during the year preceding MPM diagnosis. **Results:** In the cohort of 1,869 patients, the median age was 71 years (range 61–79) and 65% were male. 4.1% of patients underwent radical surgery and of the remaining 96%, 15.6% had first-line chemotherapy, 33.2% had first-line chemotherapy plus radiotherapy, 11.7% received radiotherapy, and 39.5% received no chemotherapy or radiotherapy. The most common diagnosis on the first lung-related visit was pleural effusion (16.5%), followed by chest pain (10.7%), shortness of breath (9.6%) and cough (8.5%). The median time from first lung-related visit to MPM diagnosis was 77 days (mean 134 days, IQR 23–258). **Conclusions:** This real-world analysis showed that only a small proportion of MPM patients (~4%) received radical surgery and a large number of patients did not receive any treatment at all, indicating a large unmet need for effective treatments in this disease area. Additionally, the pathway to MPM diagnosis may be challenging in this population with a poor prognosis, often involving multiple healthcare contacts over an extended period of time.

8555 Poster Session (Board #291), Sat, 8:00 AM-11:30 AM

Effect of FAK inhibitor defactinib on tumor immune changes and tumor reductions in a phase II window of opportunity study in malignant pleural mesothelioma (MPM). *First Author: Raphael Bueno, Brigham and Women's Hospital and Harvard Medical School, Boston, MA*

Background: Defactinib is an oral Focal Adhesion Kinase (FAK) inhibitor with preclinical activity in MPM. We assessed responses to defactinib treatment prior to planned surgical resection in naive patients with MPM. **Methods:** Three cohorts of 10 participants each received defactinib 400mg BID for 12, 35 and 21 days. Pre- and post-treatment blood, tumor biopsies and imaging were obtained for biomarker, immune cell and tumor response (modified RECIST, Tumor volume and SUV max) assessment. Toxicity was monitored for 30 days post treatment. **Results:** Between 12/2013 and 12/2017, 31 participants were registered at our center; 1 withdrew prior to intervention. Among 30 treated, 24 (80%) were male; median age 70 (47-83) years; surgery was EPP 7%, complete pleurectomy decortication (PD) 10%, extended PD 60%, partial PD 10%, unresectable 13%; MPM subtype was epithelioid 67%, biphasic 17%, sarcomatoid 17%. Expected complications of FAK inhibition, diagnostic/staging/operative procedures occurred in 83% (grade 1, 30%; grade 2, 43%; grade 3, 10%). Unexpected adverse events occurred in 77% (grade 1, 63%; grade 2, 20%; grade 3, 17% [wound-infection, prolonged QT interval, and hyperglycemia in 3% each; increased INR in 7%]; grade 5, 7% [due to progressive disease in 3%, intraoperative anaphylactoid reaction unrelated to the drug in 3%]). Objective partial response was observed in 13%, stable disease in 67%, progression in 17%. Tumor volume decreased 3-72% in 47% patients and increased 1-82% in 53%. SUV max decreased 3-69% in 50% and increased 1-61% in 50%. Biological correlates of treatment included target inhibition (75% pFAK reduction); tumor immune microenvironment changes: increased naïve (CD45RA+PD-1+CD69+) CD4 and CD8 T cells, reduced myeloid and Treg immuno-suppressive cells, reduced exhausted T cells (PD-1+CD69+), reduced peripheral MDSCs; and histological subtype change (pleomorphic or biphasic to epithelioid) in 13% of cases. **Conclusions:** Brief preoperative defactinib exposure was well tolerated, did not alter resectability or mortality compared to prior series, and showed evidence of therapeutic and immunomodulatory effects. Clinical trial information: NCT02004028.

8556 Poster Session (Board #292), Sat, 8:00 AM-11:30 AM

Patterns of metastases in malignant pleural mesothelioma in the modern era: Redefining the spread of an old disease. *First Author: Dearbhaile Catherine Collins, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: Malignant pleural mesothelioma (MPM) has been historically documented as a locally infiltrative disease in large series from the early 1980s. With the changing landscape of cancer diagnosis and treatment, increased areas of unusual metastases have been published as case reports. With no standard second-line therapies for MPM, referral to early phase trial units is common. We report the metastatic patterns of a large cohort of MPM patients treated at the Royal Marsden Drug Development Unit (DDU). **Methods:** Clinical data was gathered for MPM patients referred to the DDU from 1992 to 2016. Radiographic details were collected from CT, bone scan and FDG PET imaging. Prior treatment, response, somatic mutations, clinical trial and survival data was obtained from medical records. **Results:** From the database, 165 evaluable patients with MPM were identified. Median age at diagnosis was 64 years (range 37–90) and 76% were male. Epithelioid MPM comprised 81% and 65% were right sided. Bone metastases were reported in 20%, with the majority lytic in nature (*Table*). Peritoneal and omental disease was evident in 24% with ascites in 16%. In 11% of cases lung metastases presented as diffuse miliary-type pattern. Visceral metastases (15%) were predominantly liver (78%), but also occurred in adrenals, spleen and kidneys. Symptomatic brain metastases were recorded in 3%. Median overall survival was 24.2 months (95% CI: 20.8 - 29.2). **Conclusions:** This large study documents the metastatic patterns of advanced MPM in the 21st century and highlights an increased frequency of traditionally unexpected sites of metastases. Higher than expected incidence of lytic bone metastases (20%) suggests consideration of bone imaging in advanced MPM clinical workflow and trial protocols.

Local spread		Distant spread	
Nodal disease	65%	Parenchymal lung metastasis	27%
Pleural effusion	64%	Peritoneal/omental disease	24%
Chest wall involvement	43%	Bone metastasis	20%
Contralateral lung disease	36%	Subcutaneous metastatic nodules	19%
Pericardial infiltration	29%	Visceral metastasis	15%
Pericardial effusion	12%	Intramuscular metastasis	4%
		Brain metastasis	3%

8557 Poster Session (Board #293), Sat, 8:00 AM-11:30 AM

Biomarkers of pembrolizumab (P) activity in mesothelioma (MM): Results from a phase II trial. *First Author: Hedy L. Kindler, University of Chicago, Chicago, IL*

Background: PD-L1 expression and the Interferon-Gamma gene expression profile (IFN-G GEP) are predictive of response to checkpoint blockade in several solid tumors. Relevant biomarkers in mm pts treated with these agents have not been determined; these were evaluated in a phase 2 trial of P in mm (NCT02399371). **Methods:** Eligible pts had histologically confirmed MM, PS 0-1, disease progression on 1-2 prior regimens. P 200 mg was given Q21 days. Part A (N = 35) determined the response rate (RR) of P in PD-L1 unselected mm pts and assessed an optimal PD-L1 threshold (22C3 IHC assay). If ≥3 responses, the study proceeded to Part B (N = 30), using a biomarker enrichment strategy if a threshold was found. Nanostring nCounter was used to assess IFN-G GEP (6 gene). **Results:** 35 pts enrolled in Part A 5/15-2/16; 1 withdrew. Median age 66 (range 26-85); PS 0: 62%; male: 82%; epithelial/sarcomatoid/biphasic/NOS: 74%/21%/3%/3%; pleural/peritoneal: 85%/15%; 2nd-line: 59%. Partial response (PR): 7 (21%), stable disease (SD): 20 (59%). Median response duration: not reached. Median progression-free survival (PFS): 6.2 months (95% CI: 3.2, 8.2). Median overall survival: 11.9 months (95% CI: 6.4, –). Toxicity ≥ grade 3: adrenal insufficiency, fatigue, pneumonitis 6%; colitis, confusion, hepatitis, hyponatremia, neutropenia, rash 3%. PD-L1 expression by tumor proportion score (N = 32): none (53%); 1-49%: (22%); ≥50%: (25%). PD-L1 IHC (ROC area 0.63; 95% CI: 0.37, 0.89), CD274 mRNA expression, and IFN-G GEP did not correlate statistically with response. Responses occurred in GEP low, non-inflamed tumors, and in PD-L1- tumors. RR was numerically higher in PD-L1+ (27%) than in PD-L1- pts (12%); there was a trend towards longer PFS and OS in PD-L1+ pts. **Conclusions:** P has clinically meaningful single-agent activity in PD-L1 unselected, previously treated mm pts, achieving a 21% RR and a disease control rate of 80%. Biomarkers established in other cancers, such as PD-L1 IHC and IFN-G GEP, may not be as useful in MM. Novel biomarkers including MM-specific gene signatures may be necessary and are being evaluated. Part B of the study is ongoing with no PD-L1 pre-selection (19/30 pts enrolled), and will be used as a biomarker validation cohort. Funded by a MARF grant. Clinical trial information: NCT02399371.

8558 Poster Session (Board #294), Sat, 8:00 AM-11:30 AM

Tremelimumab in combination with durvalumab in first or second-line mesothelioma patients: Safety analysis from the phase II NIBIT-MESO-1 study. *First Author: Luana Calabro, Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy*

Background: The anti-CTLA-4 tremelimumab at two different dose-schedules of administration showed promising activity in second-line malignant mesothelioma (MM) patients (Calabrò et *al.*, *Lancet Oncol*, 2013; Calabrò et *al.*, *Lancet Respir Med*, 2015). These initial results and the efficacy of targeting the PD-1/PD-L1 axis in different tumor types, prompted the NIBIT-MESO-1 study aimed at investigating the efficacy and safety of tremelimumab combined with the anti-PD-L1 durvalumab in mm patients. We report the safety analysis from the fully-enrolled NIBIT-MESO-1 study. **Methods:** The NIBIT-MESO-1 is a phase II, open-label, single Center study. Forty mm patients received tremelimumab at 1 mg/Kg i.v. every 4 weeks (Q4W) for 4 doses, and durvalumab at 20 mg/Kg i.v. Q4W for 13 doses. Primary objective is immune-related (ir)-objective response rate; secondary are safey, ir-disease control rate, ir-progression free survival, and overall survival. Tumor assessment *per* ir-modified RECIST or ir-RECIST 1.1 for pleural or peritoneal MM, respectively, was performed at baseline and q12 weeks. Adverse events (AEs) were recorded according to CTC v4.0. (ClinicalTrials.gov Id: NCT02588131). **Results:** From October 2015 to October 2016, 40 mm patients (38 pleural and 2 peritoneal), median age 64 years (range 41-80), ECOG performance status 0 (n = 19) or 1 (n = 21) were enrolled in the study. mm histology was epithelioid (n = 32), biphasic (n = 5), sarcomatoid (n = 2) or undefined (n = 1). As of January 2017, 12 first or 28 second-line mm patients received a median of 5.5 doses of therapy (range = 1-13). Twenty-four patients (60%) experienced any grade irAEs: 5 patients (12.5%) had grade 3-4 AEs, the most frequent being hepatotoxicity (7.5%). AEs were generally manageable and reversible per protocol guidelines. Three patients (7.5%) were discontinued due to treatment-related AEs (1 trombocytopenia, 1 limbic encephalitis, 1 liver toxicity). **Conclusions:** The combination of tremelimumab and durvalumab is safe and manageable in mm patients. Clinical trial information: NCT02588131.

8559 Poster Session (Board #295), Sat, 8:00 AM-11:30 AM

Systemic therapy use and outcomes after relapse from accelerated hemithoracic radiation and surgery for malignant pleural mesothelioma (MPM). *First Author: Sara V. Soldera, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The prognosis of patients (pts) with MPM remains poor. Accelerated hemithoracic radiation followed by extrapleural pneumonectomy and adjuvant chemotherapy in ypN2 disease (SMART) provides encouraging results. The ability to administer systemic therapy (Tx) and response rate (RR) after recurrence remains unclear. We therefore examined subsequent lines of Tx and outcomes following relapse after SMART. **Methods:** A retrospective analysis of pts diagnosed with recurrent MPM following SMART was conducted at a single institution. OS was determined from date of relapse to death and was estimated using the Kaplan-Meier method. Potential prognostic variables were tested utilizing the log-rank test. **Results:** Out of 86 pts undergoing SMART from 2008 to 2016, 53 (62%) developed recurrent disease of which 36% had pathological confirmation. Two cases with initial epithelial subtype on surgical specimen relapsed with different histology (sarcomatoid and small cell). In 48% of pts, relapse was unclear at first imaging (n = 42) and a median of 98 days (range 6-966) lapsed between first suspicion and final diagnosis. The median age at relapse was 66 years (range 45-79), 47% had a performance status (PS) ≥2 (n = 45) and 64% were of epithelial subtype. After a median follow up of 7.6 mo, the median OS was 5.2 mo. PS ≥2 was associated with worse OS (2.8 vs 10.7 mo, $p < 0.001$). Of 42 pts followed after relapse, 36% received any Tx (19% 1 line; 12% 2 lines; 5% ≥3 lines). Tx was omitted in 62% of pts due to poor PS (26/42). First line Tx consisted of platinum doublet in 93% of pts (n = 15). Of 13 pts with response evaluable disease, RR was 15% (0 CR, 15% PR). Of note, 0/13 pts had neoadjuvant Tx and 3/13 pts had adjuvant Tx (10, 13 and 38 mo lapsed between end of adjuvant Tx and start of Tx in the relapsed setting). 6/15 pts discontinued Tx due to toxicity, 5/15 due to progression and median number of cycles was 4. **Conclusions:** Pts with relapsed MPM following SMART have poor prognosis and low RR to first line Tx. Poor performance status at relapse is a poor prognostic factor. Earlier detection, novel diagnostic markers of relapse and consideration of maintenance strategies should be investigated in future studies.

8560 Poster Session (Board #296), Sat, 8:00 AM-11:30 AM

Malignant mesothelioma in 91 danish women: The environmental asbestos exposure. *First Author: Vasiliki Panou, Department of Respiratory Diseases and Clinical Cancer Research Center, Aalborg University Hospital, Aalborg, Denmark*

Background: Malignant Mesothelioma (MM) is an asbestos-related malignancy that presents mainly in the pleura (MPM) and peritoneum (MAM). In a densely populated area of Aalborg city in North Jutland, Denmark, a large Eternit asbestos factory that was active for 60 years until 1986 and two shipyards were situated. The Region of North Jutland, Denmark has a high mm incidence in women of 1.0/100,000. **Methods:** From 1974-2015, 101 histological and cytological samples of women diagnosed with mm in Aalborg University Hospital were identified re-evaluated by modern immunohistochemistry. Patient information regarding asbestos exposure was retrieved from medical records and selected Danish registries. Asbestos exposure was classified as *primary* for asbestos workers; *domestic,* for women living with an asbestos worker; *environmental,* when living or working within 10.000 meters from an asbestos emitting location; *unknown,* where no source of asbestos exposure could be identified. **Results:** Clinical and histopathological mm diagnosis was certain for 91 women. Potential asbestos exposure is summarized in Table 1. The employment of the women and their relatives include work at the asbestos cement factory, shipyard, construction, laboratory, pipe factory, electrician and insulator. The women with domestic and combined domestic and environmental (secondary) exposure to asbestos were most prone to develop MPM rather than MAM while women primary exposed to asbestos developed MAM rather than MPM (p=0.016). **Conclusions:** This study showed that the vast majority (64%) of the women diagnosed with mm had documented non-occupational asbestos exposure and almost 1/5 had a sole environmental exposure, by living in proximity to asbestos industry. Environmental asbestos exposure is a serious risk factor for mm in women. Primary asbestos exposure, inferring more intense exposure through occupation, may predispose to peritoneal mesothelioma in women.

Types of asbestos exposure	Number of patients (%)
Primary	8 (9%)
Domestic	14 (15%)
Environmental	18 (19%)
Combined domestic and environmental	26 (29%)
Unknown	25 (27%)

8561 Poster Session (Board #297), Sat, 8:00 AM-11:30 AM

A nonrandomized confirmatory phase III study of sublobar surgical resection for peripheral ground glass opacity dominant lung cancer defined with thoracic thin-section computed tomography (JCOG0804/WJOG4507L). *First Author: Kenji Suzuki, Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

Background: The optimal mode of surgery for peripheral ground glass opacity (GGO) dominant lung cancer (LC) defined with thoracic thin-section computed tomography (TSCT) remains unknown. **Methods:** We conducted multi-institutional confirmatory phase III trial to evaluate the efficacy and safety of sublobar resection for peripheral GGO dominant LC. Mode of surgery is basically wedge resection, and segmentectomy is allowed when surgical margin is insufficient ($<$ 5 mm) or histological invasiveness. LC with maximum tumor diameter (MTD) $\leq$ 2.0 cm and with consolidation tumor ratio $\leq$ 0.25 based on TSCT were registered. The primary endpoint was 5-year relapse-free survival (RFS). The planned sample size was 330, with the expected 5-year RFS of 98%, threshold of 95%, one-sided α of 5% and power of 90%. Survival analyses were performed using the Kaplan-Meier method and their confidence intervals were estimated by Greenwood's formula. **Results:** Between May 2009 and April 2011, 333 pts were enrolled from 51 institutions. The primary endpoint, RFS was estimated on 314 pts who underwent sublobar resection. Median age was 62 (range 24 - 79) and 104 were smokers. Median MTD on lung window was 1.20 cm (0.53 - 2.00). Median MTD of consolidation was 0 (0.00 - 0.48). Operative modes were 258 wedge resection and 56 segmentectomy. Histological diagnosis were 310 adenocarcinomas, 27 pre-cancerous lesions, and 14 non-neoplastic lesions. Median pathological surgical margin was 15 mm (0 - 55). Grade 2 or higher postoperative complications based on CTCAE v3.0 were observed in 119 (37.9%), and Grade 3 in 17 (5.4%), without any Grade 4 or 5. The 5-year RFS was 99.7% (95% CI, 97.7 - 100.0%), which met the primary endpoint. There was no local relapse. The ratio of FEV1.0 change between preoperative and one year after surgery over preoperative value ranged -37% to +49% with a median of -5%. **Conclusions:** Sublobar resection, mainly wedge resection, offered sufficient local control and RFS for peripheral GGO dominant LC on TSCT. Sublobar resection should be the first choice of mode of surgery if surgical margin is enough preserved. Clinical trial information: 000002008.

8562 Poster Session (Board #298), Sat, 8:00 AM-11:30 AM

Optimal thoracic radiation dose in limited stage small cell lung cancer. *First Author: Madhusmita Behera, Winship Cancer Institute, Acworth, GA*

Background: Several studies have demonstrated improved overall survival in limited stage small cell lung cancer (LS-SCLC) patients (pts) with the addition of thoracic radiation therapy (RT) to chemotherapy. However, the optimal dose of thoracic RT when given daily, which is the most common practice pattern in the US, is yet to be firmly established. We analyzed outcomes associated with once-daily low dose (LD) RT relative to once-daily high dose (HD) RT for LS-SCLC in the National Cancer Data Base (NCDB). **Methods:** The NCDB was queried to capture pts with LS-SCLC treated with thoracic RT from 2004-2013. The cohort of pts that received 60 Gy (LD) was compared with the cohort that received RT $\geq$70 Gy (HD). The univariate (UV) association of overall survival (OS) was assessed using Cox proportional hazards models and log-rank tests. A multivariable (MV) Cox proportional hazard model and Kaplan-Meier (KM) analyses were performed to compare the LD vs. HD cohorts. Propensity score matching method was also implemented to reduce treatment selection bias. All analyses were performed using SAS Version 9.4. **Results:** A total of 5,159 pts (LD-3441; HD- 1718) were included in the analysis. Pt characteristics (LD/HD): median age 65/64 yrs; males 44/46%; whites 89/88%, academic centers 28/31%, Charlson-Deyo comorbidity score 0- 61%/64%; government insured 61/57%. 96% of pts in LD and 95% in HD cohorts had received chemotherapy. On MV analysis, no differences were found in OS between HD and LD RT(HR 0.98, p = 0.5), which was confirmed by KM analysis with 5-yr survival of 21% in LD vs 21.5% in HD (p = 0.8). On MV analysis of OS stratified by comorbidity score, LD was associated with significantly better survival compared to HD in pts with a comorbidity score of 1 and above (HR 0.87, p = 0.02). The LD group also had a better 5-yr survival than HD group in pts with higher comorbidity score (19% vs 14%, p = 0.01). No difference in survival was noted between the two cohorts for pts with no recorded comorbidities (HR 1.03, p = 0.6). **Conclusions:** In LS SCLC pts, survival was similar in pts who received daily RT of 60 Gy compared to those that received 70 Gy and above. In pts with worse performance status, those who received LD RT of 60 Gy had better survival.

8563 Poster Session (Board #299), Sat, 8:00 AM-11:30 AM

Disparities in the management of stage I small cell lung carcinoma (SCLC): A National Cancer Database (NCDB) analysis. *First Author: Zaheer Ahmed, Department of Medicine, University of Missouri, Kansas City, MO*

Background: Effective treatment of stage I SCLC requires both surgical resection and chemotherapy. We analyzed the National Cancer Database (NCDB) for the treatment patterns and disparities in the management of stage I SCLC. **Methods:** We identified patients with clinical stage I SCLC from the NCDB. Median and 5-year survival were calculated using Kaplan Meier analysis. Multivariable logistic regression model was used to determine the factors that can predict surgical resection. **Results:** We identified 4,849 patients with clinical stage I SCLC diagnosed between 2004 and 2012. We divided them into 4 treatment groups; surgical resection with chemotherapy (n = 774, 15.9%), surgical resection without chemotherapy (n = 423, 8.7%), non-surgical treatment (n = 2,978, 61.4%) and no treatment (n = 674, 13.9%). 5-year survival for each group was 47%, 36%, 22% and 11% respectively, (p-value $<$ 0.001). Among patients who underwent surgical resection, lobectomy (67.1%) was the most common procedure followed by sublobar resection (28.8%) and pneumonectomy (2.8%) with 5-year survival of 48%, 34% and 33% respectively, (p-value $<$ 0.001). Multivariate analysis identified that elderly (age $\geq$ 70) patients, African-Americans, patients with low income and Medicaid are less likely to undergo surgery, (p-value $<$ 0.001). Patients receiving treatment at academic cancer centers, right sided tumors and Charlson score $\geq$ 1 are more likely to receive surgery, (p-value $<$ 0.001). **Conclusions:** Despite better outcomes only 25% of patients undergo surgery for stage I SCLC. Over the years there has been only a modest increase in the proportion of patients undergoing resection. We have identified significant disparities in the treatment of patients with stage I SCLC. Our data clearly show the need to educate physicians on appropriate delivery of care for patients with stage I SCLC.

8564 Poster Session (Board #300), Sat, 8:00 AM-11:30 AM

Association of PD-L1 expression with tumor infiltrating immune cells and mutation burden in the high grade neuroendocrine carcinoma of the lung. *First Author: Hye Sook Kim, Myongji Hospital, Goyang, Republic of Korea*

Background: Large cell neuroendocrine carcinoma (LCNEC) and small cell lung cancer (SCLC) are recognized as high grade neuroendocrine carcinoma of the lung and remain among the most fatal malignancies. Programmed death-ligand 1 (PD-L1) is expressed in a group of cancers that may be suitable for specific immunotherapy. We retrospectively investigated PD-L1 expression in tumor cells (TC) and tumor infiltrating immune cells (IC) and correlated this with mutation burden and clinical outcome. **Methods:** A total of 192 patients with LCNEC (n = 72) and SCLC (n = 120) were explored. PD-L1 expression was scored by immunohistochemistry in TC and IC. We used the Ion AmpliSeq Comprehensive Cancer Panel to identify mutation in all exons in 409 cancer-related genes. **Results:** The overall prevalence of PD-L1 expression on TC was 15.1 % (29/192). No significant difference was observed between LCNEC and SCLC (16.7% vs. 14.2%, p = 0.365). Tumor-infiltrating IC and PD-L1 positive immune cells (IC) were observed in 34.4% (66/192) and 31.3% (60/192), respectively. The prevalence of tumor-infiltrating IC and PD-L1 expression on IC were significantly higher in LCNEC compared to SCLC (57.6% vs. 23.3%, p $<$ .001; 45.8% vs. 22.5%, p = .001, respectively). Tumor-infiltrating IC and PD-L1 expression on IC were correlated with higher nonsynonymous mutational load (p = 0.048 and 0.038, respectively). Tumor-infiltrating immune cells (median 11.3 vs. 6.8 months, p = 0.005), and its correlated PD-L1 expression on IC (median 11.3 vs. 7.0 months, p = 0.024) were related with better progression free survival. There was no relevance between biomarker status and overall survival. **Conclusions:** These findings suggest that the PD-1/PD-L1 pathway is activated in a fraction of HGNEC of lung with correlating higher mutational burden. Further studies are needed to determine the PD-L1 expression and correlated clinical features to refine role of anti-PD1 treatments in these patient population.

8565 Poster Session (Board #301), Sat, 8:00 AM-11:30 AM

Survival outcomes in extensive stage small cell lung cancer patients treated with thoracic radiation. *First Author: Kristin Ann Higgins, Department of Radiation Oncology, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: The benefit of consolidation thoracic radiation in extensive stage small cell lung cancer (E-SCLC) remains unclear. This study utilized the National Cancer Database (NCDB) to evaluate overall survival outcome (OS) for patients receiving chemotherapy (CT) alone for E-SCLC versus CT + thoracic radiation (TRT). **Methods:** The NCDB was queried to capture patients (pts) with stage E-SCLC from 2010-2013. Patients with brain metastases at diagnosis were excluded, as were patients receiving radiation prior to initiation of chemotherapy. Univariate association of OS was assessed using Cox proportional hazards models and log-rank tests. A multivariable Cox proportional hazard model and Kaplan-Meier analyses were performed to compare treatment with CT only to CT + TRT. Propensity score matching method was also implemented to reduce treatment selection bias. All analyses were performed using SAS Version 9.4. **Results:** A total of 14,367 (12,019 received CT, 2,348 received CT + TRT) pts were included in the analysis. Patient characteristics included a median age of 66 years; 66 years for pts receiving CT, and 63 for pts receiving CT + TRT ($p < 0.001$). Male gender comprised 51% of pts; 52% in CT group versus 49% in CT + TRT ($p < 0.001$). Charlson-Deyo comorbidity score was zero in 53% of all patients; 52% in the CT group versus 57% of CT + TRT group ($p < 0.001$). In the CT + TRT group, the median total thoracic radiation dose was 45 Gy. On multivariate analysis, CT only was associated with an increased risk of death relative to CT+ TRT (HR 1.74 [1.65 – 1.84], $p < 0.001$). 5 year OS was 7% vs. 2% for CT + TRT versus CT alone ($p < 0.001$). On propensity matched analysis, CT + TRT was associated with better 5-year OS compared to CT alone (8% vs. 2%; $p < 0.001$). On multivariate analysis of propensity matched samples, chemotherapy alone continued to be associated with worse survival (HR 1.76 [1.62 – 1.91], $p < 0.001$). **Conclusions:** For E-SCLC, CT alone as standard of care is associated with worse survival relative to CT + TRT.

8566 Poster Session (Board #302), Sat, 8:00 AM-11:30 AM

Comparing treatment strategies for stage I small cell lung cancer: A National Cancer Database study. *First Author: Peter Alexander Paximadis, Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit, MI*

Background: Concurrent chemoradiotherapy is the standard of care for limited stage small cell lung cancer (SCLC). The ideal treatment strategy for stage I SCLC, however, is less clear. The purpose of this study is to compare outcomes for patients receiving definitive surgery, stereotactic body radiation therapy (SBRT), or external beam radiation therapy (EBRT) for stage I SCLC using the National Cancer DataBase (NCDB). **Methods:** Patients with a first primary diagnosis of stage I (T1-2 N0 M0) SCLC treated between 2004 and 2013 were identified in the NCDB. Patients were defined as having a first course of treatment of either definitive surgery, EBRT (45-74 Gy in 15-40 fractions) or SBRT (40-60 Gy in $\leq$5 fractions). Other recorded information included age, gender, race, T stage, Charlson-Deyo score, and use of chemotherapy. Overall survival (OS) was determined using the Kaplan-Meier method and Cox proportional hazards regression methods were used to estimate risk of overall mortality. **Results:** A total of 5944 patients with stage I SCLC were identified; of those, 2681 fit the study criteria. The median age of patients in the cohort was 68 years and median follow up was 26.6 months. Definitive surgery was performed in 944 (35%), EBRT in 1597 (60%), SBRT in 140 (5%), and chemotherapy was delivered in 2067 (77%). The 2- and 3-yr OS for the whole cohort was 62% and 50%; 72% and 62% for surgery, 56% and 44% for EBRT, and 56% and 40% for SBRT. Patient age, female gender, Charlson-Deyo score < 2, tumor size $\leq$3 cm, receipt of surgery and receipt of chemotherapy were all associated with improved OS. Comparing treatment strategies in a multivariate model, surgical resection demonstrated improved OS over EBRT (HR 2.0, $p < 0.001$) and SBRT (HR 1.66, $p < 0.001$). When excluding patients who underwent surgery, SBRT demonstrated improved OS compared with EBRT (HR 1.28, $p = 0.04$). In addition, receipt of chemotherapy resulted in improved OS (HR 0.66, $p < 0.001$). **Conclusions:** In this hospital-based registry study, definitive surgical resection and use of chemotherapy resulted in improved survival outcomes for patients with stage I SCLC. For patients who are not candidates for surgery, SBRT may offer a survival benefit compared with standard EBRT.

8567 Poster Session (Board #303), Sat, 8:00 AM-11:30 AM

Using circulating tumor DNA analysis to depict genomic profiles and predict survival outcomes in patients with small-cell lung cancer. *First Author: Jinghui Wang, Department of Medical Oncology, Beijing Chest Hospital, Capital Medicine University, Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China*

Background: Small-cell lung cancer (SCLC) accounts for approximately 15% of lung cancers. Most patients have extensive-stage disease with widespread metastases and poor survival. Understanding the molecular mutation profile of each SCLC patient would allow precision treatment and improved clinical outcome. However, tumor tissues from surgery are not available for most SCLC patients and biopsy specimens are often have limited quantities. Several studies have provided evidence of circulating tumor DNA (ctDNA) in detecting somatic variants of multiple solid tumors. This study evaluated utility of ctDNA to depict genomic profiles and predict survival outcomes in SCLC patients. **Methods:** 22 Plasma samples were obtained before initial treatment from 22 patients with SCLC enrolled between 2012 and 2016. Targeted-capture deep sequencing was performed to identify somatic variants in 465 cancer-related genes. Genomic mutation profiles were described and the clinical implications were further analyzed. **Results:** Tumor DNA can be detected in all 22 plasma samples collected from patients with SCLC. In total, 340 variants were identified, and the mean and median mutation rate were 6.3 and 6.6 per Mb. *TP53* and *RB1* are the most frequently mutated genes, detected in 90.9% (20/22) and 59.1% (13/22) patients, respectively. Further analysis showed that high ctDNA fraction in cell-free DNA (cfDNA) was associated with heavy tumor burden ($R = 0.7$, $p = 0.0017$). Moreover, patients with high ctDNA fractions (ctDNA fraction $>=$ 18.3%) had poor progression free survival (PFS) (HR, 17.2; $p = 0.0019$). The median PFS of patients with high versus low ctDNA fractions was 5.2 months (95% CI 4.6 to 5.8 months) versus 10.0 months (95% CI 9.3 to 10.7 months), respectively. **Conclusions:** In this study, ctDNA analysis offers a promising way to depict the molecular profile in patients with SCLC. Moreover, these findings highlight the potential clinical utility of ctDNA to predicate clinical outcome in SCLC.

8568 Poster Session (Board #304), Sat, 8:00 AM-11:30 AM

Trilaciclib (G1T28): A cyclin dependent kinase 4/6 inhibitor, in combination with etoposide and carboplatin (EP) for extensive stage small cell lung cancer (ES-SCLC)—Phase 1b results. *First Author: Caio Max S. Rocha Lima, Gibbs Cancer Center and Research Institute, Spartanburg, SC*

Background: Chemotherapy (chemo) has significant clinical utility, however consequent damage to hematopoietic stem and progenitor cells (HSPCs) and the immune system may limit activity. If chemo-mediated anti-tumor activity was maximized, while minimizing myelosuppression and immunosuppression, patient outcomes would be improved. Trilaciclib (T) is an intravenous CDK4/6 inhibitor in development to reduce myelosuppression and preserve immune system function during chemo. HSPCs are dependent on CDK4/6 for proliferation. Preclinical data demonstrated that transient T-induced G1 cell cycle arrest renders HSPCs resistant to chemo cytotoxicity, allowing faster hematopoietic recovery, preservation of long-term function, and enhancement of anti-tumor immunity and activity. **Methods:** Objectives of this ongoing multicenter Phase 1b/2a study are to assess dose limiting toxicities (DLTs), safety, tolerability, hematological profile, PK, and anti-tumor activity of T administered prior to EP. Phase 1b was open-label, dose-finding, and the ongoing Phase 2a is randomized (1:1), double-blind. Eligible pts had confirmed diagnosis of ES-SCLC, adequate organ function, ECOG PS 0-2, no prior chemo, and no symptomatic brain metastases. **Results:** 19 pts were enrolled in the Phase 1b: 10 pts received T 200 mg/m^2 + EP and 9 pts received T 240 mg/m^2 + EP. T + EP was well tolerated. 2 pts at T 200 mg/m^2 and 1 pt at T 240 mg/m^2 experienced asymptomatic DLTs in cycle 1. 2 pts (1 at each dose) had an ANC < 1500 on cycle 2 day 1, delaying the start of cycle 2, and 1 pt at the T 200 mg/m^{2}dose had grade 4 thrombocytopenia. There were no cases of febrile neutropenia or bleeding. PK analysis showed no drug interactions between T and EP. 17/19 pts were evaluable: 1 pt had CR, 14 had PR (confirmed ORR = 88%); 1 pt had SD (clinical benefit rate = 94%). **Conclusions:** In the Phase 1b part of the study, T + EP was well tolerated. Early activity results are promising with a confirmed objective response rate of 88%. This novel approach allowing the administration of chemotherapy while preserving HSPC and immune system function could potentially improve treatment outcomes for SCLC pts. Clinical trial information: NCT02499770.

8569 Poster Session (Board #305), Sat, 8:00 AM-11:30 AM

Small cell lung cancer: The immune microenvironment and prognostic impact of checkpoint expression. *First Author: Gareth Rivalland, Olivia Newton-John Cancer Wellness and Research Centre, Melbourne, Australia*

Background: To date, immunotherapy has had limited success in small cell lung cancer (SCLC), despite the tumor's high mutation load. Little is understood of the immune tumor microenvironment in SCLC due to a paucity of resected tumor. We present a SCLC cohort and describe the prognostic impact of checkpoint expression. **Methods:** SCLC tissue microarrays with triplicate cores from 105 SCLC specimens underwent IHC assessment for PD-L1, PD-L2, LAG3, TIM3, FoxP3, CD4 and CD8 on tumor and/or tumor infiltrating lymphocytes (TILs). Checkpoint positivity was defined $>$ 5% tumor expression or TIL expression in $>$ 5% of the total core area. Associations with clinicopathologic characteristics and survival were assessed. A Cox model was used for univariate and multivariate survival analysis. **Results:** Tumor expression of PD-L1 was positive (+) in 17/95 (18%), PD-L2+ in 2/96 (2%), and TIM3+ or LAG3+ in no cases. TILs expressed PD-L1+ in 64/95 (67%), PD-L2+ in 22/96 (22%), TIM3+ in 57/96 (59%) and LAG3+ in 43/96 (45%). FoxP3+ lymphocytes were found in all samples (range 0.02 – 2.98% of total core). TIL expression of PD-L1, PD-L2, TIM3 and LAG3 were all significantly correlated (p value $\leq$0.001 for all comparisons), and were associated with high FoxP3+ expression. All four checkpoints were expressed on TILs in 20/105 (19%) patients. PD-L1+ and PD-L2+, but not TIM3 or LAG3, on TILs were significantly higher in limited stage compared with extensive stage SCLC (76% v 52%, p 0.045 and 28% v 7%, p 0.02 respectively). There was no association between stage and tumor expression. TIL expression of PD-L1, PD-L2, TIM3 and LAG3 were all associated with improved prognosis. PD-L1+ median OS: 17.2 v 7.9 months (HR 0.36; 95%CI 0.22 – 0.6; p $<$ 0.001). Univariate analysis showed stage and TIL expression of PD-L1, PD-L2, TIM3 and LAG3 were associated with improved survival, but only stage and PD-L1+ TILs remained significant on multivariate analysis (p $<$ 0.01). **Conclusions:** Immune checkpoint molecules are frequently expressed in SCLC-associated TILs, but not the tumor itself. TIL expression of checkpoint molecules is associated with improved survival. Limited tumor expression of PD-L1 and an exhausted immune cell phenotype may contribute to immunotherapy failure.

8570 Poster Session (Board #306), Sat, 8:00 AM-11:30 AM

Histology determination of lung cancers: A report on genomic profiling of lung cancer of mixing histology. *First Author: Ming Tang, MD Anderson Cancer Center, Houston, TX*

Background: Histopathology, largely determined by morphology, plays a critical role in choosing appropriate treatment for lung cancer. The understanding of molecular determination of lung cancer histology is rudimentary. Our recently published data (Zhang, Science, 2014 and Liu, Nature Communications, 2016) have demonstrated that within the same patients with identical genetic background and identical exposure, tumor regions with different morphologic appearances may have very similar genomic profiles while tumors with the same morphology may have distinct genomic landscape. **Methods:** We collected 12 lung cancers of mixing histology with 2 to 4 histologic components within each tumor. In total, 26 tumor regions including 9 adenocarcinomas, 6 large-cell neuroendocrine carcinoma, 6 small cell carcinomas and 4 squamous cell carcinomas and one poorly differentiated lung carcinoma were microdissected and subjected to whole exome sequencing. **Results:** A substantial number of identical mutations were shared between different histologic components within the same tumor in all 12 patients. However, the proportion of shared mutations varies in different patients ranging from as little as 4% to as much as 99%. Mutation spectrum is also similar between different histologic components within the same tumors suggesting similar mutational process in place. Identical canonical cancer gene mutations including TP53, KRAS, PIK3CA, SOS1 and STK11 are generally shared between different histologic components within the same tumors. Canonical mutations in FBXW7 and MTHFR were detected in squamous component, but not small-cell component in one patient. **Conclusions:** Different histologic components of lung cancers of mixing histology are likely derived from the same progenitor cells, but the molecular timing of branch separation of subclones giving rise to different histologic components varies in different tumors. Although genomic aberrations may play a role in a subset of tumors, histologic features may not be determined at genomic level for most lung cancers. Gene expression and methylation analyses from these tumors are underway.

8571 Poster Session (Board #307), Sat, 8:00 AM-11:30 AM

Longitudinal monitoring of circulating tumor DNA and peripheral T cell repertoire in patients with small cell lung cancer. *First Author: Wade Thomas Iams, Northwestern University, Chicago, IL*

Background: Advances in the treatment of small cell lung cancer (SCLC), an aggressive disease with poor prognosis, will require the development of diagnostic methods during treatment that are more sensitive and descriptive than are currently available. The emergence of "liquid biopsy" technologies coupled with comprehensive genomic information about common mutations in SCLC prompted us to implement a blood-based assay for simultaneous sequencing of circulating, cell-free tumor DNA (cfDNA) and determination of the peripheral a and b T cell receptor repertoire in patients with SCLC. **Methods:** Our SCLC assay uses targeted hybrid capture and next generation sequencing of cfDNA extracted from patient plasma to detect somatic mutations in 14 frequently mutated genes in SCLC. We also sequenced rearranged T cell receptor α and β genes, each with 5000 unique α and β CDR3 open reading frames per microgram of gDNA. Over 26 months we followed 27 patients with SCLC (16 with extensive stage and 11 with limited stage disease) and examined cfDNA from 141 plasma samples and T cell repertoire from 41 samples. **Results:** We detected somatic, disease-associated mutations in 85% of patient samples (23/27) with allele frequencies of cfDNA ranging from $\leq$0.5% to $\geq$85%. The most commonly mutated genes were *TP53* (17/27 patients) and *RB1* (10/27 patients). We detected 87 unique genomic alterations in 12 different genes (in addition to *TP53* and *RB1* these included *PTEN*, *NOTCH1-4*, *MYC*, *MYCL1*, *PIK3CA*, *KIT*, and *BRAF*). The observed mutant allele frequencies in longitudinal samples tracked with treatment response, including cases in which cfDNA allele frequencies increased before clinical evidence of relapse. Longitudinal monitoring of T cell repertoire demonstrated both variability between patients and sequential changes during therapy, including one case of decreased T cell numbers accompanying disease relapse. **Conclusions:** As the field of immuno-oncology matures, we anticipate that coupled determination of T cell repertoire together with cfDNA monitoring will merge into a clinically useful "molecular image" of each patient's disease status and real-time host immune response.

8572 Poster Session (Board #308), Sat, 8:00 AM-11:30 AM

Postoperative radiation for tumor control and overall survival in thymic epithelial tumors (TET): A matched-pair analysis. *First Author: Feng Ming Kong, Indiana University Department of Radiation Oncology, Indianapolis, IN*

Background: Due to lack of randomized trials, the role of postoperative radiation therapy (PORT) in thymic epithelial tumors (TET) remains controversial. This study aimed to evaluate whether PORT improves tumor control and overall survival (OS) in patients with resected TET in a large single institution database. **Methods:** This is a retrospective study of all TETs seen at Indiana University between 1975 and 2016. Patients with resected thymoma (T) or thymic carcinoma (TC) were eligible disregarding their margin status or stage. Study endpoints were progression free survival (PFS) and OS. Age, gender, race, tumor size, stage, pathology, grade, completeness of resection and adjuvant treatment modality were analyzed for significance on PFS and OS. Multivariate Cox model was used to identify significant factors for propensity score matching. Differences between the PORT and surgery alone group were estimated using stratified log-rank test. **Results:** A total of 478 patients with previous surgical resection were eligible. Masaoka Stage was: I-86 (22%); II-87 (23%); III-107 (28%); and IV-106 (27%), respectively. Multivariate analysis demonstrated that gender (HR = 1.4, p = 0.03), stage (HR = 1.3, p = 3×10^{-3}), TC (HR = 1.6, p = 0.03) and PORT (HR = 1.6, p = 0.002) were significantly associated with PFS. Age (HR = 1.1, p = 4×10^{-7}), TC (HR = 3.2, p = 3×10^{-5}), stage (HR = 1.4, p = 0.003) were associated with OS. PORT was given to 126 (26%) patients. Propensity score matching based on independent prognostic factors identified 99 patients for PORT, matched to 285 patients without. The 5-/10-year intra-thoracic progression free rates were 77%/69% and 85%/68%, for patients with and without PORT (p = 0.009), respectively. The 5-/10-year PFS rates were 39%/18% and 61%/32%, for patients with and without PORT (p = 0.002), respectively. The median survival, 5-/10-year OS rates for patients treated with PORT were 150 (95%CI 111~277) months, 87%/57% and respectively, compared to 192 months (95%CI 167~279), 88%/69% for patients receiving surgery alone (p = 0.13). **Conclusions:** This matched-paired analysis from a single institution suggests that PORT does not impact the PFS or OS in a selected population of resected TET.

8573 Poster Session (Board #309), Sat, 8:00 AM-11:30 AM

Pembrolizumab in patients with recurrent thymic carcinoma: Results of a phase II study. *First Author: Giuseppe Giaccone, Georgetown University, Washington, DC*

Background: There are few treatment options for thymic carcinoma after chemotherapy. We completed a single institution phase II study of pembrolizumab (P) in patients with recurrent thymic carcinomas. **Methods:** Main eligibility criteria included: progression after ≥ 1 chemotherapy line, ECOG PS 0-2, no history of autoimmune disease, and adequate organ function. P was given at 200mg IV every 3 weeks. The primary objective of the study was response rate (RR) by RECIST v1.1 criteria; secondary objectives were PFS and OS, and safety. **Results:** From 3/2015 to 12/2016 we accrued 41 patients. Of 40 eligible patients, 29 were male, 19 Caucasians, median age was 57 years (range 25-80), 14 had squamous carcinoma histology, and 19 ECOG PS 0. Median number of cycles delivered was 6 (range 1-31). The most common side effects were mild fatigue (10), diarrhea (4) and rhinorrhea (4). Six patients developed multiple grade 3-4 immune-relates AEs (irAEs): myocarditis/myositis (1), myositis/myocarditis/hepatitis/myasthenia gravis (1), myositis/hepatitis (1), bullous pemphigoid (1), hepatitis (1), hepatitis/pancreatitis/diabetes mellitus type 1 (1). There were no treatment related deaths. The 2 patients who developed myocarditis required a pacemaker. Three patients interrupted treatment because of irAEs (all responders) and 3 because of progression around the time of the irAE. irAEs were more frequent in females (4/6; p = .026). Five patients developed hypothyroidism and 1 hyperthyroidism. RR assessed in all 40 eligible patients was 22.5%: 1 complete response, 8 partial responses (plus 1 unconfirmed), 20 stable disease and with 11 progressions. Two partial responses show minimal residual disease with no PET uptake. Two responders have progressed and 5 responses are beyond 12 months duration. Of 29 cases tested for PD-L1 staining (Dako 22C3), high PD-L1 (≥50% tumor cells positive) was seen in 8 (28%); 6/9 responders had high PD-L1 expression. Targeted NGS in 15 cases did not show correlation between mutational burden and response. **Conclusions:** P has activity in patients with thymic carcinoma. irAEs are more frequent than in other tumors. Further analysis of NGS, Nanostring and PD-L1 expression and updated survival will be presented. Clinical trial information: NCT02364076.

8574 Poster Session (Board #310), Sat, 8:00 AM-11:30 AM

Paraneoplastic syndrome and survival in thymic epithelial tumors (TET): The Indiana University experience. *First Author: Weili Wang, Department of Radiation Oncology, Simon Cancer Center, Indiana University School of Medicine, Indianapolis, IN*

Background: Paraneoplastic syndromes (PNS) are commonly associated with thymic epithelial tumors (TET), especially thymoma. The purpose of this analysis is to examine the clinical impact of PNS in TET. **Methods:** Patients with pathologically diagnosed TET at a single institution were reviewed retrospectively. The primary and second endpoints for this study were overall survival (OS) and recurrence rates. Clinical factors included age, gender, race, performance score, histology, WHO classification, Masaoka stage, post-operative status, tumor size and number of positive lymph nodes. Cox proportional hazards model was used to identify significant prognostic factors for OS between different PNS groups. **Results:** From 1975 to 2016, 733 patients with TET (thymoma (T) -71%, thymic carcinoma (TC) -26% and neuroendocrine tumor (NET)-3%) were seen at Indiana University. Of these, 203 (28%) had PNS including myasthenia gravis (n = 130), red cell aplasia (n = 20), hypogammaglobulinemia (n = 14), systemic lupus erythematosus (n = 12) or other PNS (n = 64). Among these, 37 (18%) had two or more types of PNS. PNS were seen in 35% (183/523) of T, 9% (16/187) of TC and 15% (3/20) of NET ($p < 0.001$), respectively. Recurrence rates and mortality at 5 year were 8% and 10% in PNS (+) group compared to 13% and 16% in PNS (-) group ($p < 0.05$). Intrathoracic recurrences were more common in PNS (+) patients (89% vs 77%; $p = 0.016$). In both groups, adverse factors for survival included: older age, advanced stage, number of positive lymph nodes and TC histology (all *p-values* < 0.05). However, post-operative R1/2 status was adverse prognostic factor only in the PNS (-) group ($p = 0.001$). **Conclusions:** PNS is common in TETs. Patients with PNS have lower risk of recurrence and mortality compared to patients without PNS, but may have a higher risk of intrathoracic recurrence.

TPS8575 Poster Session (Board #311a), Sat, 8:00 AM-11:30 AM

EA5142 adjuvant nivolumab in resected lung cancers (ANVIL): The newest study in the ALCHEMIST platform. *First Author: Jamie E. Chaft, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There have been no advances in the systemic treatment of resected lung cancers in the last decade. This is in contrast to advanced disease where molecularly targeted therapies for patients with oncogene-driven tumors have replaced and/or delayed chemotherapy and where immunotherapy drugs that target the programmed death receptor pathway (PD-1 or PD-L1) are now utilized in first and second line. The Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trial (ALCHEMIST) is a National Cancer Institute (NCI) sponsored National Clinical Trials Network (NCTN) initiative to address the role of genomic testing and personalized therapies in the adjuvant treatment of non-small cell lung cancers. EA5142 is the newest of the ALCHEMIST studies, investigating adjuvant nivolumab in patients not eligible for the EGFR or ALK directed trials. **Methods:** ALCHEMIST is a clinical trial platform that consists of integrated protocols: ALCHEMIST Screening (A151216; NCT02194738), ALCHEMIST-EGFR (A081105; NCT02193282), ALCHEMIST-ALK (E4512; NCT02201992), and ALCHEMIST-nivo (EA5142; NCT02595944). In ALCHEMIST-Screening, up to 8,000 patients with pathologically confirmed stage IB (≥ 4 cm)-IIIA NSCLC will be enrolled either before or after surgical resection. Tumors that are non-squamous histology will be centrally genotyped for *EGFR* mutations and *ALK* rearrangements. Patients with *EGFR* or *ALK*-positive tumors are offered enrollment in trials evaluating adjuvant erlotinib or crizotinib, respectively. In the ~80% of patients enrolled with tumors that have wildtype *EGFR* and *ALK* or those with squamous histology central testing will be performed for PD-L1 utilizing immunohistochemistry (DAKO 28-8). Adjuvant therapy is allowed but not required. Patients are randomized to nivolumab 240 mg IV over 3 minutes every 2 weeks for up to 1 year versus standard of care observation, stratified by stage, histology, prior adjuvant treatment, and PD-L1 status (> / = 1% or < 1%). ANVIL has enrolled 52 of 714 planned patients to detect co-primary endpoints of a 30% improvement in overall survival and/or a 33% reduction in disease free survival favoring nivolumab. EA5142 is currently open at over 400 centers nationwide. Clinical trial information: NCT02595944.

TPS8576 Poster Session (Board #311b), Sat, 8:00 AM-11:30 AM

A phase III trial to compare atezolizumab (atezo) vs best supportive care (BSC) following adjuvant chemotherapy in patients (pts) with completely resected NSCLC: IMpower010. *First Author: Heather A. Wakelee, Stanford University School of Medicine, Stanford, CA*

Background: The anti–PD-L1 mAb atezo blocks the interaction between PD-L1 and its receptors PD-1 and B7.1 and restores anti-tumor immunity. In the OAK trial, pts with 2L/3L advanced NSCLC had improved mOS in the atezo arm (13.8 mo) vs the docetaxel (doc) arm (9.6 mo), with a survival benefit observed regardless of PD-L1 expression levels on tumor cells (TC) or tumor-infiltrating immune cells (IC). However, more effective treatment options are needed for pts with early-stage NSCLC. A global Phase III, randomized, open-label trial, IMpower010 (NCT02486718), is being conducted to evaluate the efficacy and safety of atezo vs BSC following adjuvant cisplatin (cis)–based chemotherapy (chemo) in pts with resected stage IB (tumors ≥ 4 cm)-IIIA NSCLC. **Methods:** Pts eligible for study must have complete tumor resection 4 to 12 weeks prior to enrollment for pathologic stage IB (tumors ≥ 4 cm)-IIIA NSCLC, be adequately recovered from surgery, be able to receive cis-based adjuvant chemo and have an ECOG PS 0-1. Pts with other malignancies, autoimmune disease, hormonal cancer or radiation therapy within 5 years and prior chemo or immunotherapy are excluded from study. Approximately 1127 pts will be enrolled regardless of PD-L1 status. Pts will receive up to four 21-d cycles of cis-based chemo (cis [75 mg/m^2 IV, d 1] + vinorelbine [30 mg/m^2 IV, d 1, 8], doc [75 mg/m^2 IV, d 1] or gemcitabine [1250 mg/m^2 IV, d 1, 8], or pemetrexed [500 mg/m^2 IV, d 1; only non-squamous NSCLC]). No adjuvant radiation therapy is permitted. After adjuvant chemo, eligible pts will be randomized 1:1 to receive 16 cycles of atezo 1200 mg q3w or BSC. Stratification factors include sex, histology (squamous vs non-squamous), disease stage (IB vs II vs IIA) and PD-L1 status by IHC (TC2/3 [≥ 5% expressing PD-L1] and any IC vs TC0/1 [< 5%] and IC2/3 vs TC0/1 and IC0/1 [< 5%]). The primary endpoint is disease-free survival; secondary endpoints include OS and safety. Exploratory biomarkers, including PD-L1 expression, immune- and tumor-related biomarkers before, during and after treatment with atezo and at radiographic disease recurrence, or confirmation of new primary NSCLC, will be evaluated. Clinical trial information: NCT02486718.

TPS8577 Poster Session (Board #312a), Sat, 8:00 AM-11:30 AM

Checkmate 816: A phase 3, randomized, open-label trial of nivolumab plus ipilimumab vs platinum-doublet chemotherapy as neoadjuvant treatment for early-stage NSCLC. *First Author: Patrick M. Forde, Johns Hopkins Kimmel Cancer Center and Bloomberg-Kimmel Institute for Cancer Immunotherapy, Baltimore, MD*

Background: At initial diagnosis, 20% of patients (pts) with NSCLC present with early-stage disease. The 5-year overall survival (OS) rate after surgery for stage IB–IIIA NSCLC is 25%–60%. Addition of adjuvant chemotherapy to surgery only provides a 5% absolute OS benefit at 5 years. Neoadjuvant treatment with immune checkpoint inhibitors may extend OS in early-stage NSCLC by enhancing systemic immunity and eradicating micrometastatic disease. In contrast to the adjuvant setting, the neoadjuvant setting is associated with a higher tumor burden, the presence of abundant tumor antigens, and the consequent potential for tumor-associated neoantigen presentation to the immune system. In an ongoing feasibility trial in pts with stage IB–IIIA NSCLC, nivolumab (nivo; a fully human PD-1 immune checkpoint inhibitor antibody) given alone as neoadjuvant treatment induced a major pathological response (MPR; $<$ 10% residual viable tumor cells) rate of 39% (7/18), did not delay or interfere with surgery, and was not associated with new safety signals. In a phase 1 study in pts with stage IIIB/IV NSCLC, first-line nivo + ipilimumab (ipi; a CTLA-4 immune checkpoint inhibitor antibody) showed a greater radiologic objective response rate than nivo alone (39% vs 23%). These data provided the rationale for Checkmate 816 (NCT02998528), a phase 3 study evaluating nivo + ipi vs platinum-doublet chemotherapy as neoadjuvant treatment for early-stage NSCLC. **Methods:** Approximately 326 pts aged $\geq$18 years with resectable stage IB/II/IIIA NSCLC, ECOG performance status 0–1, pulmonary function capable of tolerating lung resection, and available lung tumor tissue will be enrolled in North America, South America, Europe, and Asia. Pts are ineligible if they have autoimmune disease or had received prior treatment with immune checkpoint inhibitors. Pts will be randomized to receive nivo + ipi or platinum-doublet chemotherapy. The primary endpoint is MPR rate. Secondary endpoints include event-free survival, OS, and complete pathological response. Start date is January 2017. The estimated primary completion date is July 2019. Clinical trial information: NCT02998528.

TPS8578 Poster Session (Board #312b), Sat, 8:00 AM-11:30 AM

eXalt3: A phase III study of ensartinib (X-396) in anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer (NSCLC). *First Author: Leora Horn, Vanderbilt University Medical Center, Nashville, TN*

Background: Ensartinib is a novel, potent anaplastic lymphoma kinase (ALK) small molecule tyrosine kinase inhibitor (TKI) with additional activity against MET, ABL, Axl, EPHA2, LTK, ROS1 and SLK. Ensartinib has demonstrated activity in ALK treatment naïve and previously treated patients and has a generally well tolerated safety profile. **Methods:** eXalt3 (NCT02767804) is a global, randomized, open-label phase III study comparing the efficacy and safety of ensartinib to crizotinib in ALK- positive TKI naïve non-small cell lung cancer (NSCLC) patients. It is being conducted in $>$ 100 sites in North America, South America, Europe, and the Asia/Pacific region. Enrollment began in 2016. The primary efficacy endpoint is progression free survival (PFS) assessed by independent radiology review. Secondary efficacy endpoints include overall survival, response rates (overall and central nervous system [CNS]), PFS by investigator assessment, time to response, duration of response, and time to CNS progression. Approximately 270 patients with ALK+ NSCLC who have received no prior ALK TKI and up to one prior chemotherapy regimen will be randomized 1:1 to ensartinib 225 mg QD, or crizotinib 250 mg BID, with stratification based on prior chemotherapy, ECOG performance status (PS), CNS metastases and geographic region. Eligibility includes patients $\geq$ 18 years of age, stage IIIB or IV ALK+ NSCLC. Patients are required to have measurable disease per RECIST 1.1, adequate organ function, and an ECOG PS of $\leq$2. Adequate tumor tissue (archival or fresh biopsy) must be available for central testing. The study has $>$ 80% power to detect a superior effect of ensartinib over crizotinib in PFS at a 2-sided alpha level of 0.05. Clinical trial information: NCT02767804.

TPS8579 Poster Session (Board #313a), Sat, 8:00 AM-11:30 AM

Randomized phase III trial of concurrent chemoradiation followed by nivolumab or placebo for locally advanced non-small cell lung cancer (NSCLC) (RTOG 3505). *First Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Despite aggressive therapy with concurrent chemoradiation, fewer than 25% of patients with stage 3 NSCLC achieve 5-year survival and are presumably cured. To date, treatment modifications—including consolidation chemotherapy, maintenance therapy with molecularly targeted agents, concomitant administration of monoclonal antibodies, and escalation of radiation therapy (RT) dose—have not improved these outcomes. Immune checkpoint inhibitors represent an effective treatment for advanced NSCLC and may enhance RT-associated anti-tumor immunity. RTOG 3505 will test whether the addition of the anti-programmed death 1 (PD1) antibody nivolumab after chemoradiation improves overall survival (OS) and progression-free survival (PFS) in this population. **Methods:** Key eligibility criteria include surgically unresectable stage 3 NSCLC, ECOG 0-1, adequate organ function, available archival tissue, and absence of active autoimmune disease. Patients will receive thoracic RT to 60 Gy with concurrent cisplatin 50 mg/m^2 IV on Days 1, 8, 29, and 36, and etoposide 50 mg/m^2 IV on Days 1-5 and 29-33. This regimen was selected to (1) minimize risk of pulmonary toxicity and steroid requirements, and (2) optimize timing of immunotherapy. Between 4 and 12 weeks after completion of chemoradiation, eligible patients will be randomized to nivolumab 240 mg IV or placebo every 2 weeks for 1 year. Stratification factors include performance status, histology, and tumor PD-L1 status. Co-primary endpoints are OS and PFS, as determined by central radiology review. Secondary objectives include toxicity assessment, patient-reported outcomes and quality of life, and OS and PFS according to PD-L1 expression. Exploratory objectives include biomarkers to predict treatment efficacy and toxicity. A total of 660 patients will be enrolled to provide $\geq$90% power to detect (1) a hazard ratio (HR) of 0.7 for OS with two-sided type I error of 0.04, and (2) HR of 0.667 for PFS two-sided type I error of 0.01, allowing a 16.7% drop-out rate before randomization. Clinical trial information: NCT02768558.

TPS8580 Poster Session (Board #313b), Sat, 8:00 AM-11:30 AM

A phase II study of atezolizumab as neoadjuvant and adjuvant therapy in patients (pts) with resectable non-small cell lung cancer (NSCLC). *First Author: Dwight Hall Owen, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Trials of neoadjuvant and adjuvant chemotherapy have demonstrated an absolute survival benefit of 5% for patients with early stage disease. Atezolizumab is a humanized IgG1 monoclonal antibody that inhibits PD-L1 from binding to its receptors PD-1 and B7.1, thereby restoring anti-tumor immune response. In the OAK trial, a randomized phase III trial of patients with metastatic NSCLC who progressed on platinum based chemotherapy, atezolizumab improved overall survival in patients regardless of PD-L1 expression compared with docetaxel (13.8 months vs. 9.6 months, HR 0.73 [95% CI 0.62 – 0.87]) with a manageable safety profile. **Methods:** NCT02927301 is a phase II, open-label, single-arm study designed to evaluate the efficacy and safety of atezolizumab as a neoadjuvant and adjuvant therapy in patients with Stage IB, II, or IIIA NSCLC prior to curative-intent resection. Approximately 180 patients with NSCLC will be enrolled in this study at 15 academic medical centers in the United States. The study has two parts: the primary part will evaluate the ability of neoadjuvant atezolizumab to produce pathologic responses in patients with early stage NSCLC. Atezolizumab 1200 mg IV will be given every 3 weeks for two doses. Surgical resection of tumors following treatment will allow determination of pathologic response rates and potential predictive biomarkers. Part 2 is exploratory and will evaluate atezolizumab adjuvant therapy for up to 12 months in patients who demonstrate clinical benefit in Part 1. The primary endpoint is major pathologic response rate (defined as $\leq$ 10% of viable tumor tissue) based on surgical resection. Secondary end points include overall response rate by status of mutation load, neoantigen score and gene expression signatures. OS and DFS are exploratory end points. This trial presents a unique opportunity to evaluate exploratory biomarkers given the availability of pre- and post-treatment biopsy specimens for assessment of evolution of immune related markers associated with response. The study opened to accrual in January 2017. Clinical trial information: NCT02927301.

TPS8581 **Poster Session (Board #314a), Sat, 8:00 AM-11:30 AM**

Checkmate 743: A phase 3, randomized, open-label trial of nivolumab (nivo) plus ipilimumab (ipi) vs pemetrexed plus cisplatin or carboplatin as first-line therapy in unresectable pleural mesothelioma. *First Author: Gerard Zalcman, GH Bichat Claude Bernard, Paris, France*

Background: Malignant pleural mesothelioma (MPM) is an aggressive cancer with a 5-year overall survival (OS) rate of $< 10\%$. At diagnosis, most patients (pts) have unresectable disease. Combination chemotherapy of cisplatin (or carboplatin as an alternative) + pemetrexed is the approved first-line standard of care. Phase 1 and 2 data suggest that targeting immune checkpoint pathways (eg, programmed death [PD]-1/PD-ligand 1 [PD-L1] and/or cytotoxic T-lymphocyte antigen-4 [CTLA-4]) may provide benefit with acceptable safety in MPM. In pts with previously treated, malignant mesothelioma, single-agent tremelimumab (a CTLA-4 inhibitor antibody) was active but did not improve OS vs placebo. In a phase 2 study of nivo (a fully human PD-1 immune checkpoint inhibitor antibody) in 34 pts with MPM that progressed after first-line platinum-based chemotherapy, 12-week disease control rate (DCR) was 50%, 5 pts had partial response, and 12 pts had stable disease. Given the data with single-agent CTLA-4 and PD-1 inhibitors and that CTLA-4 inhibition can induce PD-L1 expression, there is reason to anticipate synergy when combining CTLA-4 and PD-1 inhibitors in MPM. A phase 2 study assessing nivo alone and nivo + ipi (a CTLA-4 inhibitor antibody) in MPM is ongoing. CheckMate 743 (NCT02899299) is a phase 3 study that will evaluate the efficacy and safety of first-line nivo + ipi vs chemotherapy for MPM. **Methods:** Approximately 600 adult pts with unresectable MPM and ECOG performance status 0–1 will be randomized. Pts are ineligible if they have primary peritoneal, pericardial, or tunica vaginalis testis mesotheliomas; have active, untreated CNS metastases; or had received prior systemic therapy for pleural mesothelioma or a prior PD-1/PD-L1 or CTLA-4 checkpoint inhibitor antibody. Pts are randomized 1:1 to receive nivo + ipi or pemetrexed + cisplatin/carboplatin. Primary endpoints are OS and progression-free survival (PFS), assessed by blinded independent central review. Secondary endpoints are objective response rate (ORR), DCR, and correlation of PD-L1 expression level and efficacy (ORR, PFS, and OS). Clinical trial information: NCT02899299.

TPS8582 **Poster Session (Board #314b), Sat, 8:00 AM-11:30 AM**

ATOMIC-Meso: A randomized phase 2/3 trial of ADI-PEG20 or placebo with pemetrexed and cisplatin in patients with argininosuccinate synthetase 1-deficient non-epithelioid mesothelioma. *First Author: Peter Wojciech Szlosarek, St Bartholomew's Hospital, London, United Kingdom*

Background: Argininosuccinate synthetase 1 (ASS1)-deficient malignant pleural mesothelioma (MPM) is sensitive to arginine deprivation therapy with pegylated arginine deiminase (ADI-PEG20), which also enhances the cytotoxicity of pemetrexed. The TRAP Phase 1 trial (NCT02029690) of ADI-PEG 20 combined with 1st-line pemetrexed (PEM) and cisplatin (CDDP) chemotherapy revealed a 94% disease control rate in non-epithelioid (biphasic and sarcomatoid) MPM subtypes characterized by a 75% rate of ASS1 loss. Thus, we plan to assess the efficacy of ADI-PEG20 or placebo combined with PEM and CDDP in patients (pts) with poor prognosis MPM in a randomized, placebo-controlled, double-blind phase 2/3 global trial. **Methods:** Up to 386 good performance (ECOG 0-1) pts with non-epithelioid malignant pleural mesothelioma will be enrolled in a phase 2/3 adaptive, biomarker-driven study design. Biopsies will be required prior to randomization: ASS1-agnostic pts will be enrolled initially (phase 2 stage) with an option to restrict enrolment to ASS1-deficient MPM (phase 3 stage). Pts will be randomized to receive weekly ADI-PEG20 (36 mg/m2 IM) or placebo with standard doses of PEM and CDDP for a maximum of 18 weeks (6 cycles) of treatment. Pts who develop CDDP toxicity may be switched to carboplatin. Pts will be assessed every 6 weeks using modified RECIST (RECIST 1.1 allowed for pts with significant extra-thoracic disease). The primary endpoint for the phase 2 stage will be overall response rate (ORR) with secondary endpoints of overall survival (OS), safety and toxicity. The phase 2 will test ORR proportions with the placebo triplet set at 15% vs. 35% for the ADI-PEG 20 triplet, with a 1:1 randomization, 80% power. After recruitment of 176 pts, the phase 2 will convert to a phase 3 study with the primary endpoint of OS. In summary, ATOMIC-Meso is the first triplet chemotherapy study to assess the role of targeted arginine deprivation in aggressive subtypes of mesothelioma. Pt accrual has commenced across the US and Asia, with enrolment due in Europe and Australia by 2nd quarter of 2017. [Trial sponsored by Polaris Group]. Clinical trial information: NCT02709512.

TPS8583 **Poster Session (Board #315a), Sat, 8:00 AM-11:30 AM**

A phase III study of rovalpituzumab tesirine maintenance therapy following first-line platinum-based chemotherapy in patients with extensive disease small cell lung cancer (ED SCLC). *First Author: Philip B. Komarnitsky, AbbVie Inc., Cambridge, MA*

Background: SCLC embodies 15-20% of lung cancers. Patients (pts) are staged with either limited or extensive disease; the standard front-line treatment for the latter is chemotherapy with carbo- or cisplatin combined with etoposide or irinotecan. Response rates are high with limited duration. Recurrence may be attributable to chemo-resistant tumor initiating cells (TICs). Delta-like protein 3 (DLL3) is an inhibitory Notch receptor ligand identified as a novel target in SCLC TICs. DLL3 is highly expressed in SCLC but not normal tissue. Rovalpituzumab tesirine (Rova-T) is an antibody-drug conjugate composed of a DLL3-targeting IgG1 monoclonal antibody tethered to a DNA cross-linking toxin. Rova-T has shown activity in recurrent/relapsed ED SCLC patients (Rudin et al., Lancet Oncol, 2016). Given DLL3 expression in TICs, exploration of Rova-T front-line maintenance strategies in ED SCLC is warranted. The postulated mechanism of action of Rova-T and its clinical activity indicate potential to improve progression-free and overall survival in this setting. **Methods:** This is a Phase 3, randomized, double-blind, placebo-controlled, international study (NCT03033511, no pts enrolled yet as of 7 February 2017). Approximately 740 ED SCLC pts will be enrolled to include ~480 pts with high DLL3 expression. Eligibility: pts $\geq$ 18 years; histologically or cytologically confirmed ED SCLC with ongoing clinical benefit (complete/partial response or stable disease) after 4 cycles of 1st line platinum-based therapy; definitively treated CNS metastases allowed; > 3 but ≤ 9 wks between the administration of the last cycle of platinum-based chemotherapy and randomization; available tumor tissue for DLL3 expression testing; ECOG performance score 0-1. Pts will be randomly assigned 1:1 to receive 0.3 mg/kg Rova-T or placebo on Day 1 of each 6-wk cycle, omitting every 3rd cycle. Primary objectives: determine if Rova-T improves progression-free and overall survival. Secondary objectives: assess Rova-T antitumor activity by determining objective response rate, clinical benefit rate, duration of response, and changes in pt reported outcomes. Clinical trial information: NCT03033511.

TPS8584 **Poster Session (Board #315b), Sat, 8:00 AM-11:30 AM**

Phase I/III trial of atezolizumab with carboplatin and etoposide in ES-SCLC in first-line setting (IMpower133). *First Author: Leora Horn, Vanderbilt University Medical Center, Nashville, TN*

Background: The first-line standard of care for the majority of patients (pts) with extensive-stage small-cell lung cancer (ES-SCLC) is platinum-based chemotherapy with etoposide, but survival outcomes remain poor (median OS, < 1 year) despite initial response rates ranging from 50-70%. Atezolizumab (atezo), an anti–PD-L1 mAb, prevents the binding of PD-L1 with its receptors PD-1 and B7.1 and restores anticancer T-cell activity. Tolerable safety with promising durability of response has been shown with atezo in pts with ES-SCLC: confirmed ORR was 6% (n = 1/17 [partial response]; DOR of 7 mo) by RECIST v1.1 and 24% by immune-related response criteria (irRC; n = 4/17, with 2 pts on atezo for $\geq$ 12 mo). Preliminary data also indicate the potential synergy between atezo and platinum-based chemotherapy in NSCLC, whereby durable responses may translate into improved survival over atezo alone. IMpower133 (NCT02763579), a global, Phase I/III, randomized, multicenter, double-blinded, placebo-controlled trial will evaluate the efficacy and safety of 1L atezo + carboplatin + etoposide compared with placebo + carboplatin + etoposide in treatment-naive pts with ES-SCLC. **Methods:** Pts with measurable (RECIST v1.1) ES-SCLC, who have ECOG PS 0-1 and no prior systemic anticancer treatment, are eligible for the study. Exclusion criteria include untreated CNS metastases and history of autoimmune disease. The study requires submission of tumor tissue, but pts will be enrolled regardless of biomarker status. Pts will be stratified by sex, ECOG PS and presence of treated brain metastases. Eligible pts will be randomized 1:1 to receive four 21-day cycles of atezo (1200 mg IV) or placebo in combination with carboplatin (AUC 5 mg/mL/min IV, d 1) and etoposide (100 mg/m^2 IV, d 1-3), followed by maintenance therapy with atezo or placebo until PD per RECIST v1.1. Pts can continue with treatment until persistent radiographic PD, symptomatic deterioration or unacceptable toxicity. Co-primary endpoints are investigator-assessed PFS per RECIST v1.1 and OS. Secondary efficacy endpoints include investigator-assessed ORR and DOR. Safety and tolerability will also be assessed. Approximately 400 pts will be enrolled. Clinical trial information: NCT02763579.

TPS8585 Poster Session (Board #316a), Sat, 8:00 AM-11:30 AM

A phase II, open-label, multi-arm study of novel combinations of immunotherapies or DDR inhibitors in platinum-refractory, extensive disease small-cell lung cancer (ED-SCLC): BALTIC. *First Author: Joachim Von Pawel, Asklepios Fachkliniken München-Gauting, Gauting, Germany*

Background: The prognosis of platinum-refractory ED-SCLC is poor, with ~95% of pts failing to respond to topotecan, the only approved 2ndline treatment. SCLC is associated with a high mutation load and genomic instability, and data suggest that enhanced DNA repair could be a resistance mechanism. As such, immunotherapies and DNA damage repair inhibitors may be beneficial in this disease setting. Durvalumab (D) is a selective, high-affinity, engineered human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80. Tremelimumab (T) is a selective human IgG2 mAb against CTLA-4. In a Phase 1b study in NSCLC (NCT02000947), D + T showed encouraging activity and manageable tolerability. AZD1775 is a small-molecule inhibitor of the DNA damage checkpoint kinase WEE1 that potentiates genotoxic chemotherapies and is being developed for the treatment of advanced solid tumors with genetic deficiencies in DNA repair mechanisms. In a Phase 2 study in platinum-refractory p53 mutated ovarian cancer (NCT01164995), AZD1775 + carboplatin showed promising activity and an acceptable safety profile. **Methods:** BALTIC (NCT02937818) is a Phase 2, open-label, multicenter, multi-arm, exploratory, signal-searching study to assess the preliminary activity of novel treatment combinations in refractory ED-SCLC. Eligible pts will have progressed during, or within 90 days of completing 1st line platinum-based chemotherapy, and have life expectancy ≥8 wks. Each arm is independent and will open sequentially to enroll up to 20 pts. The study will open initially with 2 arms: D 1500 mg + T 75 mg i.v. q4w for 4 doses, followed by D monotherapy 1500 mg i.v. q4w (Arm A); and oral AZD1775 225 mg bid for 2.5 days from Day 1 + carboplatin AUC 5 on Day 1 i.v. q3w (Arm B). Pts will receive treatment until confirmed disease progression or discontinuation. Further arms may be added to assess other combinations once safe and tolerable doses and schedules have been established. The primary endpoint is investigator-assessed ORR (RECIST v1.1). Secondary endpoints include duration of response, disease control rate, time to response, PFS, OS, PK, safety and tolerability. Recruitment is ongoing. Clinical trial information: NCT02937818.

TPS8586 Poster Session (Board #316b), Sat, 8:00 AM-11:30 AM

A phase 3, randomized study of first-line durvalumab (D) ± tremelimumab (T) + platinum-based chemotherapy (CT) vs CT alone in extensive disease small-cell lung cancer (ED-SCLC): Caspian. *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: SCLC accounts for ~13% of all lung cancers and is characterized by rapid growth and early metastases development. Standard of care CT for pts presenting with ED-SCLC is associated with the development of resistance, leading to poor treatment outcomes. As such, new therapies are needed. The high mutation burden associated with SCLC provides a rationale for investigating immune checkpoint blockade in this tumor type. D is a selective, high-affinity, engineered human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80. T is a selective human IgG2 mAb against CTLA-4. D alone and in combination with T has demonstrated a manageable safety profile and encouraging antitumor activity in non-small cell lung cancer (NSCLC). D ± T in combination with CT has also shown acceptable tolerability and preliminary signs of clinical activity in advanced NSCLC and thus may provide benefit in SCLC. **Methods:** CASPIAN (NCT03043872) is a Phase 3, randomized, multicenter, open-label, global study to determine the efficacy of CT in combination with D ± T as first-line treatment in ED-SCLC (Stage IV). Treatment-naïve pts (N = ~795; WHO/ECOG PS 0 or 1) will be randomized 1:1:1 to receive D (1500 mg) + T (75 mg) i.v. every 3 weeks (q3w) + CT (Arm 1); D (75 mg) i.v. q3w + CT (Arm 2); or CT alone (Arm 3). D ± T will be concurrently administered with CT in Arms 1 and 2 and will continue post-CT (1 further dose for T; until confirmed progressive disease for D). CT (etoposide [80–100 mg/m^2] i.v. on Days 1–3 q3w + carboplatin [AUC 5–6] i.v. on Day 1 q3w or cisplatin [75–80 mg/m^2] i.v. on Day 1 q3w) will be given for up to 4 cycles in Arms 1 and 2 and up to 6 cycles in Arm 3. The co-primary endpoints are overall survival (OS) and progression-free survival (PFS) using blinded independent central review (RECIST v1.1), for Arm 1 vs Arm 3. Secondary endpoints include OS and PFS for Arm 2 vs Arm 3 and Arm 1 vs Arm 2, ORR, OS at 18 months, proportion of patients alive and progression free at 6 and 12 months, PK, immunogenicity, HRQoL, and safety and tolerability. Exploratory endpoints include PFS after subsequent anticancer therapy and correlation of biomarkers with response to treatment. Recruitment is ongoing. Clinical trial information: NCT03043872.

8509 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Efficacy, safety, and biomarker results of trastuzumab emtansine (T-DM1) in patients (pts) with previously treated HER2-overexpressing locally advanced or metastatic non-small cell lung cancer (mNSCLC). *First Author: Tom Stinchcombe, Duke University, Durham, NC*

Background: T-DM1 is an antibody-drug conjugate approved for HER2-positive metastatic breast cancer. We report primary results from a fully enrolled, ongoing phase 2 study (NCT02289833) of pts with previously treated HER2-overexpressing mNSCLC who received single-agent T-DM1. **Methods:** Eligible pts had HER2-overexpressing mNSCLC and were previously treated with platinum-based therapy. Pts received T-DM1 3.6 mg/kg every 3 weeks and were analyzed in 2 cohorts based on centrally determined HER2 status (immunohistochemistry [IHC]2+ vs IHC3+ [≥10% cells stained with 2+ or 3+ intensity, respectively]). HER2 amplification was assessed via ISH (HER2 gene ratio ≥2.0). The primary endpoint is objective response rate (ORR; proportion of pts with confirmed [≥4 weeks] complete or partial response per RECIST v1.1). **Results:** The clinical cutoff date for this analysis was Oct 26, 2016.Of 393 screened pts, 102 (27%) were IHC2+ and 29 (7%) were IHC3+. In total, 49 pts (IHC2+, n = 29; IHC3+, n = 20) received T-DM1. At cutoff, median follow-up was 16.3 (range 0.9*–22.4; * = censored observation) months. No IHC2+ pt had a response (0%, 95% CI 0–11.9); 4 IHC3+ pts had partial responses (20%, 95% CI 5.7–43.7) with a median duration of response of 7.3 (range 2.9–8.3) months. Median progression-free survival (PFS) in IHC2+ and IHC3+ pts was 2.6 (95% CI 1.4–2.8) and 2.7 (95% CI 1.4–8.3) months, respectively. At 6 months after start of study treatment, 9 pts (IHC2+, n = 4; IHC3+, n = 5) were still at risk for a PFS event. Median overall survival was 12.2 (95% CI 3.8–not estimable [NE]) months in IHC2+ pts and 12.1 (95% CI 9.3–NE) months in IHC3+ pts. Of 16 pts with HER2 amplification (IHC2+, n = 5; IHC3+, n = 11), 3 responded, all in the IHC3+ cohort (27.3%, 95% CI 6.0–61.0). Eleven pts (22%) experienced a grade 3–4 adverse event, with fatigue and dyspnea being the only events reported in > 1 pt (n = 2 each). **Conclusions:** This is the first study to report on the clinical activity of T-DM1 in HER2-overexpressing mNSCLC. Objective responses were observed in IHC3+ pts. Additional molecular analyses are underway to refine markers for optimal pt selection. Clinical trial information: NCT02289833.

8510 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Ado-trastuzumab emtansine in patients with *HER2* mutant lung cancers: Results from a phase II basket trial. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor receptor 2 (*HER2*, *ERBB2*) mutations occur in 2% of lung cancers, resulting in receptor dimerization and kinase activation with in vitro sensitivity to trastuzumab. Ado-trastuzumab emtansine is a HER2 targeted antibody drug conjugate linking trastuzumab with the anti-microtubule agent emtansine. **Methods:** Patients (pts) with *HER2* mutant lung cancers were enrolled into a cohort of the basket trial of ado-trastuzumab emtansine in *HER2*amplified or mutant cancers, treated at 3.6mg/kg IV every 3 weeks. The primary endpoint was overall response rate (ORR) using RECIST v1.1. A Simon two stage optimal design was used with type I error rate under 2.7% (and a family wise error rate across baskets under 10%), power of 89%, H0 10%, H1 40%; the H0 will be rejected if 5 or more responses are observed in 18 pts. Other endpoints include duration of response (DOR), progression-free survival (PFS) and toxicity. HER2 testing was performed on tumor tissue by next generation sequencing (NGS), fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC). **Results:** The cohort completed accrual with 18 pts treated. The median age was 63 (range 47-74 years), 72% were female, 39% were never smokers and all had adenocarcinomas. The median lines of prior systemic therapy was 2 (range 0-4). ORR was 33% (5/15 confirmed, 95% CI 12-62%) not including a partial response awaiting confirmation and 3 pts pending response evaluation. Median DOR was not reached (range 3 to 7+ mo), median PFS was 4mo (95% CI 3mo-not reached). Toxicities were mainly grade 1 or 2 including infusion reaction, thrombocytopenia and transaminitis, there were no dose reductions or treatment related deaths. There were 10 (56%) exon 20 insertions and 8 (44%) point mutations; responders were seen across mutation subtypes (A775_G776insYVMA, G776delinsVC, V659E, S310F). *HER2*amplification was negative for all pts by NGS and positive for 1 of 12 pts by FISH. There was no IHC3+ in 10 pts tested. **Conclusions:** Ado-trastuzumab emtansine is active and well tolerated in pts with *HER2* mutant lung cancers. This study has met its primary endpoint. Further development in a multicenter study is warranted. Clinical trial information: NCT02675829.

8511 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Impact of MET inhibitors on survival among patients (pts) with *MET* exon 14 mutant (*MET*del14) non-small cell lung cancer (NSCLC). *First Author: Mark M. Awad, Dana-Farber Cancer Institute, Boston, MA*

Background: Dramatic responses to MET inhibitors have been reported in patients with NSCLC harboring activating mutations that cause *MET* exon 14 (*MET*del14) skipping. We conducted a multicenter retrospective analysis of pts with *MET*del14 NSCLC to determine if treatment with MET inhibitors impacts survival. **Methods:** We collected clinicopathologic data on pts with *MET*del14 NSCLC. Event-time distributions were estimated using Kaplan-Meier and compared with the log-rank test. Multivariable Cox models were fitted to estimate hazard ratios. **Results:** Of the 148 pts with *MET*del14 mutant NSCLC, the median age was 72 (range 43-88); 57% were women, and 41% were never smokers. The most common histologies were adenocarcinoma (77%) and pulmonary sarcomatoid carcinoma (14%). Overlap with oncogenic driver mutations in other genes was rare. At the time of diagnosis, 70% of pts had stage I-III disease, and 30% had stage IV disease. Of the 34 pts with metastatic disease who never received a MET inhibitor, the median overall survival (mOS) was 8.1 months. In this cohort, cancers that also had concurrent *MET* amplification had a trend toward worse survival compared to cancers without *MET* amplification (5.2 months vs 10.5 months, P = 0.06). Of the 27 pts with metastatic disease who received at least one MET inhibitor (including crizotinib, glesatinib, capmatinib, and ABBV-399), the mOS was 24.6 months. A model adjusting for receipt of a MET inhibitor as first- or second-line therapy as a time-dependent covariate demonstrated that treatment with a MET inhibitor was associated with a significant prolongation in survival (HR 0.11, 95% CI 0.01-0.92, P = 0.04). Among 22 patients treated with crizotinib, the median progression-free survival (PFS) was 7.36 months. **Conclusions:** Forpts with *MET*del14 NSCLC, treatment with a MET inhibitor is associated with an improvement in overall survival. The prognosis of pts who never received treatment with a MET inhibitor appears to be poor, particularly among *MET*del14 cancers with concurrent *MET* amplification.

8512 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

PD-L1 expression and response to immunotherapy in patients with *MET* exon 14-altered non-small cell lung cancers (NSCLC). *First Author: Joshua K. Sabari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *MET* exon 14 skipping alterations (*MET*Δ14) are present in 4% of NSCLCs. Response to MET inhibition has been observed in ongoing prospective trials (44% response rate, phase 1 trial of crizotinib; Drilon et al ASCO 2016), however responses to other types or therapy, such as immunotherapy, is unknown. We evaluated the immunophenotype of *MET*Δ14 lung cancers and response to PD-(L)-1-based immunotherapy. **Methods:** Pts with recurrent/metastatic NSCLC were eligible. *MET*Δ14 was identified by broad hybrid capture-based next-generation sequencing (MSK-IMPACT). PD-L1 expression was determined by immunohistochemistry. Response to immune therapy was evaluated by RECIST v1.1. **Results:** 63 pts with *MET*Δ *14*-positive non-small cell lung cancers were identified; 41 (65%) had sufficient tissue for PD-L1 analysis. Patient characteristics: median age 71 years, 58% female, median pack year smoking 5.85 years, histology: 73% (30/41) adenocarcinoma, 20% (8/41) pleomorphic carcinoma, 7% (3/41) squamous cell. Tumor PD-L1 expression was ≥50% in 44% (18/41, 95% CI 30-59%), 1-49% in 17% (7/41, 95% CI 8-32%), and < 1 in 39% (16/41, 95% CI 26-54%). The median age for patients with *MET*Δ14 and PD-L1 positive (≥1%) tumors was 65 years (range 49-87); 60% (15/25) of patients were female; Histology: 72% (18/25) adenocarcinoma, 24% (6/25) sarcomatoid carcinoma, and 4% (1/25) squamous cell carcinoma. Immunotherapy was given to 15 pts: nivolumab (5), pembrolizumab (3), atezolizumab (2), durvalumab (1), and ipilimumab+nivolumab (4). The overall response rate to immunotherapy was 13% (2/15, 95% CI 3-39%). Overall response was 33% (1/3; 95% CI 6-80%) in patients with tumors PD-L1 ≥50%, and 20% (1/5, 95%CI 2-64%) in patients with tumors PD-L1 0%. Time on therapy ranged from 2 weeks to 9.6+ months. **Conclusions:** A substantial proportion of NSCLCs harboring *MET*Δ14 alterations express PD-L1. Despite frequent PD-L1 expression, responses to immunotherapy were overall uncommon and lower than that observed with targeted therapy for this genomically defined subset of patients with lung cancers. Further exploration of this subset may reveal important mechanisms of immunotherapy resistance in PD-L1 expressing tumors.

9000 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Progression after the next line of therapy (PFS2) and updated OS among patients (pts) with advanced NSCLC and PD-L1 tumor proportion score (TPS) ≥50% enrolled in KEYNOTE-024. *First Author: Julie R. Brahmer, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: In KEYNOTE-024 (NCT02142738), pembrolizumab (pembro) was superior to chemotherapy (chemo) as first-line (1L) therapy for advanced NSCLC with PD-L1 TPS ≥50% and no sensitizing EGFR mutations or ALK translocations. After a median follow-up of 11.2 mo, HR was 0.50 for PFS by independent central radiologic review ($P < 0.001$) and 0.60 for OS ($P = 0.005$). Here we present PFS2 and updated OS. **Methods:** 305 pts were randomly assigned to pembro 200 mg Q3W (n = 154) or investigator (INV)-choice platinum-doublet chemo with optional pemetrexed maintenance for nonsquamous histology (n = 151). Pts in the chemo arm could cross over to pembro upon PD. Poststudy anticancer therapy and INV-assessed outcomes were collected. Kaplan-Meier PFS2 and OS were calculated in all allocated pts. PFS2 was defined as time from randomization to PD per INV after start of 2L+ therapy or death, whichever occurred first; pts alive and without 2L+ PD were censored at last known survival. Kaplan-Meier OS was defined as time from randomization to death. There was no adjustment for multiplicity (cutoff: Jan 5, 2017). **Results:** 2L+ therapy was received by 48 (31.2%) pts in the pembro arm and 97 (64.2%) in the chemo arm, including 80 pts who crossed over from chemo to pembro per protocol and 14 pts who received anti–PD-1 therapy outside of crossover. 56 (36%) 1L pembro pts were on 1L pembro therapy or in follow-up as of data cutoff. Updated median OS and PFS2 results are in the Table. **Conclusions:** Fewer pembro pts received 2L+ therapy vs chemo pts because of the significant improvement in PFS observed for pembro in the 1L setting. Median PFS2 was substantially improved for pembro (not reached [NR]) vs chemo (8.6 mo). Updated OS with median follow-up of 19 mo maintained consistent superiority of 1L pembro, despite increased crossover from 1L chemo. Clinical trial information: NCT02142738.

Outcomes	1L Pembro n = 154	1L Chemo n = 151

9001 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Impact of atezolizumab (atezo) treatment beyond disease progression (TBP) in advanced NSCLC: Results from the randomized phase III OAK study. *First Author: David R. Gandara, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Cancer immunotherapy (CIT) can have a positive impact on OS that exceeds response rate or PFS effects, termed post progression prolongation of survival (PPPS). This effect can also result from unconventional CIT response due to tumor immune infiltration or delayed response, reducing reliability of RECIST v1.1 (RECIST) PD as an indicator of treatment failure. In the primary analysis (N = 850) of OAK, a study of atezo vs docetaxel (doc) in 2L/3L NSCLC, OS favored atezo (HR 0.73; 95% CI: 0.62, 0.87), despite similar PFS between arms (HR 0.95; 95% CI: 0.82, 1.10). Here we evaluate clinical benefit from TBP, defined by post PD tumor regression, OS and safety. **Methods:** Patients (pts) received atezo 1200 mg IV q3w until PD or loss of clinical benefit per investigator or doc 75 mg/m^2 IV q3w until PD per RECIST. No crossover was allowed. Primary outcome measure: OS. Atezo TBP pts were evaluated for post PD tumor change and for safety pre and post PD. OS from time of PD per RECIST was evaluated in both arms (data cutoff, July 7, 2016; minimum follow-up, 19 mo). **Results:** Among 332 atezo pts with PD, 51% (n = 168) continued atezo TBP; 7% (12/168) achieved subsequent response in target lesions (≥ 30% reduction from new baseline at PD); 49% (83/168) had stable target lesions (best change between +20% and −30%). mOS was 12.7 mo (95% CI: 9.3, 14.9) post PD for pts on atezo TBP (Table). Atezo TBP was not associated with increased safety risk. **Conclusions:** This is the first report from a Phase III study of CIT in NSCLC to evaluate post PD OS in pts continuing treatment beyond RECIST PD. Atezo TBP was associated with high frequency of stable or decreased target lesions, mOS > 1 year and a tolerable safety profile, all supporting prolonged treatment benefit consistent with PPPS. NCT02008227 Clinical trial information: NCT02008227.

9002 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Efficacy of the addition of cisplatin to single-agent first-line chemotherapy in elderly patients with advanced non-small cell lung cancer (NSCLC): A joint analysis of the multicenter, randomized phase III MILES-3 and MILES-4 studies. *First Author: Cesare Gridelli, A.O.S.G. Moscati, Avellino, Italy*

Background: The role of platinum in first line treatment of elderly patients with advanced NSCLC is still debated. We tested its efficacy in two parallel phase 3 trials. **Methods:** Advanced NSCLC patients, > 70 years, ECOG performance status 0-1, were eligible. In MILES-3 (started in 2011) patients with any tumor histology were randomly assigned 1:1 to cisplatin/gemcitabine (C 60 mg/m^2 d1, G 1000mg/m^2 dd1,8) or gemcitabine (G 1200 mg/m^2 dd1,8). In MILES-4 (started in 2013 with a factorial design) patients with non-squamous histology were randomly assigned 1:1:1:1 to CG, G, cisplatin/pemetrexed (C 60 mg/m^2 d1, P 500 mg/m^2 d1) or pemetrexed (P 500 mg/m^2 d1). Six cycles were planned. In each trial, to have 80% power in detecting a HR of death 0.75 (corresponding to 3-month prolongation of median survival), with 0.05 two-tailed α, 382 events were required. The two trials were closed prematurely because of slow accrual but a joint analysis allowed to properly perform the final analysis, according to IDMC advice. Analysis was based on intention-to treat and adjusted by possible confounding factors. **Results:** From Mar 2011 to Aug 2016, 531 patients (MILES-3: 299, MILES-4: 232) were assigned to cisplatin-doublet (n = 263) or single-agent chemotherapy (n = 268). Median age was 75, 79% were male, 70% had non-squamous histology. Median number of cycles was 4 and 3 with and without cisplatin, respectively. With a median follow-up of 2 years, 384 deaths and 448 progression-free survival (PFS) events were reported. With and without cisplatin, median OS was 9.6 vs 7.5 months (HR 0.86, 95% CI: 0.70-1.04, p = 0.14); median PFS was 4.6 vs 3.0 months (HR 0.76, 95% CI: 0.63-0.92, p = 0.005); response rate was 15.5% vs 8.5% (p = 0.02). Significantly more severe hematologic toxicity and fatigue were reported with cisplatin. **Conclusions:** Although improving PFS and response rate, addition of cisplatin to single-agent chemotherapy does not significantly prolong overall survival of elderly patients with advanced NSCLC. QOL data will be reported separately. Partially supported by AIFA (grant FARM8KAJZK) and Eli Lilly. Clinical trial information: NCT01405586 and NCT01656551.

9003 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

IFCT-GFPC-1101 trial: A multicenter phase III assessing a maintenance strategy determined by response to induction chemotherapy compared to continuation maintenance with pemetrexed in patients (pts) with advanced non-squamous (NSQ) NSCLC. *First Author: Maurice Perol, Department of Thoracic Oncology, Centre Léon Bérard, Lyon, France*

Background: Benefit coming from maintenance treatment appears greater for switch maintenance in pts with disease stabilization (SD) while it might be larger for continuation maintenance in pts with objective response (OR). This study assessed a maintenance strategy conditioned by response to cisplatin-gemcitabine (CG): continuation maintenance with G for pts with OR and switch maintenance with pemetrexed (P) for pts with SD compared with a control arm using P continuation maintenance following cisplatin-pemetrexed (CP) induction regimen. **Methods:** Eligibility criteria included age 18-70 years, PS of 0-1, untreated stage IV NSQ NSCLC without EGFR mutation or ALK rearrangement, ineligibility to bevacizumab. Pts were randomized 1:1 to receive either experimental CG arm: CG (4 cycles) followed by G maintenance in case of OR followed by second-line P or switch maintenance with P for pts with SD, or standard CP arm: 4 cycles CP induction regimen followed by maintenance P. Overall survival (OS) was the primary endpoint; secondary endpoints included PFS, response rate and safety. **Results:** Between Jul 2012 and Jun 2016, 932 pts were randomized (CG: 467, CP: 465). Pts characteristics were balanced between the arms. 255 pts (54.6%) in the CG arm received maintenance treatment (G: 142, P: 113) while 274 pts (58.9%) received P maintenance in the CP arm. Median number of maintenance cycles was 5 for G and 4 for P in both arms. The OS adjusted HR was 0.97 (95% CI 0.84, 1.13; p=0.72); median OS: 10.9m CG vs. 10.4m CP. The HR for PFS was 0.96 (95% CI 0.84, 1.10; p=0.56); median PFS: 5.0m CG vs. 4.7m CP. Safety profile was as expected during induction chemotherapy. During maintenance, grade ≥3 hematological AEs occurred in 28% and 31% of pts in CG and CP, respectively, with febrile neutropenia (2.4% vs. 1.1%), anemia (9.4% vs. 11.7%), thrombocytopenia (6.7% vs. 5.8%). No grade ≥3 non-hematological AEs occurred in >5% of pts except for asthenia (3.9% CG vs. 5.1% CP). **Conclusions:** Adapting maintenance strategy according to response to induction chemotherapy does not improve patient outcome. Clinical trial information: NCT01631136.

9004 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Efficacy and safety results from AvaALL: An open-label, randomized phase III trial of standard of care (SOC) with or without continuous bevacizumab (Bev) treatment beyond progression (PD) in patients (pts) with advanced non-small cell lung cancer (NSCLC) progressing after first-line Bev and chemotherapy (chemo). *First Author: Jaafar Bennouna, Institut de Cancerologie de l'Ouest, Nantes, France*

Background: The role of treatment with Bev beyond PD is unclear in the multiline treatment strategy of advanced NSCLC.AvaALL(NCT01351415), a multinational, open-label, randomized phase III trial, assessed continuous Bev and SOC beyond first PD (PD1) in pts with NSCLC following first-line treatment with platinum-based chemo plus Bev. Here we present efficacy and safety data from AvaALL. **Methods:** Pts with NSCLC who received 4–6 cycles of chemo + Bev and ≥2 cycles of maintenance Bev were randomized after PD1 to second-line SOC therapy (docetaxel, pemetrexed or erlotinib) ± Bev. After second PD (PD2) and third PD (PD3), pts received third-line or fourth-line SOC ± Bev treatment, respectively. Primary endpoint was overall survival (OS). Secondary endpoints were OS rates (6, 12, and 18-months [mos]), progression-free survival (PFS) from PD1 to PD2/from PD2 to PD3, overall response rate (ORR), disease control rate (DCR), and safety. Data cut-off: 24 Jun 2016. **Results:** Overall, 485 pts were randomized (n = 475 treated). Pt characteristics were well balanced between the two arms. Bev plus chemo resulted in a median OS of 11.9 mos versus 10.2 mos for SOC alone (HR 0.84, 90% CI 0.71–1.00; p = 0.1016; 387 OS events). The primary endpoint was not met (416 OS events were required, at 10% two-sided significance level). OS rates were 10% higher in the Bev arm vs SOC alone at 6-, 12- and 18-mos. Median PFS2 was 4.9 mos with Bev vs 3.8 mos with SOC (HR 0.85, 90% CI 0.72–1.00; p = 0.0907). PFS3 was significantly improved (3.5 mos for Bev, 2.4 mos for SOC; HR 0.65, 90% CI 0.51–0.84; p = 0.0047). ORR and DCR were slightly higher in the Bev arm versus the SOC arm (ORR 9.7% vs 6.7%; DCR 86.2% vs 79.3%, respectively). No new safety signals were identified. Grade ≥3 adverse events were reported in 78.2% of Bev pts and 61.6% of SOC pts. **Conclusions:** Although the primary endpoint was not met, efficacy data suggest a positive trend for continued Bev plus SOC after PD1 compared with SOC alone. No cumulative safety signals were identified. Clinical trial information: NCT01351415.

9005 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

CNS response to osimertinib in patients (pts) with T790M-positive advanced NSCLC: Data from a randomized phase III trial (AURA3). *First Author: Tony Mok, Chinese University of Hong Kong, Hong Kong, China*

Background: CNS metastases (mets) are common in pts with advanced NSCLC. Preclinical studies have shown CNS penetration of osimertinib, and clinical data from a pooled analysis of 2 Phase II trials (AURA extension: NCT01802632, AURA2: NCT02094261) showed activity in the CNS. We report the first evidence of osimertinib efficacy in CNS mets from a randomized Phase III study (AURA3; NCT02151981) in pts with T790M-positive advanced NSCLC who have progressed on or after prior EGFR-TKI therapy. **Methods:** Pts were randomized 2:1 to osimertinib 80 mg once daily or platinum-based doublet chemotherapy every 3 wks for up to 6 cycles; maintenance pemetrexed was allowed. Pts with stable, asymptomatic CNS mets were eligible for enrolment. A prespecified subgroup analysis was conducted in pts with CNS mets present on baseline brain scan, as assessed by blinded independent central neuroradiology review (BICR), to define CNS objective response rate (ORR), duration of response (DoR) and progression-free survival (PFS) by RECIST v1.1. The CNS full analysis set (cFAS) included pts with ≥1 measurable and/or non-measurable CNS mets present on baseline brain scan by BICR; the CNS evaluable for response set (cEFR) included only pts with ≥1 measurable CNS mets. **Results:** As of 15 April 2016, 116/419 (28%) pts were included in the cFAS. In the cEFR (n = 46), CNS ORR was 70% (21/30; 95% CI 51, 85) with osimertinib and 31% (5/16; 95% CI 11, 59) with chemotherapy (OR, 5.13; 95% CI 1.44, 20.64; p = 0.015). In the cFAS, CNS ORR was 40% (30/75; 95% CI 29, 52) with osimertinib and 17% (7/41; 95% CI 7, 32) with chemotherapy (OR, 3.24; 95% CI 1.33, 8.81; p = 0.014). In the cEFR and cFAS, median CNS DoR was 8.9 months (m) (95% CI 4.3, NC and 4.3, NC) for osimertinib and 5.7 m (95% CI NC, NC and 4.4, 5.7; respectively) for chemotherapy. Median CNS PFS in the cFAS was significantly longer with osimertinib than with chemotherapy (11.7 vs 5.6 m; HR 0.32; 95% CI 0.15, 0.69; p = 0.004). **Conclusions:** Consistent with the overall response to osimertinib reported in pts with T790M-positive advanced NSCLC, osimertinib was superior to chemotherapy in the treatment of pts with CNS mets; CNS response rate was higher, responses were more durable and CNS PFS was longer. Clinical trial information: NCT02151981.

9006 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Efficacy and safety of lorlatinib in patients (pts) with ALK+ non-small cell lung cancer (NSCLC) with one or more prior ALK tyrosine kinase inhibitor (TKI): A phase I/II study. *First Author: Alice Tsang Shaw, Massachusetts General Hospital, Boston, MA*

Background: Lorlatinib is a selective, potent, brain-penetrant, next generation ALK/ROS1 TKI active against most known resistance mutations. In Ph I of this Ph I/II study, lorlatinib showed robust clinical activity in ALK+ or ROS1+ advanced NSCLC pts, most of whom had CNS metastases (mets) and were heavily pre-treated. In Ph II of this study, efficacy was explored based on prior ALK TKI tx as well as safety across all patients treated at the recommended Ph II dose. **Methods:** In this ongoing Ph II study (NCT01970865), pts with ALK+ or ROS1+ NSCLC, ± asymptomatic untreated or treated CNS mets, were enrolled into 6 expansion cohorts (EXP) based on prior tx (EXP 1-5, ALK+) and rearrangement status (EXP 6, ROS1+). Pts received lorlatinib 100mg QD. Primary objective was ORR and intracranial ORR (IC-ORR) by independent central review (ICR). **Results:** Efficacy (ALK+ pts with prior tx): At data cut-off (15 Aug 2016), 82 ALK+ pts were enrolled in cohorts EXP 2-5, received C1 no later than 31 Mar 2016 and were evaluated for ORR (ITT population); 52 were evaluated for IC-ORR and 35 were evaluated for IC-ORR response based on target lesions only (≥5mm; no prior radiotherapy or progression post prior radiotherapy). Confirmed response rates by ICR are reported in the table below. Safety (all pts): 116 ALK/ROS1+ pts were evaluated for safety at data cut-off. Most common tx-related AEs (TRAEs) and grade 3/4 TRAEs were hypercholesterolemia (90%, 17%) and hypertriglyceridemia (72%, 17%). Dose interruptions and reductions due to TRAEs were reported in 29% and 20% of pts, respectively. 14% of pts had tx-related SAEs. 5 pts (4%) discontinued tx due to TRAEs and there were no tx-related deaths. 74/116 pts (64%) remain on tx. **Conclusions:** Lorlatinib showed compelling clinical activity, with substantial IC activity, in ALK+ pts who received ≥1 prior ALK TKI, many of whom were heavily pre-treated. Clinical trial information: NCT01970865.

Evolution and clinical impact of genomic alterations detectable in circulating tumor DNA of 1150 advanced EGFR-mutant (mt) lung cancer patients. *First Author: Collin M. Blakely, Department of Medicine, University of California San Francisco, San Francisco, CA*

Background: Advanced EGFR-mt lung adenocarcinomas (LUAD) frequently harbor additional genetic alterations. The clinical significance of these concurrent alterations and how they evolve with treatment are unclear. **Methods:** We performed next-generation sequencing (NGS) of ~70 cancer related genes from the circulating tumor DNA (ctDNA) of 1150 consecutive advanced LUAD patients (pts) with detectable EGFR mts. The analysis included 113 samples from 81 pts for whom clinical outcome data were known. Clinical response to EGFR TKI treatment was correlated to mutational status in 12 cancer-related pathways. **Results:** EGFR-mt cases contained an average of 3.6 genetic alterations (range 1-18). There was enrichment for co-alterations in TP53, CDK6, CTNNB1 and SMAD4 in EGFR-mt cases compared to a control cohort of 1008 EGFR WT cases. Enrichment for the EGFR T790M mutation was found upon progression to first-line EGFR TKI treatment, as expected. Analysis of 450 T790M-mt cases showed enrichment for co-alterations in genes controlling the cell cycle (28% vs. 21%, p = 0.01), DNA repair (12% vs. 8%, p = 0.03), and WNT (16% vs. 11%, p = 0.03) signaling. The number of genetic alterations increased during progression on each line of therapy in a manner unlinked to age, gender, or tobacco exposure (mean 3.2 pre-TKI vs. 6.4 after 2nd line, p = 0.001). Upon progression to second-line treatment, analysis revealed further selection for co-alterations in TP53, CCNE1, MYC and PIK3CA and the associated pathway-level classifications. We found an increased frequency of co-alteration in cell cycle genes in EGFR TKI non-responders versus responders (33% vs. 0%, p = 0.0005). **Conclusions:** Within the landscape of advanced EGFR-mt LUAD, we uncover features of evolutionary selection for multiple concurrent oncogenic pathway alterations including TP53, WNT, PI3K, MYC, and cell cycle genes. This large clinical and genetic dataset prompts a re-evaluation of the prevailing paradigm of monogenic-based molecular stratification to monotherapy, and highlights an alternative model of genetic collectives as a previously underappreciated determinant of lung cancer progression and therapy resistance.

Association of *ALK* resistance mutations by *EML4-ALK* variant (v3 vs. non-v3) in *ALK*+ non-small cell lung cancer (NSCLC). *First Author: Sai-Hong Ignatius Ou, University of California Irvine Chao Family Comprehensive Cancer Center, Orange, CA*

Background: *ALK* rearrangements are established targetable drivers in NSCLC. Recent reports indicate differential progression-free survival to ALK inhibitors according to specific *EML4-ALK* variant. **Methods:** We analyzed samples from 634 unique NSCLC patients (704 samples) with tumors harboring *ALK* rearrangements (*ALK*+) detected using hybrid-capture based genomic profiling performed on DNA isolated from FFPE tissue specimens (676 samples) or ctDNA isolated from blood (28 samples) during the course of clinical care. **Results:** Of the 634 *ALK*+ cases, we identified 200 (32%) *EML4-ALK*v1 (E13; A20), 50 (8%) *EML4-ALK*v2 (E20; A20), 204 (32%) *EML4-ALK*v3 (E6; A20), 78 (12%) other *EML4-ALK*, and 102 (16%) non-*EML4 ALK* rearrangements. Despite relatively equal frequency of *EML4-ALK* v1 and v3 in this dataset, the presence of a known *ALK* resistance mutation (n = 40 cases) was significantly associated with v3 as compared to v1 ($P < 0.0002$). G1202R mutation in particular was significantly associated with *EML4-ALK* v3 versus v1 ($P < 0.002$), and as compared to all non-v3 (P = 0.02). The tumor mutation burden (TMB) was generally low (median v1: 1.8, v3: 2.5, non-v3: 1.8 mutations/Mb), and although significantly different between v1 and v3 (P = 0.0008) and v3 and non-v3 (P = 0.003), the difference is not expected to be clinically relevant. Available *ALK*+ cases with paired pre- and post-treatment samples tested for a single patient will also be evaluated by *ALK*fusion variant, as well as for novel non-ALK mechanisms of acquired resistance, including a case with MET kinase domain duplication acquired post-ALK targeted therapy. **Conclusions:** The use of tissue and blood-based next generation sequencing allows for detection of the specific *ALK* fusion partner, increases the understanding of the biology of *ALK*+ NSCLC, and may have value to foretell potential mechanisms of resistance and inform the selection of ALK inhibitor therapy.

KEYNOTE-001: 3-year overall survival for patients with advanced NSCLC treated with pembrolizumab. *First Author: Natasha B. Leighl, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Pembrolizumab (pembro) is approved as first-line (1L) treatment for advanced NSCLC patients (pts) with PD-L1 tumor proportion score (TPS) ≥50% and as treatment for previously treated advanced NSCLC pts with PD-L1 TPS ≥1%. Here we present 3-y OS results for pts enrolled in KEYNOTE-001 (NCT01295827), the first trial evaluating pembro in advanced NSCLC pts. **Methods:** 550 pts received pembro 2 or 10 mg/kg Q3W or 10 mg/kg Q2W until intolerable toxicity, progression, or investigator or pt decision to withdraw. PD-L1 expression was assessed by IHC using the 22C3 antibody. Survival was assessed every 2 mo after treatment discontinuation. **Results:** 550 advanced NSCLC pts enrolled; 101 were first line (1L), and 449 were previously treated. As of the Sept 1, 2016, data cutoff, median follow-up duration was 34.5 mo (range, 25.7-51.5 mo); 8 (7.9%) 1L pts and 28 (6.2%) previously treated pts were still on treatment. 3-y OS was 26.4% (95% CI, 14.3%-40.1%) in 1L pts and 19% (95% CI, 15.0%-23.4%) in previously treated pts. 3-y OS rate and median OS by PD-L1 status are in the Table. Additional description of the pts with long-term survival, including updated safety data as well as 3-y OS by smoking history, histology, *EGFR*status, and prior radiation therapy, will be presented. **Conclusions:** Pembro provides promising long-term OS benefit for 1L and previously treated advanced NSCLC pts expressing PD-L1. The current data represent the longest efficacy and safety follow-up for pts with advanced NSCLC treated with pembro. Clinical trial information: NCT01295827.

Population	n	Median OS (95% CI), mo	24-mo OS rate, % (95% CI)	36-mo OS rate, % (95% CI)
Treatment naive	101*	22.3 (17.1-31.5)	49.0 (38.9-58.3)	26.4 (14.3-40.1)
TPS ≥1%	79	22.2 (16.7-31.5)	47.4 (36.1-58.0)	16.4 (4.0-36.3)
TPS ≥50%	27	34.9 (20.3-NR)	66.7 (45.7-81.1)	25.2 (5.0-53.1)
TPS 1%-49%	52	19.5 (10.7-26.3)	37.3 (24.3-50.2)	Not yet available
Previously treated	449*	10.5 (8.6-13.2)	29.9 (25.6-34.2)	19.0 (15.0-23.4)
TPS ≥1%	306	11.1 (8.3-14.0)	31.8 (26.6-37.1)	21.1 (16.1-26.6)
TPS ≥50%	138	15.4 (10.5-18.5)	38.6 (30.4-46.7)	29.7 (21.9-37.9)
TPS 1%-49%	90	8.5 (6.0-12.7)	26.2 (19.8-33.1)	13.5 (7.8-20.9)
TPS <1%	90	8.6 (5.5-10.6)	23.8 (15.4-33.2)	8.5 (2.9-18.1)

*Includes unknown PD-L1 status and TPS <1% pts.

Safety of retreatment with immunotherapy after immune-related toxicity in patients with lung cancers treated with anti-PD(L)-1 therapy. *First Author: Fernando Costa Santini, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Anti-PD(L)-1 therapy is generally well tolerated, but immune-related adverse events (irAEs) can occur. No data currently exists to guide decisions related to considering re-treatment following an irAE. **Methods:** Patients (pts) with lung cancer treated with anti-PD(L)-1 (+/- anti-CTLA-4) between 4/2011 to 5/2016 who had a treatment delay of at least one week were identified. Those in whom delay was a result of a definite irAE were included, and subsequent treatment details and outcomes were captured. Pts with an irAE concurrent with disease progression were excluded. **Results:** Among 482 pts treated, 71 (14.7%) had treatment delay related to an irAE. Most events were Grade 2 (38/71, 54%) or Grade 3 (30/71, 42%), and predominantly included pneumonitis (21%), colitis (17%), rash (14%), or hepatitis (13%). 32 pts (45%) were permanently discontinued after the irAE and 39 (55%) were later retreated with anti-PD(L)-1 therapy. In retreated pts, the same irAE recurred in 10/39 (26%), a new irAE occurred in 9/39 (23%), and 20/39 (51%) had no subsequent irAE. The rate of recurrent/new irAEs was similar in those with Grade 3 compared to Grade 2 irAEs (p = 1.0), but were more common following initial irAE that occurred early ($<$ 3 months) compared to later ($\geq$3 months) in treatment course (16/24 [67%] vs 3/15 [20%], p = 0.0079). The rate of recurrent/new irAE was 33% (2/6) in those with pneumonitis, 40% (2/5) with rash, 57% (4/7) with colitis, and 80% (4/5) with arthralgia. Recurrent/new irAEs were successfully managed with immunosuppression in 17/19 (90%) pts. However, 2 pts died, both related to a new irAE different from the one initially experienced. Of the pts retreated, 3 (8%) had onset of objective response to anti-PD(L)-1 therapy following resumption of treatment. **Conclusions:** In pts who develop irAEs and improve, re-treatment with anti-PD(L)-1 therapy was associated with recurrent or new irAEs in half of pts, and was more common in early-onset irAEs. The majority of the pts with recurrent/new irAEs were managed successfully, but two deaths occured. Few objective responses occurred following retreatment.

A phamacoeconomic analysis of personalized dosing versus fixed dosing of pembrolizumab in first-line PD-L1 positive non-small cell lung cancer. *First Author: Daniel A. Goldstein, Davidoff Cancer Center, Petah Tikva, Israel*

Background: In October 2016 pembrolizumab became the new standard of care for first-line treatment of patients with metastatic non-small cell lung cancer (mNSCLC) whose tumors express programmed death ligand 1 in at least 50% of cells. The FDA recommended dose is 200mg every three weeks. Multiple studies have demonstrated equivalent efficacy with weight-based doses between 2mg/kg to 10 mg/kg. The objective of this study was to compare the economic impact of using personalized dosing (2mg/kg) versus fixed dosing (200mg) in the first line setting of mNSCLC. **Methods:** We performed a budget impact analysis from the US societal perspective to compare fixed dosing with personalized dosing. We calculated the target population and weight of patients that would be treated with pembrolizumab annually in the first-line setting. Using survival curves from the KEYNOTE 024 trial with Weibull extrapolation we estimated the mean number of cycles that patients would receive. Using the Medicare average sales price we calculated the difference in cost between personalized and fixed dosing. **Results:** Our base case model demonstrates that the total annual cost of pembrolizumab with fixed dosing is US$ 3,440,127,429, and with personalized dosing it is US$ 2,614,496,846. The use of personalized dosing would lead to a 24% annual saving of US$ 825,630,583 in the United States. **Conclusions:** Personalized dosing of pembrolizumab may have the potential to save approximately 0.825 billion dollars annually in the United States, likely without impacting outcomes. This option should be considered for the first-line management of PD-L1 positive advanced lung cancer.

Efficacy and safety of epacadostat plus pembrolizumab treatment of NSCLC: Preliminary phase I/II results of ECHO-202/KEYNOTE-037. *First Author: Tara C. Gangadhar, Abramson Cancer Center, Philadelphia, PA*

Background: ECHO-202/KEYNOTE-037 is an open-label, phase 1/2 study of epacadostat (a potent and selective oral inhibitor of the immunosuppressive enzyme indoleamine 2,3-dioxygenase 1) plus pembrolizumab (E + P) in patients (pts) with advanced tumors. We report preliminary efficacy and safety outcomes for the phase 1/2 NSCLC cohort. **Methods:** Adult pts with prior platinum-based therapy (tx) and no prior checkpoint inhibitor tx were eligible. Phase 1 dose-escalation tx was E (25, 50, 100, 300 mg PO BID) + P (2 mg/kg or 200 mg IV Q3W); MTD was not exceeded. E (100 mg BID) + P (200 mg Q3W) tx doses were selected for phase 2 cohort expansion. Efficacy was evaluated by tumor proportion score (TPS [% viable tumor cells, PD-L1 staining]: $<$ 50% and $\geq$50%) and by prior lines of tx in RECIST 1.1 evaluable pts. Safety was assessed in pts receiving $\geq$1 E + P dose. **Results:** As of 29OCT2016,43 pts (phase 1, n = 12; phase 2, n = 31) were evaluated. Median age was 65 years, 58% of pts were women, 12% were *EGFR*-positive, and 23% were *KRAS*-positive. Most pts had a history of smoking (84%), $\leq$2 prior lines of tx (84%), and no prior TKI tx (93%). For the 40 efficacy-evaluable pts, ORR (CR+PR) and DCR (CR+PR+SD) were 35% (14/40; 14 PR) and 60% (24/40; 10 SD), respectively. PD-L1 TPS test results were available in 28/40 efficacy-evaluable pts. ORR and DCR for pts with TPS $\geq$50% and $\leq$2 prior tx were 43% (3/7; all PR) and 57% (4/7; 1 SD), respectively; for pts with TPS $<$ 50% and $\leq$2 prior tx, ORR and DCR were 35% (6/17; all PR) and 53% (9/17; 3 SD). Among the 40 efficacy-evaluable pts, 12/14 responses were ongoing (range, 1+ to 519 days) at data cutoff. PFS and biomarker analyses are ongoing. Across all 43 pts, most frequent TRAEs were fatigue (19%), arthralgia (9%), and increased AST (9%); 16% of pts had grade $\geq$3 TRAEs, and increased lipase (asymptomatic) was the only grade $\geq$3 TRAE that occurred in $>$ 1 pt (n = 2). Two pts discontinued due to TRAEs (grade 3 increased AST, grade 2 increased ALT [n = 1]; grade 2 brain edema [n = 1]). **Conclusions:** E + P was generally well tolerated and associated with promising responses in pts with NSCLC. A phase 3 NSCLC study is planned. Clinical trial information: NCT02178722.

Molecular determinants of response and resistance to anti-PD-(L)1 blockade in patients with NSCLC profiled with targeted next-generation sequencing (NGS). *First Author: Matthew David Hellmann, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Anti-PD-(L)1 therapy has revolutionized treatment for patients (pts) with NSCLC. We previously reported that non-synonymous tumor mutation burden (TMB) by whole exome sequencing associates with immunotherapy benefit. Targeted NGS is increasingly routine in clinical practice and may be a useful tool for predicting benefit to anti-PD-(L)1 blockade. **Methods:** Pts had advanced NSCLC treated with anti-PD-(L)1 (+/- aCTLA-4) therapy and profiling by hybrid-capture NGS of 341-468 genes (MSK-IMPACT). Efficacy assessed by RECIST v1.1; durable clinical benefit (DCB) defined as PR or SD $>$ 6mo. TMB and copy number alteration burden ("fraction of genome altered", FGA) were normalized by size of genome covered. Comparisons were also made to a cohort of all NSCLCs profiled by MSK-IMPACT (n = 1679). **Results:** Of 437 evaluable pts treated with anti-PD-(L)1, 197 (45%) had NGS profiling, of whom 30% had DCB. TMB was higher in those with DCB vs no DCB (mean 10.2 vs 7.1 SNV/MB, p = 0.02) and compared to all NSCLCs ($<$ 0.0001). DCB was more common and PFS was longer in pts with $>$ vs $<$ 85th percentile TMB of all NSCLCs (Odds ratio 2.3, 95% CI 1.1-4.9, p = 0.03; HR = 0.59, p = 0.004), but were similar when dichotomized at the 50th or 75th percentile. FGA was higher in pts with no DCB compared to all NSCLCs (p = 0.02). Molecular signatures related to deficient homologous-recombination-based DNA repair and smoking were more common in DCB vs no DCB (p = 0.042, p = 0.058) and vs all NSCLCs (p = 0.026, p = 0.01). Compared to all NSCLCs profiled by NGS, alterations in *STK11*and *EGFR*were enriched in no DCB (p = 0.0008, p = 0.02). Alterations in *JAK2*and *CD274*(PD-L1) were uncommon (2.1%, 1.6%) but exclusively associated with no DCB. For a subset (n = 52) of these cases also profiled by whole exome sequencing, comparison with targeted NGS will be presented. **Conclusions:** In pts with NSCLC, targeted NGS profiling is a routinely available tool that can provide insight into predicting benefit with anti-PD-(L)1 therapy. Increased TMB associates with clinical benefit. Increased copy number alterations (FGA) and alterations in genes including *STK11*, *JAK2*, and *CD274* may associate with resistance to anti-PD-(L)1 therapy.

STK11/LKB1 co-mutations to predict for de novo resistance to PD-1/PD-L1 axis blockade in KRAS-mutant lung adenocarcinoma. *First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Identification of molecular predictors of response to PD-1/PD-L1 inhibitors is critical in order to maximize their therapeutic potential. We previously reported that *KRAS*-mutant lung adenocarcinomas (LUAC) with co-occurring genetic events in *STK11/LKB1*(KL) or *TP53* (KP) define subgroups with marked differences in immune contexture, including a paucity of CD8+ TILs in KL LUAC. Here, we assess clinical responses to PD-1/PD-L1 therapy in KL and KP subsets, with data assembled under the auspices of the SU2C/ACS Lung Cancer Dream Team. **Methods:** Patients (pts) with metastatic *KRAS*-mutant LUAC who received at least one cycle of PD-1/PD-L1 therapy, were alive for ≥14 days thereafter, and had available molecular profiling were identified retrospectively. Efficacy assessment was based on RECIST v1.1. PD-L1 expression was tested using 22C3 pharmDx or E1L3N IHC assays and quantified as percent of staining tumor cell membranes. Isogenic derivatives of the LKR10 *Kras*$^{LA1/+}$ murine LUAC cell line with CRISPR/Cas9-mediated *Lkb1*knockout were used in preclinical experiments. **Results:** 165 pts with *KRAS*-mutant LUAC who received PD-1/PD-L1 therapy were included [KL: 27%, KP: 36%, K-only: 37%]. Best overall response differed significantly in the KL (PR: 9.1%, SD: 15.9%, PD: 75%) and KP (PR: 33.3%, SD: 20%, PD: 46.7%) sub-groups (P = 0.005, Fisher's exact test). PFS was significantly longer in KP compared to KL LUAC (median 12.9 wks vs 8.4 wks, HR = 0.64, 95% CI 0.39-0.95, P = 0.032, log-rank test). ORR in K-only tumors was 21.3% and median PFS 11.4 wks. PD-L1 positivity (≥1%) was more frequent in KP tumors compared to KL (75% vs 22%, P = 0.03, Fisher's exact test). In syngeneic murine models of *KRAS*-mutant LUAC, loss of LKB1 promoted resistance to PD-1 inhibitor monotherapy, suggesting a causative role. **Conclusions:** Mutational inactivation of *STK11/LKB1* represents a novel genomic predictor of *de novo* resistance to immune checkpoint blockade in *KRAS*-mutant LUAC, whereas *TP53* co-mutations are associated with high likelihood of response. Precision immunotherapy will require tailoring to the co-mutation status of individual tumors.

Osimertinib compared to docetaxel-bevacizumab as third-line treatment in EGFR T790M mutated non-small cell lung cancer. *First Author: Keke Nie, Qingdao Central Hospital, Qingdao University, Qingdao, China*

Background: Osimertinib, an oral irreversible EGFR tyrosine kinase inhibitor, had promising results in patients with EGFR T790M resistance mutation of non-small-cell lung cancer (NSCLC). This study compared efficacy and toxicities of osimertinib versus docetaxel -bevacizumab as third-line treatment in EGFR T790M mutated NSCLC. **Methods:** In this phase 3, open-label, three-center study, we randomly assigned previously treated with TKI-chemotherapy or chemotherapy-TKI recurrent or metastatic advanced non-squamous lung cancer patients who had acquired EGFR T790M resistance mutation confirmed by tumor tissues or serum genetic test. Patients were randomly assigned in a ratio of 1:1 to receive oral osimertinib (80mg/day) or receive intravenous infusion docetaxel (75mg/m2) and bevacizumab (7.5mg/kg) until disease progression or unacceptable toxic effects. Docetaxel -bevacizumab group patients might crossover to osimertinib group after disease progression. The primary end-point of this study was progression-free survival and the secondary end-point were response rates, toxicities and OS. **Results:** A total of 147 patients were treated. Among them, 74 enrolled in the osimertinib group and 73 in the docetaxel-bevacizumab group. The median progression-free survival was 10.20 months and 2.95 months in the osimertinib group and docetaxel -bevacizumab group respectively (Hazard ratio 0.23; 95% confidence interval, 0.12 to 0.38; P < 0.0001). The overall response rate and disease control rate was 61.6% or 87.6% in osimertinib group 8.3% or 43.0% in docetaxel-bevacizumab group respectively. The median overall survival time was not reached. The main grade 3 or 4 toxic effects were diarrhea (2.7%) and interstitial lung disease (1.2%) in the osimertinib group and alopecia (15.1%), anorexia (12.3%), neutropenia (9.6%) and nausea (8.6%) in docetaxel -bevacizumab group. **Conclusions:** Response rate and progression-free survival of osimertinib group were superior to docetaxel-bevacizumab group in third-line treatment of EGFR T790M positive NSCLC. There was no survival difference between patients with EGFR 19 Del-T790M mutation and EGFR L858R-T790M mutation. Clinical trial information: NCT02959749.

Complete clearance of plasma EGFR mutations as a predictor of outcome on osimertinib in the AURA trial. *First Author: Kenneth Stephen Thress, AstraZeneca, Waltham, MA*

Background: Osimertinib, an EGFR T790M-selective tyrosine kinase inhibitor (TKI), provides high and durable response rates in patients (pts) with T790M positive advanced NSCLC whose disease has progressed following EGFR-TKI therapy. We investigated whether changes in the levels of plasma *EGFR*mutations post-osimertinib treatment are associated with clinical outcome. **Methods:** We studied pts from the AURA Phase I study (NCT01802632) with acquired resistance to EGFR-TKIs, T790M positive baseline genotyping (in tumor or plasma), and plasma samples collected at baseline and 6 weeks (wks) post- osimertinib (20–240 mg daily) treatment. Plasma samples were analyzed for the presence of detectable *EGFR* mutations (Ex19del, L858R and T790M) using BEAMing digital PCR (Sysmex/Inostics). In pts with detectable plasma *EGFR* mutations at baseline, clinical outcomes (by investigator, per RECIST 1.1) were compared for pts with or without detectable plasma *EGFR*mutations at 6 wks. **Results:** Evaluable baseline and 6 wk plasma samples were collected from 160 pts with T790M positive genotyping, of whom 143 had detectable *EGFR* mutations at baseline (median allelic fraction for Ex19del: 7.09%; L858R: 3.81%; T790M: 2.12%). In this cohort, the overall median progression-free survival (mPFS) was 9.3 months (m; 95% CI 8.2, 9.7). Clearance of plasma *EGFR*mutations at 6 wks was seen in 92/143 (64%) pts. mPFS was longer in pts with plasma clearance (10.9 m; 95% CI 9.5, 15.2) compared with pts without (5.5 m; 95% CI 3.9, 6.7), as was objective response rate (ORR; 70%; 95% CI 59%, 79% vs. 35%; 95% CI 22%, 50%). **Conclusions:** Clearance of plasma *EGFR* mutations after 6 wks of osimertinib therapy appears to be associated with improved ORR and mPFS in pts with T790M positive NSCLC. Evidence or lack of such a "plasma response" measured at 6 wks could, potentially, be used to predict subsequent outcomes on therapy. Further research is needed to better understand whether continued detection of plasma *EGFR* mutations at 6 wks may indicate the presence of heterogeneous resistance mechanisms, which could, potentially, be targeted by combination therapies. Validation of these results in an independent cohort of pts is ongoing. Clinical trial information: NCT02228369.

9019 Poster Discussion Session; Displayed in Poster Session (Board #345), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

A randomized, controlled, open label phase II study of erlotinib (E) with or without the MET antibody emibetuzumab (Emi) as first-line treatment for *EGFR*mt non-small cell lung cancer (NSCLC) patients who have disease control after an 8-week lead-in treatment with erlotinib. *First Author: Giorgio V. Scagliotti, Department of Oncology - University of Torino, Turin, Italy*

Background: MET expression is a mechanism of resistance to EGFR inhibition in *EGFR*mt NSCLC and correlated with poor prognosis. Emi (LY2875358) is a humanized IgG4 monoclonal bivalent MET antibody that blocks ligand dependent and independent HGF/MET signaling. This Phase 2 study compared the clinical activity of Emi + E versus single agent E in 1st line *EGFR*mt metastatic NSCLC. **Methods:** Stage IV, *EGFR*mt NSCLC pts with disease control following an 8-week lead-in E (150 mg PO QD) treatment were randomized 1:1 to receive Emi (750 mg IV Q2W) + E or E alone. Pts were stratified by ECOG PS, ethnicity, MET expression status, and response at the end of the lead-in. The primary endpoint was PFS from randomization. Additional endpoints included safety, OS, PK, and exploratory analysis of MET-expressing populations. **Results:** Out of181 pts enrolled, 141 pts were randomized (Emi+E: 71; E: 70). In the ITT population, median PFS for EMI+E was 9.3 months (m) compared with 9.5 m for E (HR = 0.89: 90% CI 0.64-1.23; p = 0.534). Exploratory analysis of MET-high expressing pts (MET 3+ expression in ≥90% of tumor cells; n = 24 pts) showed a 15.3 m improvement in PFS (EMI+E: 20.7 m; E: 5.4 m [HR: 0.39; 90% CI: 0.17-0.91]). No difference in PFS was observed in the complementary population (HR: 1.1 [90% CI: 0.7-1.7]). Similar frequencies of related AEs were reported for both treatment arms. Drug-related TEAEs that were more frequent (> 10%) for Emi+E were peripheral edema and fatigue (all grade 1 or 2). Emi serum concentrations were consistent with previously obtained PK results, and no apparent exposure-response was observed. Median OS in the ITT population was not achieved (NA) for either arm. In MET-high expressing pts, median OS was 20.6 m for E (90% CI: 8.87, NA) whereas it was not achieved for Emi+E (90% CI: NA, NA). **Conclusions:** No statistically significant difference in PFS was noted in the ITT population.Exploratory analysis confirmed that high MET expression is a negative prognostic marker for pts treated with E and indicated that these pts may receive clinically meaningful benefit from Emi+E. Clinical trial information: NCT01897480.

MET amplification (amp) as a resistance mechanism to osimertinib. *First Author: Zofia Piotrowska, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Osimertinib (osi) is an EGFR T790M inhibitor. Mechanisms (mech) of acquired resistance (AR) are under study. We report a cohort of osi-AR pts with extensive pre/post-osi tissue and plasma. **Methods:** We analyzed 23 pts with AR to osi. Tumor biopsies (bx) underwent NGS (SNaPshot, MGH) and FISH for EGFR, MET amp (target: CEP7 > 2.2.) Plasma underwent ctDNA NGS (Guardant360). **Results:** Of the 23 osi-treated EGFR-mutants (13 with EGFR del19, 10 L858R), 2 had *de novo* T790M, 21 acquired T790M. 13 had prior 3rd gen EGFR TKIs before osi - rociletinib(11), ASP8273 (1), EGF816(1). Median time on osi was 12 mo (range 2-25), med total time on 3rd-gen EGFR TKIs was 18 mo. Bx types were tissue (16), plasma (18), and both (11, med interval 31d). All pts retained their founder EGFR mutation, but 15/23 (65%) "lost" T790M post-osi, suggesting AR arose from a T790wt subclone (Table). Common AR mech were MET amp (7/23; 30%) and EGFR C797S (5/23; 22%). 1 pt each had SCLC transformation, PIK3CA E545K/PIK3CA amp and FGFR1 D60N/FGFR1 amp. 2 pts had 2 distinct post-osi tissue bx showing heterogeneity. Pt 8 had plasma and a lung nodule with C797S/T790M while a mediastinal LN was wt at both loci. Pt 22 had MET-amp in pleural fluid but no MET amp on lung bx. Plasma identified AR mech not seen in tissue in 2/11 pts with both bx types. Among 7 pts with MET amp, 3 received combo EGFR/ MET TKI; all 3 had a RECIST PR. **Conclusions:** In this osi-resistant cohort, we commonly saw MET amp (30%) and C797S (22%). MET amp seems more common post-osi than after 1st-line TKIs, and 3/3 pts responded to EGFR+MET TKIs. AR heterogeneity was seen in 2 pts with matched tissue/plasma and 2 with >1 tissue bx, underscoring the complementary roles of plasma and tissue.

Pt	Tissue Result (T790M Status)	Plasma Result (T790M)
1	METa (-)	METa (-)

9021 Poster Session (Board #347), Sat, 8:00 AM-11:30 AM

Characteristics and outcomes of patients (pts) with metastatic KRAS mutant lung adenocarcinomas: Lung Cancer Mutation Consortium (LCMC) database. *First Author: Badi Edmond El Osta, Atlanta VA Medical Center; Winship Cancer Institute of Emory Unviersity, Atlanta, GA*

Background: To better understand outcome heterogeneity in pts with KRAS mutant lung cancers, we analyzed the largest multi-institutional database of pts with metastatic KRAS mutant lung adenocarcinomas. **Methods:** We reviewed data of all pts who consented to LCMC between 2009-2015. Pts with known KRAS status were included in analyses. Mutation data along with co-mutations were obtained along with clinical outcomes. We evaluated baseline characteristics and association of KRAS data with overall survival (OS), calculated from date of distant metastasis to death, in a univariate and multivariable analyses. The median follow-up was 2.15 years (95% CI: 2.01-2.27). **Results:** 1655 (86%) of 1918 pts' data were analyzed. Comparative characteristics are summarized in the Table. Among 450 (23%) pts with KRAS mutations: 58% female, 93% ever smokers, and median age 65 years. Main KRAS subtypes: G12C 39%, G12D and G12V were 18% each. Never smokers with KRAS mutation were more likely to have G12D subtypes (18%; $p < 0.001$). Pts with KRAS mutation, the median OS was 1.96 years, with 2-year OS rate of 49%. Co-mutations (1-16) were checked in all KRAS mutant pts. Co-mutations were rare (14 pts; 3%). KRAS co-mutations were associated with improved OS in multivariable analyses (HR 0.35; 95% CI: 0.13-0.97; $p = 0.04$), but not KRAS main subtypes / codons. Co-mutation STK-11 in particular (17 of 92 pts; 18%) was associated with poor OS in univariate (HR 2.16; 95% CI: 1.03-4.54; $p = 0.04$) and multivariable analyses (HR 2.31; 95% CI: 1.18-5.50; $p = 0.02$). Pts with KRAS mutations had a trend towards a shorter survival (median OS 1.96 vs. 2.22 years; $p = 0.08$) and a decreased 2-year OS when compared to KRAS wildtype [49% (95% CI: 44-54%) vs. 55% (95% CI: 52-58%)], respectively. **Conclusions:** KRAS mutation is a significant predictor of worse survival outcomes in pts with metastatic lung adenocarcinomas. The presence of STK-11 co-mutation was associated with especially poor OS.

Characteristics	KRAS mutant N=450	KRAS wild type N=1205	P-value
Age, median	65 years	62 years	< 0.001
White	89%	81%	< 0.001
Ever smoker	93%	64%	< 0.001
Co-mutations	3%	41%	< 0.001

9022 Poster Session (Board #348), Sat, 8:00 AM-11:30 AM

NGS to reveal heterogeneity between cerebrospinal fluid and plasma ctDNA among non-small cell lung cancer patients with leptomeningeal carcinomatosis. *First Author: Ben-Yuan Jiang, Division of Pulmonary Oncology, Cancer Center, Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: In current clinical setting, NSCLC patients harboring specific driver mutation were usually treated guiding by prior profiling of the primary tumor when developed to brain metastasis. Some studies have shown that circulating tumor DNA (ctDNA) derived from cerebrospinal fluid (CSF) can reveal unique genomic alterations present in brain malignancies. We assessed CSF as a liquid biopsy media and compared to matched plasma. **Methods:** We performed capture-based ultra deep sequencing on ctDNA derived from matched CSF, plasma of 40 non-small cell lung cancer (NSCLC) patients with suspected leptomeningeal carcinomatosis (LC) using a panel consisting of 168 genes. **Results:** Among the 40 suspected LC cases, 35 were confirmed to have LC, ctDNA in CSF from the 5 non-LC cases are all undetectable. Circulating tumor DNA was detected in 93.8% of CSF and 66.7% of plasma. We compared mutation profiles and identified 86 and 46 SNVs from CSF and plasma, respectively, with 42 SNVs overlapping. Furthermore, ctDNA from CSF revealed many copy number variations (CNVs) that were not detected from plasma (189 CNVs vs. 3 CNVs). The average maximum allelic fraction (AF) of CSF ctDNA is significantly higher than in plasma (56.7% vs. 4.4% $p < 10\text{^-}6$). Twenty-eight patients were pre-treated with EGFR-TKIs and developed subsequent resistance. *EGFR* T790M and MET amplification were detected in 21% and 39% in CSF, respectively, showing a unique resistance profile among leptomeningeal metastases patients compared to the general population. Interestingly, 60% of CSF samples harbor TP53 loss of heterozygosity, only 11% of which were detected in the matched plasma samples. Such heterogeneity may reflect unique biological themes for brain metastatic tumor sub-clones. Furthermore, 26 patients received molecular targeted therapy based on the results from CSF, and 23 reported alleviation of symptoms at subsequent evaluations. **Conclusions:** Collectively, our data reveal that ctDNA derived from CSF provides a unique and more comprehensive characterization of genomic alterations of leptomeningeal carcinomatosis than plasma, supporting the importance of CSF as a liquid biopsy media.

9023 Poster Session (Board #349), Sat, 8:00 AM-11:30 AM

Rapid/warm autopsy to reveal APOBEC-mutagenesis as driver of heterogeneity of metastatic thoracic tumors. *First Author: Nitin Roper, National Cancer Institute, Bethesda, MD*

Background: Intratumor heterogeneity has been characterized among multiple cancer types. In lung adenocarcinoma, APOBEC-mutagenesis has been shown to be a source of heterogeneity. However, these data are largely limited to early stage primary tumors. There is limited information about the role of APOBEC-mutagenesis and somatic variants, copy number changes, transcript and protein expression in influencing tumor heterogeneity in metastatic lung adenocarcinoma and other thoracic tumors. **Methods:** We applied whole exome sequencing, RNA-seq, OncoScan CNV and mass spectrometry-based proteomic analyses on 46 tumor regions from metastatic sites including lung, liver and kidney, obtained by rapid/warm autopsy from 4 patients (pts) with stage IV lung adenocarcinoma, 1 pt each with pleural mesothelioma and thymic carcinoma. The autopsy procedure was initiated between 2-4 hours of death. **Results:** All tumors displayed organ-specific, branched evolution that was consistent across exome, transcriptome and proteomic analyses. The degree of heterogeneity at the genomic and proteomic level was patient-specific. There was extensive heterogeneity within the tumors of one of four patients with lung adenocarcinoma and in the thymic carcinoma patient (both non-smokers) with multiple driver mutations and copy number changes occurring in only some of the tumors suggesting ongoing late tumor evolution. Further examination of the heterogenous thymic and lung adenocarcinoma tumors showed strong enrichment with the APOBEC-mutagenesis pattern and high associated levels of APOBEC3B mRNA. **Conclusions:** Metastatic lung adenocarcinoma, thymic carcinoma and mesothelioma evolve through a branched, organ-specific process with marked differences in the acquisition of significant driver mutations and copy number changes. APOBEC3B is a potential driver of heterogeneity in pts with advanced, heterogeneous metastatic lung adenocarcinoma and thymic carcinoma and needs to be evaluated further.

9024 Poster Session (Board #350), Sat, 8:00 AM-11:30 AM

Evaluation of stored liquid biopsies for molecular profiling in patients with non-small cell lung cancer (NSCLC). *First Author: Penelope Ann Bradbury, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Molecular profiling is often limited by access to sufficient tumour tissue for comprehensive analysis and due to tumour heterogeneity, the complete range of tumor DNA abnormalities may not be represented nor accurately reflect the clinical evolution of disease. Circulating tumour DNA (ctDNA) can be used as a liquid biopsy for molecular abnormalities detection, quantification and monitoring for personalised treatment strategies. **Methods:** Plasma was collected at baseline (BL) and during study therapy from advanced NSCLC patients (pts) enrolled in a placebo controlled phase III trial of a novel irreversible EGFR inhibitor; all patients had received standard therapy with chemotherapy and gefitinib or erlotinib. Archival tissue was collected when available but biopsy was not required prior to enrolment. BL Plasma ($<$ 3ml), stored for ~8 years was used to extract DNA and analysed using InVision (enhanced tagged-amplicon sequencing). **Results:** BL plasma from 387 pts was tested; 289 pts had available tissue results (from archival tissue collected at diagnosis) for *EGFR* (174WT/115Mut) and 243 for *KRAS* (205WT/38Mut). Despite age of plasma samples, ctDNA analysis detected cancer mutations in 310 pts (82%): *TP53 (45%), KRAS (15%)*, and *EGFR* (43%; 56% were *EGFR* del19 and 29% L858R); T790M was detected in 80 patients. *EGFR* mutations were identified in 29 patients and *KRAS* in 10 patients with unknown tissue status. Also of note, STK11 (32 pts, 12 with *KRAS*), *BRAF* (5pts, 3 with V600E), *MET*(7 pts, 4 with MET_{amp}), *ERBB2* (16pts, 10 with $ERBB2_{amp}$) were identified in ctDNA analysis. Median time and median number of lines of systemic therapy between tissue biopsy and blood was 714 days and 3 lines respectively. Further analyses of ctDNA analyses in context of patient and trial outcomes are in progress. **Conclusions:** Liquid biopsies provide opportunity to evaluate molecular mutation profile in NSCLC patients. We demonstrate a highly sensitive method for ctDNA analysis which is complementary to tissue molecular analysis.

9025 Poster Session (Board #351), Sat, 8:00 AM-11:30 AM

Genomic profiling of circulating tumor DNA (ctDNA) from patients (pts) with advanced non-small cell lung cancer (NSCLC). *First Author: Ibiayi Dagogo-Jack, Dana-Farber Cancer Institute, Boston, MA*

Background: Tissue biopsy is the gold standard for detection of genomic alterations (GA) and selection of matched targeted therapies in NSCLC, but ctDNA assay provides a possible complementary approach for some pts. **Methods:** Hybrid-capture based genomic profiling of 62 genes using a ctDNA assay (FoundationACT™) was performed on blood samples from 1,019 consecutive NSCLC pts. The fraction of ctDNA in the blood was estimated using the maximum somatic allele frequency (MSAF) for each sample. **Results:** Pt characteristics: Median age 69 years (range 8-94); 54% were female. Histologies included adenocarcinoma (n = 720), NSCLC not otherwise specified (NSCLC NOS; n = 179), squamous cell (n = 57), LC NOS (n = 51), large cell (n = 6), and sarcomatoid (n = 6). $\geq$1 reportable GA was detected in 71% of all cases and in 83% of cases with evidence of ctDNA in the blood (MSAF $>$ 0). For 22 pts with paired blood and tissue samples collected within 30 days and MSAF $>$ 0, 33/64 (52%) GA detected in tissue were also detected in ctDNA. In 55 pts for whom tissue was insufficient for analysis, $\geq$1 GA was detected in ctDNA in 43 (78%) cases. For 856 cases with MSAF $>$ 0, an average of 1.8 GA/sample were reported. GA were most frequently detected in *TP53* (57%), *EGFR* (23%) and *KRAS* (17%). Comparative analysis with the tissue-based FoundationCORE™ database (n = 19,264) showed similar frequencies of GA per gene, although *KRAS* mutation was more frequent in tissue than ctDNA (27% vs 17%, P $<$ 0.0001), and EGFR T790M was more frequent in ctDNA than tissue (7% vs 2%, P $<$ 0.0001), likely reflecting use of liquid versus tissue biopsy after relapse on targeted therapy.Kinase fusions (*ALK*, *ROS1*, *RET*, *FGFR3*, *PDGFRA*) were identified in 5% (39/856) of cases. Diverse and novel mechanisms of acquired resistance (AR) were detected in ctDNA including MET Y1230C and *EGFR* amplification post-crizotinib, *FGFR3-TACC3* fusion post-EGFR inhibitor, and multiple *EGFR*AR mutations post-osimertinib. **Conclusions:** In this series, use of a rigorously validated capture-based assay revealed evidence of ctDNA in the blood in 84% of cases. Our results provide clinical support for use of this assay as a complementary technology to tissue-based genomic testing in a subset of pts with NSCLC.

9027 Poster Session (Board #353), Sat, 8:00 AM-11:30 AM

Predictive impact of complete molecular response in plasma: A phase II, liquid biopsy study in *EGFR* mutated NSCLC patients treated with afatinib (WJOG 8114LTR). *First Author: Kohei Otsubo, Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan*

Background: Liquid biopsy has been approved as an alternative method to detect clinically relevant *EGFR* mutations in NSCLC. However, it is unknown whether the early assessment of molecular response in plasma could be a surrogate of clinical response and/or longer efficacy. Here, we conducted a prospective, multi-institutional study of liquid biopsy in *EGFR*mutated NSCLC patients (WJOG 8114LTR). **Methods:** Chemotherapy naïve, advanced NSCLC patients with EGFR-sensitizing mutation received afatinib monotherapy (40 mg/body) until progressive disease (PD) or unacceptable toxicity. Plasma DNA was obtained from patients at baseline, weeks 2, 4, 8, 12, 24, 48, and at PD. Three types of clinically relevant *EGFR*mutations (exon 19 deletion, exon 20 T790M and exon 21 L858R) will be analyzed using plasma DNA with multiplexed, pico-droplet digital PCR assay (RainDrop system, RainDance Technologies, Billerica, MA). Complete molecular response (CMR) was defined as mutant allele event/frequency of exon 19 deletion or exon 21 L858R below the cutoff for the positivity by digital PCR in plasma. This study was registered at UMIN (ID: 000015847). **Results:** Fifty-seven patients were registered in the study. Efficacy of afatinib was comparable to previous reports (overall response rate: 78.6%, and median progression-free survival (mPFS): 14.2 months). At baseline, 62.5% of patients were positive for *EGFR* mutation in plasma. Plasma positive patients had slightly shorter PFS than plasma negative patients, but not significant (p = 0.24, log-rank). Among those who were positive at baseline, CMR was achieved in 60.6% of patients at two weeks, and 87.5% at four weeks, respectively. Patients with CMR at two weeks had significantly longer PFS than those without one (13.6 versus 7.5 months, $p = 0.0001$). Patients with CMR at four weeks also demonstrated longer PFS than those without one (13.6 versus 5.1 months, $p < 0.0001$). Among patients who achieved CMR by week four, time to achieve CMR did not affect PFS (p= 0.59). **Conclusions:** This is the first report on the predictive impact of early CMR in plasma for longer therapeutic efficacy of afatinib in *EGFR* mutated NSCLC patients. Clinical trial information: 000015847.

9028 Poster Session (Board #354), Sat, 8:00 AM-11:30 AM

The predictive value of uncommon *EGFR* mutation in patients with non-small-cell lung cancer. *First Author: Haiyan Tu, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Non-small-cell lung cancers with uncommon epidermal growth factor receptor (*EGFR*) mutations are regarded as a heterogeneous group with variable responses to EGFR-targeted drugs. Here we designed this retrospective study to describe the epidemiology and clinical outcomes of uncommon *EGFR* mutations in a Chinese cohort of lung cancer patients. **Methods:** Between June 2007 and June 2014, 5363 lung cancer patients whose *EGFR* genotyping was performed successfully at Guangdong Lung Cancer Institute (GLCI, Guangzhou, China) were screened. 1837 patients were included in the epidemiological analysis. The clinical outcome was analyzed in 97 advanced-stage patients harboring uncommon *EGFR* mutations with follow-up data. **Results:** 218 patients harbored uncommon *EGFR* mutations, making up 11.9% of all cancers with documented *EGFR* mutations. Compared with common mutants, those with uncommon mutations were more commonly found in smokers and male patients. The most frequently detected uncommon mutations were exon 20 insertions, G719X mutations and L858R complex mutations, occurring in 30.7%, 21.1% and 17.0% of all *EGFR*-uncommon-mutation cases. G719X and L858R complex mutations were associated with similar benefit from EGFR-TKI; median PFS was 15.2 (95% CI 8.7-21.7) and 11.6 (95% CI 3.6-19.6) months, respectively. T790M or 20INS was associated with a poorer EGFR-TKI response; median PFS was 1.0 (95% CI 0.0-2.2) and 3.0 (95% CI 1.3-4.7) months, respectively. Of note, two patients with 23% and 65% tumor shrinkages had N771_P772insN and H773_V774insQ, with PFS of 5.7 and 6.1 months respectively. **Conclusions:** Favorable responses were observed in specific subtypes including complex L858R and G719X, and our results suggested first-line EGFR-TKI should be preferable in such patients.

9029 Poster Session (Board #355), Sat, 8:00 AM-11:30 AM

Lung cancers with mutations in *EGFR* exon 18: Molecular characterization and clinical outcomes in response to tyrosine kinase inhibitors. *First Author: Wei-Chu Victoria Lai, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Little data is available to guide clinical management of individuals with less common oncogenic drivers such as exon 18 mutations (ex18m) in *EGFR*. To better understand the impact of these rare mutations on treatment outcomes, we reviewed clinicopathologic data in patients (pts) with ex18m treated with tyrosine kinase inhibitors (TKI) in *EGFR*-mutant lung cancers. **Methods:** Pts with *EGFR* ex18m were detected via molecular diagnostics using Sequenom™, FoundationOne™ or MSK IMPACT™ NGS testing from 2003-2016. We reviewed their clinical data for molecular alterations in *EGFR*, treatment outcomes in response to TKI (time on treatment) and median overall survival (OS). **Results:** We identified mutations in *EGFR* ex18m in 63 pts. Median age at diagnosis was 68; 63% were women; 29% never smokers. Overall, 74 ex18m were found in 63 pts, including: G719A = 38, G719S = 11, G719C = 8, E709K = 6, E709_T710delinsD = 6, E709A = 3, G719D = 2. E709 and G719 co-mutations in ex18 were found in 9 pts, and 1 pt was found to have 3 separate tumors, each with a distinct ex18m. 29/63 (46%) patients with ex18m had a co-occurring *EGFR* mutation: 9 with another ex18m; 20 with ex19-21m. Using our IMPACT NGS, the median number of co-mutations was 8 (range 1-17). Two out of 63 pts had a pre-treatment T790M mutation. The 25 pts with non-metastatic disease presented in the following stages: IA = 19; IB = 3; IIB = 1; IIIA = 2; IIIB = 2. 34/38 pts with metastatic disease were treated with the following first-line EGFR-TKIs: erlotinib = 28, afatinib = 5, osimertinib = 1. Median duration on TKI treatment in months was: erlotinib = 10 mo, (range 1-25), afatinib = 3 mo (range 2-9), osimertinib = 4 mo. Median OS from the date of diagnosis of metastatic disease was 22 months (95% CI 18-29). In comparison, a similar cohort of pts with sensitizing *EGFR* exon19del/L858R mutations had a median OS of 31 months (95% CI 28-33) (Naidoo *Cancer*2015). **Conclusions:** Almost half of ex18m occur concurrently with another *EGFR* mutation. Overall, ex18m pts have a shorter median OS when compared to similar patient cohorts. EGFR-TKIs appear to be an effective treatment for pts with ex18m in *EGFR*-mutant lung cancers.

9030 Poster Session (Board #356), Sat, 8:00 AM-11:30 AM

Antitumor activity of osimertinib in NSCLC harboring EGFR exon 20 insertions. *First Author: Jonathan Riess, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: EGFR exon 20 insertions (Ex20Ins), the 3rd most common EGFR activating mutation, are generally unresponsive to 1st and 2nd generation EGFR-TKIs. Development of EGFR-TKIs that effectively target NSCLC with Ex20Ins mutations represents a major unmet need. Osimertinib is an EGFR TKI approved for the treatment of advanced NSCLC harboring EGFR T790M, but the potential of osimertinib remains to be fully assessed in patients (pts) with Ex20Ins NSCLC. **Methods:** CRISPR engineered Ex20Ins cell line xenografts representing the two most common Ex20Ins (D770_N771InsSVD and V769_D770InsASV) and pt derived xenograft (PDX) of 3 EGFR Ex20Ins (V769_D770InsASV, M766_A767insASV, H773_V774insNPH) were used for in vivo experiments. Xenografts were treated by oral gavage with vehicle, erlotinib (50 mg/kg/day) or afatinib (20 mg/kg/day), osimertinib metabolite AZ5104 (50 mg/kg/day) and osimertinib (25 mg/kg/day) and assessed for tumor growth inhibition (TGI). Immunoblotting was performed for EGFR and relevant signaling pathways. A pt from whom the V769_D770InsASV Ex20ins PDX was derived was treated on a UC Davis IRB approved protocol with osimertinib at 160 mg PO once-daily (QD). **Results:** At completion of treatment, QD administration of osimertinib or AZ5104 induced significant TGI in xenografts across the 4 EGFR Ex20ins tested (range 60-95% TGI, $p < 0.001$ compared to control for all models) that was superior to either afatinib or erlotinib. Robust decrease in p-EGFR, p-ERK, p-Akt, p-Stat3 was observed with osimertinib treatment. The patient corresponding to the V769_D770InsASV Ex20ins PDX treated with osimertinib exhibited clinical improvement and tumor shrinkage; unfortunately he was found to have interstitial pneumonitis that necessitated drug discontinuation. **Conclusions:** Osimertinib at clinically representative doses has *in vivo* activity across multiple EGFR Ex20ins that comprising the most common Ex20ins detected in patients (~50% prevalence); metabolite AZ5104 may contribute to efficacy. Tumor shrinkage was observed in a patient with lung cancer harboring an Ex20ins treated for a limited time with osimertinib. Based on this in vivo xenograft and pt data, osimertinib warrants further study in pts with EGFR Ex20ins NSCLC.

9031 Poster Session (Board #357), Sat, 8:00 AM-11:30 AM

Clinical implications of the T790M mutation in disease characteristics and treatment response in patients with EGFR-mutated NSCLC. *First Author: Daria Gaut, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: The secondary T790M mutation accounts for more than 50% of acquired tyrosine kinase inhibitor (TKI) resistance in epidermal growth factor receptor (EGFR)-mutant NSCLC patients. Recent reports suggest this resistance mutation may be more common among patients with longer progression-free survival (PFS) on first-line TKI therapy, but much is still unknown about this resistance mechanism's association with response to other therapies. **Methods:** Our group collected medical records from patients who underwent a biopsy for T790M mutation testing in the process of screening for clinical trials involving third generation EGFR inhibitors. Medical records were retrospectively analyzed for demographic data, PFS, best response (BR) to previous therapies, and presence or absence of an acquired T790M mutation. Progression-free survival was estimated using the Kaplan-Meier method and compared across two groups using the log-ranked test followed by univariate and multivariate cox proportional hazard regression analysis. Response rates were compared using Fisher's exact test. **Results:** Out of 102 patients who obtained a diagnostic biopsy, 73 patients had a T790M mutation. Patients who later developed a T790M mutation had a longer PFS on first-line TKI therapy (12.0 months in T790M+ vs. 8.0 months in T790M-, p = 0.038, HR 1.66, 95% CI 1.03-2.67), though there was no difference in response rate (75.5% in T790M+ vs 77.3% in T790M-, p = 1.00). T790M+ patients also had a longer PFS on initial chemotherapy treatment (5.0 months in T790M+ vs. 4.0 months in T790M-, p = 0.020, HR 1.97, 95% CI 1.11-3.49) and a higher response rate to chemotherapy (22.7% in T790M+ vs 0% in T790M-, p = 0.033). Median PFS was short (3.0 months) for patients treated with immunotherapy with no difference based on T790M mutation status (p = 0.33). **Conclusions:** Our study confirms that tumors expressing T790M have a more indolent progression of disease compared to their T790M negative counterparts when treated with both first-line TKI and cytotoxic chemotherapy. This data provides context for therapeutic decision making in EGFR-mutant NSCLC patients.

9032 Poster Session (Board #358), Sat, 8:00 AM-11:30 AM

The novel detection of EGFR-T790M mutations in exhaled breath condensate. *First Author: Robert Smyth, Department of Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: The EGFR-T790M somatic mutation is the most common mechanism of resistance to Tyrosine Kinase Inhibitors (TKI) in NSCLC. However patients with advanced disease are not always amenable to repeat biopsy for further molecular analysis. Developing non-invasive methods to detect T790M in cell-free DNA (cfDNA), in the absence of tissue is being actively investigated. Furthermore these 'liquid biopsies' may also overcome the problem of tumour genomic heterogeneity. Unfortunately the sensitivity of plasma for T790M detection has been disappointing with a significant chance of a false negative result. Exhaled breath condensate (EBC) is an easily collected sample and is known to harbour cfDNA, including lung cancer mutations. We explored the potential of EBC as a novel method of T790M detection. **Methods:** We recruited 26 patients who were either 1) known T790M positive pre/during Osimertinib therapy or 2) other mEGFR positive patients on 1st/2nd generation TKI. We collected matched plasma and EBC samples in the majority of cases. EBC samples were collected using the RTube device. Plasma was collected using standard EDTA tubes and extracted within 90 minutes. Using UltraSEEK chemistry, a targeted PCR for ultra-sensitive somatic mutation profiling on the MassARRAY system (Agena Bioscience), we compared the performance of EBC to plasma for the detection of T790M. **Results:** See Table. **Conclusions:** In this pilot study we describe the first ever report of the successful and consistent detection of T790M in the EBC of patients with EGFR mutated NSCLC, using a commercially available targeted assay. Our results suggest EBC is responsive to recognised dynamic molecular changes that occur on TKI treatment. We believe this makes EBC analysis an attractive avenue for future research, to optimise the detection of T790M mutations in liquid biopsies.

Status	EBC	Plasma	p value
T790M+ pre- osimertinib	4/4 (100%)	2/4 (50%)	0.43
T790M+ on osimertinib	1/8 (12.5%)	1/7 (14%)	1.0
mEGFR (non-T790M)	3/17 (18%)	2/15 (13%)	1.0

9033 Poster Session (Board #359), Sat, 8:00 AM-11:30 AM

A phase 1 study of osimertinib and bevacizumab as initial treatment for patients with EGFR-mutant lung cancers. *First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: EGFR tyrosine kinase inhibitors (TKI) are the recommended first line treatment for EGFR-mutant lung cancers. Osimertinib, an EGFR TKI that inhibits both sensitizing EGFR mutations and EGFR T790M, is approved for use after progression on an EGFR TKI with evidence of EGFR T790M, and is currently being assessed as initial treatment for EGFR-mutant lung cancers. The addition of bevacizumab to erlotinib resulted in improved progression free survival (PFS) compared to erlotinib alone as initial treatment (16 vs 10 months, HR 0.41). This phase 1/2 study is assessing osimertinib and bevacizumab as initial treatment for patients with EGFR-mutant lung cancers. **Methods:** We evaluated toxicity and efficacy of osimertinib and bevacizumab as initial treatment for patients with advanced EGFR-mutant lung cancers. Using a 3+3 design, full doses of osimertinib (80mg PO daily) and bevacizumab (15mg/kg IV q3 weeks) were given, with a planned dose de-escalation (osimertinib 40mg PO daily) should grade 3 or greater toxicity be seen. Six patients must be treated without a dose-limiting toxicity (DLT) to determine the MTD. 43 additional patients will be treated at the MTD in the phase 2 study, with a primary endpoint of PFS at 12 months. Response was evaluated by RECIST 1.1. **Results:** From Sept 2016 to Jan 2017, 15 patients were enrolled. Median age: 63; Women 11; EGFR L858R = 8, Ex19del = 6, G709A/G719S = 1. After median duration of treatment of 2.7 months, no DLTs were seen in any patient. The MTD was determined to be osimertinib 80mg, bevacizumab 15mg/kg q3 weeks. In total, 15 patients are being treated at the MTD to date. Treatment-related adverse events (AE) were all grade 1-2, except for grade 3 hypertension. The most frequent treatment-related AEs (any grade) were rash (53%), diarrhea (40%), hypertension (33%), fatigue (20%), and itching (20%). All 15 patients continue on study. **Conclusions:** Combination osimertinib and bevacizumab is a tolerable first-line treatment for patients with EGFR-mutant lung cancers and the MTD is osimertinib 80mg and bevacizumab 15mg/kg q3 weeks. Assessment of efficacy with an endpoint of PFS at 12 months is ongoing. Supported by AstraZeneca (NCT02803203). Clinical trial information: NCT02803203.

9034 Poster Session (Board #360), Sat, 8:00 AM-11:30 AM

Afatinib (Afa) plus bevacizumab (Bev) combination after acquired resistance (AR) to EGFR-tyrosine kinase inhibitors (TKIs) in *EGFR*-mutant non-small cell lung cancer (NSCLC): Multicenter single arm phase II trial (ABC-study). *First Author: Akito Hata, Division of Integrated Oncology, Institute of Biomedical Research and Innovation, Kobe, Japan*

Background: Irreversible EGFR-TKI monotherapies showed only moderate efficacy after AR to reversible EGFR-TKIs. Preclinical studies suggested that addition of Bev to EGFR-TKIs could overcome AR, and Bev demonstrated synergistic effects with Afa in TKI-resistant xenograft models. **Methods:** ECOG PS 0-2 patients (pts) with *EGFR*-mutant NSCLC after AR to EGFR-TKIs were enrolled at any lines. Rebiopsy was essential to confirm T790M status after AR. Afa was prescribed at 30 mg, and Bev administered at 15 mg/kg tri-weekly until progression. **Results:** Between October 2014 and September 2016, 33 eligible pts were enrolled. Median age was 66 (range, 48-86). Twenty-one (64%) pts were female, and 22 (67%) were never smoker. Mutation subtypes were 20 (61%) Del-19, 12 (36%) L858R, and 1 (3%) L861Q. T790M was detected in 14 (42%) pts. Median number of prior regimens was 4 (range, 1-10). First prior TKIs were 20 (61%) gefitinib, 10 (30%) erlotinib or 3 (9%) Afa. Six pts obtained partial response and 23 stable disease, resulting in response rate (RR) of 18.2% (95% confidence interval [CI], 7.0-35.5%) and disease control rated of 87.9% (95% CI, 71.8-96.6%). Median progression-free survival (PFS) and overall survival were 5.9 (95% CI, 3.5-8.8) months and not reached, respectively. Median RR and PFS of T790M+ vs. T790M- were 14.3% vs. 21.2% ($p = 0.6189$) and 6.2 vs. 5.2 months ($p = 0.8619$), respectively. Median RR and PFS of Del-19 vs. L858R were 20.0% vs. 8.3% ($p = 0.3789$) and 5.9 vs. 5.1 months ($p = 0.8996$), respectively. Afa dosage was reduced to 20 mg in 15 (45%) pts and increased to 40 mg in 2 (6%) pts. Median number of Bev administrations was 6 (range, 1-14). Bev was interrupted in 5 (15%) pts. Adverse events ≥grade 3: rash (3%); paronychia (24%); mucositis (6%); diarrhea (3%); liver dysfunction (3%); hypertension (39%); and proteinuria (15%) were observed. There were no treatment-related deaths, interstitial lung disease, nor Bev-associated severe bleedings. **Conclusions:** Afa + Bev demonstrated the efficacy and safety after AR to EGFR-TKIs. It could be a therapeutic salvage option for T790M- populations. Clinical trial information: UMIN000014710.

9035 Poster Session (Board #361), Sat, 8:00 AM-11:30 AM

Gefitinib as third-line re-challenge treatment in advanced NSCLC patients with *EGFR* activating mutation who benefited from first-line gefitinib treatment followed by second-line chemotherapy. *First Author: Yong Song, Nanjing General Hospital of Nanjing Military Command, Nanjing, China*

Background: Several studies show that *EGFR*-mutant NSCLC patients (pts) gained response to EGFR-TKI treatment again after a TKI free interval. To date, no prospective evaluation of the clinical effects of EGFR-TKI re-challenge in *EGFR*-mutant NSCLC pts has been performed. **Methods:** This was a multicenter, open-label, single-arm, phase II study (CTONG1304, NCT01933347). Stage IIIB/IV NSCLC pts with *EGFR* exon 19del/L858R mutation, who previously benefited from first-line gefitinib treatment followed by second-line chemotherapy, took gefitinib 250mg/d until disease progression or death or intolerable toxicity occurred. Blood samples were dynamically collected for *EGFR*mutation testing using droplet digital PCR at every visit (from baseline to the end of gefitinib treatment). The primary objective was disease control rate (DCR) at week 8. Secondary objectives were objective response rate (ORR), progression free survival (PFS), and overall survival (OS). **Results:** From March 2014 to May 2016, 45 eligible pts were enrolled and 43 pts were included in the full analysis set (FAS) for efficacy analysis. Gefitinib re-challenge achieved DCR of 69.8%. ORR was 4.7%. Median PFS and OS were 4.4 and 8.0 months (m) respectively. T790M- subgroup at baseline had higher DCR, longer mPFS and mOS, compared with T790M+ subgroup. *EGFR*status changed significantly after gefitinib re-challenge. **Conclusions:** Gefitinib re-challenge was an effective option in *EGFR*-mutant NSCLC pts. T790M negativity is a potentially predictive efficacy biomarker for gefitinib re-challenge. Clinical trial information: NCT01933347.

Efficacy and EGFR testing data for Iressa re-challenge (*p value for T790M+ vs. T790M-).

	Efficacy			
	FAS (n = 43)	T790M+ subgroup (n = 11)	T790M - subgroup (n = 32)	*p* value*
DCR	30/43 (69.8%)	5/11 (45.5%)	25/32 (78.1%)	p = 0.0418
ORR	2/43 (4.7%)	0	2/32(6.3%)	p = 1.0
mPFS (m)	4.4	1.9	4.7	p = 0.0006

9036 Poster Session (Board #362), Sat, 8:00 AM-11:30 AM

ASTRIS: A real world treatment study of osimertinib in patients (pts) with EGFR T790M positive non-small cell lung cancer (NSCLC). *First Author: Filippo De Marinis, European Institute of Oncology, Milan, Italy*

Background: Osimertinib is an oral, irreversible, central nervous system (CNS) active EGFR tyrosine kinase inhibitor (TKI) selective for both EGFR-TKI sensitizing and T790M resistance mutations. We report results from the first predefined interim analysis of the ongoing ASTRIS study (NCT02474355). **Methods:** Pts received osimertinib 80 mg once daily. Eligible pts had Stage IIIB-IV NSCLC harbouring a T790M mutation determined by local validated molecular test (not restricted by sample type), received prior EGFR-TKI therapy, WHO performance status (PS) 0−2, acceptable organ and bone marrow function and no history of interstitial lung disease (ILD) or QTc prolongation. Asymptomatic, stable CNS metastases were permitted. The primary efficacy outcome was overall survival; other outcomes included investigator-assessed response rate (RR), progression-free survival and time to treatment discontinuation. Safety data are also reported. **Results:** From study start (18 Sept 2015) to data cut-off (DCO; 3 Nov 2016), 1217 pts received osimertinib from 120 sites with a median follow-up of 4.1 mths (< 1−14 mths), median age 64 yrs (27–92 yrs), 67% female, 61% White, 37% Asian, 87% WHO PS 0/1, 44% prior chemotherapy, 45% prior radiotherapy. All pts tested positive for T790M, identified from tissue in 682 pts (56%), plasma ctDNA in 433 pts (36%) and from other specimens in 102 pts (8%). At DCO, 317 pts (26%) had discontinued treatment, 900 pts (74%) were ongoing, median duration of exposure 3.8 mths (< 1–13.2 mths), 168 pts (14%) had disease progression and 156 pts (13%) had died. In pts evaluable for response, the investigator-assessed RR was 64% (569/886; 95% CI 61, 67). Adverse events (AEs) leading to dose modification and treatment discontinuation were reported in 122 (10%) and 54 pts (4%), respectively. Serious AEs were reported in 165 pts (14%) and AEs leading to death in 30 pts (2%). ILD/pneumonitis-like events were reported in 25 pts (2%), and QTc prolongation in 9 pts (1%). **Conclusions:** ASTRIS, the largest reported clinical study of osimertinib in T790M-positive NSCLC, demonstrates clinical activity similar to that observed in the osimertinib clinical trial program with no new safety signals. Clinical trial information: NCT02474355.

9037 Poster Session (Board #363), Sat, 8:00 AM-11:30 AM

Tolerability and antitumor activity of ASP8273 in TKI-naive Japanese subjects with EGFR mutation–positive non-small cell lung cancer. *First Author: Shunichi Sugawara, Department of Pulmonary Medicine, Sendai Kousei Hospital, Sendai, Japan*

Background: EGFR-activating mutations (eg, exon 19 deletions [ex19del], L858R) occur in ~50% of East Asian patients with non-small cell lung cancer (NSCLC) and confer sensitivity to tyrosine kinase inhibitor (TKI) treatment. ASP8273, an orally administered EGFR TKI that inhibits EGFR-activating mutations, has demonstrated clinical activity in subjects with EGFR mutation-positive ($EGFR^{mut+}$) NSCLC. **Methods:** EGFR TKI-naïve adult subjects (≥20 yr) with $EGFR^{mut+}$ NSCLC were enrolled in this single arm Phase 2 study conducted in Japan (NCT02500927). Subjects received open-label ASP8273 300 mg once daily until discontinuation criteria were met. Primary endpoint was tolerability; secondary endpoint was antitumor activity defined by RECIST v1.1. **Results:** A total of 31 Japanese subjects (12 M/19 F; median age 64 years [range: 31–82]) were enrolled. Based on local testing, 27 subjects had an ex19del (n = 13, 42%) or a L858R (n = 14, 45%) EGFR activating mutation; 4 subjects (13%) had other EGFR activating mutations (L861Q [n = 2], G719X [n = 2]). ASP8273 300 mg had tolerable adverse events with diarrhea and peripheral neuropathy being most common; no interstitial lung disease events were reported (Table). Across all 31 subjects, based on investigator assessment, treatment with 300 mg ASP8273 was associated with an overall response rate (ORR) of 52%, disease control rate (DCR) of 94%, and a median duration of progression-free survival (PFS) of 11.3 months (95% CI: 7.2, 15.5). In subjects with ex19del, ASP8273 300 mg was associated with an ORR of 46% and DCR of 85%; median PFS was 8.3 months (95% CI: 2.9, -). In subjects with the L858R, ASP8273 300 mg was associated with an ORR of 57% and DCR of 100%; median PFS was 15.5 months (95% CI: 7.2, 15.5). **Conclusions:** Once-daily ASP8273 300 mg was tolerable in TKI-naïve Japanese subjects with $EGFR^{mut+}$ NSCLC and demonstrated antitumor activity. Clinical trial information: NCT02500927.

9038 Poster Session (Board #364), Sat, 8:00 AM-11:30 AM

Updated survival outcomes of NEJ005/TCOG0902, a randomized phase II study of concurrent (C) versus sequential alternating (S) gefitinib and chemotherapy in previously untreated non-small cell lung cancer (NSCLC) with sensitive epidermal growth factor receptor (*EGFR*) mutations. *First Author: Satoshi Oizumi, Department of Respiratory Medicine, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan*

Background: North East Japan Study Group (NEJ) 005/ Tokyo Cooperative Oncology Group (TCOG) 0902 study has demonstrated that first-line concurrent (C) and sequential alternating (S) combination therapies of EGFRtyrosine kinase inhibitor (gefitinib) plus platinum-based doublet chemotherapy (carboplatin/pemetrexed) offer promising efficacy with predictable toxicities for patients with *EGFR*-mutant NSCLC (ASCO2014, Ann Oncol 2015). However, overall survival (OS) data were insufficient because of the lack of death events in the primary report. **Methods:** Progression-free survival (PFS) and OS were re-evaluated at the final data cutoff point (November 2016) for the entire population (N = 80). **Results:** At the median follow-up time of 35.6 months, 88.8% of patients had progressive disease and 72.5% of patients had died. Median PFS was 17.5 months for the C regimen and 15.3 months for the S regimen (p = 0.13). Median OS time was 43.3 with the C regimen and 30.7 months with the S regimen (p = 0.018). Updated response rates were similar in both groups (90.2% and 82.1%, respectively; p = 0.34). Patients who had common mutations showed no significant differences in PFS according to type of mutation. Patients with Del19 displayed relatively better OS (median: 45.3 and 33.3 months for C and S regimens) than those with L858R (31.4 and 28.9 months). No severe adverse events including interstitial lung disease have occurred during the follow-up period since the primary report. **Conclusions:** This updated analysis has confirmed that PFS is improved with first-line combination therapies compared to that with gefitinib monotherapy, and the C regimen in particular offers an overall survival benefit of 43 months in the *EGFR*-mutated setting. Our on-going NEJ009 study will clarify whether this combinational strategy can be incorporated into routine clinical practice. Clinical trial information: UMIN000002789.

9039 Poster Session (Board #365), Sat, 8:00 AM-11:30 AM

Pulse-continuous dose erlotinib as initial targeted therapy for patients with *EGFR*-mutant lung cancers with untreated brain metastases. *First Author: Mark G. Kris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clarke (Neurooncol 2010) reported responses with intermittent high pulse doses of erlotinib (leading to higher concentrations in CSF) given to patients with *EGFR*-mutant central nervous system metastases developing on standard erlotinib doses. In a phase 1 study of pulse-continuous dose erlotinib, no patient developed progression in existing or new brain or leptomeningeal metastases (Yu Ann Oncol 2016). This phase 2 trial tested pulse-continuous dose erlotinib in patients with lung cancers with *EGFR*-mutations with brain metastases. **Methods:** Patients had no prior EGFR TKI or radiation to the brain and at least 1 target brain metastasis. All received initial daily "pulse" doses of erlotinib 1200 mg days 1&2 and "continuous" 50 mg doses days 3-7 (doses and schedule from the Yu Phase 1 study), weekly until progression. The co-primary endpoints were overall and brain metastasis response by RECIST 1.1. **Results:** We enrolled 19 patients with *EGFR*-mutant lung cancers: median age 61yrs (range 45-80), 74% women, 95% Karnofsky PS ≥80%, 1 leptomeningeal disease, 33% prior pemetrexed-based chemotherapy. The median size of target brain metastases was 13 mm (range 10-19 mm). 32% were on dexamethasone for cerebral edema. The partial response rate overall was 74% (95% CI 51-89%) and also 74% in brain metastases. Of 10 patients with progression, 9/10 occurred in non-brain sites (4 *EGFR*T790M, 1 with progression in brain as well), 1 with leptomeningeal. The median progression free survival was 10 mo (range 7-NR mo). Pulse doses were reduced in 68% (median delivered pulse dose 1050 mg days 1&2, range 600-1200 mg). Incidences of *any grade*of rash and diarrhea were 84% and 63% respectively. There were no grade 4 or 5 toxicities. **Conclusions:** Pulse-continuous dose erlotinib alone controlled brain and leptomeningeal metastases in 89% (95% CI 67-98%) of patients with *EGFR*-mutant lung cancers with central nervous system spread pretreatment, with an overall response rate of 74% and progression free survival and rates of rash and diarrhea comparable to series with erlotinib 150 mg daily. Supported by Astellas, CA 129243, CA 008748. NCT01967095 Clinical trial information: NCT01967095.

9040 Poster Session (Board #366), Sat, 8:00 AM-11:30 AM

EGFR analysis of 21,039 patients with NSCLC: Age-related gradual increase of the L858R mutation frequency in adenocarcinomas and high occurrence of ex19del/L858R mutations in squamous cell carcinomas from females and/or nonsmokers. *First Author: Evgenii Imianitov, N. N. Petrov Research Institute of Oncology, St. Petersburg, Russia*

Background: EGFR testing in Russia is carried out upon the patronage of Russian Society of Clinical Oncology (RUSSCO), and the results are accumulated in a centralized database. Squamous cell carcinomas (SCC) constitute 60-70% of NSCLC incidence in Russia, however physicians are often discouraged to send NSCLC-SCC for EGFR testing due to low frequency of mutations. **Methods:** We considered all NSCLC patients analyzed by means of PCR for the presence of EGFR mutations (ex19del and L858R) within years 2012-2017. **Results:** 21,039 NSCLC patients were tested. EGFR analysis was successful in 20,768 patients (98.7%). EGFR mutations were detected in 3566/17717 (20.1%) adenocarcinomas (AdCa) of the lung (ex19del: 2203 (12.4%); L858R: 1363 (7.7%)). There was an evident age-related increase in the frequency of L858R substitution in AdCa patients (p =0.000, Table). This set of patients included 1,139 NSCLC-SCC cases, and the EGFR mutation was observed in 41 (3.6%) subjects. Among 189 females with NSCLC-SCC, ex19del or L858R were detected in 25 (13.2%) cases. Stratification by smoking status revealed EGFR mutation in 19/242 (7.9%) non-smokers. **Conclusions:** Elderly NSCLC patients have particularly increased probability to be diagnosed with L858R mutation. In the real-world setting, patients with NSCLC-SCC may have high frequency of EGFR mutations, either due to imprecise histological subtyping or due to yet unknown reasons. All female and non-smoking patients with NSCLC have to undergo EGFR testing irrespectively of tumor histology.

Age, years	EGFR mutation frequency
18-30	2/87 (2.3%)
31-40	19/431 (4.4.%)
41-50	78/1601 (4.9%)
51-60	348/5819 (6.0%)
61-70	560/6773 (8.3%)
71-80	291/2425 (12.0%)
81-100	35/197 (17.8%)

9041 Poster Session (Board #367), Sat, 8:00 AM-11:30 AM

Molecular panel sequencing of pre-treatment samples to reveal mechanisms of innate resistance to 3rd generation EGFR TKI treatment in T790M-positive NSCLC patients. *First Author: Sebastian Yves Friedrich Michels, Lung Cancer Group Cologne, Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

Background: Resistance to early generation epidermal growth factor receptor (*EGFR*) tyrosine kinase inhibitors (TKI) inevitably develops in *EGFR*-mutant lung cancer. The secondary *EGFR* p.T790M mutation is the driving factor in 60% of cases and 3rd generation EGFR TKIs have been developed to overcome T790M-mediated resistance. However, besides T790M other genetic aberrations such as amplifications of *MET* may contribute to resistance to EGFR inhibition in the same patient. We here report on the systematic analysis of co-occurring genetic aberrations that may influence response to 3rd generation EGFR TKIs. **Methods:** Thirty-six patients were treated with 3rd generation EGFR TKIs in the setting of acquired resistance to EGFR inhibition in cancer centers in Germany and Switzerland. Pre-treatment samples were analyzed for co-occurring genetic aberrations in a subset of resistance-related genes including *MET*, *HER2*, *RAS*-gene family, *PIK3CA*, *CTNNB1* and *PTEN* using next-generation sequencing and fluorescence in-situ hybridization assays. We investigated the association between clinical, epidemiological and molecular data and response to treatment (RECIST 1.1). **Results:** Co-occurring genetic aberrations were found in 68% of the pre-treatment samples where both, analyses by sequencing and FISH were feasible (N = 25). Efficacy of 3rd generation EGFR TKIs significantly dropped in the presence of high-level *MET* amplification as compared to wild-type *MET* (ORR, 0.0%; 95% CI, 0.0-60.4 vs. 70.0%; 95% CI, 45.7-87.2; p = 0.02; median PFS, 1.0 month; 95% CI, 0.37-1.72 months vs. 8.2 months; 95% CI, 1.69-14.77 months; $p \leq 0.001$). No statistically significant association was found between treatment efficacy and the molecular status of the genes analyzed or the number of prior EGFR TKIs. **Conclusions:** Prevalence of additional genetic aberrations is frequent in the setting of acquired resistance to early generation EGFR TKIs and may not necessarily mediate resistance to 3rd generation EGFR TKIs. However, in our analysis high-level amplification of *MET* was associated with primary treatment failure and might be the main factor underlying resistance in this setting.

9042 Poster Session (Board #368), Sat, 8:00 AM-11:30 AM

Trastuzumab and paclitaxel in patients (pts) with EGFR mutated non-small-cell lung cancer (NSCLC) that express HER2 after progression on EGFR TKI treatment. *First Author: Joop De Langen, VU University Medical Center, Amsterdan, Netherlands*

Background: HER2 expression as well as amplification has been well recognized in tumor biopsies of pts with an EGFR mutation who developed EGFR TKI resistance. It is unknown whether HER2 targeting in this setting can result in tumor responses. **Methods:** Single arm open label phase II study to study the safety and efficacy of paclitaxel-trastuzumab treatment in pts with a sensitizing EGFR mutation who show tumor membrane HER2 expression in a tumor biopsy (immunohistochemistry (IHC) $\geq$1) after progression on EGFR TKI treatment. Paclitaxel (60 mg/m2) and trastuzumab (first dose 4 mg/kg, thereafter 2 mg/kg) were dosed weekly until disease progression or unacceptable toxicity. Primary end-point was tumor response according to RECIST. Sample size of 20 pts was calculated to evaluate the primary objective of $\geq$30% objective response rate. The study was deemed positive when $\geq$7 pts would show a partial or complete response. **Results:** 21 pts were enrolled from 08-2012 to 02-2017. 7 pts were exon 21 L858R positive and 14 exon 19 del. Last TKI was erlotinib (n = 6), gefitinib (n = 4), rociletinib (n = 3) or osimertinib (n = 8). Median HER2 IHC was 2+ (range 1-3). 17 pts were evaluable for response assessment, while 4 pts are awaiting their first response scan. The primary end-point was met with 7/17 pts (41%) showing a partial response. 2 pts showed stable disease, 7 progressive disease and 1 pt had clinical progression before CT response evaluation. Median duration of response was 9 (range 6-18) months with one ongoing responder. 3 pts experienced grade $\geq$3 toxicity, including fatigue, neuropathy and neutropenia. Upon progression on study treatment, all responding pts were rebiopsied. 4/6 samples were negative for HER2 (IHC), suggesting that the combination effectively targeted HER2 positive tumor cells. **Conclusions:** The study met its primary end-point. Paclitaxel-trastuzumab induces durable objective tumor responses in EGFR TKI pretreated pts with an activating EGFR mutation and HER2 bypass track activation. The treatment was well tolerated. Post-progression tumor biopsies showed absence of HER2 staining in the majority of pts, suggesting effective HER2 targeting. Clinical trial information: NCT02226757.

9043 Poster Session (Board #369), Sat, 8:00 AM-11:30 AM

YES1 amplification as a mechanism of acquired resistance (AR) to EGFR tyrosine kinase inhibitors (TKIs) identified by a transposon mutagenesis screen and clinical genomic testing. *First Author: Pang-Dian Fan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Overcoming AR to EGFR TKIs remains challenging, and in many cases the mechanisms are still unclear. To identify novel mechanisms of resistance to EGFR TKIs, we performed a forward genetic screen using transposon mutagenesis in *EGFR*-mutant lung adenocarcinoma cells. **Methods:** EGFR TKI-sensitive PC9 cells were co-transfected with plasmids encoding a mutagenic *piggyBac*transposon and hyperactive piggyBac transposase. Transposon-tagged, afatinib-resistant clones were generated by sequential selection of transfected cells with puromycin and 1μM afatinib. Transposon insertion sites were mapped using a modified TraDIS-type method and next-generation sequencing (NGS). Selected clones were characterized using Western blots, receptor tyrosine kinase (RTK) arrays, and viability assays following treatment with TKIs or siRNA-mediated gene knockdowns. We reviewed MSK-IMPACT™ NGS data on 100 patient tumors with EGFR TKI AR. Available tumor samples were analyzed by fluorescence in situ hybridization (FISH). **Results:** In 187/188 afatinib-resistant clones, transposon insertion sites consistent predominantly with gene upregulation were found in *MET*, the Src family kinase (SFK) member *YES1*, or both. Clones with activating *YES1* insertions exhibited resistance to all three generations of EGFR TKIs; high levels of expression of tyrosine-phosphorylated YES1; sensitivity to the SFK TKI dasatinib and to siRNA-mediated knockdown of *YES1*; and tyrosine phosphorylation of YAP1 and ERBB3. A query of the MSK-IMPACT™ data on EGFR TKI AR patients revealed amplification of *YES1* and no alteration of *MET*, *ERBB2* or *BRAF* in 3/54 T790M-negative (95% CI 1 to 16%) and 1/46 (95% CI 1 to 12%) T790M-positive cases. Amplification of *YES1*was confirmed by FISH in 2/2 cases, and was absent in matched pre-TKI samples in 2/2 cases. **Conclusions:** *YES1* amplification is found in 4% of patients with acquired resistance to EGFR TKIs and is potentially targetable by Src family kinase inhibitors. Forward genetic screens using transposon mutagenesis and routine clinical NGS of patient samples can identify novel mechanisms of resistance to targeted therapies.

9044 Poster Session (Board #370), Sat, 8:00 AM-11:30 AM

Association between hospital volume and overall survival of patients with metastatic non-small cell lung cancer. *First Author: Gaurav Goyal, Creighton University Medical Center, Omaha, NE*

Background: Prior studies have shown superior surgical outcomes of stage I-III non-small cell lung cancer (NSCLC) in centers with higher patient volumes. However, there is a lack of such information in stage IV NSCLC. In this study, we aim to determine the association between the number of patients with stage IV NSCLC treated annually at a treatment facility (volume) and all-cause mortality (outcome). **Methods:** Using the National Cancer Database, we identified patients diagnosed with stage IV NSCLC between 2004 and 2013. We classified the facilities by quartiles (Q; mean patients with NSCLC treated per year): Q1: $<$ 13.8; Q2: 13.8 to 23.6, Q3: 23.6 to 30.3, and Q4: $>$ 30.3. We used sandwich variance estimators to account for clustering of patients within facilities and Cox regression to determine the volume-outcome relationship, adjusting for demographic (sex, age, race), socio-economic (insurance type), receipt of chemotherapy, and comorbid (Charlson-Deyo score) factors and year of diagnosis. **Results:** There were 281,654 patients with stage IV NSCLC treated at 1,275 facilities. The median age at diagnosis was 66 years, and 55.7% were men. The median annual facility volume was 23.6 patients per year (range, 1.0 to 301.4). The distribution of patients according to facility volume was: Q1: 6.6%, Q2: 14.9%, Q3: 25.4%, and Q4: 53.1%. The unadjusted median overall survival by facility volume was: Q1: 4.4 months, Q2: 4.5 months, Q3: 4.7 months, and Q4: 5.3 months ($P<$ .001). Multivariable analysis showed that facility volume was independently associated with all-cause mortality. Compared with patients treated at Q4 facilities, patients treated at lower-quartile facilities had a small but significantly higher risk of death (Q3 hazard ratio [HR], 1.05 [95% CI, 1.03 to 1.07]; Q2 HR, 1.06 [95% CI, 1.03 to 1.09]; Q1 HR, 1.09 [95% CI, 1.06 to 1.13]). **Conclusions:** Patients who were treated for stage IV NSCLC at lower-volume facilities had a significantly higher risk of all-cause mortality compared with those who were treated at lower-volume facilities.

Outcomes in stage IV non-small cell lung cancer based on hospital volume.

Survival	Q1 (%)	Q2 (%)	Q3 (%)	Q4 (%)
1-year	22.7	23.6	24	27
2-year	10	10.4	10.8	12.5
5-year	3	3.2	3	3.6

9045 Poster Session (Board #371), Sat, 8:00 AM-11:30 AM

Recurrent versus de novo metastatic NSCLC: Impact on outcomes. *First Author: Sara Moore, BC Cancer Agency, Vancouver, BC, Canada*

Background: Metastatic non-small-cell lung (NSCLC) cancer has a poor prognosis, with a 5 year survival less than 5%. The majority of patients present with stage IV and many patients treated curatively with stage I-III will develop recurrent metastatic disease. It is unknown if the natural history differs between patients with recurrent versus de novo metastatic NSCLC. We hypothesized that de novo metastatic disease is associated with decreased overall survival compared to recurrent metastatic disease. **Methods:** A retrospective review was completed of all patients with NSCLC referred to the BC Cancer Agency from 2005-2012. Two cohorts were created; de novo metastatic disease and patients treated with curative intent (surgery or radiotherapy) that developed recurrent, metastatic disease. Information was collected on known prognostic and predictive factors. Overall survival was calculated from the date of diagnosis of metastatic disease. **Results:** A total of 9656 patients were referred, 5783 (60%) with de novo stage IV disease, and 3873 (40%) with stage I-III disease. Of patients with initial stage I-III, 1801 received curative therapy (751 surgery, 1050 radiotherapy) and 802 developed metastases. Patients in the de novo cohort were more likely to be male (52% vs 47%), have poorer performance status (ECOG≥2 50% vs 43%), and receive no palliative chemotherapy (67% vs 61%). The median overall survival in the de novo cohort was 4.7 m vs 6.9 m in the recurrent cohort ($p < 0.001$). De novo status was associated with shorter overall survival and this remained significant in a multivariate model that incorporated gender, ECOG and lines of palliative chemotherapy (hazard ratio 1.228[95% confidence interval 1.134-1.330], p-value < 0.001). **Conclusions:** In a large population based study of NSCLC, de novo metastatic status was independently associated with decreased overall survival from the time of metastatic disease diagnosis. De novo versus recurrent status should be used as a prognostic factor to inform patient decisions and ensure balanced stratification of patients in clinical trials.

9046 Poster Session (Board #372), Sat, 8:00 AM-11:30 AM

Describing the value of the most common first line NSCLC regimens in a real world setting. *First Author: Lee N. Newcomer, UnitedHealth Group, Edina, MN*

Background: We aim to describe clinical and economic outcomes of common chemotherapy regimens for first line therapy of metastatic non-small cell lung cancer (mNSCLC).The data are intended to help clinicians and patients understand the real world results for patients like themselves. **Methods:** This retrospective analysis used clinical data obtained from a prior authorization (PA) program for chemotherapy linked with administrative claims data from 6/1/2015 to 5/31/2016 from a large national managed care organization. Clinical data included cancer type, stage at diagnosis, biomarkers, treatment line and evidence of progression/relapse. Eligible patients were commercially insured members with a PA request for commonly used NCCN recommended regimens for first line therapy of mNSCLC. Outcomes, including duration of therapy, % of patients hospitalized and total cost of care were tracked from first claim for chemotherapy until end of treatment due to discontinuation, death or start of a second line, with remaining patients censored at 5/31/2016 or end of enrollment. **Results:** Of 830 mNSCLC patients, 498 (60%) completed first line therapy during the study period. 345 initiated one of the following: Carbo/cisplatin + pemetrexed (CA), Carbo/cisplatin + paclitaxel (CP), Carbo/cisplatin + bevacizumab + pemetrexed (CBA), nivolumab (N), and docetaxal (D). Outcomes are summarized in the Table. **Conclusions:** Patients treated with the five most commonly prescribed first line therapies for mNSCLC have much shorter duration of therapies (52-76 days) than reported in published clinical trials with a significant risk of hospitalization (18% -30%) and at substantial cost ($34,971 - $108,100). These data are an important consideration for the patient and clinician making treatment decisions in routine clinical practice and will become more valuable as the database grows over time.

9047 Poster Session (Board #373), Sat, 8:00 AM-11:30 AM

Phase 2 trial of chemotherapy followed by consolidative radiation therapy for initial treatment of oligometastatic NSCLC. *First Author: Tamjeed Ahmed, Wake Forest Baptist Health, Winston-Salem, NC*

Background: Unselected patients with stage 4 lung cancer who receive front line platinum based chemotherapy and maintenance chemotherapy have demonstrated a PFS less than 6 months with very few patients alive at 5 years. Patients with a small number of metastatic lesions may have a different biology, and aggressive local treatment of oligometastases is an active area of investigation. **Methods:** Patients were required to have stable disease or response after 3-6 cycles of platinum based chemotherapy and PS 0-2. Oligometastatic disease was defined as a maximum number of 5 metastatic lesions for all disease sites including no more than 3 active extracranial metastatic lesions. Limited mediastinal lymph node involvement was allowed. **Results:** 29 patients were enrolled between 10/2010 and 10/2015. 3 patients were excluded from analysis due to concerns regarding eligibility/treatment response. Despite closing early due to slow accrual, the study met its primary endpoint for success which was PFS greater than 6 months. The median PFS (95% CI) was 11.0 months (7.4-15.9 months) and the median OS was 22.2 months (13.3-45.7 months). The 1-year, 3-year, and 5-year OS were 73%, 35%, and 29%. **Conclusions:** Patients with oligometastatic NSCLC who received platinum based chemotherapy followed by oligometastatic consolidative radiation without maintenance chemotherapy demonstrated prolonged disease control and overall survival. Clinical trial information: nct01185639.

9048 Poster Session (Board #374), Sat, 8:00 AM-11:30 AM

Microwave ablation in combination with chemotherapy versus chemotherapy in advanced non small cell lung cancer: A prospective, randomized, phase III clinical trial. *First Author: Zhig Wei, Shandong Provincial Hospital Affliated to Shandong University, Jinan, China*

Background: Previous studies showed that advanced non small cell lung cancer (NSCLC) benefited from microwave ablation in combination with platium-based doublet chemotherapy. This prospective, randomized, phase III clinical trial aimed to determining the survival benefit and safety of MWA combined with chemotherapy compared with chemotherapy alone, which was registered in ClinicalTrials. gov (NCT02455843). **Methods:** Patients with untreated, stage IIIB or IV NSCLC and at least one additional measurable site other than the primary tumor site were recruited. They were divided into MWA/chemotherapy group and chemotherapy group, the former received MWA in the primary tumor sites, followed by chemotherapy and the latter treated with chemotherapy only. The primary endpoint was progression-free survival (PFS), the second endpoint included objective response rate (ORR), overall survival (OS) and adverse events (AE). **Results:** From Mar 1st, 2015 to Oct 31th, 2016, Two hundreds and eighty-six patients were enrolled , including 141 in MWA/chemotherapy group and 145 in chemotherapy group. Complete ablation was observed in 95.0 % patients. ORR were 38.3 % and 34.1 % in the MWA/chemotherapy group and chemotherapy group, respectively($p = 0.677$). MWA prolonged PFS [MWA/chemotherapy group 7.3 (95 % CI,5.3–13.6) ms vs. chemotherapy group 5.2 (95 % CI, 4.0–12.4) ms, $p = 0.003$]. Multivariate analyses showed that MWA was an independent prognostic factor of PFS. OS was immature. AEs of MWA were observed in 67.4 % patients, mainly was pheumothorax, and only 15% needing chest tube insertion. No ablation associated death was observed. Chemotherapy-associated AEs were observed in 49.1 and 53.6 % of patients in the MWA/chemotherapy and chemotherapy group, respectively. **Conclusions:** MWA plus chemotherapy combination improved the PFS of advanced NSCLC compared to chemotherapy alone. Adverse events of MWA was tolerable. Clinical trial information: NCT02455843.

9049 Poster Session (Board #375), Sat, 8:00 AM-11:30 AM

Objective response rate and progression-free survival as surrogate endpoints for overall survival and the impact of crossover and unbalanced post-progression treatments: A systematic review and meta-analysis in first-line therapy of advanced non-small cell lung cancer. *First Author: Boris Pfeiffer, Merck KGaA, Darmstadt, Germany*

Background: Correlations between overall survival (OS) and objective response rate (ORR) or progression-free survival (PFS) are poor. We aimed to evaluate the impact of crossover and unbalanced subsequent treatments on ORR and PFS as surrogate endpoints for OS in patients with advanced NSCLC receiving first-line therapy. **Methods:** A systematic literature review of randomized clinical trials of systemic treatment for patients with stage IIIB/IV NSCLC receiving first-line therapy was performed. Weighted (by trial size) linear regression models were fitted with the absolute difference in ORR or median PFS as an independent variable and the absolute difference in median OS as a dependent variable. The analysis was repeated in predefined subsets based on crossover and balance of post-progression therapies. Surrogate threshold effect (STE) was estimated using prediction intervals. **Results:** 317 trials (78,644 patients) fulfilled the eligibility criteria. In all treatment arms, the mean ORR, median PFS, and median OS were 28.2% (standard deviation (SD) = 12.4%), 5.1 months (SD = 2.1), and 10.4 months (SD = 2.5), respectively. ORR and PFS had weak (R = 0.351; 95% CI: 0.251-0.443) and (R = 0.397; 95% CI: 0.267-0.512) associations with OS, respectively. However, within phase III trials that did not allow crossover and reported balanced post-progression treatments, both ORR and PFS had stronger associations with OS (ORR and OS: R = 0.601, 95% CI: 0.399-0.747; PFS and OS: R = 0.695, 95% CI: 0.446-0.844). STE estimation indicated that trials that show statistically significant treatment effect size of $\geq$43% ORR or $\geq$3.2 median PFS months can be expected to show significant OS benefit with sufficient certainty. **Conclusions:** Surrogacy of ORR and PFS for OS might be better estimated in trials that do not allow crossover and report balanced post-progression treatments. Presented STE calculation can be used to estimate the expected effect on OS when either ORR or PFS are used as primary endpoints.

9050 Poster Session (Board #376), Sat, 8:00 AM-11:30 AM

Clinical comparison of ABP 215 and bevacizumab in patients with NSCLC: Pharmacokinetic results and justification for extrapolation across bevacizumab indications. *First Author: Nick Thatcher, The Christie Hospital, Manchester, United Kingdom*

Background: Approval of biosimilars is based on totality of evidence (TOE) that includes demonstration of analytical, functional, and pharmacokinetic (PK) similarity, and comparable clinical efficacy, safety, and immunogenicity. The TOE supports scientific justification for extrapolation across other indications that a share common mechanism of action (MOA). The proposed biosimilar ABP 215 is similar to bevacizumab (BEV) with respect to inhibition of vascular endothelial growth factor (VEGF)-induced signaling; PK in healthy adults; and clinical efficacy, safety, and immunogenicity in patients with non-small cell lung cancer (NSCLC). The PK results from the NSCLC study are reported here. **Methods:** In this double-blind study, adults with non-squamous NSCLC receiving first-line chemotherapy with carboplatin and paclitaxel were randomized 1:1 to ABP 215 or BEV (15 mg/kg IV Q3W for 6 cycles). Trough (pre-dose) PK samples were collected at baseline, at weeks 4, 7, and 13, and at end of study. Clinical evaluations included efficacy, safety, and immunogenicity. **Results:** 642 patients (ABP 215, n = 328; BEV, n = 314) were randomized. Demographic and baseline characteristics were well balanced. The primary endpoint of risk ratio for objective response rate was 0.93 (2-sided 90% CI, 0.80-1.09), which was contained within the pre-specified equivalence margin. The incidence of adverse events was comparable between ABP 215 and BEV. During the study, 4 (1.4%) and 7 (2.5%) patients in the ABP 215 and BEV group, respectively, developed binding antibodies; no patient tested positive for neutralizing antibodies. Steady-state trough serum concentrations for both ABP 215 and BEV were reached by week 13 (median 124.9 vs 124.4 μg/mL, respectively) and were consistent between ABP 215 and BEV throughout the study. **Conclusions:** ABP 215 is similar to BEV in multiple analytical, functional, and clinical assessments. PK results in patients presented here provide further evidence for similarity between ABP 215 and BEV and contribute to the TOE supporting extrapolation of clinical similarity across BEV indications based on its common MOA. Clinical trial information: NCT01966003.

9051 Poster Session (Board #377), Sat, 8:00 AM-11:30 AM

Impact of prior radiation on survival in metastatic lung cancer ECOG-ACRIN trials. *First Author: Saad A. Khan, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Up to 50% of advanced NSCLC patients receive radiation therapy at some point in their course. We sought to determine whether patients with prior radiation demonstrate altered outcomes on subsequent metastatic clinical trials. **Methods:** We reviewed 8 ECOG-ACRIN advanced non-small cell lung cancer studies conducted between 1993 and 2011 in which information was collected about receipt of prior radiation. Whether radiotherapy was given with curative or palliative intent, or to specific sites was not recorded. Median follow-up among all trials was 66 months. We used the log-rank, Wilcoxon and Fisher's exact tests to compare patients, and Cox Model and Kaplan-Meier method to calculate survival. **Results:** 574/3041 (18.9%) patients had received prior radiation. These patients were more likely to be male (64% vs 58%), have squamous histology (20% vs 14%) and have had prior surgery (48% vs 33%) compared to those with no prior radiation. At registration, prior radiation patients were more likely to have an ECOG PS of 1 (66% vs 58%), while they were less likely to have a PS of 0 (24% vs 36%) or have a pleural effusion (23% vs 37%). Patients who received radiation were more likely to have been registered on to studies between 1993-1999 than 2000-2011 (69% vs 31%) (all $p < 0.001$). Median Overall Survival (OS) for patients with prior radiation was 7.6 months (range 7-8.3) vs 9.5 (9.1-9.8) for those without ($p < 0.001$). Median Progression Free Survival (PFS) for those with prior radiation was 3.5 months (3-3.9) vs 4.2 (4.1-4.4) for those without ($p < 0.001$). In multivariable analysis controlling for stage IIIB/IV, sex, PS, histology, and prior surgery, the impact of prior radiation on overall survival remained significant (p = 0.042, HR (95% CI) = 1.11 (1.00, 1.22)). **Conclusions:** Almost one-fifth of lung cancer patients on systemic therapy trials for advanced disease previously received radiation. They are more likely to be male, have squamous histology, have an ECOG PS of 1 and have had prior surgery. Prior radiation is significantly associated with inferior OS and PFS. For advanced NSCLC clinical trials, documentation of whether curative intent/palliative intent radiation was given and stratification by prior radiation exposure should be considered.

9052 Poster Session (Board #378), Sat, 8:00 AM-11:30 AM

A phase 1b/2 study of napabucasin with weekly paclitaxel in advanced, previously treated non-squamous non-small cell lung cancer. *First Author: Carlos Becerra, Texas Oncology, Dallas, TX*

Background: Napabucasin is a first-in-class cancer stemness inhibitor, identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al PNAS 112 (6):1839, 2015). Napabucasin has shown potent synergistic preclinical anti-tumor activity with paclitaxel (PTX). In a phase Ib dose escalation study in patients (pts) with advanced solid tumors, napabucasin plus weekly PTX was well tolerated. A phase II expansion cohort was opened for pts with advanced non-small cell lung cancer (NSCLC). **Methods:** Pts with metastatic non-squamous NSCLC were enrolled to confirm safety and preliminary anti-cancer activity. Prior platinum-based systemic therapy was required, and patients with an EGFR or ALK mutation required appropriately targeted therapy. Napabucasin was administered orally at a starting dose of 240 or 480 mg BID with PTX 80 mg/m2 IV weekly 3 of every 4 weeks. AEs were evaluated using CTCAE v4.03 and objective assessments were performed every 8 weeks per RECIST 1.1. **Results:** A cohort of 23 pts with advanced non-squamous NSCLC was evaluated. The median number of prior systemic treatment lines was 3, including taxane-based therapy in 100% and immune checkpoint inhibitor in 48% (n = 11). Treatment was well tolerated; related grade 3 AE included diarrhea (n = 4) and fatigue (n = 1). The objective response rate was 26% (6 partial responses [PR]) and the disease control rate (DCR; proportion with SD at 8 weeks plus PR per RECIST) was 70% (n = 16). Tumor regression, including PR, occurred in 35% (n = 8). The median progression-free survival (mPFS) was 5.4 months, and 43% (n = 10) of pts were alive and free of progression at the 24 week time-point or longer. The median overall survival (mOS) was 11.0 months, and 30% (n = 7) of pts were alive for 52 weeks or longer. **Conclusions:** Clinical safety and encouraging signs of anti-cancer activity were observed in pts with heavily pretreated non-squamous NSCLC who received napabucasin plus weekly paclitaxel. The objective response rate, progression free survival, and overall survival in this population warrant further clinical evaluation and a controlled phase 2/3 trial (CanStem43L) has been initiated. Clinical trial information: NCT01325441.

9053 Poster Session (Board #379), Sat, 8:00 AM-11:30 AM

Third-line treatment: A randomized, double-blind, placebo-controlled phase III ALTER-0303 study—Efficacy and safety of anlotinib treatment in patients with refractory advanced NSCLC. *First Author: Baihui Han, Department of Pulmonary, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: Anlotinib hydrochloride, an oral TKI targeting VEGFR, FGFR, PDGFR and c-Kit, showed promising efficacy in PhaseIIstudy. Here, we evaluated the efficacy and safety of anlotinib as third-line treatment for advanced NSCLC, a randomized, double-blind, placebo-controlled Phase IIItrial (ALTER-0303). **Methods:** Eligible IIIB/IV NSCLC pts who progressed after at least 2 lines of prior therapies were randomized 2:1 to receive anlotinib or placebo (12 mg QD from day 1 to 14 of a 21-day cycle) till progression or intolerable toxicity. Enrolled pts harboring EGFR or ALK mutations must had failed in previous match-targeted therapies. The primary endpoint is OS; secondary endpoint includes PFS, DCR and ORR. **Results:** As of Aug 2016, total of 437 pts from 31 sites were randomized. The baseline characteristics of Anlotinib arm (N=294) and placebo arm (N=143) were well balanced in the age, gender, ECOG PS and gene states. With 292 OS events (66.82%), significant superiorities in OS, PFS, DCR and ORR were observed in Anlotinib arm according to investigator-assessed results. Grade ≥ 3 treatment-related AEs were hypertension, dermal toxicity and hypertriglyceridemia. There was no treatment–related death in either arm. (Data presented in the Table.) **Conclusions:** ALTER-0303 trial met its primary endpoint. Anlotinib significantly improved OS and PFS in advanced NSCLC with a manageable safety profile. The results strongly suggest that anlotinib should be considered as a candidate for the third-line treatment or beyond in advanced NSCLC. Clinical trial information: NCT02388919.

	Anlotinib arm N = 294	Placebo arm N = 143	p-value
Efficacy

9054 Poster Session (Board #380), Sat, 8:00 AM-11:30 AM

A phase II study of GDC-0032 (taselisib) for previously treated PI3K positive patients with stage IV squamous cell lung cancer (SqNSCLC): LUNG-MAP sub-study SWOG S1400B. *First Author: James Lloyd Wade, Heartland NCORP, Decatur, IL*

Background: Lung-MAP (S1400) is a National Clinical Trials Network "umbrella" trial for previously-treated SqNSCLC. Sub-study S1400B included patients (pts) with tumors harboring PI3K mutations.Taselisib (GDC-0032), a potent, small molecule inhibitor of Class 1 PI3K with beta isoform sparing selectivity, has been shown to be a potent inhibitor in preclinical models of PIK3CA-mutant tumors. **Methods:** Eligibility stipulated progressive SqNSCLC after primary platinum-based therapy and presence of a PIK3CA mutation as determined by Foundation Medicine (FMI+) NGS. . The primary analysis population was a subgroup of the total PIK3CA mutation group (GNE+) with alterations limited to substitutions: E542K, E545A, E545G, E545K, E545Q, H1047L, H1047R, H1047Y. Primary endpoint was response rate (RR) in GNE+ pts. The initial protocol randomized PIK3 mt (+) pts to taselisib 4 mg po daily or docetaxel, but was amended to single arm phase II trial of taselisib with interim analysis based on first 20 eligible GNE+ pts evaluable for response, stipulating closure for futility if < 2 responses were observed. **Results:** 26 eligible pts, 7% of those registered to S1400, received taselisib; of these , 21 (81%) were GNE+. Of the 20 eligible, response-evaluable GNE+ pts, one pt with PIK3CA E545K gene alteration responded (5% RR, 95% Confidence Interval [CI] 1%, 24%). 13 pts had stable disease. Median PFS was 2.5 mos (95% CI, 1.7-4.0 mos) and 2.7 mos (95% CI, 1.8-3.4 mos) among GNE+ and FMI+ pts, respectively. 26 FMI+ pts were evaluable for toxicity: two grade 5 events (cardiac arrest, respiratory failure), neither clearly attributable to treatment, were recorded, along with one instance each of grade 4 AEs (dyspnea, thrombocytopenia, pneumonitis). Grade 3 AEs included 5 pts each with hyperglycemia or diarrhea, and 3 with lymphopenia. Overall survival data is premature. **Conclusions:** Study S1400B failed to meet its primary endpoint and was closed December 2016 at interim analysis for futility. Toxicities were manageable. The trial is unique in cataloguing the diversity of mutations in the PI3K pathways in SqNSCLC Clinical trial information: NCT02785913.

9055 Poster Session (Board #381), Sat, 8:00 AM-11:30 AM

Phase II study of the FGFR inhibitor AZD4547 in previously treated patients with FGF pathway-activated stage IV squamous cell lung cancer (SqNSCLC): LUNG-MAP sub-study SWOG S1400D. *First Author: Charu Aggarwal, Abramson Cancer Center, Philadelphia, PA*

Background: LungMAP is a National Clinical Trials Network umbrella trial for previously-treated SqNSCLC. S1400D is a phase II biomarker-driven therapeutic sub-study evaluating the FGFR inhibitor AZD4547 in patients (pts) with FGFR positive chemo-refractory SqNSCLC. **Methods:** Eligible pts had tumor FGFR alteration and/or mutation by next generation sequencing (Foundation Medicine), measurable disease, Zubrod PS 0-2, progression after 1 line of systemic therapy, and adequate end organ function. Receipt of prior immunotherapy was allowed. Eligible pts received AZD4547 80 mg bid orally. Primary endpoint was overall response rate (ORR) by RECIST; secondary endpoints included progression-free survival (PFS) and duration of response (DoR). Originally designed as a randomized trial of AZD4547 versus docetaxel, it was redesigned to be a single arm AZD4547 trial with the emergence of immunotherapy as standard 2ndline therapy. Forty pts were required to rule out an ORR of < = 15% if the true ORR was > 35% (90% power, alpha 0.05). **Results:** 93 pts (13% of pts screened on S1400) were assigned to S1400D; 43 were enrolled with 28 receiving AZD4547. Pt characteristics: median age 66.3 y (49-88), female (n = 8, 29%), & Caucasian (n = 25; 89%). Biomarker profile: FGFR1 amplification (n = 38; 86%); FGFR3 S249C (n = 4; 9%); FGFR3 amplification (n = 3; 7%); and FGFR3 fusion (n = 2; 5%). Nine pts (26%) had more than one biomarker alteration. The study was closed at interim analysis for futility in October 2016. Treatment related Grade 3 AEs were seen in 5 pts (dyspnea, fatigue, hyponatremia, lung infection & retinopathy); 1 pt had Grade 4 sepsis. There were no Grade 5 AEs. Median follow up among alive pts was 4.3 months (mos). Of 25 response evaluable pts, one with FGFR3 S249C had unconfirmed PR (4%, 95% CI 1-20%) with DoR of 1.5 mos. Median PFS was 2.7 mos (95% CI 1.4 - 4.3 mos). **Conclusions:** This is the first Phase II trial to evaluate AZD4547 as a targeted approach in pts with previously treated FGFR-altered SqNSCLC. AZD4547 had an acceptable safety profile but minimal activity in this biomarker-enriched cohort. Evaluation of other targeted agents in LUNG-MAP is currently ongoing. Clinical trial information: NCT02965378.

9056 Poster Session (Board #382), Sat, 8:00 AM-11:30 AM

A phase II study of palbociclib (P) for previously treated cell cycle gene alteration positive patients (pts) with stage IV squamous cell lung cancer (SCC): Lung-MAP sub-study SWOG S1400C. *First Author: Martin J. Edelman, Fox Chase Cancer Center, Philadelphia, PA*

Background: S1400 is a master platform trial designed to assess targeted therapies in SCC. Study C evaluated the response rate (RR) to P, a CDK 4/6 inhibitor, in pts with cell cycle gene abnormalities. **Methods:** Pts with SCC, PS 0-2, normal organ function, who had progressed after at least one prior platinum-based chemotherapy for any NSCLC indication were eligible. Tumor specimens were required and evaluated for gene alterations (Foundation Medicine, Foundation One NGS assay). Pts with CDK 4 or CCND1/2/3 amplifications were eligible. The study was originally designed as a phase II/III trial comparing P to docetaxel (D), but was modified to a 2-stage phase II trial with primary endpoint of response rate. If > 3 responses (R) of the first 20 pts were seen the study would continue to 40 pts, with 10 R for the 40 pts considered a positive study. **Results:** 89 pts (14% of pts screened) were assigned to S1400C, 53 pts enrolled (including 17 to D). One pt assigned to D re-registered to P. Frequency of cell cycle gene alterations for the enrolled pts: CCND1 amplification (n = 44, 83%); CCND2 amplification (n = 7, 13%); CCND3 amplification (n = 5, 9%); and CDK4 amplification (n = 3, 6%). (Note: some pts with multiple alterations.) Of the 37pts enrolled to P: 5 were ineligible (4 inadequate baseline labs, 1 did not progress on prior therapy). 1 not determinable for response. For the 32 eligible pts the median age was 67 (53-81), 21M/11F. Response: 2 PR (6% RR, 95% CI: 2%, 20%), 12 SD (38%, 95% CI: 21%, 54%) for a disease control rate (DCR) of 44% (95% CI: 27%, 61%). Median PFS was 1.7 mo (95% CI 1.6-2.9 mo). Of the 2 PR, one has progressed (duration of response, DOR, 7.7 mo), one still responding (DOR, 4 mo). Both responders had CCND1 amplification. 32 pts have been assessed for adverse events (AE). 4 experienced Grade 4 AE including lymphopenia (3), and thrombocytopenia (1). 13 others experienced Grade 3 treatment-related AE. **Conclusions:** 1. P failed to demonstrate the pre-specified RR to justify advancement to phase III. 2. P was well tolerated in this population. 3. Further analysis of those who derived benefit (e.g. response or prolonged SD) is underway. Clinical trial information: NCT02785939.

9057 Poster Session (Board #383), Sat, 8:00 AM-11:30 AM

Clinical features of squamous cell lung cancer with targetable gene alterations in a nationwide genomic screening network in Japan (LC-SCRUM-Japan). *First Author: Eri Sugiyama, Division of Cancer Immunology, National Cancer Center, Kashiwa, Japan*

Background: Molecular-targeted therapies for precision medicine in squamous cell lung cancer (SqLC) have not yet been established. To identify precise patients for targeted therapies and to reveal their clinical characteristics, we have operated clinical sequencing of advanced SqLCs in our nationwide genomic screening project in Japan (LC-SCRUM-Japan) since March 2015. **Methods:** As of December 2016, 190 institutions across Japan were participating and 263 advanced SqLC patients had been enrolled in this project. Submitted tumor samples were subjected to a next-generation sequencing system, Oncomine™ Comprehensive Assay, enabling the simultaneous analysis of 143 cancer-related genes. **Results:** The median age of the 263 patients was 74 years (range, 27-87 years). Two hundred thirty (87%) were male and most patients (97%) were smokers. Among 211 available samples, potentially targetable gene alterations were detected in 58 (27%). Based on these gene alterations, the patients were subdivided into 4 groups, consisting of 25 (12%) with genetic alterations of FGFR family (FGFR type; 23 FGFR1 amplifications, 1 FGFR2 amplification and 1 FGFR3 fusion), 20 (9%) with genetic alterations of the PI3K pathway (PI3K type; 10 PIK3CA mutations, 8 PTEN mutations and 2 AKT mutations), 15 (7%) with other oncogene alterations (KRAS/EGFR/ALK type; 10 KRAS mutations, 3 EGFR mutations and 2 ALK fusions) and others. Comparative analyses of clinical characteristics between the 4 types showed that brain metastases were significantly more frequent in the FGFR type than the others (24% vs. 5%, p = 0.0007), and females (40% vs. 11%, p = 0.0009) and never-smokers (21% vs. 3%, p = 0.0004) were significantly frequent in the KRAS/EGFR/ALK type compared to the others. The prognostic significance of these genetic alterations has not yet been evaluated because of short follow-up time (median, 8.5 months). **Conclusions:** A series of potentially targetable gene alterations have been identified in SqLC patients. The SqLC patients had distinct clinical features according to the molecular subtypes, and genotype-directed therapeutic strategy should be developed for the individual subtypes.

9058 Poster Session (Board #384), Sat, 8:00 AM-11:30 AM

Safety and efficacy of *nab*-paclitaxel (*nab*-P)–based therapy in patients (pts) with non-small cell lung cancer (NSCLC) and performance status (PS) 2: Results from ABOUND.PS2. *First Author: Ajeet Gajra, State University of New York Upstate Medical University, Syracuse, NY*

Background: Chemotherapy can benefit pts with advanced NSCLC with poor Eastern Cooperative Oncology Group (ECOG) PS, despite an increased toxicity risk vs those with good PS. Safety and efficacy of *nab*-P/carboplatin (*nab*-P/C) induction followed by *nab*-P monotherapy in pts with advanced NSCLC and ECOG PS 2 are reported. **Methods:** Chemotherapy-naive pts with histologically/cytologically confirmed stage IIIB/IV NSCLC and ECOG PS 2 received 4 cycles of *nab*-P 100 mg/m^2 d 1, 8 + C AUC 5 d 1 q3w. Pts without disease progression were eligible for monotherapy with *nab*-P 100 mg/m^{2}d 1, 8 q3w until progression/unacceptable toxicity. Primary endpoint: percentage of pts discontinuing within the first 4 cycles due to treatment-emergent adverse events (TEAEs). Other endpoints: PFS, DCR, OS, ORR, and QoL. **Results:** Forty pts were treated during the first 4 cycles. Median age was 67.5 y, 60.0% were male, 92.5% were white, and 65.0% had nonsquamous histology. In the primary analysis, 9/40 pts (22.5%) discontinued due to TEAEs during induction. In total, 16/40 pts (40.0%) received *nab*-P as monotherapy. At the time of data cutoff, 4/40 pts remained on therapy beyond 11 cycles. In all treated pts, the median percentage of per-protocol dose of *nab*-P was 79.8% and the median *nab*-P dose intensity was 53.2 mg/m^2/week (expected, 66.67 mg/m^2/week). See table for other key safety and efficacy data. QoL by LCSS (global) was improved during the study, and similarly EQ-5D-5L dimensions were stable/improved at least once in the majority of pts. **Conclusions:** This *nab*-P–based regimen was well tolerated in PS 2 pts with advanced NSCLC. Efficacy outcomes are comparable with previous chemotherapy data with promising QoL. The results support the efficacy and tolerability of this regimen in these pts. NCT02289456. Clinical trial information: NCT02289456.

Safety	All Treated Pts N = 40
Grade ≥ 3 TEAEs of special interest, n (%)	
Neutropenia	9 (22.5)
Anemia	7 (17.5)

9059 Poster Session (Board #385), Sat, 8:00 AM-11:30 AM

ABOUND.70+: Safety and efficacy of *nab*-paclitaxel/carboplatin (*nab*-P/C) in elderly patients (pts) with advanced non-small cell lung cancer (NSCLC). *First Author: Corey J. Langer, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Treatment (tx) of elderly pts with NSCLC is challenging. *nab*-P/C demonstrated efficacy in a subset of pts with NSCLC ≥ 70 y in a phase III trial. ABOUND.70+ was designed to determine whether a 1-week break can further improve tolerability of *nab*-P/C in pts ≥ 70 y with NSCLC. Safety and efficacy were evaluated and are reported. **Methods:** Pts ≥ 70 y with tx-naive locally advanced/metastatic NSCLC were randomized (1:1) *nab*-P 100 mg/m^2 d 1, 8, 15 + C AUC 6 d 1 q3w (Arm A) or the same *nab*-P/C dose q3w followed by a 1-week break (Arm B). Primary endpoint: percentage of pts with either grade ≥ 2 peripheral neuropathy (PN) or grade ≥ 3 myelosuppression AEs. Key secondary endpoints: PFS, ORR, OS, for which statistical analyses do not control for type I error (*P* values unadjusted). **Results:** At interim evaluation, the primary endpoint was similar across arms, resulting in early closure of enrollment. In Arms A and B, 71 and 72 pts were randomized; median age was 76 and 75 y, majority of pts were male (57.7% vs 55.6%) and had ECOG PS 1 (70.4% vs 72.2%). There were no differences in histology across tx arms. See table for primary endpoint data. Median number of tx cycles for Arms A and B was 4.0 and 5.5, median cumulative *nab*-P dose was 875.0 and 1287.5 mg/m^2, and median weekly dose intensity was 62.0 and 54.1 mg/m^2. *nab*-P dose modifications (Arms A and B): ≥ 1 dose reduction in 64.7% and 58.6%, ≥ 1 dose delay in 58.8% and 48.6%, and ≥ 1 missed dose in 80.9% and 72.9%, respectively. Median PFS (Arms A and B) 3.9 vs 7.0 mo (HR 0.49; 95% CI, 0.30 - 0.79; *P* = 0.003), confirmed ORR 23.9% vs 40.3% (*P* = 0.037), and median OS 15.2 vs 16.2 mo (HR 0.76; 95% CI, 0.46 - 1.26; *P* = 0.292). **Conclusions:** Incidence of grade ≥ 2 PN or grade ≥ 3 myelosuppression AEs was similar between the 2 *nab*-P/C schedules in pts ≥ 70 y with advanced NSCLC. There appears to be a signal of improvement in PFS and ORR observed in Arm B, potentially due to increased tx exposure. NCT02151149 Clinical trial information: NCT02151149.

Primary endpoint.

Event, n (%)	Arm A n = 68	Arm B n = 70
Pts with either grade ≥ 2 PN or grade ≥ 3 myelosuppression	51 (75.0)	54 (77.1)
Grade ≥ 2 PN	25 (36.8)	25 (35.7)
Grade ≥ 3 myelosuppression	47 (69.1)	45 (64.3)
Neutropenia	38 (55.9)	38 (54.3)
Anemia	14 (20.6)	16 (22.9)
Thrombocytopenia	17 (25.0)	12 (17.1)

9060 Poster Session (Board #386), Sat, 8:00 AM-11:30 AM

Retinoblastoma mutation to predict poor outcomes in non-small cell lung cancer (NSCLC). *First Author: Priyanka Bhateja, University Hospital Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Genomic profiling of tumor DNA has revealed the diversity in NSCLC. The retinoblastoma gene (*RB1)* encodes for RB pocket protein that plays an important role in cell cycle progression by interacting with various transcriptional factors. Here we determine the frequency and prognostic significance of *RB1*mutation in NSCLC and compare it to that in small cell lung cancer (SCLC). **Methods:** This IRB-approved retrospective review on NSCLC patients included Stage III and IV patients with genomic and clinical data. Primary outcome was median overall survival (OS) and secondary outcome was progression-free survival (PFS). OS and PFS were calculated by the Kaplan-Meier method and compared between mutant and wild-type (wt) *RB1*using the Log-Rank test. The effect of *RB1*mutation status on OS and PFS was further evaluated using the multivariable Cox model, controlling the effects of age, sex, stage, smoking history and chemotherapy. All tests are two-sided and *p*-values ≤ 0.05 were considered statistically significant. **Results:** We identified *RB1* mutation in 8.2% of NSCLC patients (16 of 195 patients). With a median follow-up of 15.1 months, the median OS for wt *RB1*was 28.3 months and for mutant *RB1* was 8.3 months (HR = 2.59, *p*-value = 0.002). The median PFS for wt *RB1* was 21.8 months vs 6.4 months for mutant *RB1* (HR = 2.85, *p*-value = 0.0002). *RB1* mutation was associated with worse OS (*p*= 0.017, HR = 2.17) and PFS (*p*= 0.005, HR = 2.37) in multivariate analyses after adjusting for traditional risk factors like, age, sex, stage, smoking history and chemotherapy. Interestingly, a previously described benign deletion (A16-A18) in RB1 protein was identified in 5 of the 16 *RB1* mutant patients and was associated with far worse outcomes compared to other *RB1* mutations. In contrast to NSCLC, *RB1* mutation was identified in 75% of 64 SCLC patients. Furthermore, wt *RB1* was associated with significantly shorter OS (*p*= 0.002), PFS (*p*= 0.004) and chemotherapy refractoriness (*p*= 0.033) in SCLC. **Conclusions:** *RB1* mutation is present in a minority of patients with advanced NSCLC and is associated with poor prognosis. In contrast, *RB1* mutation is present in the majority of SCLC patients and is associated with a favorable prognosis.

9061 Poster Session (Board #387), Sat, 8:00 AM-11:30 AM

Genetic subtypes of large cell neuroendocrine carcinoma (LCNEC) to predict response to chemotherapy. *First Author: Jules Derks, Maastricht University Medical Centre+, GROW School for Oncology and Developmental Biology, Maastricht, Netherlands*

Background: To treat LCNEC with non-small cell lung carcinoma type chemotherapy (NSCLC-ct, i.e. gemcitabine/taxanes or pemetrexed) or small cell lung carcinoma type (SCLC-ct, i.e. platinum-etoposide) is subject of debate. Molecular studies have identified two mutually exclusive subtypes in LCNEC, the co-mutated *TP53* and *RB1*and the *STK11*/*KEAP1* (predominantly *RB1* wildtype(^{wt})) group. We investigated if overall survival (OS) and progression free survival (PFS) correlates with targeted next-generation sequencing (TNGS) results in LCNEC treated with NSCLC-ct or SCLC-ct. **Methods:** For this population based retrospective cohort study all diagnoses of stage IV ct treated high grade neuroendocrine carcinomas (NEC, not being SCLC) were retrieved from the Netherlands Cancer Registry and Pathology Registry (PALGA) (2003-2012). Panel-consensus pathology revision of original tumor slides was performed on (N = 230) and TNGS for genes *TP53*, *RB1*, *STK11* and *KEAP1* analyzed with a multi-sample variant caller (Needlestack). **Results:** LCNEC was consensus diagnosed in 146/230 and 77 passed quality control for TNGS. Mean coverage was 2832x, a mutation(^{mt}) in *TP53* was present in 87%, *RB1*^{mt} in 46%, *STK11*^{mt} in 13% and *KEAP1*^{mt} in 18% of sequenced LCNEC. *RB1* was co-altered with *TP53* in 94% of LCNEC; mutually exclusive to *STK11*^{mt} (100%) but not *KEAP1*^{mt} (57%). NSCLC-ct or SCLC-ct was specified in 92% of patients and *RB1*^{wt} LCNEC treated with NSCLC-ct (n = 22) showed a trend to better OS compared to SCLC-ct (n = 13) (8.5 months (95% confidence interval (CI): [6.3-10.6]) vs. 5.8 [5.5-6.1] months, p = 0.055). Due to reported resistance in NECs we analyzed NSCLC-ct without pemetrexed-ct; OS was significantly longer for NSCLC-ct (n = 15) compared to SCLC-ct (9.6 [7.7-11.6] vs. 5.8 [5.5-6.1] months, p = 0.026). PFS of *RB1*^{wt} NSCLC-ct treated patients was significantly longer than SCLC-ct (p = 0.044), without pemetrexed (p = 0.018). In patients with *RB1*^{mt} LCNEC OS/PFS was not significantly different for NSCLC-ct vs. SCLC-ct. **Conclusions:** In LCNEC with *RB1*^{wt}, NSCLC-ct correlates with a more favorable outcome compared to SCLC-ct. However, *RB1*^{mt} *LCNEC* treated with NSCLC-ct do similarly worse as SCLC-ct.Prospective studies should be initiated.

9062 Poster Session (Board #388), Sat, 8:00 AM-11:30 AM

Response of germline and somatic smoothened (SMO) mutations in non-small cell lung cancer (NSCLC) to hedgehog inhibitor vismodegib. *First Author: Anne S. Tsao, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Smoothened (SMO) gene somatic mutations activate hedgehog signaling in basal cell cancers (BCC) and medulloblastomas but have not been reported in NSCLC. We detected somatic and germline *SMO*mutations in NSCLC patients (A-C) and sought to characterize the mutations further. **Methods:** We performed tumor/blood germline sequencing of *SMO* mutations, familial germline mutation testing (saliva specimens), somatic mutation analysis of TCGA lung carcinoma datasets, and germline mutation analysis of the TCGA and 3 additional large cohorts (n = 1933). To evaluate the functional significance of *SMO*P641A, HCC4011 lung cancer cells were transfected with a wild-type SMO or *SMO*P641A expression vector and a predictive model was created. **Results:** NSCLC *SMO*P641A *in vitro* activated the hedgehog pathway, and vismodegib/cyclopamine inhibited tumor cell growth. Structural modeling suggests that *SMO* P641A induces conformational changes and disrupts PTCH-SMO interaction leading to constitutive activation. In the NSCLC TCGA databases, somatic *SMO* mutations occur 1.7%. In the overall TCGA database, germline *SMO* P641A occurred in 0.11% of cancer patients (multiple cancers) compared with 0% in cancer-free individuals. Patient A (never-smoking SCC) had a 46% RECIST reduction within 6 weeks for 6 months on vismodegib. His 3-generation family pedigree identified germline *SMO*P641A in one daughter (who developed BCC early). Two additional NSCLC patients (B – germline P641A and C –M525L received vismodegib; B initially stabilized but stopped vismodegib after 14 weeks for toxicity while patient C had no response. **Conclusions:** *SMO* mutations are targetable, potentially heritable, oncogenic drivers in NSCLC and other cancers. Tumor genetic profiling should consider including *SMO* gene, especially in never-smoking lung SCC patients. Additional studies are needed to define the role of germline/somatic SMO alterations in promoting carcinogenesis, interactions with P53 alterations, and the responsiveness of different SMO mutations to hedgehog inhibitors. Currently, the ongoing ECOG-ACRIN MATCH study (NCT02465060) treats SMO/PTCH mutated patients with vismodegib.

9063 Poster Session (Board #389), Sat, 8:00 AM-11:30 AM

Primary resistance to *ALK* inhibitor in *ALK*-positive non-small-cell lung cancer. *First Author: Jin Kang, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Crizotinib is a standard of care in anaplastic lymphoma kinase (ALK)-positive advanced non-small-cell lung cancers (NSCLC). Undoubtedly, the resistance to crizotinib is a current bottleneck which resists its clinical application. However, there are few reports about the primary resistance to crizotinib, especially the difference between the primary and acquired resistance. **Methods:** Totally,171 ALK-positive NSCLC patients treated with crizotinib were reviewed at the Guangdong General Hospital in China from October 2010 to July 2016. The status of an ALK gene rearrangement was assessed by Vysis ALK Break Apart fluorescence in situ hybridization (FISH), reverse transcription polymerase chain reaction (RT-PCR), or ALK Ventana immunohistochemistry (IHC). Among 18 patients with primary resistance, 12 had tumor tissue (n = 6) or plasma (n = 6) at the baseline and meanwhile tumor tissue (n = 2) or plasma (n = 2) specimens were collected for 4 patients after primary resistance. Next generation sequencing was used to test the tissue or plasma from 16 patients with primary resistance to crizotinib. **Results:** Among 171 patients treated with crizotinib, 47.9% (82/171) developed acquired resistance, and 10.5%(18/171) had primary resistance. Using the specimens at the baseline, there were 6 (33.0%) patients with uncommon ALK fusion partners, 4 (22.2 %) with BIM deletion polymorphism, 2 (11.1%) with PTEN/mTOR mutations, and 1 (5.5 %) with a pre-existing ALK G3709A mutation.These uncommon ALK fusion partners included ZC3H8-ALK, ALK-LOC102723854 and ALK-DTNB-ASXL2. In addition, one patient was found to coexsist with *KIT* mutation after primary resistance. Median PFS was significantly shorter in patients with primary resistance than those with acquired resistance (2.2 vs. 10.8 months, P < 0.001). **Conclusions:** Uncommon ALK fusion partners, *BIM* deletion polymorphism, PTEN/mTOR mutation, pre-existing ALK G3709A mutation and *KIT* mutation might contribute to molecular mechanisms of primary resistance to crizotinib in ALK-positive NSCLC. Further investigations are warranted to overcome these primary resistances.

9064 Poster Session (Board #390), Sat, 8:00 AM-11:30 AM

Updated efficacy and safety of the j-alex study comparing alectinib (ALC) with crizotinib (CRZ) in ALK-inhibitor naïve *ALK* fusion positive non-small cell lung cancer (*ALK*+ NSCLC). *First Author: Yuichi Takiguchi, Graduate School of Medicine Chiba University, Chiba, Japan*

Background: ALC is a highly selective, CNS-active ALK tyrosine kinase inhibitor. In the J-ALEX study, ALC proved superior efficacy and tolerability compared to CRZ at the pre-planned interim analysis at 83 progression free survival (PFS) events (51% of target events) . Here we report the updated data with a further 10 months of follow up. **Methods:** Patients with advanced *ALK+* NSCLC were randomized 1:1 to receive ALC 300 mg b.i.d or CRZ 250 mg b.i.d and stratified by ECOG PS, treatment line, and clinical stage. Study Treatment was continued until disease progression or unacceptable toxicity. The primary endpoint was PFS according to the blinded independent review. Secondary endpoints included investigator-assessed PFS, overall survival, objective response rate and safety. **Results:** From Nov 2013 to Aug 2015, 207 patients were enrolled. Data cut off for the present analysis was Sep 2016. Median durations of PFS follow up were 20.5 months in the ALC arm and 20.4 months in the CRZ arm with 116 events by independent review observed. The updated PFS HR was 0.38 (95% CI: 0.26-0.55, $p< 0.0001$). Median PFS was 25.9 months (95% CI: 20.3-not estimated) with ALC and 10.2 months (95% CI: 8.3-12.0) with CRZ. For patients without brain metastasis at baseline (n = 164), ALC prevented CNS metastasis onset compared to CRZ (HR = 0.19, 95% CI: 0.07-0.53). For patients with brain metastasis at baseline (n = 43), ALC also prevented CNS progression compared to CRZ (HR = 0.51, 95% CI: 0.16-1.64). Adverse events (AEs) with frequency of more than 30% were constipation (37.9%) and nasopharyngitis (32.0%) in the ALC arm, while in the CRZ arm nausea (76.0%), diarrhea (74.0%), vomiting (57.7%), visual disturbance (54.8%), dysgeusia (51.9%), constipation (46.2%), increased ALT (32.7%), and increased AST (31.7%) were observed. Grade 3-4 AEs occurred with greater frequency in the CRZ arm (ALC: 32.0% vs CRZ: 56.7%). There were no Grade 5 AEs in either arm. **Conclusions:** In the updated analysis, ALC consistently showed superior efficacy compared to CRZ in systemic disease and prevention of CNS progression. ALC was also associated with a more favorable tolerability profile than CRZ. Clinical trial information: JapicCTI-132316.

9065 Poster Session (Board #391), Sat, 8:00 AM-11:30 AM

Activity of brigatinib (BRG) in crizotinib (CRZ)-resistant ALK+ NSCLC patients (pts) according to ALK plasma mutation status. *First Author: Lyudmila Bazhenova, University of California San Diego Moores Cancer Center, La Jolla, CA*

Background: BRG is a potent and selective ALK inhibitor with preclinical and clinical activity against wild-type ALK and a broad range of mutants associated with clinical CRZ resistance, including G1202R. Herein we examine the association between BRG efficacy and ALK mutation status using plasma specimens from the initiation of BRG treatment (baseline [BL]) and the end of BRG treatment (EOT) in CRZ-resistant ALK+ NSCLC pts enrolled in the BRG Ph1/2 or pivotal Ph2 (ALTA) trials. **Methods:** Plasma samples were analyzed using the Resolution Bioscience ctDx Lung Panel v3.0. BRG activity was described using the confirmed objective response rate (cORR) (RECIST v1.1). Data are reported as of May 31, 2016 for the Ph1/2 (NCT01449461) and ALTA (NCT02094573) trials. **Results:** Of 291 CRZ-resistant ALK+ NSCLC pts enrolled in the Ph1/2 (N = 69) and ALTA (N = 222) trials, evaluable plasma samples were obtained from 67 pts at BL. cORR to BRG in these pts was 49% (33/67). An ALK fusion was detected in plasma in 45% (30/67) of these pts (cORR 57% [17/30]), of whom 33% (10/30) had secondary ALK mutations (cORR 50% [5/10]) and 67% (20/30) did not (cORR 60% [12/20]). Best responses in pts with secondary ALK mutations were: 2 CR (ALK amplification [Amp] copy number [CN] = 10; T1151M); 3 PR (L1196M; E1408V; Amp CN = 6); 4 SD (L1196M; E1419K; F1174C; C1156Y+S1206F+G1269A); 1 PD (T1151R+C1156Y+E1161D+F1174L). Of 67 pts with evaluable plasma at BL, 35 discontinued BRG therapy, of whom 20 had evaluable samples collected at EOT. No new mutations were detected at EOT in 75% (15/20) of pts. Complex mutation patterns were associated with resistance in the remaining 25% (5/20): High-level ALK-Amp (CN = 58); ALK-Amp (CN = 14)+MET-Amp (CN = 6); ALK-S1206F+S1206C+Amp (CN = 6); ALK-G1202R+L1196M+L1198Q; ALK-G1202R+BRAF-V600E+KRAS-G12D. **Conclusions:** ALK fusions were detected in plasma in $<$ 50% of CRZ-resistant ALK+ NSCLC pts. BRG had substantial activity in ALK fusion–positive pts with a range of CRZ-resistance mutations. Neither primary nor secondary resistance to BRG was associated with any single plasma ALK mutation. The therapeutic implications of complex secondary resistance patterns associated with BRG require further exploration. Clinical trial information: NCT01449461, NCT02094573.

9066 Poster Session (Board #392), Sat, 8:00 AM-11:30 AM

Patient-reported outcomes and quality of life in ALTA: The randomized phase 2 study of brigatinib (BRG) in advanced ALK+ non–small cell lung cancer (NSCLC). *First Author: Corey J. Langer, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: The ALTA trial (NCT02094573), an open-label, phase 2, randomized, multicenter, international study, evaluated the efficacy and safety of BRG (arm A: 90 mg qd and arm B: 180 mg qd with 7-day lead-in at 90 mg) in patients (pts) with advanced anaplastic lymphoma kinase–positive (ALK+) NSCLC whose disease had progressed on prior therapy with crizotinib (CRZ). The objective of this analysis was to describe pt-reported outcomes (PROs) in the ALTA study. **Methods:** PROs were collected using the EORTC QLQ-C30 at baseline and on the first day of each cycle. Multivariable mixed effects models were constructed to estimate adjusted mean changes from baseline in QLQ-C30 scores. Cumulative distribution function (CDF) plots of EORTC QLQ-C30 change scores from baseline to Cycle 5 were generated to evaluate a clinically meaningful threshold of individual pt change, which was determined through anchor- and distribution-based methods. **Results:** Among 222 randomized pts, 208 (94%) completed the questionnaire at baseline and at least 1 on-treatment PRO follow-up. In multivariable analyses, there were no statistically significant differences in Global Health Status (GHS)/QOL between arms over time when adjusted for baseline score, ECOG status, and presence of liver or bone metastases. At Cycle 5, CDF plots indicated that 80% of all pts experienced an increase or no change in GHS/QOL scores; 50% of all pts experienced a clinically meaningful improvement. At Cycle 5, 80% of all pts reported a reduction or no change in pain score, and 90% of all pts reported a reduction or no change in dyspnea score. Approximately 30% of pts had clinically meaningful reductions in these symptoms. Less than 15% and $<$ 5% of all pts reported clinically meaningful worsening of nausea/vomiting and diarrhea scores, respectively, at Cycle 5. **Conclusions:** Treatment with BRG for CRZ-refractory ALK+ NSCLC resulted in improved GHS/QOL scores and reduction in pain and dyspnea scores, while rates for nausea/vomiting and diarrhea were minimally worse. These pt-level benefits support BRG as a promising treatment option. Clinical trial information: NCT02094573.

9067 Poster Session (Board #393), Sat, 8:00 AM-11:30 AM

Differential crizotinib efficacy among ROS1 fusion partners in ROS1-positive non-small cell lung cancer. *First Author: Shun Lu, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: ROS1 rearrangement non–small-cell lung cancers can be effectively treated with ALK inhibitor such as crizotinib, but the response magnitude and duration are heterogeneous. Several ROS1 fusion partners have been identified, but few studies have focused on the effects of different fusion partners on the efficacy of crizotinib. **Methods:** Among 49 RT-PCR assay ROS1 rearrangement patients treated with crizotinib between April 2014 and November 2016, we identified 36 patients with tumor specimens that could be evaluated for the presence of different ROS1 fusion partners by Sanger sequencing. Patients continued crizotinib until RECIST-defined progression. We retrospectively evaluated the efficacy of crizotinib on the basis of the objective response rate(ORR), progression-free survival (PFS) and overall survival (OS) according to the different ROS1 fusion partners. **Results:** The most frequent ROS1 fusion partner was CD74-ROS1 (CD74-E6; ROS1-E34) in 16 patients (44.4%), followed by EZR-ROS1 (EZR-E10; ROS1-E34) in 7 patients (19.4%), SDC4 (SDC4-E2; ROS1-E32) in 4 patients (12%), SLC34A2-ROS1 (SLC34A2-E14del; ROS1-E32) in 2 patients (5.6%) and TPM3 (TPM3-E8; ROS1-E35) in 2 patients (5.6%). We also found that SDC4+EZR (SDC4-E2; ROS1-E32/EZR-E10; ROS1-E34) in 2 patients (5.6%), dual CD74-ROS1 (CD74-E6; ROS1-E32/34) in 2 patients (5.6%), CD74+SDC4 (SDC4-E2; ROS1-E32/CD74-E6; ROS1-E34) in 1 patient (2.8%). ORR was 83.3% in all patients, whereas it was 70.58% and 92.35% in the CD74 and non–CD74 groups, respectively (P = 0.17). The median PFS was longer in non–CD74 than in those with CD74 (median PFS, 17.67 months [95% CI, 12.14 to 23.19] vs 19.30 months [95% CI, not reached], respectively; P = 0.405) with no statistical significance. The median OS was significantly longer in patients with non–CD74 than in those with CD74 (median OS, 28.07 months [95% CI, 23.93 to 32.1] vs not reached, respectively; P = 0.043). Multivariable analysis identified 1 significant factor associated with OS, brain metastasis before crizotinib treatment (P $<$ 0.001). **Conclusions:** Our results indicate the better OS of crizotinib in patients with non–CD74 vs CD74. The ROS1 fusion partnerS might affect the efficacy of ALK-TKIs.

9068 Poster Session (Board #394), Sat, 8:00 AM-11:30 AM

Cost-effectiveness analysis comparing companion diagnostic tests for EGFR, ALK and ROS-1 versus next-generation sequence (NGS) in advanced adenocarcinoma lung cancer patients. *First Author: Luciene Schluckebier, Brazilian Cancer Foundation, Rio De Janeiro, Brazil*

Background: Success of a target therapy is directly correlated with the accuracy of its companion diagnostic test. Without a corresponding biomarker, target therapy may yield shorter survival, waste time, increase burdens and costs. As important as conducting cost-effectiveness studies for therapies, it is also valuable to compare different molecular tests. In lung cancer, the mutational status of EGFR and translocation of ALK and ROS-1 are commonly tested to offer the best intervention. Our objective is to evaluate the cost-effectiveness of a unique exam using NGS versus other routinely used tests such as the ones which involve RT-PCR and FISH. **Methods:** Target population is NSCLC, adenocarcinoma, and candidates to first-line therapy. Strategy 1: test EGFR mutation if EGFR test is negative, individual follow to FISH for ALK; if FISH is negative, follow to FISH for ROS-1. Strategy 2: differs from 1 since FISH for ALK and ROS are requested together. Strategy 3: all individuals are submitted to NGS (multicomplex platform which include EGFR, ALK, ROS-1 and other genes). Tests could also be classified as unknown due to the quality of tumor sample. Prevalence of biomarker, test accuracy and proportion of unknown results were used to calculate each decision tree branch. Sensitivity and specificity was obtained from literature review using Sanger as reference standard for RT-PCR tests and NGS. The study was analyzed from a healthcare-payer perspective based on Brazilian private sector. Costs were based on data from diagnostic companies, ANS and AMB-CBHPM 2016. **Results:** The use of NGS added 24% extra cases correct identified as well as extra costs (US$ 800.76; PPP 2015) attributed to the molecular testing. The ICER comparing NGS with sequential tests was US$ 3,381.82/correct case detected. Comparing strategy 2:1, the ICER was US$937.86/correct case detected. **Conclusions:** this study is part of an effort to integrate companion diagnostics discussions on precision medicine and covered drugs in the Brazilian health system. These findings can also subsidy cost-effectiveness studies that incorporates subsequent treatments and survival.

9069 Poster Session (Board #395), Sat, 8:00 AM-11:30 AM

Baseline frequency of brain metastases and outcomes with multikinase inhibitor therapy in patients with *RET*-rearranged lung cancers. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In phase 2 trials, multikinase inhibitors with activity against RET are active in a subset of patients (pts) with *RET*-rearranged lung cancers (response rate of 28%, phase 2 study of cabozantinib; Drilon et al Lancet Oncol 2016). Data on the incidence of brain metastases and outcomes with multikinase inhibitor therapy in pts with intracranial disease have not previously been reported. **Methods:** The frequency of brain metastases at diagnosis of metastatic disease was evaluated in pts accrued to a global registry of *RET*-rearranged lung cancer pts identified by a multicenter network of thoracic oncologists (Gautschi et al JCO 2017). A proportion of pts were treated with 9 multikinase inhibitors including cabozantinib, vandetanib, lenvatinib, alectinib, and ponatinib. On a prospective phase 2 trial (NCT01639508), patients with asymptomatic brain metastases were eligible. Intracranial response to cabozantinib (RECIST v1.1) was evaluated in an exploratory fashion. **Results:** 114 registry pts with *RET*-rearranged lung cancers had metastatic disease at diagnosis. Baseline brain metastases were identified in 27% (95%CI 18-34%, n = 20/75) of pts with available information. No differences ($p > 0.05$) in age, smoking history, or upstream fusion partner (*KIF5B* 100% vs 84%, with and without brain metastases, p = 0.53) were noted. In 37 pts treated with multikinase inhibitors with activity against RET, there were no significant differences in median PFS (2.1 vs 2.1 months, p = 0.41) or median OS (3.9 vs 7.0 months, p = 0.10) in pts with (n = 10) and without (n = 27) brain metastases. On a phase 2 trial of cabozantinib, baseline untreated brain metastases were present in 5 pts. Intracranial disease control (stable disease; -34% and -1% in 2 pts with measurable disease) was achieved in 4 of 4 pts with measurable or evaluable intracranial disease with time to treatment discontinuation ranging from 2.4 months to 2.9 years. **Conclusions:** Brain metastases are present in a substantial proportion of *RET*-rearranged lung cancer pts. Intracranial disease control can be achieved in select pts by a multikinase inhibitor. Novel RET-directed targeted therapy strategies should address intracranial disease. Clinical trial information: NCT01639508.

9070 Poster Session (Board #396), Sat, 8:00 AM-11:30 AM

A single-arm phase II trial of afatinib in pretreated patients with advanced NSCLC harboring a *HER2* mutation: The ETOP NICHE trial. *First Author: Egbert F. Smit, Vrije Universiteit VU Medical Centre, Amsterdam, Netherlands*

Background: *HER2* mutations are identified in about 2% of lung adenocarcinomas and are critical for lung carcinogenesis. Afatinib is a selective and irreversible erbB family blocker with a manageable toxicity profile and promising results in small retrospective studies targeting HER2 in NSCLC. **Methods:** NICHE is a single-arm phase II trial exploring the potential of afatinib to control disease (complete or partial response or disease stabilization for ≥12 weeks) in pre-treated patients with advanced NSCLC harboring *HER2* exon 20 mutations. Patients were treated with afatinib 40 mg/day *p.o.* until tumor progression or lack of tolerability. A Simon's two stage phase II design was adopted, to explore whether afatinib can achieve a DCR of 75%, as opposed to a DCR of 50% under the current treatment options. For a 1-sided type I error of 10% and power of 80%, a total of 22 patients were needed. **Results:** As of 24 November 2016, 13 patients were recruited into the trial. Median age was 60 years, 69% female and 62% never smokers. The overall toxicity profile was in the expected range, with 5 patients experiencing serious adverse events (dyspnea, diarrhea, dehydration, epistaxis, pleural, pericardial and renal insufficiency). The median follow-up was 23 weeks (IQR 12 – 39). Three patients died and 10 were still on follow-up, among them five were still on treatment. Total of 7 patients (54%) achieved DC at 12-weeks, 3 patients had PD before and 3 at 12-weeks. The 12-week PFS was 51% (95% CI: 22 - 75) and the median PFS 13 weeks (95% CI 6 - NE). In the 1st stage analysis of the Simon's design, with 9 patients included, the stopping boundary was crossed. Therefore and upon recommendations of the ETOP IDMC, recruitment into the trial was stopped prematurely in December 2016. Treatment and follow-up of the enrolled patients continues as planned. **Conclusions:** Based on the interim results, afatinib did not show the expected potential to control disease in this patient population. However in the full analysis set with 13 patients, clear signs of activity were seen. A comprehensive biomolecular analysis of the tumors is currently ongoing in order to identify a subgroup of patients who might still derive benefit from afatinib treatment. Clinical trial information: NCT02369484.

9071 Poster Session (Board #397), Sat, 8:00 AM-11:30 AM

Afatinib in patients with metastatic *HER2*-mutant lung cancers: An international multicenter study. *First Author: Wei-Chu Victoria Lai, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor 2 (*HER2, ERBB2*) mutations have been identified as oncogenic drivers in 3% of lung cancers. Afatinib is an irreversible tyrosine kinase inhibitor of HER1 (EGFR), HER2 and HER4 and has been described in case reports to have activity in *HER2*-mutant lung cancers. However, there is little data to inform the clinical use of afatinib. **Methods:** We reviewed patients with metastatic *HER2*-mutant lung cancers treated with afatinib among 7 institutions between 2009 and 2016. The primary endpoint was investigator assessed overall response rate using RECIST v1.1. Other data collected included types of *HER2* mutations, duration of afatinib treatment and overall survival. **Results:** We identified 27 patients with metastatic *HER2*-mutant lung cancers treated with afatinib. Median age at diagnosis was 63 (range 40 to 84); majority were men (n = 16; 59%) and never-smokers (n = 18; 67%). All tumors were adenocarcinomas, and the majority were Stage IV at initial diagnosis (n = 16; 59%). A 12-base pair (bp) in-frame insertion YVMA in exon 20 (p.A775_G776insYVMA) was present in 16 patients (59%). In addition, there were three 9-bp insertions, two 3-bp insertions and two single bp substitutions (L755F and D769H) in exon 20; two single bp substitutions (S310F) in exon 8; one exon 17 V659E mutation; and one single-nucleotide polymorphism (Ile655Val). Median duration on afatinib was 2 months (range 1 to 27); median line of prior treatment was 3 (range 1 to 6). Eight patients had previously received trastuzumab prior to afatinib and one concurrently with afatinib. Overall response rate was 15% (n = 4; 95% CI 4 to 34%); the four partial responses lasted 5, 5, 6 and 10 months. The 3 longest partial responders had a 12-bp insertion in exon 20 (YVMA); the remaining partial responder had a 9-bp insertion in exon 20. Median overall survival from diagnosis date of metastatic disease was 23 months (95% CI 18 to 62). **Conclusions:** Afatinib produced partial responses in 15% of patients with metastatic *HER2*-mutant lung cancers, including insertion YVMA. Our findings confirm the activity of afatinib and provide data supporting a framework for its use in the care of patients with *HER2*-mutant lung cancers.

9072 Poster Session (Board #398), Sat, 8:00 AM-11:30 AM

***BRAF* fusions in clinically advanced non-small cell lung cancer: An emerging target for anti-*BRAF* therapies.** *First Author: Venkataprasanth P. Reddy, Shawnee Mission Cancer Center, Westwood, KS*

Background: Although far less common than *BRAF* V600E base substitutions (subs) classically associated with melanomas and colorectal carcinomas, *BRAF* subs occur in 1-2% of non-small cell lung cancer (NSCLC). *BRAF* fusions are emerging treatment targets for Spitzoid melanomas and other solid tumors. The frequency of *BRAF* fusions and targeting potential in NSCLC has not been widely described. **Methods:** Hybridization capture-based comprehensive genomic profiling (CGP) was performed on 17,128 NSCLC FFPE samples sequenced to a mean coverage depth of > 550X for up to 315 cancer-related genes plus 37 introns from 19 genes frequently rearranged in cancer. Genomic alterations (GA) included short variant (SV) base subs and insertions/deletions, copy number alterations, and rearrangements/fusions. Tumor mutational burden (TMB; mut/Mb) was calculated on up to 1.1 Mb of sequenced DNA. **Results:** *BRAF* fusions were identified in 42/17,128 (0.2%) NSCLC profiled. Median patient age was 67 (range 44-93 yrs). Of the *BRAF* fusion positive NSCLC, 55% were female. Biopsies were obtained from primary lung tumor (48%) and metastatic sites (52%). The most frequent 5' partners were *AGK*, *DOCK4*, and *TRIM24*. Multiple novel *BRAF* fusions were identified. The genes most frequently co-altered with *BRAF* fusions were *TP53* (67%), *CDKN2A* (31%), *EGFR* (29%) and *CDKN2B* (26%). Overall TMB in the *BRAF* fusion positive cohort was low (median 3.8 mut/Mb), although 3/42 cases (7%) had > 20 mut/Mb. Of the *BRAF* fusion driven NSCLC, 10 cases (24%) featured *EGFR* SV alterations. Two *BRAF* fusion/*EGFR* SV cases featured primary exon 19 deletion and T790M mutation. Examples of *BRAF* fusion driven NSCLC responding to a combination of *BRAF* and MEK inhibitors (MEKi) will be presented. **Conclusions:** NSCLC *BRAF* fusions are a rare GA that may be associated with acquired resistance in a subset of *EGFR*-mutated NSCLC progressing on anti-*EGFR* TKI therapies. Given clinical evidence for the activity of targeted therapy approaches, molecular eligibility for clinical trials of MEKi should include these variants. The clinical evidence for responsiveness of *BRAF* fusion driven NSCLC provides an opportunity to personalize treatments and improve clinical outcomes for patients.

9073 Poster Session (Board #399), Sat, 8:00 AM-11:30 AM

Targeted therapy for non-small cell lung cancer (NSCLC) with HER2, BRAF, or hedgehog alterations: Interim data from MyPathway. *First Author: John D. Hainsworth, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: Treatments targeting critical molecular alterations (EGFR, ALK, and ROS1) in NSCLC are highly effective. MyPathway (NCT02091141) is an ongoing, phase 2, multi-basket study evaluating the efficacy of targeted treatment in non-indicated tumor types harboring alterations in the HER2, BRAF, Hedgehog (Hh), or EGFR pathways. Interim results in NSCLC are presented. **Methods:** Patients with previously treated advanced NSCLC and alterations in the HER2 (amplification and/or mutation), BRAF (V600E or other mutations), Hh (SMO or PTCH-1 mutations), or EGFR (mutations other than known activating mutations) pathways received standard doses of pertuzumab + trastuzumab, vemurafenib, vismodegib, or erlotinib, respectively, until disease progression or unacceptable toxicity. The HER2, BRAF, and Hh cohorts are included in this analysis. The primary endpoint is investigator-assessed objective response rate (ORR, defined as complete response [CR] + partial response [PR]) by RECIST v1.1. **Results:** As of November 30, 2016, 61 patients with NSCLC and HER2 (n = 36), BRAF (n = 22), or Hh (n = 3) alterations have been treated (median age of 64 years, 49% male, 85% adenocarcinoma, and a median of 2 previous regimens). Median treatment duration was 1.8 (range, 0–21.4) months. Efficacy in the 55 patients with the minimum required follow-up for efficacy analysis is summarized in the table. **Conclusions:** Targeted therapy is active in patients with previously treated NSCLC harboring BRAF V600E mutations or HER2 alterations (amplifications and/or mutations). These cohorts have been expanded as MyPathway accrual continues. Additional efficacy data and details regarding molecular alterations will be presented. Clinical trial information: NCT02091141.

	Patients, n	ORR, n (%)	Clinical benefit rate[a], n (%)	Durations of objective responses, months
HER2 alterations[b]	31	6 (19)	10 (32)	< 1+, 3+, 5+, 6, 8, 10
BRAF V600E	14	6 (43) (1 CR)	8 (57)	4, 4, 5, 5+, 10+, 14
BRAF other	7	0	1 (14)	NA
Hh	3	0	1 (33)	NA

+ indicates response is ongoing. [a]CR + PR + stable disease > 4 months. [b]HER2 amplified and/or mutated.

9074 Poster Session (Board #400), Sat, 8:00 AM-11:30 AM

Efficacy of vemurafenib in patients (pts) with non-small cell lung cancer (NSCLC) with *BRAF*^{V600} mutation. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *BRAF*^{V600} mutations occur in 1–2% of pts with NSCLC. We previously reported the efficacy of vemurafenib, a selective BRAF^{V600} inhibitor, in *BRAF* mutation-positive non-melanoma tumors (VE-BASKET study). We now present final data for the expanded NSCLC cohort. **Methods:** This open-label, histology-independent, phase 2 study included 6 prespecified cohorts (including NSCLC) plus one 'all-others' cohort. Pts received vemurafenib (960 mg bid) until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (RECIST v1.1). Secondary endpoints included best overall response rate, duration of response (DoR), progression-free survival (PFS), and overall survival (OS). Because the pre-specified clinical benefit endpoint was met in the initial NSCLC cohort, the cohort was expanded. ClinicalTrials.gov identifier NCT01524978. **Results:** Database lock was 12 Jan 2017. Of 208 pts enrolled at 25 centers worldwide, 62 pts had NSCLC: median age 65 years; 56% male; 13% had no prior systemic therapy; 50% had ≥2 prior therapies. Responses were seen in previously treated and untreated pts (Table). The most common all-grade adverse event (AE) was nausea (40%); grade 3–5 AEs included keratoacanthoma (15%) and squamous cell carcinoma of the skin (15%). Six pts discontinued vemurafenib due to AEs; two had non-treatment-related fatal AEs. **Conclusions:** Vemurafenib showed evidence of encouraging efficacy in pts with NSCLC with *BRAF*^{V600} mutation, with prolonged PFS in previously untreated pts; median OS was not estimable due to ongoing responses. The safety profile of vemurafenib was similar to that seen in melanoma studies. Our results suggest a role for BRAF inhibition in NSCLC with *BRAF* mutations. Clinical trial information: NCT01524978.

	Previously untreated (n=8)	Previously treated (n=54)	All (n=62)
Confirmed response, n (%) 95% CI	3 (38) 9–76	20 (37) 24–51	23 (37) 25–50
Stable disease, n (%)	5 (63)	21 (39)	26 (42)
Missing/not evaluable, n (%)	0	5 (9)	5 (8)
Median DoR, months (95% CI)	NE (7.2–NE)	6.1 (5.5–18.4)	7.2 (5.5–18.4)
Median PFS, months (95% CI)	12.9 (4.0–NE)	6.1 (5.1–8.3)	6.5 (5.2–9.0)
Median OS, months (95% CI)	NE (6.0–NE)	15.4 (8.2–22.6)	15.4 (9.6–22.8)

NE: not estimable (insufficient progression and death events)

9075 Poster Session (Board #401), Sat, 8:00 AM-11:30 AM

Updated survival of patients (pts) with previously treated *BRAF* V600E–mutant advanced non-small cell lung cancer (NSCLC) who received dabrafenib (D) or D + trametinib (T) in the phase II BRF113928 study. *First Author: David Planchard, Gustave Roussy, Villejuif, France*

Background: *BRAF* V600E mutations occur in 1% to 2% of lung adenocarcinomas and act as oncogenic drivers. Initial cohorts of the BRF113928 (NCT01336634) trial evaluated efficacy and safety of D monotherapy (cohort A; n = 78) or D + T (cohort B; n = 57) in pts with previously treated *BRAF*V600E–mutant metastatic NSCLC. At primary analysis, overall response rates (ORRs) were 33.3% and 63.2% in pts who received D or D + T, respectively. Furthermore, durable response (median duration of response [DOR], 9.0 mo) was observed in D + T pts. Here, we present an updated survival analysis based on additional follow-up. **Methods:** In this phase 2 trial, 2 cohorts (A and B) of pts with previously treated metastatic *BRAF*V600E–mutant NSCLC were enrolled sequentially. The primary endpoint was investigator-assessed ORR. Secondary efficacy endpoints included progression-free survival (PFS), DOR, and overall survival (OS). D and T were dosed orally at the established phase 2 dose of D 150 mg twice daily and T 2 mg once daily. **Results:** This updated analysis had a median follow-up of 16.2 mo, which represented an additional 10 mo of follow-up. Median OS was 12.7 mo (95% CI, 7.3-16.3) with 57 deaths reported for pts treated with D monotherapy and 18.2 mo (95% CI, 14.3-not estimable [NE]) with 33 deaths reported for pts treated with D + T. Detailed efficacy results are presented in the table. Investigator-assessed ORR, DOR, and PFS were supported by independent review committee assessments. No new safety signals were observed for D + T. **Conclusions:** This update of the BRF113928 study confirms that durable responses and encouraging survival were achieved with combination D + T in pts with *BRAF*V600E–mutant NSCLC. Clinical trial information: NCT01336634.

Immune marker profiling and PD-L1, PD-L2 expression mechanisms across non-small cell lung cancer mutations. *First Author: Maria Toki, Yale School of Medicine, New Haven, CT*

Background: PD-1/PD-L1 axis inhibitors have been proven effective, especially in patients expressing Programmed Death Ligand 1 (PD-L1). Their clinical efficacy in patients with epidermal growth factor receptor (EGFR) activating mutations is still unclear, while KRAS mutations seem to be associated with high response rates. In this study we investigated the expression of PD-L1, PD-L2 and Tumor Infiltrating Lymphocyte (TIL) status as a function of mutation status in Non-Small Cell Lung Cancer (NSCLC). **Methods:** We used the AQUA method of quantitative fluorescence (QIF) to compare PD-L1 and PD-L2 expression and to characterize TILs populations and their activation status in over 150 NSCLC patient tumors with known mutation status. EGFR activation was assessed in situ using the proximity ligation assay (PLA) for EGFR and GRB2 and T cell activation was assessed using a novel multiplexed QIF assay including CD3, Granzyme B and Ki67. **Results:** PD-L1 tumor and stroma expression was significantly lower in EGFR mutant compared to KRAS mutant ($p = 0.009$) and EGFR/KRAS Wild Type ($p < 0.0001$) tumors, while they had a higher frequency of PD-L2 expression. Conversely, KRAS mutants had significantly lower PD-L2 tumor and stroma expression but they were also more inflamed with higher CD4+, CD8+ and CD20+ TILs. Subgroup analysis of patients by their TILs activation status revealed that EGFR mutants had a very high frequency of inactive TILs even though lymphocytes were present in the tumor microenvironment. In contrast, in KRAS mutants, when TILs were present, they were almost always active. Finally, we find that PLA-defined activated EGFR correlated with increased PD-L1 expression in EGFR mutants but not in EGFR WT, while TIL activation was associated with higher PD-L1 in EGFR/KRAS WT. **Conclusions:** Our findings are consistent with the unique biology of EGFR mutant tumors. The high frequency of inactive TILs could explain the low immune therapy response rates in this patient group. Similarly, in this group, the reason PD-L1 expression fails to predict response may be due to expression as a result of constitutive oncogenic signaling rather than immune signaling, which would be associated with high PD-L1 levels and TILs activation.

9077 Poster Session (Board #403), Sat, 8:00 AM-11:30 AM

Nivolumab-induced interstitial lung disease (ILD) in Japanese patients with non-small cell lung cancer: A study on risk factors for fatal outcome. *First Author: Terufumi Kato, Kanagawa Cancer Center, Yokohama, Japan*

Background: We investigated case reports of nivolumab-induced ILD in patients with non-small cell lung cancer to identify risk factors for poor prognosis of ILD. **Methods:** Among data obtained during post-marketing surveillance of nivolumab, case reports of ILD with detailed clinical course and chest imaging (CT) findings were assessed by the ILD Expert Review Committee, which consists of respiratory medicine specialists and expert chest radiologists. The imaging findings were examined and classified into those with typical or atypical patterns. Atypical patterns included shadows limited to surrounding tumors designated as "peritumoral infiltration", relapse of radiation pneumonitis, worsening of underlying infection, and predominant shadow in diseased side. CT pattern was classified as DAD (diffuse alveolar damage) or non-DAD. Data were analyzed using a multivariate stepwise logistic regression analysis. **Results:** Among 160 reported cases of ILD, 140 cases were considered to be induced by nivolumab. Imaging findings showed typical patterns in 92 patients, and 23 (25.0%) died of ILD. Atypical patterns were noted in 48 patients, and 5 (10.4%) died of ILD. The following table summarizes the results of univariate and multivariate analyses of risk factors for poor prognosis of ILD. See table. DAD pattern was observed in 20, 14 (70%) among them showed fatal outcome, whereas non-DAD pattern showed it in 14/120 (11.7%). Male and pretreatment CRP level were significant risk factors for fatal outcome. **Conclusions:** Nivolumab-induced ILD may show some atypical pattern that was not seen in conventional chemotherapy or EGFR-TKI. Outcome of patients with atypical patterns was better than those with typical patterns. DAD pattern at CT, male, and pretreatment level of CRP were identified as risk factors of fatal outcome.

Factors	Category	N	Death due to ILD N (%)	Univariate analysis Odds ratio [95% confidence interval]	Multivariate analysis P value
Gender	Male	117	25 (21.4)	1.8	0.0135

9078 Poster Session (Board #404), Sat, 8:00 AM-11:30 AM

Nivolumab-induced interstitial lung disease (ILD) in Japanese patients with non-small cell lung cancer: A study on risk factors using interim results of post-marketing all-case surveillance. *First Author: Hirotsugu Kenmotsu, Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: We investigated case reports of ILD in patients receiving nivolumab for the treatment of unresectable, advanced or recurrent non-small cell lung cancer to identify risk factors for the occurrence of nivolumab-induced ILD. **Methods:** In Japan, post-marketing all-case surveillance of nivolumab is currently underway in patients with non-small cell lung cancer who received nivolumab from December 17, 2015 to March 31, 2016. The data were retrospectively analyzed using a multivariate stepwise logistic regression analysis with a level of significance of 5% to identify risk factors for the occurrence of nivolumab-induced ILD. **Results:** A total of 3,648 patients received nivolumab during the surveillance period, and data from 1,005 patients whose case report forms were available by November 30, 2016 were analyzed. Among them ILD was reported in 58 (5.8%). The median time to onset in 42 patients who were recovering or recovered from ILD was 50 days (range: 2 to 246 days). Eleven patients died of ILD. The following table summarizes univariate and multivariate analyses of risk factors for the occurrence of ILD. **Conclusions:** In this interim analysis of Japanese lung cancer patients treated with nivolumab, incidence of ILD as immune-related AE was 5.8%. Age, abnormal findings of chest CT, and treatment line were identified as risk factors for the occurrence of ILD during treatment with nivolumab.

Factors	Category	N	patients with ILD N (%)	Univariate analysis Odds ratio [95% confidence interval]	Multivariate analysis P value

9079 Poster Session (Board #405), Sat, 8:00 AM-11:30 AM

Immune-related adverse events (IRAEs) in metastatic lung cancer patients receiving PD-1/PD-L1 inhibitors and thoracic radiotherapy. *First Author: William L. Hwang, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment but are associated with unique IRAEs, including pneumonitis (PNS). Thoracic radiotherapy (TRT) is also associated with PNS but it is unknown whether TRT+ICI increases the risk of PNS or other IRAEs. Furthermore, low serum LDH levels are associated with better response/survival to ICI but its potential role as a biomarker for IRAEs is unexplored. **Methods:** We retrospectively reviewed 164 pts with metastatic lung cancer (95% NSCLC, 5% SCLC) consecutively treated at our institution from 2013-2016 with PD-1/PD-L1 inhibitors and a minimum of one month follow-up, except in cases of rapid death from an IRAE (n =4). Pts were grouped according to TRT received (+ vs -). IRAE grades were assigned using NCI CTCAE v4.0. Outcomes were compared using Fisher's exact test and two-sided Student's t-test. **Results:** Baseline characteristics such as age, gender, smoking status, supplemental oxygen requirement, median number of chemotherapy lines prior to ICI (1 vs 1), median ICI cycles (5 vs 3), and median follow-up after ICI initiation (8 vs 7 months) were similar in the +TRT (n = 73) and -TRT (n =91) groups. Rates of grade ≥ 2 IRAEs (18.1 vs 14.4%, p = 0.67), all-grade PNS (8.2 vs 5.5%, p= 0.54), and grade ≥ 2 PNS (4.1 vs 3.3%, p = 1) were not significantly different between the +TRT and -TRT cohorts. Mean TRT dose was similar between those pts who developed PNS and those who did not (55.8 vs 55.9 Gy). In the +TRT group, 85% received TRT a median of 8.6 months before ICI. Among 7 pts (10%) who had concurrent TRT+ICI, none developed symptomatic PNS. Patients who developed grade ≥ 2 IRAEs (n= 26) had significantly higher mean serum LDH before initiation of ICI than patients who did not (283 vs 214, ref 98-192 IU/L, p= 0.03). **Conclusions:** TRT in lung cancer pts receiving ICI was not associated with increased risk of PNS in this series. LDH may be a negative predictive biomarker as pts who suffered grade ≥ 2 IRAEs had significantly higher baseline LDH than those who did not. Larger cohorts and prospective studies would be helpful to validate these findings.

9080 Poster Session (Board #406), Sat, 8:00 AM-11:30 AM

Impact of immune-related adverse events (irAE) on overall survival (OS) in patients treated with immunotherapy for non-small cell lung cancer (NSCLC). *First Author: Dwight Hall Owen, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Immunotherapy (IO) has brought dramatic clinical benefit to patients with NSCLC. Most patients tolerate IO, but serious irAE have been reported. In melanoma, a correlation between development of irAE and clinical benefit has been suggested. For NSCLC, the risk of irAE including pneumonitis has been described in clinical trials but not for the wider population. Risk factors for irAE and the impact of irAE on OS are unknown. **Methods:** A retrospective review of patients with NSCLC treated with single-agent IO between September 2014 and June 2016 was carried out at The Ohio State University. Patients had confirmed pathologic disease and received IO either on clinical trial or as standard of care. IrAE were assessed based on the treating physician diagnosis. OS was calculated from the date of initiation of IO to death from any cause or date or last follow-up. **Results:** A total of 90 patients met criteria. Median age was 67. Histology was nonsquamous in 58 (64%) and squamous in 32 (35%). Most patients received nivolumab (n = 87). Median months of IO was 2.6 (95% CI 1.9 – 4.2). IrAE occurred in 24 patients (26.67%). The most common irAE were pneumonitis (n = 8), thyroid dysfunction (n = 6), and rash/pruritus (n = 5). Other irAE included colitis in 2 patients and new onset diabetes and autoimmune hepatitis in 1 patient each. Development of pneumonitis did not have a statistically significant impact on overall survival (median OS 5.8 vs 8.1 months, p = 0.11). Prior thoracic radiation (TR) was not associated with pneumonitis (11.54% vs 8.33%, p = 0.69), but was associated with shorter survival (median OS 3.9 vs 8.7 months, p = 0.018). Development of irAE was not associated with histology (p = 1.00), KRAS mutation (p = 0.10), TP53 mutation (p = 0.09), or recent flu vaccination (p = 1.00). Patients with irAE had longer median OS (13.2 vs 5.8 months, p = 0.018). **Conclusions:** The incidence of irAE and pneumonitis match that seen in published clinical trials. The development of irAE was associated with better prognosis, whereas patients with prior TR had worse outcomes. Further prospective research is warranted to investigate the correlation of irAE with clinical benefit from IO in patients with NSCLC.

9081 Poster Session (Board #407), Sat, 8:00 AM-11:30 AM

Use of PD-1 pathway inhibitors among patients with non-small cell lung cancer (NSCLC) and preexisting autoimmune disorders. *First Author: Giulia Costanza Leonardi, Dana-Farber Cancer Institute, Boston, MA*

Background: Since patients (pts) with NSCLC and autoimmune (AI) disease were largely excluded from immune checkpoint inhibitor clinical trials, we aimed to determine the safety of PD-1 inhibitors in NSCLC pts with a history of AI diseases. **Methods:** As part of a multi-center, retrospective study, we collected clinicopathologic data from pts with advanced stage IIIB or stage IV NSCLC with a history of AI disease and who received treatment with a PD-1 inhibitor as monotherapy. Qualifying AI disorders included but were not limited to: thyroiditis (excluding hypothyroidism without clear autoimmune etiology), inflammatory bowel disease, as well as rheumatologic, neurologic and dermatologic conditions. **Results:** We identified 46 pts with NSCLC treated with a PD-1 inhibitor who also had a history of AI disease. At the time of PD-1 inhibitor treatment initiation, 13% of pts had active AI symptoms and 19% were receiving immunomodulatory agents for their AI condition. The median period of follow up after initiation of anti-PD-1 therapy was 17.4 weeks (range 0.6-72.1 weeks). Exacerbation of the underlying AI condition occurred in 8 pts (17%). Two of these pts required steroid treatment (both for rheumatoid arthritis), and three of these pts required temporary interruption of treatment due AI disease flare. Overall, twelve (26%) pts developed at least one immune-related adverse event (irAE) unrelated to the underlying AI condition (8 grade 1-2, 4 grade 3); there were no cases of grade 4-5 irAEs. PD-1 therapy was permanently discontinued in 3 cases due to the development of an irAE (1 for grade 1 pneumonitis, 1 for grade 3 transaminitis, 1 for grade 3 diabetes insipidus). **Conclusions:** In pts with NSCLC and a history of AI conditions treated with PD-1 blockade, symptomatic flare of underlying AI disease was uncommon. The rate of immune-related toxicities in this population appears similar to published studies in pts without baseline AI conditions. Further analysis of pts with active AI conditions is needed to clarify the safety profile in this population.

9082 Poster Session (Board #408), Sat, 8:00 AM-11:30 AM

Clinical outcomes of patients with non-small cell lung cancer (NSCLC) receiving chemotherapy after immune checkpoint blockade. *First Author: Claud Grigg, Columbia University Medical Center, New York, NY*

Background: Objective response rates (ORR) to chemotherapy beyond the first-line for advanced NSCLC are low (5-10%). Pre-clinical studies suggest that some chemotherapies may act, in part, through immune mediated mechanisms. Additionally, results from phase I/II studies of chemotherapy combined with immune checkpoint inhibitors (ICIs) suggest high response rates ($>$ 50%) and potential synergy. It is unknown whether chemotherapy is more efficacious when given after ICIs. **Methods:** We reviewed demographics, imaging, treatment history, and clinical course for all patients at our institution with a diagnosis of metastatic NSCLC who received at least one dose of nivolumab, pembrolizumab, atezolizumab, or durvalumab prior to December 8, 2016. Patients who received any subsequent chemotherapy were included for analysis. Objective response was determined by RECIST v1.1, and date of progression was determined radiographically or clinically (treatment discontinuation with documented clinical deterioration). **Results:** 145 patients received at least one dose of any ICI, and 38 patients received subsequent chemotherapy. The median age was 68 years (range 44-88). Six chemotherapy-naïve patients received carboplatin + pemetrexed +/- bevacizumab. There were 3 partial responses (PR) including one exceptional response that is ongoing after 2 years. Among 32 chemotherapy non-naïve patients, the median number of prior chemotherapy regimens was 2 (range 1-6). Post-ICI chemotherapy included docetaxel + ramucirumab (n = 12), vinorelbine (n = 7), gemcitabine-based chemotherapy (n = 6), carboplatin doublets (n = 4), pemetrexed + bevacizumab (n = 2), and paclitaxel (n = 1). Six patients had documented poor performance status and died within 1 month of starting treatment. The ORR was 25% (1CR, 7PR), median time to progression was 116 days, and 9 patients (28%) experienced stable disease (SD) or better lasting $>$ 150 days. Exceptional responses occurred across regimens. Nine patients received a further line of chemotherapy, with 3 ongoing PR or SD lasting $>$ 100 days. **Conclusions:** For NSCLC, chemotherapy response rates may be higher when administered after an ICI.

9083 Poster Session (Board #409), Sat, 8:00 AM-11:30 AM

Response to single-agent (SA) chemotherapy (CTx) after immunotherapy exposure in non-small cell lung cancer (NSCLC). *First Author: Gustavo Schvartsman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Overall response rates (ORR) to 2nd-line SACTx in NSCLC have consistently not exceeded 15%. Exploratory analysis of clinical trials in various tumor types have demonstrated potential improvements in ORR to CTx after exposure to vaccine-based immunotherapy. The objective of this retrospective study was to determine if SACTx (3rd-line or beyond) would yield improved ORR when given after exposure to programmed-death-(ligand)1 inhibitors (PD1i) in metastatic NSCLC. **Methods:** Eligibility criteria - patients registered in the Thoracic GEMINI database of MD Anderson treated between 06/12 and 11/16 who received at least one SACTx as 3rd-line or beyond, following progression after platinum-based CTx and PD1i. We computed efficacy outcomes to each therapy, including ORR by RECIST v1.1, progression-free survival (PFS) and overall survival (OS). **Results:** Of 306 PD1i-treated patients registered in the database, 28 met eligibility criteria - 54% were male, median age 66 years, 82% adenocarcinoma, 29% never smokers. The PD1i and SACTx most commonly used were nivolumab (82%) and docetaxel (54%). ORR to SACTx after exposure to PD1i was 39% (11/28 patients, 8 confirmed). In contrast, ORR to 1st-line CTx in this cohort was 30% (Table). Liver metastasis and pembrolizumab as the PD1i of choice were the only factors associated with response to SACTx on univariate analysis ($p < 0.05$). **Conclusions:** In NSCLC patients, ORR to SACTx after immunotherapy exposure was higher compared to historical data from the pre-PD1i era, and approached ORR to 1st-line platinum-based CTx. Further investigation of a possible chemosensitization effect by immunotherapy is warranted.

	1st Line CTx n = 27*	At least 2nd Line PD1i n = 28	At least 3rd Line SACTx n = 28

9084 Poster Session (Board #410), Sat, 8:00 AM-11:30 AM

Response to salvage chemotherapy following exposure to immune checkpoint inhibitors in patients with non-small cell lung cancer. *First Author: Paul Denis Leger, Vanderbilt University Medical Center, Nashville, TN*

Background: Immune checkpoint inhibitors are active for patients with stage IV NSCLC who have progressed following platinum-based chemotherapy. We evaluated responses to chemotherapy in patients who had progressed on a checkpoint inhibitor. **Methods:** Eligible patients were adults with NSCLC who received salvage chemotherapy following PD-1/PD-L1 inhibitors (cases) versus no PD-1/PD-L1 inhibitors (controls). CT-imaging was done within 4 weeks of initiation of salvage chemotherapy and every 6 weeks thereafter. Revised RECIST guidelines were used to define response. Clinical and imaging data were abstracted from review of electronic medical records. Multivariate logistic regression analysis was used to calculate probability of response. **Results:** Three-hundred and fifty patients' charts were reviewed and 82 patients met eligibility criteria. Among evaluable patients, 46 were males. Sixty-seven patients were cases versus 15 controls. Fifty-six patients received nivolumab, 7 pembrolizumab and 4 atezolizumab. Sixty-three (77%) had adenocarcinoma, 18 (22%) squamous cell carcinoma and 1 (1%) large cell carcinoma. The mean number of chemotherapy regimens prior to salvage chemotherapy was 2.37 (95% C.I. 2.10-2.64)) in cases versus 1.93 (95% C.I: 1.32-2.54) in controls. Salvage drugs included docetaxel (62%), pemetrexed (20%), gemcitabine (12%), paclitaxel (6%). Eighteen (27%) cases had partial response to chemotherapy versus 1(7%) controls. Fifteen (22%) cases had progressive disease versus 6 (40%) controls. Thirty-four (51%) cases had stable disease versus 8 (53%) controls. The odd ratio for achieving a partial response was 0.30 (95% CI: 0.18 to 0.50, P = 0.000). In multiple logistic regression model, age, gender, number of prior chemotherapy regimens, tumor histology, smoking status, different salvage chemotherapy regimens were not associated with the likelihood of achieving a partial response. **Conclusions:** The odds of achieving a partial response to salvage chemotherapy were more than 3 times higher inpatients with prior exposure to PD-1/PD-L1 inhibitors. Ongoing investigations include the duration of response as well as evaluation of toxicity.

9085 Poster Session (Board #411), Sat, 8:00 AM-11:30 AM

Updated safety and clinical activity of durvalumab monotherapy in previously treated patients with stage IIIB/IV NSCLC. *First Author: Ani Sarkis Balmanoukian, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Preliminary analyses of an ongoing Phase 1/2 study of single-agent durvalumab showed antitumor activity and a tolerable safety profile in advanced NSCLC, with higher ORR and longer OS in pts with high vs. low/negative PD-L1 tumor expression. Here we present updated safety analyses (primary endpoint) for all NSCLC pts and clinical activity based on investigator-assessed RECIST v1.1 in pts who had received prior treatment for advanced NSCLC. **Methods:** Durvalumab (10 mg/kg q2w) was given until unacceptable toxicity or disease progression, or for up to 12 mos; retreatment was permitted upon disease progression after completion of 12 mos of treatment. PD-L1 expression was assessed using the Ventana PD-L1 (SP263) Assay (PD-L1 high = ≥25% and PD-L1 low/negative = <25% of tumor cells with membrane staining). **Results:** As of 24 Oct 2016, 245 pts with previously treated NSCLC (53% squamous) received durvalumab and were followed for a median of 29.2 (range 0.3–40.5) mos; 142 pts (58%) had treatment-related adverse events (AEs), most frequent: fatigue (18%), decreased appetite (9%), and nausea, rash, and diarrhea (each 8%). 25 pts (10%) had treatment-related Grade 3/4 AEs, most frequent: fatigue and hyponatremia (each 2%); there were no treatment-related deaths. 4% had treatment-related serious AEs including colitis and pneumonitis (each 2%). In the overall population, 12 mo OS rate was 47% (95% CI 40–53) and 18 mo OS rate was 38% (95% CI 31–45). Antitumor activity and survival by PD-L1 status are shown in the table. **Conclusions:** Consistent with earlier reports, durvalumab had a manageable safety profile in Stage IIIB/IV NSCLC, with encouraging clinical activity as 2L+ therapy. Higher tumor PD-L1 expression enriched clinical benefit of response rate and survival endpoints. Clinical trial information: NCT01693562.

9086 Poster Session (Board #412), Sat, 8:00 AM-11:30 AM

Exposure-response and PD-L1 expression analysis of second-line avelumab in patients with advanced NSCLC: Data from the JAVELIN Solid Tumor trial. *First Author: James L. Gulley, Genitourinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Avelumab is a fully human anti–PD-L1 IgG1 antibody showing promising efficacy and safety in patients (pts) with non-small cell lung cancer (NSCLC) and other tumors. Here, we present exposure–response (E–R) and PD-L1 expression analyses of second-line (2L) avelumab treatment in pts with NSCLC from a phase 1 trial (NCT01772004). **Methods:** Pts with NSCLC received 2L avelumab 10 mg/kg IV every 2 weeks (Q2W) until progression or unacceptable toxicity. Serum samples were taken at various time points for pharmacokinetic (PK) analysis. Trough concentrations after first dose ($C\text{trough}_{\text{first-dose}}$) were predicted using an identified linear 2-compartment population PK (popPK) model without covariates other than pt body weight. Objective response rate (ORR) was evaluated (RECIST v1.1), and correlated with tumor cell (TC) PD-L1 expression (clone 73-10). Pooled safety data from various tumors in the large phase 1 trial were assessed. **Results:** In 184 avelumab-treated pts, unselected for PD-L1 expression, ORRs were 8.7%, 10.9%, 19.6%, and 17.4% for increasing quartiles of $C\text{trough}_{\text{first-dose}}$ (Q1–4). Using ≥1%, ≥5%, ≥50%, and ≥80% PD-L1 staining cutoffs, pts in the upper half of exposure ($C\text{trough}_{\text{first-dose}}$ Q3–4 [n = 92]), had ORRs of 25% (n = 59), 26% (n = 39), 33% (n = 21), and 43% (n = 14), respectively. Higher avelumab exposure was associated with a modest increase in immune-related adverse events (irAEs). PopPK modeling suggested $C\text{trough}_{\text{first-dose}}$ could be optimally increased with alternate avelumab dosing (10 mg/kg weekly vs Q2W, or 20 mg/kg Q2W [simulated median $C\text{trough}_{\text{first-dose}}$ 48 μg/mL vs 18 μg/mL, or 36 μg/mL]). **Conclusions:** Avelumab has shown clinical activity and acceptable safety in multiple tumors similar to other agents in class. Preliminary analysis of a cohort of pts with 2L advanced NSCLC shows a trend for higher ORR with increasing avelumab $C\text{trough}_{\text{first-dose}}$ quartiles and with higher levels of TC PD-L1 expression. Although this apparent E–R observation may be confounded by single-dose testing or other factors, this analysis provides rationale for studies of more intensive avelumab dosing regimens to assess further clinical benefit in pts with advanced NSCLC. Clinical trial information: NCT01772004.

9087 Poster Session (Board #413), Sat, 8:00 AM-11:30 AM

Tumor response dynamics of advanced non-small-cell lung cancer (NSCLC) patients (pts) treated with commercial PD-1 inhibitors in the clinical setting. *First Author: Mizuki Nishino, Dana-Farber Cancer Institute, Boston, MA*

Background: PD-1 inhibitors have shown promising activity in advanced NSCLC, with increasing clinical use. We evaluated tumor burden dynamics in advanced NSCLC pts treated with commercial PD-1 inhibitors to identify imaging markers for clinical benefit. **Methods:** The study included 160 advanced NSCLC pts (79 males; median age: 65) treated with commercial nivolumab or pembrolizumab monotherapy at DFCI as a part of routine clinical care. Tumor burden dynamics were assessed on serial CT scans during therapy by irRECIST1.1, which uses unidimensional measures and includes new lesions in tumor burden [Clin Cancer Res. 2013;19:3936-43]. **Results:** Tumor burden change at best overall response (BOR) ranged from -100% to +278% (median: +3.5%). Objective response rate (ORR) was 18% (29/160). Current and former smokers had higher ORR than never smokers (ORR:14% (8/58), 25% (20/79), 4% (1/23); Fisher p = 0.04). Durable disease control with tumor burden < 20% increase from baseline for at least 6 months was noted in 27 pts (17%), which included 11 pts with stable disease as their irBOR. Using an 8-week landmark analysis, pts with < 20% tumor burden increase from baseline at 8 weeks had longer OS than pts with ≥20% increase (median OS: 12.4 vs. 4.6 months, p < 0.001). In Cox models using a time varying covariate, pts with < 20% tumor burden increase during therapy had significantly reduced hazards of death (HR = 0.24, p < 0.0001) after adjusting for smoking (HR = 1.77, p = 0.016) and baseline tumor burden (HR = 1.66, p = 0.032). Two pts (1.3%) had atypical response pattern or "pseudoprogression", where tumor burden showed initial increase and subsequent decrease, which was noted after confirmed irPD on consecutive scans in both pts. **Conclusions:** An objective response or durable disease control was noted in 25% of advanced NSCLC pts treated with PD-1 inhibitors in the clinical setting. Tumor burden increase of < 20% from the baseline during therapy was associated with longer OS, proposing a practical marker of clinical benefit. Pseudoprogression was uncommon, with tumor decrease noted after confirmed irPD, indicating a limitation of the current strategy for immune-related response evaluation.

9089 Poster Session (Board #415), Sat, 8:00 AM-11:30 AM

Baseline-derived neutrophil-to-lymphocyte ratio (dNLR) and lactate dehydrogenase (LDH) to predict the benefit of immune checkpoint inhibitors (ICI) in advanced non-small cell lung cancer (NSCLC) patients. *First Author: Laura Mezquita, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Villejuif, France*

Background: dNRL (Neutrophils/Leucocytes-Neutrophils) and LDH were recently correlated to ICI benefit in melanoma. We tested if dNLR and LDH could have the same role in NSCLC patients. **Methods:** Baseline dNLR and LDH were collected in 234 patients treated with PD1/PDL1 inhibitors from Nov. 2013 to Dec. 2016, in a discovery (D) cohort (N = 161) from Gustave Roussy and an independent validation (V) cohort (N = 73) from 2 centers. ICI benefit was analyzed according to overall survival (OS), progression free survival (PFS) and response rate (RR) by RECIST 1.1. Kaplan-Meier and Cox regression were performed. **Results:** In the D cohort, 100 patients (62%) were males, 136 (85%) smokers and PS ≤1, with median age 61.5; 133 patients (81%) stage IV; 100 (62%) had adenocarcinoma and 46 (29%) squamous cells carcinoma; 35 (22%) were *KRAS*mut, 13 (8%) *EGFR*mut and 3 (2%) *ALK*positive. PDL1 expression was positive in 43 (75%), negative in 14 (25%) and unknown in 78. 132 (82%) patients received PD1 inhibitors; the median of prior lines was 1 (1-11). dNLR > 3 and LDH > upper normal limit (UNL) were independent factors for poor OS (HR 4,67, p = 0.011 and HR 2,65, p = 0.002, respectively) and poor PFS (HR 4,71, p = 0.001 and HR 1,68, p = 0.042 respectively). The median follow-up (FU) was 12 months (m) [95% CI 11-14], the median PFS 3m [2-4] and the median OS 10m [8-13]. In the V cohort, with a median FU of 11m [8-14], dNLR > 3 and LDH > UNL were significantly associated with poor OS (both p = 0.001), with a trend toward association with PFS (p = 0.06, p = 0.08, respectively). A Lung Immune Predictive Index (LIPI) was tested considering dNLR > 3 and LDH > UNL, with three groups. In D cohort, the median OS for good (no factor), intermediate (one factor) and poor (two factors) was 34m [17-NR], 10m [8-NR], 3m [1-NR], respectively (p = 0.0001), and PFS was similarly correlated (p = 0.001). Same results were demonstrated in the V cohort. **Conclusions:** Baseline dNLR > 3 and LDH > UNL can predict the benefit of ICI in advanced NSCLC patients. The LIPI at baseline is an easy tool to identify the candidates to immunotherapy. Confirmation cohorts are ongoing to validate the predictive role of the LIPI.

9090 Poster Session (Board #416), Sat, 8:00 AM-11:30 AM

Factors associated with better overall survival (OS) in patients with previously treated, PD-L1–expressing, advanced NSCLC: Multivariate analysis of KEYNOTE-010. *First Author: Roy S. Herbst, Yale Cancer Center, New Haven, CT*

Background: We identified factors associated with better OS for previously treated, PD-L1–expressing advanced NSCLC using data from KEYNOTE-010 (NCT01905657; Herbst et al. *Lancet.* 2016;387:1540-50), in which pembrolizumab had superior OS over docetaxel. **Methods:** 1033 patients were randomly assigned 1:1:1 to pembrolizumab 2 or 10 mg/kg every 3 weeks (Q3W) or docetaxel 75 mg/m^2 Q3W. Response was assessed per RECIST v1.1 by independent central review. Multivariate analyses were performed using a Cox proportional hazards regression model on OS in the pembrolizumab arms. A set of variable selection methods was applied to 19 baseline demographic and disease characteristics, including smoking status, and identified 7 factors that contributed to OS. Data cut was September 30, 2016. **Results:** Adjusted hazard ratios (HRs) for the factors in the pembrolizumab arm from the model are shown in the Table. Updated OS with an additional 6 months of follow-up from this data lock for KEYNOTE-010 will be presented. **Conclusions:** While the overall result of KEYNOTE-010 revealed improved OS with pembrolizumab compared with docetaxel in previously treated patients with PD-L1–positive advanced NSCLC, exploratory, post hoc multivariate analyses showed that some laboratory and tumor characteristics such as nonsquamous histology, normal baseline lactate dehydrogenase (LDH), PD-L1 TPS ≥50%, and wild-type *EGFR* mutation status were associated with better OS among patients treated with pembrolizumab. Clinical trial information: NCT01905657.

Characteristics (nonreference vs reference)	Pembrolizumab n = 690 HR (95% CI); *P* value
Race (Asian vs non-Asian)	0.70 (0.54-0.91); 0.0067
Baseline tumor size (≤80 mm vs > 80 mm)	0.71 (0.59-0.87); 0.0007
ECOG performance status at screening (0 vs ≥1)	0.79 (0.65-0.97); 0.0265
Histology (nonsquamous vs squamous)	0.55 (0.43-0.70); < 0.0001
Baseline LDH (normal vs elevated)	0.61 (0.49-0.76); < 0.0001
PD-L1 status (TPS ≥50% vs TPS 1%-49%)	0.64 (0.52-0.77); < 0.0001
EGFR mutation status (wild type vs mutant)	0.65 (0.46-0.91); 0.0122

9091 Poster Session (Board #417), Sat, 8:00 AM-11:30 AM

Efficacy, safety, and immune activation with pegylated human IL-10 (AM0010) in combination with an anti-PD1 in advanced NSCLC. *First Author: Deborah Jean Lee Wong, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Although IL-10 has anti-inflammatory properties, it stimulates cytotoxicity and proliferation of intratumoral antigen activated CD8+ T cell at higher concentrations. AM0010 is anticipated to activate antigen stimulated, intratumoral CD8 T cells while PD-1 inhibits them, providing the rationale for combining AM0010 and anti-PD-1 antibody. **Methods:** We treated a cohort of 34 NSCLC pts with AM0010 (10-20mg/kg QD, SC) and a PD-1 inhibitor [pembrolizumab (2mg/kg, q3wk IV; n=5) or nivolumab (3mg/kg, q2wk IV; n=29)]. Tumor responses were assessed by irRC every 8 weeks. Immune responses were measured by analysis of serum cytokines (Luminex), activation of blood derived T cells (FACS) and peripheral T cell clonality (TCR sequencing). Tumor PD-L1 expression was confirmed by IHC (22C3). **Results:** Pts had a median of 2 prior therapies. Median follow-up is 9.6 mo (range 0.5-77.3) in this fully enrolled cohort. AM0010 plus anti-PD-1 was well-tolerated. TrAEs were reversible and transient, with most being low grade, most commonly fatigue and pyrexia. G3/4 TrAEs were thrombocytopenia (7), anemia (6), fatigue (4), rash (3), pyrexia (2), hypertriglyceridemia (1) and pneumonitis (1). As of Jan. 31 2017, 22 pts had at least 1 tumor assessment. Partial responses (PRs) were observed in 8 pts (36.4%). 17 of these 22 pts had tissue for analysis of percent of tumor cells with PD-L1 expression (22C3): 58.8% had <1%, 17.7% had 1-49% and 23.5% had >50%. Best response data stratified for PD-L1 are shown in the table. Median PFS and OS for the entire cohort have not been reached. Updated outcome data that includes all enrolled pts will be available at the meeting. AM0010 plus anti-PD1 increased serum Th1 cytokines (IL-18, IFNγ), the number and proliferation of PD1+ Lag3+ activated CD8+ T cells and a de-novo oligoclonal expansion of T cell clones in the blood while decreasing TGFβ. **Conclusions:** AM0010 in combination with anti-PD1 is well-tolerated in advanced NSCLC pts. The efficacy and the observed CD8+ T cell activation is promising. Clinical trial information: NCT02009449.

PD-L1 (22C3 IHC) (n=22)	<1% (n=10)	1-49% (n=3)	>50% (n=4)	Not available (5)
PR, n (%)	3 (30%)	1 (33%)	3 (75%)	1 (20%)

9092 Poster Session (Board #418), Sat, 8:00 AM-11:30 AM

Atezolizumab (atezo) plus platinum-based chemotherapy (chemo) in non-small cell lung cancer (NSCLC): Update from a phase Ib study. *First Author: Stephen V. Liu, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Platinum-based chemo is a standard first-line (1L) therapy for NSCLC lacking actionable gene alterations. Preclinical evidence suggests that chemo can play an immunomodulatory role and induce tumor antigen release, supporting combining chemo with immunotherapy. Atezo is a humanized and Fc-region-modified monoclonal anti-programmed death-ligand-1 (PD-L1) antibody that blocks interaction with PD1 or B7.1. The GP28328 study (NCT01633970) assessed safety and efficacy of atezo plus 1L chemo regimens in multiple tumor types. **Methods:** In this multicenter, multi-arm study, patients (pts) with locally advanced or metastatic NSCLC with no prior chemo for advanced disease received 15 mg/kg atezo IV q3w with standard doses of chemo (Arm C: carboplatin [carbo]+paclitaxel q3w; Arm D: carbo+pemetrexed q3w; Arm E: carbo+nab-paclitaxel qw) all for ≤6 cycles followed by atezo maintenance until loss of clinical benefit (+ pemetrexed maintenance until progression, Arm D). The primary endpoint was safety; secondary endpoints were overall response rate (ORR), PFS, and OS. **Results:** By the 30 Aug 2016 cut-off, 76 NSCLC pts were evaluable (n = 25, 25, 26 for Arms C, D, E, respectively). At this cut-off, the most common treatment-related grade 3–4 adverse events (AEs) were neutropenia (36% C, 36% D, 42% E) and anemia (16% C, 16% D, 31% E). Three potentially related grade 5 AEs were seen (arm C: pneumonia; arm D: systemic candida; arm E: autoimmune hepatitis). Confirmed ORRs were 36%, 64%, 46% for Arms C, D (1 CR), and E (4 CR). Median PFS (95% CI) was 7.1 months (4.2–8.3) for C, 8.4 months (4.7–11) for D, and 5.7 months (4.4–14.8) for E. Median OS (95% CI) was 12.9 months (8.8–not evaluable) for C, 19.3 months (14.7–27.4) for D, and 14.8 months (12.7–not evaluable) for E. **Conclusions:** Atezo was well tolerated when combined with various chemo regimens for advanced NSCLC. Clinical activity in terms of ORR was favorable supporting potential synergy between atezo and chemo. PFS and OS data show promising benefits, but are limited by small numbers and wide confidence intervals. Phase III studies that include chemotherapy and atezolizumab are currently ongoing. Clinical trial information: NCT01633970.

9093 Poster Session (Board #419), Sat, 8:00 AM-11:30 AM

Nivolumab (N) plus ipilimumab (I) as first-line (1L) treatment for advanced (adv) NSCLC: 2-yr OS and long-term outcomes from CheckMate 012. *First Author: Jonathan Wade Goldman, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: The fully human anti–PD-1 antibody N offers long-term OS benefit in patients (pts) with previously treated adv NSCLC. Adding I (anti–CTLA-4 antibody) to N has been shown to improve clinical activity vs either agent alone in multiple tumor types. We present long-term data for 1L N+I treatment of pts with adv NSCLC from CheckMate 012. **Methods:** In two cohorts in this phase 1 study, pts with recurrent stage IIIb/IV, chemotherapy-naive NSCLC and ECOG PS 0–1 received N 3 mg/kg Q2W combined with I 1 mg/kg Q12W (n=38) or Q6W (n=39) until disease progression, unacceptable toxicity, or consent withdrawal. The primary endpoint was safety and tolerability. Secondary endpoints included investigator-assessed ORR (RECIST v1.1) and PFS. Exploratory endpoints included OS and efficacy by tumor PD-L1 expression. **Results:** In the N+I Q12W and N+I Q6W cohorts, respectively, 42% and 31% of pts experienced grade 3–4 treatment-related (TR) AEs; 18% in each cohort discontinued due to any-grade TRAEs. The most frequently reported any-grade TRAEs were pruritus (26%) and diarrhea (21%) with N+I Q12W, and fatigue (26%) and diarrhea (23%) with N+I Q6W. There were no TR deaths. N+I showed promising efficacy (table). While efficacy was enhanced with increasing PD-L1 expression, activity was noted in pts with <1% PD-L1 (table). Of 6 complete responses (CRs), 3 were in pts with <1% PD-L1. **Conclusions:** 1L therapy with N+I demonstrates a manageable safety profile and promising, durable efficacy (including pathological CRs) in adv NSCLC; efficacy was enhanced in pts with ≥1% PD-L1 tumor expression. Longer follow-up data, including 2-yr OS and characteristics of long-term survivors, will be presented. Clinical trial information: NCT01454102.

Cohorts	ORR, %	mDOR[a] (95% CI), mo	mPFS[a] (95% CI), mo	1-yr OS, %
N+I Q12W[b] (n=38)	47	NR (11.3, NA)	8.1 (5.6, 16.7)	83
N+I Q6W[c] (n=39)	38	NR (11.2, NA)	3.9 (2.6, 13.4)	69
Pooled (n=77)	43	NR (14.0, NA)	8.0 (4.1, 13.2)	76
≥50% PD-L1 (n=13)	92	NR (4.2, NA)	NR (7.8, NA)	100
≥1% PD-L1 (n=46)	57	NR (11.2, NA)	12.7 (7.8, 23.0)	87
<1% PD-L1 (n=19)	21	NR (NA)	3.3 (2.3, 5.3)	53

Based on Sept. 2016 database lock. [a]Kaplan−Meier method; [b]mFU 15.8 mo; [c]mFU 16.1 mo. Abbreviations: DOR = duration of response; FU = follow-up; m = median; NA = not available; NR = not reached.

9094 **Poster Session (Board #420), Sat, 8:00 AM-11:30 AM**

First-line carboplatin and pemetrexed (CP) with or without pembrolizumab (pembro) for advanced nonsquamous NSCLC: Updated results of KEYNOTE-021 cohort G. *First Author: Vassiliki Papadimitrakopoulou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Data from the randomized, phase 2 cohort G of KEYNOTE-021 (NCT02039674) showed that adding pembro to first-line CP in patients (pts) with advanced nonsquamous NSCLC significantly improved the primary end point of ORR (55% vs 29%, P = 0.0016) and the key secondary end point of PFS (HR 0.53, *P*= 0.0102) compared with CP alone and had a manageable safety profile (grade 3-4 treatment-related AEs, 39% vs 26%; treatment-related AEs leading to discontinuation, 10% vs 13%). We present updated efficacy for cohort G based on 5 mo additional follow-up. **Methods:** 123 pts with stage IIIB/IV, chemotherapy-naive, nonsquamous NSCLC and no *EGFR* mutation or *ALK* translocation were randomized to 4 cycles of carboplatin AUC 5 + pemetrexed 500 mg/m^2 Q3W ± 24 mo of pembro 200 mg Q3W; maintenance pemetrexed was permitted in both arms. Eligible pts in the CP arm who had radiologic progression could crossover to pembro monotherapy. Response was assessed per RECIST v1.1 by blinded, independent central review. All *P*values are nominal. **Results:** As of Dec 31, 2016, median follow-up was 14.5 mo (range, 0.8-24.0). 36 of 48 pts (75.0%) in the CP arm who discontinued CP received subsequent anti–PD-1 or PD-L1 therapy. There was 1 additional response in each arm, and ORR was 56.7% (95% CI 43.2%-69.4%) with pembro + CP vs 30.2% (95% CI 19.2%-43.0%) with CP (*P*= 0.0016). Median DOR was not reached for pembro + CP (range, 1.4+ to 18.6+ mo) and was 16.2 mo (range, 2.8 to 20.7+) for CP alone. PFS remained longer with pembro + CP (HR 0.49, 95% CI 0.29-0.83, *P* = 0.0035; median [95% CI] NR [9.7 mo-NR] vs 8.9 mo [6.2-10.3]; 12-mo estimate, 56% vs 34%). With 16 deaths in the pembro + CP arm and 23 deaths in the CP arm, HR for OS was 0.69 (95% CI 0.36-1.31, *P*= 0.13). Median OS was not reached in either arm; at 12 mo, estimated OS was 76% in the pembro + CP arm and 69% in the CP alone arm. **Conclusions:** With 5 mo additional follow-up, first-line pembro + CP continues to provide a substantial, clinically relevant improvement in efficacy over CP alone in pts with advanced nonquamous NSCLC, including an almost doubled ORR, halved risk of progression or death, and a trend toward improved OS despite a 75.0% crossover rate in the CP arm. Clinical trial information: NCT02039674.

9095 **Poster Session (Board #421), Sat, 8:00 AM-11:30 AM**

Nivolumab (nivo) + *nab*-paclitaxel (*nab*-P) + carboplatin (C) in patients (pts) with non-small cell lung cancer (NSCLC): Interim results from a multicenter phase I study. *First Author: David Michael Waterhouse, Oncology Hematology Care, Inc., Cincinnati, OH*

Background: Despite success of single-agent immune checkpoint inhibitors, an unmet therapeutic need remains in pts with NSCLC. Chemotherapy and immunotherapy may have synergistic antitumor activity, but safety and efficacy need to be established. Here, we present interim results for pts with NSCLC (Arm C) from the phase I safety trial of nivo + *nab*-P in pancreatic cancer (± gemcitabine), NSCLC (+ C), and metastatic breast cancer. **Methods:** Part 1 evaluated potential dose-limiting toxicities (DLTs) before Part 2 expansion. Chemotherapy-naive pts with histologically/cytologically confirmed stage IIIB/IV NSCLC received 4 cycles of *nab*-P 100 mg/m^{2}d 1, 8, 15 + C AUC 6 d 1 + nivo 5 mg/kg d 15 of each 21-d cycle; in cycles 5+, nivo was continued as maintenance monotherapy. Primary endpoints: number of pts with DLTs (Part 1) and percentage of pts with grade 3/4 treatment-emergent adverse events (TEAEs) or treatment discontinuation due to TEAEs (Parts 1 and 2). DLT-evaluable pts included those who received ≥ 2 complete nivo cycles and remained on study for 14 d after the last nivo dose in cycle 2, received ≥ 1 nivo dose and discontinued due to DLT before completing 2 nivo cycles, or experienced equivocal DLT after ≥ 1 nivo dose. Secondary endpoints included safety, PFS, OS, DCR, ORR, and DOR. **Results:** All pts (n = 22) received *nab*-P/C; results for nivo-treated pts (n = 20) are presented. Of the nivo-treated pts, the median age was 66 y (55% ≥ 65 y), 75% were female, 80% were white, and 70% had ECOG PS 1. More pts had adenocarcinoma (50%) than squamous cell carcinoma (35%; 10% other, 5% data pending). No DLTs reported (5 DLT-evaluable pts). Most common grade 3/4 TEAEs were neutropenia (45%) and anemia (35%). No grade 3/4 immune-related colitis or pneumonitis reported. Best ORR (RECIST v1.1) was 50% (1 CR [unconfirmed, 5%] and 9 PRs [45%]; 6 pts had SD [30%]; 4 pts had PD [20%]). Best ORR by histology: squamous, 71%; nonsquamous, 54%. Median PFS was 10.5 months (squamous, 10.5 months; nonsquamous, not evaluable). **Conclusions:** Results demonstrated safety of the nivo + *nab*-P/C combination in NSCLC with no unexpected safety signals. Preliminary efficacy results are promising. (NCT02309177) Clinical trial information: NCT02309177.

TPS9097 **Poster Session (Board #422b), Sat, 8:00 AM-11:30 AM**

NIVORAD: A randomised phase 2 trial of nivolumab and stereotactic ablative body radiotherapy in advanced non-small cell lung cancer, progressing after first or second line chemotherapy. *First Author: Paul Mitchell, Austin Health, Heidelberg, Australia*

Background: Recent data has demonstrated improvements in overall survival in patients with advanced non-small cell lung cancer (NSCLC) treated with nivolumab. Radiation may augment the immune response through abscopal effects - evidence of tumour control at sites other than those irradiated. We hypothesize that the addition of stereotactic ablative body radiotherapy (SABR) to immunotherapy with nivolumab will improve progression free survival (PFS) compared with nivolumab alone. **Methods:** DESIGN: Open label, randomised phase II trial with 25 sites across Australia and New Zealand. ELIGIBILITY: Metastatic NSCLC progressing after 1 or 2 lines of chemotherapy with an extrapulmonary metastasis suitable for SABR. STRATIFICATION: Age, lines of chemotherapy, histology and treating institution. TREATMENT: A single dose of SABR (18-20Gy) plus nivolumab or nivolumab alone (240mg 2-weekly) given until disease progression or prohibitive adverse events. ENDPOINTS: PFS at 6 months (PFS6; primary), objective tumour response rate, adverse events, overall survival, PFS at 1 and 2 years. Tertiary correlative objectives include associations between possible prognostic/ predictive biomarkers and outcomes (including PD-L1 expression). STATISTICS:Total sample size of 120 participants allocated in a ratio of 2:1, 80 to nivolumab + SABR and 40 nivolumab alone to provide 80% power, one-sided type I error rate of 5% for PFS6 of 50% (worthy of pursuit) vs 35% (not worthy of pursuit). BIOSPECIMENS: Tumour tissue and serial bloods (4 time points) will be collected for translational research. CURRENT ENROLLMENT (as of Feb 2017): 2 out of 20 sites are open. NIVORAD is an investigator-initiated, cooperative-group trial led by the ALTG in collaboration with the NHMRC Clinical Trials Centre, University of Sydney and the Trans Tasman Radiation Oncology Group (TROG). Australian New Zealand Clinical Trials Registry: ACTRN12616000352404.

TPS9098 **Poster Session (Board #423a), Sat, 8:00 AM-11:30 AM**

Design of ALTA-1L (ALK in lung cancer trial of brigatinib in first-line), a randomized phase 3 trial of brigatinib (BRG) versus crizotinib (CRZ) in tyrosine kinase inhibitor (TKI)-naive patients (pts) with advanced anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer (NSCLC). *First Author: Marcello Tiseo, University Hospital of Parma, Parma, Italy*

Background: BRG is an investigational, next-generation ALK inhibitor with potent preclinical activity against rearranged ALK and CRZ-resistant mutants. In an ongoing phase 1/2 trial, BRG has shown promising intracranial and whole-body activity in ALK+ NSCLC pts with or without prior CRZ therapy (*Lancet Oncol*. 2016;17:1683-96). In an ongoing pivotal randomized phase 2 trial (ALTA) evaluating 2 BRG regimens (90 mg qd and 180 mg qd with a 7-d lead-in at 90 mg), BRG has shown substantial objective response rates (ORRs) and robust progression-free survival (PFS) in pts with CRZ-resistant ALK+ NSCLC, particularly at 180 mg (with lead-in), and acceptable safety (*J Thorac Oncol*. 2017;12:S612-3). Based on these results, the ALTA-1L trial was designed to assess the efficacy and safety of BRG vs CRZ in pts with advanced ALK+ NSCLC naive to TKI therapy (including ALK inhibitors). **Methods:** ALTA-1L (NCT02737501) is an open-label, multicenter, randomized phase 3 trial. Pts (≥18 y of age) are required to have locally advanced or metastatic ALK+ NSCLC, no prior TKI therapy, and ≤1 prior systemic anticancer regimen in the advanced setting. Approximately 270 pts will be stratified by presence of brain metastases at baseline and prior chemotherapy (yes/no) and randomized 1:1 to receive oral BRG (180 mg qd with a 7-d lead-in at 90 mg) or CRZ (250 mg bid). The primary endpoint is PFS per RECIST v1.1 assessed by a blinded independent review committee (BIRC); secondary endpoints include ORR, duration of response, overall survival, safety/tolerability, pt-reported outcomes, and intracranial ORR/PFS. The primary endpoint will be analyzed with the Kaplan-Meier method and a 2-sided stratified log-rank test after 198 events; 2 interim analyses are planned after approximately 50% and 75% of expected events. CRZ-treated pts may cross over to BRG (180 mg [with lead-in]) after BIRC-assessed disease progression. ALTA-1L was initiated in April 2016; 150 sites are planned in North America, Europe, and the Asia-Pacific region. 97 pts were enrolled as of February 6, 2017. Clinical trial information: NCT02737501.

TPS9099 Poster Session (Board #423b), Sat, 8:00 AM-11:30 AM

Deciphering antitumour response and resistance with intratumour heterogeneity (DARWIN II). *First Author: Crispin T. Hiley, King's College London, London, United Kingdom*

Background: The importance of intratumour heterogeneity (ITH) is increasingly recognised as a driver of cancer progression and survival outcome. However understanding how tumour clonal heterogeneity impacts upon therapeutic outcome is still an area of unmet clinical and scientific need. The TRACERx trial (NCT01888601), a prospective study of patients with radically resected primary non-small cell lung cancer (NSCLC), aims to define the evolutionary trajectories of lung cancer in both space and time through genetic analysis of multi-region and longitudinal tumour sampling. DARWIN II is an investigator initiated study for patients who are enrolled within the TRACERx trial, or who have multi-region sequencing of their primary disease, but subsequently relapse with metastatic disease. This study will examine the role of intra-tumour heterogeneity and predicted neoantigens on the anti-tumour activity of anti-PDL1 immunotherapy. **Methods:** This multicentre non-randomised phase II molecularly stratified umbrella study will examine how clonal dominance and ITH influence outcomes after treatment, offering a unique opportunity to decipher mechanisms of resistance to immunotherapy with anti-PDL1. These data will help improve future study design by developing greater understanding of patient selection for immunotherapies in patients with NSCLC. The relationship between ITH and cfDNA/CTCs will also be explored in DARWIN II. The study arms: Arm 1: Patients either -1) without an actionable mutation and PDL1 positive or 2) without an actionable mutation and PDL1 negative following first line cytotoxic chemotherapy - Atezolizumab. Arm 2: BRAFV600 - Vemurafenib. Arm 3: ALK/RET gene rearrangement - Alectinib. Arm 4: Her2 Amplification - Trastuzumab Emtansine. Primary Outcome Measures: Progression free survival (PFS), defined as the period between the date of registration to the date of subsequent progression or death will be assessed according to: Neo-antigen burden, mutational burden, ITH as assessed using an ITH ratio index and genomic instability as assessed using a weighted genome instability index (wGII). Trial Sponsor: University College London. Clinical trial information: NCT02314481.

TPS9100 Poster Session (Board #424a), Sat, 8:00 AM-11:30 AM

Early rebiopsy to identify mechanisms and biomarkers of tumor cell survival following epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) therapy. *First Author: Caroline Elizabeth McCoach, University of Colorado School of Medicine, Aurora, CO*

Background: Significant advances in the clinical outcomes of lung cancer patients have been achieved in part due to the identification of targetable driver mutations. The success of targeting oncogenic drivers with TKIs has allowed for improvements in response rates, progression free survival and overall survival. Despite these improvements, patients ultimately relapse. Acquired resistance has been evaluated in post-progression tumor samples and is caused by a variety of mechanisms including secondary resistance mutations, gene copy number gains, gene amplification, or bypass pathway activation. Residual tumor burden with surviving cancer cells are the origin of the ultimate tumor progression. Studies analyzing signaling pathways and other markers of these tumor cells or microenvironmental cells in tumor samples before clinical resistance develops are needed to determine how best to target this compartment. **Methods:** Eligible patients will have a new diagnosis of advanced NSCLC with an EGFR TKI sensitizing mutation. Additional inclusion criteria include ECOG 0-2, a tumor measurable by RECIST 1.1 and at least 2cm in one dimension, and tumor site that is accessible and safe to biopsy. Patients will undergo a pretreatment target lesion biopsy, begin treatment with an EGFR TKI then receive a second biopsy of the same target lesion after two weeks of therapy. Our primary objective is to identify differences between pretreatment and early treatment tumor samples. To do this we will be using a combination of RNA seq, multiplex protein expression analysis and proximity ligation assays. Secondary objectives include identification of predictive markers that can be used to determine which tumors will undergo epithelial to mesenchymal transition or activate other survival pathways and determination of the success rate and adverse event rate of repeat biopsy. Patients are currently being enrolled at a single academic institution however, additional clinical site openings are pending. Our goal enrollment for this study is 47 patients to achieve 20 paired biopsy samples. We will present updated enrollment and demographic information. Clinical trial information: NCT03042221.

TPS9101 Poster Session (Board #424b), Sat, 8:00 AM-11:30 AM

IMpower132: A phase III clinical program—1L atezolizumab plus platinum-based chemotherapy in chemo-naive advanced non-squamous NSCLC. *First Author: Howard Jack West, Swedish Cancer Institute, Seattle, WA*

Background: Platinum-based chemotherapy (chemo) is the current standard of care for patients (pts) with newly diagnosed advanced non-squamous NSCLC. The combination of platinum-based chemo and pemetrexed (pem) provides comparable benefit to pts as other standard platinum doublets commonly used and has a favorable toxicity profile. However, the survival benefit conferred by this combination leaves considerable room for improvement. The anti–PD-L1 mAb atezolizumab (atezo) inhibits the interaction of PD-L1 with its receptors PD-1 and B7.1, thereby restoring tumor-specific T-cell immunity. In the OAK trial, pts with 2L/3L advanced NSCLC had improved mOS in the atezo arm (13.8 mo) vs the docetaxel arm (9.6 mo), with a survival benefit observed across PD-L1 expression levels. The potential for chemo to further augment responses to atezo, with tolerable safety, has also been demonstrated. A global, Phase III, randomized, open-label trial, IMpower132 (NCT02657434), is being conducted to evaluate 1L atezo + platinum-based chemo + pem in chemo-naive pts with stage IV NSCLC. **Methods:** Eligibility criteria include stage IV NSCLC, measurable disease (RECIST v1.1), no prior chemo and ECOG PS 0-1. Exclusion criteria include tumors known to harbor *EGFR* or *ALK* driver mutations, untreated CNS metastases, autoimmune disease and prior exposure to immunotherapy. Pts will be enrolled regardless of PD-L1 expression status and randomized to the treatment arms. Pts will be stratified by sex, ECOG PS, type of chemo (carboplatin [carbo] vs cisplatin [cis]) and smoking status. Pts will receive four or six 21-day cycles of either atezo + carbo/cis + pem or carbo/cis + pem. Following the induction phase, pts will receive maintenance atezo + pem or pem alone, depending on their allocated treatment regimen. Pts receiving atezo may continue until loss of clinical benefit.Co-primary endpoints are investigator-assessed PFS and OS. Secondary endpoints include IRF-assessed PFS, investigator-assessed ORR and safety. Predictive biomarkers associated with efficacy will be evaluated. Approximately 568 pts will be enrolled. Clinical trial information: NCT02657434.

TPS9102 Poster Session (Board #425a), Sat, 8:00 AM-11:30 AM

Randomized, open-label phase Ib/II study of atezolizumab with or without daratumumab in previously treated advanced or metastatic non-small cell lung cancer (NSCLC). *First Author: Rathi Narayana Pillai, Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: Daratumumab (DARA), a human CD38 monoclonal antibody, is approved for treatment of relapsed/refractory multiple myeloma (RRMM). DARA produces deep clinical responses in RRMM and induces T-cell expansion through reduction of immune suppressive cell populations ($CD38^+$ myeloid-derived suppressor cells and regulatory T and B cells). Atezolizumab (atezo) blocks programmed death-ligand 1 (PD-L1) and was recently approved for metastatic NSCLC that progressed on or during platinum therapy based on data showing improved overall survival (OS) in the atezo vs docetaxel treatment arm. A combination of DARA and atezo may improve clinical responses in NSCLC by enhancing anti-tumor T-cell responses facilitated by checkpoint inhibition. This study will assess the anti-tumor activity and safety profile of DARA plus atezo vs atezo alone in patients (pts) with previously treated advanced or metastatic NSCLC. **Methods:** This is an ongoing phase 1b/2 randomized, open-label, multicenter study of atezo (1200 mg intravenous [IV]; Day 2 of Cycle 1 and Day 1 of each 21-day cycle thereafter) alone or in combination with DARA (16 mg/kg IV weekly for 3 cycles [Days 1, 8, and 15] and then Day 1 of each 21-day cycle thereafter). Eligible pts (≥18 years) must have advanced or metastatic NSCLC and received standard platinum-based therapy with disease progression or intolerance to therapy. ECOG performance status of ≤1 and known PD-L1 tumor status are required. Pts previously treated with anti-CD38 therapy, including DARA, CD137 agonists, or immune checkpoint inhibitors are excluded. The primary endpoint is overall response rate. Secondary outcomes include safety, duration of response, clinical benefit rate (≥16 weeks duration), progression-free survival, OS, and pharmacokinetics and immunogenicity of DARA and atezo when given in combination. Approximately 96 pts will be enrolled; 6 pts will receive combination therapy in a safety run-in cohort for evaluation of dose-limiting toxicity followed by 90 pts randomly (1:1) assigned to the 2 treatments. Clinical trial information: NCT03023423.

TPS9103 **Poster Session (Board #425b), Sat, 8:00 AM-11:30 AM**

B-F1RST: Assessment of novel blood-based biomarkers in patients with first-line advanced or metastatic NSCLC receiving atezolizumab monotherapy. *First Author: Edward S. Kim, Levine Cancer Institute, Charlotte, NC*

Background: The anti–PD-L1 monoclonal antibody atezolizumab inhibits the interaction of PD-L1 with its receptors PD-1 and B7.1, thereby restoring T-cell immunity. In the Phase III OAK study, patients with previously treated advanced NSCLC had improved mOS in the atezolizumab arm (13.8 mo) vs the docetaxel arm (9.6 mo) (HR 0.73 [95%CI: 0.62, 0.87]; *P*= 0.0003), irrespective of PD-L1 expression or histology. A Phase III clinical trial of atezolizumab monotherapy for first-line, PD-L1–selected patients with NSCLC is underway; however, first-line atezolizumab monotherapy for NSCLC treatment in a biomarker-unselected population has not yet been investigated. Current assays to measure PD-L1 expression by IHC require tumor biopsies, which can be difficult to obtain in some patients. Novel blood-based biomarkers will be evaluated retrospectively in B-F1RST (Blood-First-Line Ready Screening Trial) in patients receiving atezolizumab monotherapy in first-line NSCLC. **Methods:** A Phase II, open-label, single-arm study, B-F1RST (NCT02848651), will evaluate the efficacy and safety of atezolizumab in PD-L1–unselected patients with first-line locally advanced or metastatic NSCLC. Eligibility criteria include stage IIIB-IVB NSCLC, ECOG PS 0-1, measurable disease per RECIST v1.1 and adequate hematologic and end-organ function. Exclusion criteria include the presence of *EGFR*mutations or *ALK*fusions, active CNS metastases and prior immunotherapy for NSCLC. Patients will receive atezolizumab 1200 mg IV q3w until disease progression or loss of clinical benefit. Prospective collection of blood samples is mandatory; collection of tissue biopsies is optional. The co-primary endpoints of the study are investigator-assessed ORR per RECIST v1.1 for the efficacy objective and PFS per RECIST v1.1 for evaluating blood-based predictive biomarkers for atezolizumab efficacy, including mutation status. Approximately 150 patients will be enrolled at 25 or more centers in the United States. Clinical trial information: NCT02848651.

TPS9104 **Poster Session (Board #426a), Sat, 8:00 AM-11:30 AM**

Detect T790M in cell free tumor DNA of Chinese advanced non-small cell lung cancer adenocarcinoma patients by different platforms and evaluate clinical outcomes of T790M positive patients with osimertinib monotherapy. *First Author: Zhiyong Liang, Peking Union Medical College Hospital, Beijing, China*

Background: EGFR T790M mutation occurs in approximately 50-60% of non-small cell lung cancer adenocarcinoma (NSCLC) patients with acquired EGFR-TKI resistance, based on tumor re-biopsies using an invasive clinical procedure. Recently, Cell free tumor DNA (ctDNA) has emerged as a specific and sensitive blood-based biomarker and studies have demonstrated ctDNA as a feasible and minimally invasive alternative to tissue biopsy. Data on different technology platforms used for EGFR T790M detection in blood in China is limited. We aim to compare the methods currently available in hospital practise, including cobas EGFR Mutation Test (Roche Molecular Systems), super-ARMS, digital PCR and NGS, to compare each platform and clinically validate each as companion diagnostic to osimertinib. **Methods:** This is an open-label, multi-center study in 250 locally advanced or metastatic NSCLC patients with documented EGFR sensitizing mutation and progression on previous EGFR-TKI. T790M mutation in plasma ctDNA will be tested by four methods: cobas, super-ARMS, digital PCR and NGS in order to evaluate the concordance, sensitivity and specificity of T790M testing in plasma between the cobas test and the other platforms. T790M positive patients by any of the four platforms will receive osimertinib treatment (administered orally as one 80 mg tablet once a day in ASTRIS study, NCT02474355) and the clinical outcomes (PFS, ORR, OS) will be followed. Patients will continue to receive osimertinib until disease progression (PD), as assessed by investigators. Digital PCR and NGS will be used to monitor the molecular evolution of T790M and C797S in plasma from NSCLC patients during osimertinib treatment. NGS will also be used to explore acquired resistance mechanisms before osimertinib treatment and after PD. 23 of planned 250 patients have been enrolled in the study as of January 2017. Clinical trial information: NCT02997501.

TPS9105 **Poster Session (Board #426b), Sat, 8:00 AM-11:30 AM**

Phase II clinical trial of atezolizumab (A) in advanced non-small cell lung cancer (NSCLC) patients (pts) previously treated with PD1-directed therapy. *First Author: Saveri Bhattacharya, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: While inhibition of the PD1 axis is associated with improved response rates vs cytotoxic therapy in pts with previously treated NSCLC, the majority of pts will not benefit from objective response. Anti-PD1 and PD-L1 antibodies block distinct inhibitory pathways, possibly resulting in different clinical outcomes. While anti-PD1 antibodies block PD1 binding to PD-L1 and PD-L2, they do not affect the inhibitory signal of the PD-L1/B7.1 interaction. This trial is critical to establishing the clinical activity of sequencing PD-L1 inhibition in pts previously treated with PD1 directed and identifying candidate biomarkers of response and resistance to PD1/PD-L1 directed therapies. **Methods:** In this phase II clinical trial, pts with advanced NSCLC with stable or progressive disease on anti-PD1 therapy (nivolumab or pembrolizumab) will be treated with A1200 mg day 1 of a 21-day cycle until disease progression, unacceptable toxicity or death. The kinetics of response to anti-PD1 therapy can be variable and in some cases characterized by pseudo-progression. In order to account for variable response kinetics to PD1 therapy, pts will be enrolled in 3 parallel cohorts based on best overall response (BOR) to PD1 therapy (stable disease; progressive disease; complete or partial response followed by progressive disease). The primary objective is BOR to A. Secondary endpoints include duration of response, progression free survival, overall survival, and safety. 37 pts will be enrolled per cohort. A Simon 2-stage design will be employed with a stopping rule for futility if 0 of the first 11 evaluable patients within a cohort have a confirmed objective response in Stage 1. A promising result would be if ≥3 responses are seen at the conclusion of stage 2. This design has 80% power to detect a true response rate of 15% in each cohort (null rate 2%; alpha 0.05). Mandatory biopsies at time of enrollment, archival tumor pre-PD1 directed therapy, and optional biopsy at the time of progression on A will be collected for exploratory studies of immune biomarkers of response and resistance. Clinical trial information: NCT03014648.

TPS9106 **Poster Session (Board #427a), Sat, 8:00 AM-11:30 AM**

METIS: A phase 3 study of radiosurgery with TTFields for 1-10 brain metastases from NSCLC. *First Author: Minesh P. Mehta, University of Maryland Medical Center, Baltimore, MD*

Background: Tumor Treating Fields (TTFields) are non-invasive regional anti-mitotic treatment modality, based on low intensity alternating electric fields. Efficacy of TTFields in non-small cell lung cancer (NSCLC) has been demonstrated in multiple *in vitro* and *in vivo* models, and in a phase I/II clinical study. TTFields treatment to the brain was shown to be safe and to extend overall survival in newly-diagnosed glioblastoma patients. **Methods:** 270 patients with 1-10 brain metastases (BM) from NSCLC will be randomized in a ratio of 1:1 to receive stereotactic radio surgery (SRS) followed by either TTFields or supportive care alone. Patients are followed-up every two months until 2nd cerebral progression. Patients in the control arm may cross over to receive TTFields at the time of 2st cerebral progression. Objectives: To test the efficacy, safety and neurocognitive outcomes of TTFields in this patient population. Endpoints: Time to 1st cerebral progression based on the RANO-BM Criteria or neurological death (primary); time to neurocognitive failure based on the following tests: HVLT, COWAT and TMT; overall survival; radiological response rate; quality of life; adverse events severity and frequency (secondary). Main eligibility criteria: Karnofsky performance status (KPS) of 70 or above, 1 inoperable or 2-10 brain lesions amenable to SRS, optimal standard therapy for the extracranial disease, no brain-directed therapy, no signs of significantly increased intracranial pressure, no electronic implantable devices in the brain. Treatment: Continuous TTFields at 150 kHz for at least 18 hours per day will be applied to the brain within 7 days of SRS. The treatment system is a portable medical device allowing normal daily activities. The device delivers TTFields to the brain using 4 Transducer Arrays, which may be covered by a wig or a hat for cosmetic reasons. Patients will receive the best standard of care for their systemic disease. Statistical Considerations: This is a prospective, randomized, multicenter study for 270 patients. The sample size was calculated using a log-rank test (based on Lakatos 1988 and 2002) and has 80% power at a two sided alpha of 0.05 to detect a hazard ratio of 0.57. Clinical trial information: NCT02831959.

TPS9107 Poster Session (Board #427b), Sat, 8:00 AM-11:30 AM

A phase II, noncomparative, open label, multicentre, study of AZD9291 in patients with locally advanced or metastatic EGFR mutated "T790M undetectable or unknown" non-small cell lung cancer (stage IIIB-IV) after no immediate prior EGFR TKI (OSIRIS study). *First Author: Hector J. Soto Parra, Medical Oncology, University Hospital Policlinico, Vittorio Emanuele, Catania, Italy*

Background: Osimertinib (OSI), is an oral, potent, irreversible inhibitor of both epidermal growth factor receptor (EGFR) sensitizing and resistance mutations (T790M) indicated for the treatment of pts with advanced EGFR T790M mutation-positive NSCLC. In the AURA study, OSI was associated with an ORR of 21% (13/61) among all patients with T790M negative mutation. Response rate broken down by immediate versus no immediate prior EGFR TKI was 11% (4/36 pts) versus 36% (9/25) respectively. This better activity with deferred OSI, drug able to inhibit also the EGFR sensitizing mutations, could be explained by a selection of sensitive tumor cells during chemotherapy (re-challenge strategy). Aim of the current study is prospective evaluate the efficacy of OSI in EGFR mutated, T790M "undetectable or unknown" patients as third-line therapy after a first-line EGFR TKI and a subsequent chemotherapy. **Methods:** OSIRIS study is a prospective single-arm, phase 2, open label, italian multicenter study. T790M "undetectable or unknown" is defined by the following conditions: inconclusive/negative tumor test result for T790M at the time of disease progression or medical inaccessible/contraindications/declined tumor biopsy or insufficient tumor tissue for testing. Pts are treated with OSI 80 mg once daily until disease progression or unacceptable toxicity. The single-arm design is appropriate, as there is no accepted standard therapy for these pts after chemotherapy. The primary endpoint is ORR according to RECIST version 1.1. The null hypothesis that the true response rate is 9% will be tested against a one-sided alternative. In the first stage, 32 pts will be accrued. If there are 3 or fewer responses in these 32 pts, the study will be stopped. Otherwise, 49 additional pts will be accrued for a total of 81. This design yields a type I error rate of 0.05 and power of 80% when the true response rate is 19%. Secondary endpoints are PFS, OS and safety. Exploratory: mutational analysis of a panel of genes involved in resistance to EGFR-TKIs is planned. Clinical trial information: 2016-002555-17.

9500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A phase III randomized study of adjuvant ipilimumab (3 or 10 mg/kg) versus high-dose interferon alfa-2b for resected high-risk melanoma (U.S. Intergroup E1609): Preliminary safety and efficacy of the ipilimumab arms. *First Author: Ahmad A. Tarhini, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: In the U.S., 3 regimens have regulatory approval as adjuvant therapy for high-risk melanoma, including high-dose interferon-alfa (HDI) and ipilimumab 10 mg/kg (ipi10). Ipilimumab 3 mg/kg (ipi3) has regulatory approval for metastatic inoperable melanoma. The toxicity of ipi is dose- dependent, and following the recent approval of adjuvant ipi10, it has become urgent to evaluate the relative safety and efficacy of adjuvant ipi at the 2 dose levels that have been tested in E1609. **Methods:** E1609 randomized patients (pts) with resected high-risk melanoma (stratified by stages IIIB, IIIC, M1a, M1b) to ipi10 or ipi3 versus HDI. Co-primary endpoints were RFS and OS. The current analysis investigates the relative safety and preliminary, non-comparative RFS of the ipi arms as of 3/2/17. **Results:** E1609 was activated on 5/25/11 and completed adult pt accrual on 8/15/14. Accrual to ipi10 was suspended due to toxicity between 9/23-11/16/2013. Final adult pt accrual was 1670 including 511 ipi10, 636 HDI and 523 ipi3 pts. Treatment related adverse events (AEs) were reported among 503 ipi10 and 516 ipi3 pts. Worst degree (Gr 3+) AEs were experienced by 57% ipi10 and 36.4% ipi3 pts and were mostly immune related (Table 1). AEs led to discontinuation of treatment in 271 (53.8 %) of 503 ipi10 and in 180 (35.2 %) of 512 ipi3 pts during the initial 4 dose induction phase. Gr5 AEs considered at least possibly related were 8 with ipi10 and 2 with ipi3. At a median follow-up of 3.1 years, an unplanned RFS analysis of ipi3 and ipi10 on concurrently randomized pts showed no difference between the 2 arms. Three-year RFS rate was 54% (95% CI: 49, 60) with ipi10 and 56% (50, 61) with ipi3. **Conclusions:** Adjuvant therapy of pts with high-risk melanoma is associated with significantly more toxicity at ipi10 compared to ipi3. An unplanned RFS analysis of concurrently randomized pts on the 2 ipi arms showed no difference in RFS. Clinical trial information: NCT01274338.

Common treatment-related Gr3+ AEs by treatment arm.

	Ipi10 (%)	Ipi3 (%)
Diarrhea/colitis	19.5	13
Endocrine	10.7	5.4
Liver	8.2	3.5
Skin	8.8	5.8
Pancreas	5	3.7
Neurologic	1.8	1.2

9501 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Adjuvant bevacizumab as treatment for melanoma patients at high risk of recurrence: Final results for the AVAST-M trial. *First Author: Philippa Corrie, Cambridge Cancer Trials Centre, Cambridge, United Kingdom*

Background: Bevacizumab (Bev) is a recombinant humanised monoclonal antibody to vascular endothelial growth factor (VEGF) shown to improve survival in several advanced solid tumours. As VEGF is a relevant target in melanoma, AVAST-M aimed to evaluate the role of Bev in melanoma patients at high risk of recurrence. **Methods:** AVAST-M (ISRCTN81261306) is a randomised phase III trial evaluating single agent Bev (7.5mg/kg IV 3 weekly for 1 year) as adjuvant therapy after resection of AJCC stage IIB, IIC and III cutaneous melanoma compared to standard observation (Obs). 1320 patients were needed to detect 8% differences in 5 year overall survival (OS) rate from 40% to 48%; 85% power, 5% alpha level. Primary endpoint was OS; secondary endpoints included disease free interval (DFI), distant-metastasis free interval (DMFI). *BRAF* and *NRAS*mutation status were obtained in 682 patients in a translational sub-study. **Results:** From July 2007 to March 2012, 1343 patients were recruited (671 to Bev; 672 to Obs). 56% were male, median age was 56 years (range 18-88 years), 14% were stage IIIA and 59% were stage IIIB/C. With 6 years median follow-up, 505 (38%) patients had died (251 [37%] on Bev; 254 [38%] on Obs); 699 (52%) patients had recurred (335 [50%] on Bev, 369 [55%] on Obs). OS at 5 years was 64% on Bev versus 63% on Obs (Hazard ratio [HR] 0.99; 95% confidence interval [CI] 0.84-1.18, p=0.96). At 5 years, 51% were disease free on Bev versus 45% on Obs (HR 0.85; 95% CI 0.74-0.99, p=0.04) and 59% were distant metastasis free on Bev versus 54% on Obs (HR 0.91; 95% CI 0.77-1.07, p=0.24). A *BRAF*V600 mutation was found in 44% of tumours assessed; 20% were *NRAS* mutant. *BRAF* mutant patients treated with Bev tended to have better DFI (HR=0.79 95% CI 0.58-1.08, p=0.14) and OS (HR=0.79; 95% CI 0.55-1.13, p=0.20); this was not evident for *BRAF*WT. *NRAS* mutant patients tended to have worse DFI (HR=1.39; 95% CI 1.03-1.88; p=0.03) and OS (HR=1.18; 95% CI 0.85-1.62, p=0.20) than *NRAS*WT patients. **Conclusions:** This large, multi-centre trial of melanoma patients at high risk of recurrence has shown that adjuvant Bev improves DFI, but this does not translate into an overall survival benefit. Funding:Cancer Research UK; drug supplied by Roche Products Ltd. Clinical trial information: ISRCTN81261306.

9502 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A randomized multicenter phase 3 trial of adjuvant fotemustine versus surveillance in high risk uveal melanoma (UM) patients (FOTEADJ). *First Author: Sophie Piperno-Neumann, Medical Oncology, Institut Curie, Paris, France*

Background: Up to 30% of UM patients will develop metastases, with a median survival of 12 months in the metastating setting. Prognostic factors combine clinical features of the primary tumor (diameter, thickness, retinal detachment, extra-scleral extension) and genetic factors (monosomy 3, 8 q gain and class 1 /2 gene expression profiling).The genomic analysis is feasible by fine needle aspiration biopsies before radiotherapy for small UM or on enucleated eyes. **Methods:** Multicenter randomized phase 3 trial with adjuvant fotemustine, 6 cycles, 100 mg/m2 versus surveillance for 3 years (liver tests/3 months, liver MRI or CT/6 months, whole body CT/12 months) in patients with high risk of recurrence, defined by clinical criteria (diameter $>$ 15 mm with extra scleral extension and/or retinal detachment or diameter $>$ 18 mm) or genomic high risk signature by array-CGH (monosomy 3 or deletion of 3p associated with gain of chromosome 8). The primary objective was 5-year Metastasis Free Survival (MFS). With an expected increase of 5-year MFS from 50 to 70%, 302 patients and 99 events were required to achieve an 95%-power with a 5% type I error rate. Secondary objectives were overall survival (OS), safety (NCI-CTC v3), quality of life (QLQ-C30). Interim analyses were planned for safety and after 50 events, disclosed to an independent safety monitoring board. **Results:** The trial was stopped for futility after 244 patients had been recruited between June 2009 and January 2016. No unexpected toxicity was found in the chemotherapy group. The study was amended to go on with intensive surveillance in new high risk patients. Ninety-one metastases and 43 deaths were reported, with no treatment-related death. With a median follow-up of 3 years, the 3-year MFS is 60.3% in the chemo group and 60.7% in the surveillance group (HR 0.97 [0.64-1.47]). The 3-year OS is 79.4% [73.2-85.7], with no difference between the 2 groups of patients. **Conclusions:** FOTEADJ is the first adjuvant randomized phase 3 trial based on genomic analysis in high risk UM patients. Despite negative results, it shows the feasibility of multicenter adjuvant studies in this rare cancer and provides genomic data in small tumors for future trials. Clinical trial information: NCT02843386.

9503 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

REGN2810: A fully human anti-PD-1 monoclonal antibody, for patients with unresectable locally advanced or metastatic cutaneous squamous cell carcinoma (CSCC)—Initial safety and efficacy from expansion cohorts (ECs) of phase I study. *First Author: Kyriakos P. Papadopoulos, START, San Antonio, TX*

Background: There is no established standard of care for unresectable locally advanced or metastatic CSCC. UV-induced DNA damage causes hypermutation in most CSCCs. Therefore, these tumors may be responsive to PD-1 checkpoint blockade. In the dose escalation portion of the phase 1 study of REGN2810, a durable (19 + months) radiologic complete response was observed in a patient (pt) with metastatic CSCC (ASCO 2015, #3024). **Methods:** ECs enrolled pts with distantly metastatic (EC 7) and locally advanced (EC 8) CSCC. All patients received 3 mg/kg REGN2810 by intravenous infusion over 30 minutes every 2 weeks for up to 48 weeks. Research biopsies were performed at baseline and Day 29 (and at progression, if possible). Tumor measurements were performed every 8 weeks according to RECIST 1.1 to determine overall response rate (ORR). Data cutoff date was 31 Jan 2017. **Results:** 26 pts were enrolled (10 in EC 7 and 16 in EC 8): median age, 72.5 y (range, 56-88y); median PS 1 (range, 0 – 1); 21M:5F; median number of prior systemic therapy regimens, 1 (range, 0 – 2). Median exposure to REGN2810 was 7 doses (range, 1-22). The most common treatment-related adverse event of any grade was fatigue (19.2%). Each of the following $\geq$ Grade 3 related AEs occurred once: AST elevation, ALT elevation, arthralgia, and rash. ORR (PR + CR, including unconfirmed) and disease control rate (ORR+SD) were 52% (12/23; 4uPR, 5 PR, 2CR, 1 uCR) and 70% (16/23, including 4SD), respectively. Three patients are not yet evaluable. Median PFS and OS have not been reached, and only one patient has experienced PD during REGN2810 treatment after initial response. Correlative studies are in process, including PD-L1 status and whole exome tumor DNA sequencing. **Conclusions:** REGN2810 is well tolerated and produces antitumor activity in patients with advanced CSCC. A pivotal trial of REGN2810 for patients with advanced CSCC is enrolling patients (NCT02760498). Clinical trial information: NCT02383212.

9504 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Long-term outcomes in patients (pts) with ipilimumab (ipi)-naive advanced melanoma in the phase 3 KEYNOTE-006 study who completed pembrolizumab (pembro) treatment. *First Author: Caroline Robert, Gustave Roussy, Villejuif, France*

Background: Pembro demonstrated superior PFS and OS vs ipi in ipi-naive pts with advanced melanoma in the phase 3 KEYNOTE-006 study (NCT01866319). Here, we present long-term outcomes for all pts and in those pts who completed pembro therapy. **Methods:** Eligible pts (N = 834) were randomized 1:1:1 to pembro 10 mg/kg Q2W, pembro 10 mg/kg Q3W, or ipi 3 mg/kg Q3W for 4 doses. Treatment was continued for 2 yr (pembro only) or until disease progression, intolerable toxicity, or pt/investigator decision to discontinue. Per protocol, pts could interrupt pembro for ≤12 wk before discontinuation was required. Tumor imaging was performed at wk 12, then every 6 wk up to wk 48 and every 12 wk thereafter. After the prespecified final analysis, response assessments were per immune-related response criteria (irRC) by investigator review. **Results:** As of the data cutoff (Nov 3, 2016), median follow-up in the total population was 33.9 mo (range, 32.1-37.6). 33-mo OS rates were 50% in the pooled pembro arms (n = 556) and 39% in the ipi arm (n = 278); 33-mo PFS rates were 31% and 14%. ORR was 42% and 16%. Median duration of response was not reached for pembro (range 1.0+ to 33.8+ mo) or ipi (1.1+ to 34.8+ mo); 46 (68%) pembro-treated pts and 7 (58%) ipi-treated pts had a response lasting ≥30 mo. Among the 104/556 (19%) pts who completed pembro, median exposure to pembro was 24.0 mo (range 22.1-25.9). After a median follow-up of 9.0 mo after completion of pembro, 102 (98%) pts were alive. Responses were durable in pts who completed pembro; 9.7 mo after completion of pembro, estimated PFS (95% CI) was 91% (80-96) in all 104 pts, 95% (69-99) in pts with complete response (n = 24), 91% (74-97) in pts with partial response (n = 68), and 83% (48-96) in pts with stable disease (n = 12). **Conclusions:** Pembro provides durable efficacy after stopping the protocol-specified duration of treatment in pts with ipi-naive advanced melanoma in KEYNOTE-006. The estimated risk for progression or death nearly 10 mo after completing pembro is 9% and does not appear to differ by best response to pembro. Clinical trial information: NCT01866319.

9505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Five-year overall survival (OS) update from a phase II, open-label trial of dabrafenib (D) and trametinib (T) in patients (pts) with *BRAF* V600–mutant unresectable or metastatic melanoma (MM). *First Author: Georgina V. Long, University of Sydney, Sydney, Australia*

Background: D (BRAF inhibitor) + T (MEK inhibitor) combination therapy is associated with rapid clinical responses and has improved clinical outcomes in pts with *BRAF*V600–mutantMM, but long-term (˃ 3 y) clinical efficacy and safety data are limited. The longest follow-up to date of a randomized trial evaluating D+T at the approved dose (150 mg BID/2 mg QD [150/2]) was of the phase II study BRF113220 (part C; median, 45.6 mo) in which durable outcomes were achieved in some pts with *BRAF*V600–mutantMM (3-y OS, 38%). Here, we report updated 5-y landmark analyses to further characterize the impact of D+T in MM. **Methods:** Pts with *BRAF*V600–mutant mm enrolled in BRF113220 part C (NCT01072175) were randomized 1:1:1 to receive monotherapy D (150 mg BID), D+T (150 mg BID/1 mg QD), or D+T (150/2). Pts who progressed on D alone could cross over to the D+T 150/2 arm. Pt disposition, pt demographics, and 4- and 5-y efficacy and safety were analyzed for both the D-alone and D+T (approved 150/2 dose) arms. **Results:** This updated analysis represents an additional ≈ 2 y of follow-up (D and D+T arms; n = 54 each). As of 13 Oct 2016, 45 pts (83%) on D alone had crossed over to D+T. 20 pts were ongoing (D, n = 7 [13%]; D+T, n = 13 [24%]); 80% of D pts and 70% of D+T pts had died. D+T OS remained superior to D alone. The 4- and 5-y OS rates with D+T were 30% and 28%, respectively, demonstrating a stabilization of the OS curve. The PFS curve for D+T also remained stable (4- and 5-y: both 13%). Consistent with earlier results, the best OS for pts who received D+T was seen in pts with normal LDH (5-y, 45%) and normal LDH with disease in < 3 organ sites (5-y, 51%). At the 5-y landmark, 1 additional pt who received D+T improved from a partial to a complete response. Additional follow-up revealed no new safety signals with D+T. Detailed analyses of D crossover pts, responders, and post-progression therapy will be presented. **Conclusions:** This longest follow-up to date of BRAF + MEK inhibitor combination therapy in pts with *BRAF*V600–mutant mm revealed stable OS and PFS lasting ≥ 5 y with consistent tolerability. These results demonstrate that some pts with mm can achieve durable benefit with D+T therapy. Clinical trial information: NCT01072175.

9506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

COMBI-MB: A phase II study of combination dabrafenib (D) and trametinib (T) in patients (pts) with *BRAF* V600–mutant (mut) melanoma brain metastases (MBM). *First Author: Michael A. Davies, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CNS metastases are common and associated with very poor prognosis in pts with metastatic melanoma (MM). In the phase II BREAK-MB trial, D had clinical activity in *BRAF* V600–mut MBM. D + T has shown superiority over D alone in pts with *BRAF* V600–mut mm without MBM; however, efficacy of this regimen on MBM has not been characterized. Here, we report results from a phase II trial of D + T in *BRAF*V600–mut MBM (COMBI-MB; NCT02039947). **Methods:** This open-label, phase II study evaluated D 150 mg BID + T 2 mg QD in 4 MBM cohorts: (A) *BRAF*V600E, asymptomatic MBM, no prior local treatment (Tx); (B) *BRAF*V600E, asymptomatic MBM, prior local Tx; (C) *BRAF*V600D/K/R, asymptomatic MBM, with or without prior local Tx; and (D) *BRAF*V600D/E/K/R, symptomatic MBM, with or without prior local Tx. The primary objective was intracranial response rate (IRR) in cohort A (null hypothesis, IRR ≤ 35%). Secondary endpoints included IRR in cohorts B, C, and D; extracranial (ERR) and overall (ORR) response rates; intracranial (IDCR), extracranial (EDCR), and overall (ODCR) disease control rates; duration of IR, ER, and OR; PFS; OS; and safety. **Results:** 125 pts were enrolled (A, n = 76; B, n = 16; C, n = 16; D, n = 17). In cohort A, median age was 52, 53% were male, and 37% had LDH > ULN. At data cutoff (28 Nov 2016; median f/u, 9.0 mo), in cohort A, investigator-assessed IRR was 58% (IDCR, 78%), ERR was 55% (EDCR, 80%), and ORR was 58% (ODCR, 80%). Median duration of IR, ER, and OR was 6.5 mo (95% CI, 4.9-10.3), 10.2 mo (95% CI, 6.5-13.0), and 6.5 mo (95% CI, 4.9-10.3), respectively. Median PFS was 5.6 mo (95% CI, 5.3-7.4). Independent review supported these results. 6-mo OS was 79%; with 31 pts (41%) still in f/u, preliminary median OS was 10.8 mo (95% CI, 8.7-19.6). Efficacy in cohorts B, C, and D will be reported. AEs across cohorts (any, 98%; grade 3/4, 48%) were consistent with prior D + T studies; 10% of pts (8% in cohort A) discontinued due to AEs. **Conclusions:** In this first report of a phase II trial evaluating a BRAF and MEK inhibitor combination in *BRAF*V600–mut MBM, the primary endpoint was met. Promising IRR and IDCR were seen with D + T, but responses appear less durable than reported for mm without MBMs. No unexpected safety issues were observed. Clinical trial information: NCT02039947.

9507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Efficacy and safety of nivolumab (NIVO) plus ipilimumab (IPI) in patients with melanoma (MEL) metastatic to the brain: Results of the phase II study CheckMate 204. *First Author: Hussein Abdul-Hassan Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Brain metastases (BMts) are a major cause of morbidity/death in MEL. We report the first efficacy data in MEL patients (pts) with BMts who received NIVO+IPI in study CheckMate 204. **Methods:** In this multicenter US trial (NCT02320058), MEL pts with ≥1 measurable BMt 0.5-3.0 cm and no neurologic symptoms or steroid Rx received NIVO 1 mg/kg + IPI 3 mg/kg Q3W x 4, then NIVO 3 mg/kg Q2W until progression or toxicity. Pts with severe adverse events (AEs) during NIVO+IPI could receive NIVO when toxicity resolved; stereotactic radiotherapy (SRT) was allowed for brain oligo-progression if an assessable BMt remained. The primary endpoint was intracranial (IC) clinical benefit rate (complete response [CR] + partial response [PR] + stable disease [SD] > 6 months). The planned 90-pt accrual is complete; we report efficacy and updated safety for 75 pts with disease assessment before the Nov 2016 database lock. **Results:** Median age was 59 yrs (range 22–79). Median number of induction doses was 3; 26 pts (35%) received 4 NIVO+IPI doses and 38 pts (51%) began NIVO maintenance. Response data are reported at a median follow-up of 6.3 months (Table). The IC objective response rate (ORR) was 56% (95% CI: 44–68); 19% of pts had a complete response. IC and extracranial responses were largely concordant. Rx-related grade 3/4 AEs occurred in 48% of pts, 8% neurologic, including headache and syncope. Only 3 pts (4%) stopped Rx for Rx-related neurologic AEs. One pt died of immune-related myocarditis. **Conclusions:** In CheckMate 204, prospectively designed to investigate NIVO+IPI in MEL pts with BMts, NIVO+IPI had high IC antitumor activity with objective responses in 56% of pts, CR in 19%, and no unexpected neurologic safety signals. The favorable safety and high anti-melanoma activity of NIVO+IPI may represent a new Rx paradigm for pts with asymptomatic MEL BMts and could change practice to avoid or delay whole brain RT or SRT. Clinical trial information: NCT02320058.

	Global	Intracranial	Extracranial

9508 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A randomized phase II study of nivolumab or nivolumab combined with ipilimumab in patients (pts) with melanoma brain metastases (mets): The Anti-PD1 Brain Collaboration (ABC). *First Author: Georgina V. Long, University of Sydney, Sydney, Australia*

Background: Nivolumab (nivo) and the combination of nivo + ipilimumab (ipi) improve response rates (RR) and progression-free survival (PFS) compared with ipi alone in clinical trials of metastatic melanoma pts, but pts with untreated brain mets were excluded. Brain mets are a major cause of morbidity and mortality in melanoma and their management is critical. We sought to determine the antitumour activity and safety of nivo and nivo+ipi in pts with active melanoma brain mets (NCT02374242). **Methods:** This open-label, ph II trial enrolled 3 cohorts of pts naïve to anti-PD1/PDL1/PDL2/CTLA4 from Nov 2014 - Feb 2017. Pts with asymptomatic melanoma brain mets with no prior local brain therapy were randomised to cohort A (nivo 1mg/kg + ipi 3mg/kg, Q3W x4, then nivo 3mg/kg Q2W) or cohort B (nivo 3mg/kg Q2W). Cohort C (nivo 3mg/kg Q2W) had brain mets 1) that failed local therapy (new +/- progressed in previously treated met), 2) were neurologically symptomatic and/or 3) with leptomeningeal disease. Prior BRAF inhibitor (BRAFi) was allowed. The primary endpoint was best intracranial response (ICR) ≥ wk12. Secondary endpoints were best extracranial response (ECR), best overall response (OR), IC PFS, EC PFS, overall PFS, OS, and safety. **Results:** A total of 66 pts (med f/u 14 mo) were included in this analysis of total 76 planned; median age 60y, 77% male. For cohorts A, B and C: elevated LDH 48%, 58% and 19%; V600BRAF 44%, 56% and 81%; prior BRAFi 24%, 24%, 75%. Table shows RR, PFS and OS. ICR in cohort A treatment naïve vs prior BRAFi was 53% vs 16%. Treatment-related gd 3/4 toxicity in cohorts A, B and C were 68%, 40% and 56%, respectively. There were no treatment-related deaths. **Conclusions:** Nivo monotherapy and ipi+nivo and are active in melanoma brain mets. Ipi +nivo had reduced activity in pts who progressed on BRAFi. Pts with symptomatic brain mets, leptomeningeal mets or previous local therapy responded poorly to nivo alone. Clinical trial information: NCT02374242.

	A N = 25 nivo+ipi	B N = 25 nivo	C N = 16 nivo

Primary results from a randomized (1:1), open-label phase II study of talimogene laherparepvec (T) and ipilimumab (I) vs I alone in unresected stage IIIB- IV melanoma. *First Author: Jason Alan Chesney, University of Louisville, Louisville, KY*

Background: T is a HSV-1-based oncolytic virus designed to selectively replicate in tumors and produce GM-CSF to stimulate antitumor immune responses. I is an anti-CTLA-4 Ab that blocks inhibition of activated T cells. This is the first randomized study to evaluate the addition of an oncolytic virus to a checkpoint inhibitor. **Methods:** The 1° endpoint was ORR by immune-related response criteria. Key 2° endpoints: duration of response, disease control rate (DCR), PFS, OS, and safety. Prior treatment was allowed but not required. Pts had unresected stage IIIB-IV melanoma with measurable/injectable tumor(s) and no evidence of immunosuppression. T was given at approved dosing until no injectable tumors, disease progression (PD), or intolerance. I was started at w6 in T+I and at w1 in I at 3 mg/kg IV q3w x 4. Primary analysis occurred 6 m after last pt enrolled. **Results:** 198 pts were randomized: 98 T+I; 100 I. Characteristics were similar: 54% stage IIIB-IVM1a, 46% IVM1b/c. Median follow up time was 68 w (T+I) and 58 w (I). ORR was 38.8% (T+I) and 18.0% I, $P = 0.002$, Odds ratio (OR) 2.9. 89% T+I and 83% I pts remain in response. Unconfirmed visceral lesion response was 35.5% T+I vs 13.6% I. OS is immature. Of 190 pts (safety set: 95 T+I, 95 I), most common adverse events (AEs) for T+I, I (%) were fatigue (59, 42), chills (53, 3), and diarrhea (42, 35). 28% T+I and 18% I pts had gr ≥3 tx-related AE. There were 3 deaths (all unrelated) in T+I: 1 myocardial infarction and 2 PD. **Conclusions:** The study met the 1° endpoint. ORR was significantly higher for T+I vs I; responses were not limited to injected lesions. Toxicity of T+I combination was tolerable with no unexpected AEs. Clinical trial information: NCT01740297.

Final results of a phase II multicenter trial of HF10, a replication-competent HSV-1 oncolytic virus, and ipilimumab combination treatment in patients with stage IIIB-IV unresectable or metastatic melanoma. *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: HF10 is a bioselected replication-competent oncolytic virus derived from HSV-1. Herein, we report the safety and efficacy data of HF10 + ipilimumab (ipi) combination treatment in a Phase II trial in melanoma. **Methods:** Key entry criteria: age ≥ 18 yrs, ECOG ≤ 2, Stage IIIB, IIIC, or IV unresectable melanoma, ipi naïve (IV administration) and measurable non-visceral lesion(s) suitable for injection. HF10 injected into single or multiple tumors (1×10^7 $TCID_{50}$/mL/dose, up to 5mL depending on tumor size and number); 4 injections q1wk; then up to 15 injections q3wk. Four ipi IV infusions (3 mg/kg; concurrent with HF10) were administered q3wk. AEs assessed per CTCAE 4.0. Tumor responses were assessed per mWHO and irRC at 12, 18, 24, 36 and 48 wks for patients (pts) continuing on HF10 monotherapy. Primary endpoint was Best Overall Response Rate (BORR) at 24 wks. Dose limiting toxicity (DLT) defined as ≥ G3 non-hematologic/hematologic toxicity, ≥ G2 neurologic toxicity, or allergic event occurring within 1st 3wks of therapy. **Results:** Of 46 pts enrolled and treated: 59% men, median age 67 yrs (range 28 to 91); disease stage 20% IIIB, 43% IIIC and 37% IV; 57% were treatment naïve and 43% with ≥ 1 prior cancer therapy for unresectable/metastatic melanoma. Most HF10-related AEs were ≤G2, similar to HF10 monotherapy. No DLTs were reported. 37% had ≥G3 AEs, the majority due to ipi. HF10-related ≥G3 AEs (n=3) were embolism, lymphedema, diarrhea, hypoglycemia, and groin pain. Of the 44 efficacy evaluable pts per irRC, BORR at 24 weeks was 41% (16% irCR and 25% irPR); disease stability rate was 68% (16% irCR, 25% irPR and 27% irSD). As of Feb 06, 2017, median PFS was 19 months and median overall survival was 21.8 months. **Conclusions:** The combination HF10 and ipilimumab treatment demonstrated a favorable benefit/risk profile and encouraging antitumor activity in pts with stage IIIB, IIIC, or IV unresectable or metastatic melanoma. Clinical trial information: NCT02272855.

9511 Poster Discussion Session; Displayed in Poster Session (Board #119), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

STREAM: A randomized discontinuation, blinded, placebo-controlled phase II study of sorafenib (S) treatment of chemonaïve patients (pts) with metastatic uveal melanoma (MUM). *First Author: Max E. Scheulen, Innere Univ Klinik Und Poliklinik, Essen, Germany*

Background: There is no established systemic treatment for pts with MUM. The STREAM study evaluated the efficacy of the oral multikinase inhibitor S in chemonaïve pts with MUM with the primary endpoint progression-free survival (PFS). **Methods:** During the initial 56d run-in period all pts received oral S 400 mg bid with concomitant monitoring by magnetic resonance imaging including diffusion weighted imaging (DWI-MRI). Pts with partial remission (PR) on d56 according to RECIST 1.1 were further treated with open-label S and monitored, pts with progressive disease (PD) were taken off study, and pts with stable disease (SD) were randomly assigned to blinded S or placebo (P) and were further monitored every 8 wks and unblinded in case of PD. Pts on S were taken off study and pts on P were offered S with further monitoring. **Results:** Altogether, 118 (79.2%) of 149 pts entering the run-in period were evaluable for response on d56. Two pts had PR (1.7%), 78 pts had SD (66.1%) and 38 pts had PD (32.2%), respectively. Median PFS from randomization was significantly longer with S (5.5 mths) than P (1.9 mths, HR = 0.527, p = 0.0079). S was readministered to 23 pts with PD under P (59.0%) with a median PFS of 2.0 mths (range 1.2-15.7 mths). Overall survival (OS) was not different between the S group (median 14.8 mths, range 3.7-38.3 mths) and the P group (median 14.4, range 3.3-37.3 mths). During the entire study there were 43 NCI-CTCAE grade 3 and 9 grade 4 adverse events requiring dose reduction of S to 200 mg bid or treatment discontinuation, respectively. No pt died from toxicity. The evaluation of the apparent diffusion coefficient (ADC) ratio derived from DWI-MRI in 47 pts of the run-in period showed a significant difference between pts with SD and pts with PD ($p < 0.05$). **Conclusions:** The primary endpoint of STREAM was reached. S is clinically active and tolerable in first-line treatment of pts with MUM with an increase of median PFS from 1.9 mths for P to 5.5 mths for S (p = 0.0079). The median OS of 14.8 mths compares favorably with previous findings in pts with MUM. Besides morphological MRI features, ADC ratio may be used as an additional functional response criterion. Clinical trial information: NCT01377025.

Re-challenge with BRAF-directed treatment: A multi-institutional retrospective study. *First Author: Sara Valpione, The Christie Hospital and University of Padova, Manchester, United Kingdom*

Background: Most patients treated with BRAF inhibitors (BRAFi) +/- MEK inhibitors (MEKi) eventually progress on treatment. Along with genetic acquired resistance, epigenetic mechanisms that could be reversed after BRAFi discontinuation have been described. The purpose of this study was to analyse outcomes for patients (pts) retreated with BRAF-directed therapy. **Methods:** 116 pts who received BRAFi based therapy and, after a break, were re-challenged with BRAFi +/- MEKi treated at 14 centres in Europe, US, and Australia were analysed for progression free survival (PFS) and response rate (RR), as well as factors predicting overall survival (OS) (demographics, disease stage, treatment, LDH level, duration of first BRAFi treatment, reason for first BRAFi discontinuation and interval between BRAFi stop and re-challenge). Multivariate Cox regression, regression trees and Kaplan Meier method were used. **Results:** Median duration of 1st BRAFi +/- MEKi treatment was 9.4 months (mts) and 7.7 mts for the subsequent treatment after discontinuation (immunotherapy 72%, other 17 %, drug holiday 11%). Brain metastases were present in 51 pts (44%). RR to re-challenge with BRAFi +/- MEKi was 43%: complete response (CR) 3%, partial response (PR) 39%, stable disease 24% and progressive disease (PD) 30%, 4% missing. Of 80 pts who previously discontinued BRAFi for PD, 31 (39%) responded (30 PR and 1 CR). Median OS from retreatment was 9.8 mts. Independent prognostic factors for survival at re-challenge included number of metastatic sites (HR = 1.32 for each additional organ with metastases, $p < .001$), LDH (HR = 1.37 for each multiple of the upper normal limit, $p < .001$), while combination of BRAFi+MEKi conferred a better prognosis vs BRAFi alone (HR = 0.5, p = .006). Pts with < 3 metastatic sites treated with BRAFi and MEKi had a better survival (median OS not reached) and pts with ≥ 3 metastatic sites and raised LDH treated with BRAFi alone had the worse outcome (median OS 4 mts). Number of metastatic sites (HR = 1.44, $p < .001$) and combination of BRAFi and MEKi (HR = 0.45, $p < .001$) were independent prognostic factors for PFS (median 5.0 mts). **Conclusions:** Re-challenge with BRAFi +/- MEKi induces a clinically significant response and should be considered for selected cases.

Incidence, features and management of radionecrosis (RN) in melanoma patients (pts) treated with cerebral radiotherapy (RT) and anti-PD-1 antibodies (PD1). *First Author: Ines Esteves Domingues Pires Da Silva, Melanoma Institute Australia, Sydney, Australia*

Background: Melanoma brain metastases confer poor prognosis, with various treatments used including RT and PD1. While RT and PD1 may have a synergistic effect to improve efficacy, RN may complicate RT, and whether PD1 potentiates this is unknown. We examined the incidence and features of RN and other neurotoxicities in melanoma pts treated with PD1 and whole brain radiotherapy (WBRT) or stereotactic radiosurgery (SRS). **Methods:** Pts treated with PD1 who received WBRT/SRS during or within 1 year (y) of PD1 who survived > 1y were examined for short and long term neurotoxicity. 2 cohorts were included: (A) consecutive pts fulfilling eligibility criteria from 8 melanoma centers, (B) additional cases of RN from 3 centers. Pt demographics, disease features, treatment details, neurotoxicity, and outcome data were collected. **Results:** Cohort A included 118 pts, with median follow-up of 24.3 months (mo). Median age was 56yo, 51% had mutant BRAF, 41% elevated LDH and 65% were ECOG 1-2 at PD1 start. 58% had prior ipilimumab and 43% prior MAPK inhibitors. 85% were treated with pembrolizumab, 10% nivolumab and 5% combination ipilimumab/nivolumab. Most pts (82, 69%) had SRS, 22 (19%) had WBRT alone and 14 pts (12%) had both. Median PFS was 24mo and OS was 45.8mo. 21 pts (18%) developed RN, (14/82) 17% after SRS, (2/22) 9% after WBRT and (5/14) 36% after both. With 13 further cases from cohort B (total 34), all had radiological signs on MRI, 78% had neurological symptoms and 56% had pathological confirmation of RN. Median time to symptom onset and to first radiological sign was 9.8mo and 10.8mo, respectively. 52% were treated with steroids and 30% had bevacizumab, with clinical improvement in 64% and 100%, respectively. Updated analysis including clinical variables associated with RN development will be presented, including RT dose and schedule. **Conclusions:** RN is a significant toxicity in melanoma pts with brain metastases treated with RT and PD1, particularly in long term survivors. Further research to identify those at risk of RN, those who do not require RT, and studies exploring RT and PD1 schedules are required.

The demand for psycho-oncological support in 820 melanoma patients: What are the determinants for the development of distress? *First Author: Andrea Forschner, Department of Dermatology Eberhard-Karls University of Tuebingen, Tuebingen, Germany*

Background: There is limited data about the impact of melanoma on the psychological burden of patients. Despite some known predictors for distress like female gender or younger age, melanoma stages have not been found being related to distress in melanoma patients and there is no data concerning distress in melanoma patients under systemic treatment for metastases. **Methods:** Between July and September 2016, 820 melanoma patients at the outpatient clinic at the Department of Dermatology at the University of Tuebingen underwent psycho-oncological screening. The patients routinely completed the distress thermometer (DT), supplemented by a problem list, before consulting the physician. DT scores ≥ 5 are above-threshold, indicating the need for psycho-oncological support. We matched psycho-oncological data with tumor and patient specific data to examine tumor or patient specific influence on distress using logistic regression. **Results:** 406 (49.5%) men and 414 (50.5%) women were included, mean age was 62.35 years (IQR 52-75), mean time since primary diagnosis of melanoma was 54.84 months (IQR 15-76). 359 (44%) of the patients suffered from advanced melanoma (stage III n = 182, stage IV n = 177). 120 patients (14.6%) received systemic treatment for metastases: 90/120 (75%) checkpoint inhibitors, 27/120 (22.5%) targeted therapy and 3/120 (2.5%) chemotherapy. 338/820 (41.2%) of the patients met the cut-off score for distress. Significant influencing factors ($p < 0.05$) for DT values of ≥ 5 were: female gender, younger age, melanoma stage III and IV. Interestingly we found a lower risk for values above-threshold for patients under systemic treatment, although this was not significant (p = 0.252). **Conclusions:** This is the first analysis to demonstrate the impact of advanced melanoma stages on DT scores above-threshold. Our study is also the first to indicate a lower risk for distress in patients under systemic treatment. This might be due to the closer contact between these patients and their physicians. Nevertheless, more than 40% of our patients needed psycho-oncological support. Departments that care for melanoma patients should therefore be fitted by a sufficient number of psycho-oncologists.

Association of distinct baseline tissue biomarkers with response to nivolumab (NIVO) and ipilimumab (IPI) in melanoma: CheckMate 064. *First Author: Scott Rodig, Brigham and Women's Hospital, Boston, MA*

Background: CheckMate 064 (open label, phase 2) randomized advanced melanoma pts to NIVO 3 mg/kg Q2W for 6 doses then IPI 3 mg/kg Q3W for 4 doses (n = 70; cohort A), or the reverse (IPI then NIVO; n = 70; cohort B). More cohort A than cohort B pts had complete or partial response (54% and 31%, respectively). We sought to determine whether common or distinct baseline biomarkers were associated with response for each cohort. **Methods:** Protein expression of biomarkers identifying a broad array of cell lineages and immunoregulatory factors was determined by IHC and evaluated by 2 pathologists, with concordance. Global transcript expression was determined by RNAseq from frozen tissue. An elastic net predictor was trained on cohort A ($\alpha = 0.1$, $\lambda = 0.05$) using leave-one-out cross-validation. RECIST v1.1 was used to assess tumor response. **Results:** Patients with tumors showing a pro-inflammatory transcriptional signature at baseline had superior overall response in cohort A, but not cohort B. Consistent with this observation, a parsimonious classifier of 10 immune/IFNγ-related genes predicted BOR (AUC 0.87) and OS (CPH log-likelihood $P = 0.0003$) for patients in cohort A, but not cohort B. In contrast, low baseline expression of MHC class I protein by malignant cells (< 50% positive) was associated with disease progression (MHCI < 50% vs ≥50%: 12/13 vs 16/28 progressed) and inferior OS for patients in cohort B (MHCI < 50%: 6.42 mo [2.20, 9.66]; MHCI ≥50%: mOS 18.02 mo [7.98, not reached]: $P = 0.0021$, log-rank test), but not cohort A. **Conclusions:** Different pre-treatment biological characteristics of melanoma are associated with clinical response to NIVO followed by a planned switch to IPI (cohort A) and clinical response to IPI followed by NIVO (cohort B). Improved outcome with initial NIVO is strongly associated with a pro-inflammatory signature enriched for IFNγ targets. Inferior outcome with initial IPI is associated with reduction/loss of MHC I antigen presentation machinery. These data imply that NIVO broadly activates innate and adaptive immunity, whereas IPI is reliant upon CD8/MHC class I mediated adaptive immunity to effect clinical response. Clinical trial information: NCT01783938.

Metagenomic shotgun sequencing to identify specific human gut microbes associated with immune checkpoint therapy efficacy in melanoma patients. *First Author: Arthur E. Frankel, The University of Texas Southwestern, Dallas, TX*

Background: Immune checkpoint inhibitor therapy, ICT, achieves durable remissions in 30-50% of patients (pts) with metastatic melanoma (Larkin et al. *NEJM* 2015). It is still unclear what host factors modulate response to ICT. Preclinical mouse studies with B16 melanoma demonstrated that ICT response was dependent on the presence of specific commensal gut bacteria (Vetizou et al. *Science* 2015; Sivan et al. *Science*2015). These specific gut bacteria induced the maturation of dendritic cells (DCs) and T-cells needed for effective ICT. We sought to determine whether specific gut microbiota are associated with improved response to ICT in melanoma patients. **Methods:** 37 melanoma pts treated with ICT (nivolumab plus ipilimumab or pembrolizumab alone) at UTSW Medical Center were enrolled. Fecal samples were collected prior to ICT. Genomic DNA was extracted, and metagenomic shotgun sequencing (MSS) performed on an Illumina HiSeq 2500 PE-100. Taxonomic (MetaPhlAn) and functional (HUMAnN) analysis was performed on MSS data. Disease status was assessed by CT scans and physical exams every two months. **Results:** Among the 23 evaluable pts, 8 were classified as RECIST responders, 5 with stable disease and 10 with progression. RECIST responder microbiomes were significantly enriched with *Methanobrevibacter smithii* ($p = 0.03$; LDA coupled with effect size measurements, LEfSe; Kruskal-Wallis test), *Bacteroides thetaiotamicron*($p = 0.03$), *Lactobacillus plantarum* ($p = 0.04$), and *Eubacterium limosum*($p = 0.01$) compared to those with progressive disease. **Conclusions:** MSS identified 4 specific gut microbiota associated with improved response to ICT therapy in melanoma pts. All of these bacteria have been shown to modulate host immune response (Bang *PLoS One* 2014; Hickey *Cell Host Microbe* 2016; Rigaux *Allergy* 2009; Kaunachi *World J Gastroent*ertol 2006). To gain mechanistic insight and confirm causality, shotgun metabolomics on the same fecal specimens used for MSS, *in vitro*immune cell assays using the gut microbiota identified, and preclinical modeling in a mouse melanoma model with ICT are underway. These studies may lay the foundation for optimizing the host response to ICT.

Quantitative spatial profiling of PD-1/PD-L1 interaction and HLA-DR/IDO1 to predict outcomes to anti-PD-1 in metastatic melanoma (MM). *First Author: Douglas Buckner Johnson, Vanderbilt University Ingram Cancer Center, Nashville, TN*

Background: Although PD-1/L1 axis directed therapies induce durable responses in some mm patients (pts), biomarkers of response remain elusive. We hypothesized that quantifying key immune suppression mechanisms within the tumor microenvironment would provide superior predictors of response to anti-PD-1 compared with single marker assessment. **Methods:** Pre-treatment tumor biopsies from 124 mm pts treated with anti-PD-1 at 7 academic centers were fluorescently stained with multiple immune markers in discovery ($n = 24$) and validation ($n = 100$) cohorts. Selected biomarker signatures, PD-1/PD-L1 interaction score (proportion of PD-1+ cells co-localized with PD-L1) and IDO1/HLA-DR co-expression were evaluated for anti-PD-1 treatment response and survival. Slides were imaged using Vectra; biomarker positive cells and their co-localization were objectively quantified in pathologist-selected regions using novel Automated Quantitative Analysis (AQUA) algorithms. **Results:** In the discovery cohort, high levels of PD-1/PD-L1 interaction score and/or IDO1/HLA-DR coexpression was strongly positively associated with response to anti-PD-1 ($p = 0.0005$). In contrast, other individual biomarkers (PD-1, PD-L1, CD8) were not associated with response or survival ($p > 0.10$). This finding was replicated in the validation cohort: pts with high PD-1/PD-L1 and/or IDO1/HLA-DR were more likely to respond to treatment ($p = 0.009$). These pts also experienced a three-fold increase in progression free survival (hazards ratio (HR) = 0.33; $p = 0.003$) and overall survival (HR = 0.34; $p = 0.004$). Multivariate analyses revealed that these findings were independent of BRAF mutation, stage, LDH and prior therapy. In the combined cohort ($n = 124$), 80% of responding pts had higher levels of PD-1/PD-L1 interaction scores and/or IDO1/HLA-DR. In contrast, PD-L1 expression alone ($\geq$1% or $\geq$50%) was not predictive of PFS or OS ($p > 0.1$). **Conclusions:** This novel multiplexed method profiling key tumor-immune suppression pathways identified mm pts likely to respond to anti-PD-1 therapy. This method could help stratify patients for PD-1 monotherapy and be useful in guiding future clinical trials.

A phase Ib/II dose-escalation study evaluating triple combination therapy with a BRAF (encorafenib), MEK (binimetinib), and CDK 4/6 (ribociclib) inhibitor in patients (Pts) with *BRAF V600*-mutant solid tumors and melanoma. *First Author: Paolo Antonio Ascierto, Istituto Nazionale Tumori "Fondazione G.Pascale"- IRCCS, Naples, Italy*

Background: The benefits of BRAF + MEK inhibition (dual combo) in pts with *BRAF V600*-mutant ($BRAF^{V600}$) melanoma are known. Preclinical data supports inhibiting CDK 4/6 and BRAF + MEK (triple combo) to improve antitumor activity. We report safety and preliminary efficacy from a phase 1b/2 study (NCT01543698) of encorafenib (ENCO; a selective BRAF kinase inhibitor), binimetinib (BINI; a MEK inhibitor), and ribociclib (RIBO; a CDK 4/6 inhibitor). **Methods:** Phase 1b of this open-label, multicenter study enrolled pts with confirmed $BRAF^{V600}$advanced solid tumors. Escalating doses of RIBO 100 mg-600 mg QD for 3 wk on/1 wk off were administered with ENCO 200 mg QD + BINI 45 mg BID in successive cohorts (6 pts each) until the maximum tolerated or recommended phase 2 dose (RP2D) was reached. Due to potential pharmacokinetic interactions with RIBO, the ENCO dose was lower than the dual combo RP2D (450 mg QD). Dose escalations followed an adaptive Bayesian model. In phase 2, the triple combo was tested in pts with $BRAF^{V600}$melanoma naïve to prior BRAF inhibitor treatment; the primary endpoint was objective response rate (ORR) per RECIST v1.1. **Results:** In phase 1b ($n = 21$), no dose-limiting toxicities were reported and the triple combo RP2D was ENCO 200 mg QD + BINI 45 mg BID + RIBO 600 mg QD. ENCO AUC was slightly lower than at the dual combo RP2D. In phase 2 ($n = 42$), 59.5% pts had an ECOG PS of 0 and 43% of pts had elevated lactate dehydrogenase. The most common ($\geq$5%) grade 3/4 toxicities were neutropenia (26.2%), increased alanine transaminase (14.3%), diarrhea (7.1%), and anemia (7.1%). Ten pts (23.8%) discontinued treatment due to an AE, of which 4 were increased transaminases.The confirmed ORR was 52.4%, including 4 complete responses, 18 partial responses, and 15 pts with stable disease. Median duration of exposure in phase 2 was 9.1 mo (range, 0.0-21.6). Median progression-free survival was 9.0 mo (95% confidence interval, 7.0-11.1). **Conclusions:** Triple therapy with ENCO + BINI + RIBO in this small trial of pts with high disease burden was associated with responses in over half of pts and some evidence of increased toxicity. Clinical trial information: NCT01543698.

Phase 1b/2 trial of ribociclib+binimetinib in metastatic *NRAS*-mutant melanoma: Safety, efficacy, and recommended phase 2 dose (RP2D). *First Author: Martin H. Schuler, West German Cancer Center, University Hospital, Essen, Germany*

Background: Simultaneous inhibition of MEK and CDK4/6 may suppress MAPK pathway activation and cell-cycle checkpoint dysregulation in *NRAS*-mutant melanoma, resulting in enhanced antitumor activity. Phase 1b data are reported. **Methods:** The phase 1b primary objective was to determine maximum tolerated dose (MTD)/RP2D. A 28-d cycle of oral ribociclib (RIBO) once daily (QD) for 21 d + oral binimetinib (BINI) twice daily (BID) for 28 d, and a 21-d cycle of RIBO QD + BINI BID, both for 14 d per cycle, were evaluated. Secondary objectives were to evaluate efficacy, safety and pharmacodynamics. **Results:** Based on dose escalation (van Herpen, ESMO 2015), MTD was 600mg RIBO/45mg BINI for the 21-d and 200/45 for the 28-d regimens. Due to promising activity, the 28-d cycle was selected as RP2D(unconfirmed partial response [PR] with limited follow-up occurred in 35% of pts). This finding was supported by comparable and manageable safety and the Bayesian logistic regression model.As of Jan 2017, the RP2D was received by 16 pts in phase 1b (ECOG PS 0/1/2, 63%/31%/6%; elevated lactate dehydrogenase, 44%; stage IVM1c disease, 50%; prior ipilimumab [ipi], 44%; prior anti–programmed death [PD]-1/PD-L1, 31%). Median (range) exposure was 4 (0–13) mo. Common adverse events (AEs) were increased blood creatine phosphokinase, elevated AST, peripheral edema, acneiform dermatitis, diarrhea and fatigue. Common grade 3/4 AEs were elevated AST and ALT (19%/6%), nausea (19%/0%), rash (19%/0%), vomiting (6%/6%) and neutropenia (12%/0%). Confirmed PR (cPR) occurred in 4 pts (25%; time to response, 48–168 d), stable disease in 7 pts (44%), disease progression in 3 pts (19%); 2 pts (12%) were not evaluable. Among cPR pts, 3 had prior ipi and/or anti–PD-1/PD-L1. Median progression-free survival (mPFS) was 6.7 (95% CI, 3.5–9.2) mo. Sequence analysis of synchronous non-*RAS* genetic alterations will be presented. **Conclusions:** Combined RIBO/BINI at the selected RP2D had a manageable safety profile and favorable efficacy (based on mPFS) for *NRAS*-mutant melanoma in phase 1b. Based on these promising data, the phase 2 expansion is underway to assess antitumor activity at the RP2D. Clinical trial information: NCT01781572.

9520 Poster Discussion Session; Displayed in Poster Session (Board #128), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Initial efficacy of anti-lymphocyte activation gene-3 (anti–LAG-3; BMS-986016) in combination with nivolumab (nivo) in pts with melanoma (MEL) previously treated with anti–PD-1/PD-L1 therapy. *First Author: Paolo Antonio Ascierto, Istituto Nazionale Tumori "Fondazione G.Pascale"- IRCCS, Naples, Italy*

Background: Signaling via LAG-3 and other T-cell inhibitory receptors (eg, PD-1) can lead to T-cell dysfunction and tumor immune escape. Simultaneous blockade of LAG-3 + PD-1 may synergistically restore T-cell activation and enhance antitumor immunity. In a phase 1/2a study, BMS-986016 (IgG4 mAb targeting LAG-3) ± nivo (IgG4 mAb targeting PD-1) demonstrated tolerability, peripheral T-cell activation, and preliminary clinical activity (NCT01968109; Lipson E, et al. *J Immunother Cancer.* 2016;4[s1]:173 [P232]). Here we describe preliminary efficacy of BMS-986016 + nivo in pts with MEL whose disease progressed on/after prior anti–PD-1/PD-L1 therapy, along with updated safety from all dose expansion pts. **Methods:** Pts with MEL must have had prior anti–PD-1/PD-L1 (± anti–CTLA-4 or BRAF/MEK inhibitors) and progressive disease (PD). Pts received BMS-986016 80 mg + nivo 240 mg IV Q2W. Primary objectives were safety and objective response rate (ORR; complete [CR] + partial [PR] response), disease control rate (DCR; CR + uCR + PR + uPR + stable disease [SD] > 12 wk), and duration of response (RECIST v1.1). **Results:** At data cutoff, 43 pts with MEL had been treated with BMS-986016 + nivo following PD on/after prior anti–PD-1/PD-L1 with known prior best responses of 1 CR, 9 PR, 12 SD, and 16 PD. Of the 43 pts, 30 (70%) also had prior anti–CTLA-4, 20 (47%) had ≥ 3 prior therapies, and 15 (35%) had *BRAF*mutations.In the 31 efficacy-evaluable pts to date, ORR was 16% (confirmed/unconfirmed) and DCR was 45% with benefit observed even in some pts refractory to prior anti–PD-1. Evaluations are ongoing for most pts, with median treatment duration of 10 wk for all 43 pts. Immunopathologic (eg, PD-1/PD-L1 and LAG-3 expression) and clinical characteristics of responders vs nonresponders will be presented. Any grade and grade 3/4 treatment-related AEs occurred in 46% and 9%, respectively, across all dose expansion pts (n = 129). **Conclusion:** Addition of BMS-986016 to nivolumab demonstrates encouraging initial efficacy in pts with MEL whose disease progressed on/after prior anti–PD-1/PD-L1 therapy, and a safety profile similar to nivolumab monotherapy. Clinical trial information: NCT01968109.

9521 Poster Session (Board #129), Sat, 1:15 PM-4:45 PM

Immune-related tumor response dynamics in melanoma patients (pts) treated with pembrolizumab: Identifying markers for clinical outcome and treatment decisions. *First Author: Mizuki Nishino, Dana-Farber Cancer Institute, Boston, MA*

Background: PD-1 inhibitors have shown marked efficacy in advanced melanoma and are associated with unique response patterns. We aimed to characterize the tumor burden dynamics and identify quantitative imaging markers for overall survival (OS) in melanoma pts treated with pembrolizumab. **Methods:** The study included 107 advanced melanoma pts (63 males; median age: 63) treated with pembrolizumab monotherapy at DFCI. Tumor burden dynamics were assessed on serial CT scans during therapy by irRECIST, which uses unidimensional measurements and includes new lesions in tumor burden [Clin Cancer Res. 2013;19:3936-43]. The relationships between tumor burden dynamics and OS were studied. **Results:** Among 107 pts, 96 pts had measurable tumor burden at baseline and 11 had non-target lesions alone at baseline. Among the 96 pts, maximal tumor shrinkage ranged from -100% to 567% (median:-18.5%). Overall response rate was 44% (42/96; irCR in 5, irPR in 37). Tumor burden remained < 20% increase from baseline throughout therapy in 57 pts (55%). Using a 3-month landmark analysis, pts with < 20% tumor burden increase from baseline at 3 months had longer OS than pts with ≥ 20% increase (12-month OS rate: 82 vs. 53%). In extended Cox models, pts with < 20% tumor burden increase during therapy had significantly reduced hazards of death (HR = 0.19, 95%CI: 0.08–0.43, p < 0.0001 univariate; HR = 0.18, 95%CI: 0.08-0.41, p < 0.0001, multivariable). Five pts (5%) experienced pseudoprogression; 3 pts had increase of target lesions with subsequent response, which was noted after confirmed irPD on consecutive scans. Two pts with no measurable tumor burden progressed with new/non-target lesions that subsequently regressed. **Conclusions:** Tumor burden increase of < 20% from the baseline during pembrolizumab therapy was associated with longer OS, proposing a practical prognostic marker to guide treatment decisions. Pseudoprogressors may experience response after confirmed irPD, indicating a limitation of the current strategy for immune-related response assessment. Evaluations of non-measurable tumor burden may require further attention in the clinical setting of immuno-oncology.

9522 Poster Session (Board #130), Sat, 1:15 PM-4:45 PM

Overall survival (OS) analysis from an expanded access program (EAP) of nivolumab (NIVO) in combination with ipilimumab (IPI) in patients with advanced melanoma (MEL). *First Author: David Hogg, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: NIVO (anti-PD-1) and IPI (anti-CTLA-4), alone and in combination, are approved for the treatment of MEL. Phase II and III trials showed improved efficacy for NIVO+IPI versus IPI alone, but with a higher frequency of adverse events (AEs). In the phase II CheckMate 069 trial, the 2-year OS rate was 63.8% for all patients (pts) in the NIVO+IPI group. We report the first OS analysis, as well as updated safety data, from a North American EAP of NIVO+IPI in pts with MEL (CheckMate 218; NCT02186249). **Methods:** CheckMate 218 included pts with MEL who could have progressed on other therapies, but were anti-CTLA-4 and anti-PD-1 treatment-naive. Pts received NIVO 1 mg/kg + IPI 3 mg/kg Q3W x 4, followed by NIVO 3 mg/kg Q2W until disease progression or a maximum of 48 weeks from the first monotherapy dose. We assessed OS in the US cohort (n = 580) and safety in all pts (n = 732). Pts were followed for a minimum of 1 year in the USA and 6 months in Canada. **Results:** Of 732 pts, 43% had a *BRAF*mutation, 84% stage IV MEL, 51% M1c disease, 31% LDH > ULN (9% LDH > 2x ULN), and 13% received ≥1 prior systemic therapy in the metastatic setting. All pts received a median of 3 doses each for NIVO (range: 1–4) and IPI (range: 0–4) in the induction phase; 34% of pts received at least 1 dose of NIVO maintenance. The 1- and 2-year OS rates were 78.6% (95% CI: 74.2–82.4) and 65.3% (95% CI: 56.1–73.0), respectively. AEs of any grade occurred in 717 pts (98%), with grade 3/4 AEs in 470 pts (64%). Immune-modulating medications were used to manage any grade AEs, including grade 1/2 skin and gastrointestinal AEs, in 538 of 717 pts (75%), and to manage grade 3/4 AEs in 279 of 470 pts (59%). The most common treatment-related AEs of any grade were diarrhea (39%), pruritus (26%), and an increase in aspartate aminotransferase level (23%). Treatment-related deaths in 2 pts were reported as drug-induced liver injury and myocardial infarction. **Conclusions:** In this EAP, which included pts who had received prior systemic therapies for MEL and pts with poor prognostic factors generally not included in clinical trials, NIVO+IPI treatment demonstrated survival outcomes and a safety profile consistent with clinical trial data. Clinical trial information: NCT02186249.

9523 Poster Session (Board #131), Sat, 1:15 PM-4:45 PM

Management of gastrointestinal (GI) toxicity associated with nivolumab (NIVO) plus ipilimumab (IPI) or IPI alone in phase II and III trials in advanced melanoma (MEL). *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: NIVO and IPI are approved as monotherapy and in combination for treatment of MEL. These treatments are associated with select (potentially immune-related) adverse events (AEs) of the GI tract, most commonly diarrhea and colitis. We describe the management of GI toxicity in patients (pts) treated with NIVO+IPI or IPI from phase II (CheckMate 069) and III (CheckMate 067) trials. **Methods:** Pts received NIVO 1 mg/kg + IPI 3 mg/kg Q3W x 4, followed by NIVO 3 mg/kg Q2W until progression or unacceptable toxicity, or IPI 3 mg/kg Q3W x 4, followed by placebo. Minimum follow-up was 2 yrs for CheckMate 069 and 18 months for CheckMate 067. **Results:** Of 407 pts treated with NIVO+IPI, 195 (48%) experienced any grade select GI AEs, and of 357 pts treated with IPI, 132 (37%) experienced any grade select GI AEs. Grade 3/4 select GI AEs were reported in 67 (16%) pts treated with NIVO+IPI and in 41 (11%) pts treated with IPI; median time to onset was 7.1 weeks (range 0.9-48.9) with NIVO+IPI and 7.3 weeks (range 0.6-14.9) with IPI. To manage these AEs, immune-modulating medications (IMM) were used in 61/67 (91%) pts in the NIVO+IPI group and in 41/41 (100%) in the IPI group. Corticosteroids (CS) were used in 61/67 (91%) and 41/41 (100%) pts, and infliximab (IFX) was used in 21/67 (31%) and 14/41 (34%) pts in the NIVO+IPI and IPI groups, respectively. In the NIVO+IPI group, the resolution rate of grade 3/4 select GI AEs was 96%, 97%, and 95% with a median time to resolution of 3.3, 3.0, and 3.9 weeks in all treated pts, CS, and CS+IFX managed pts, respectively; 88%, 92%, and 79% resolved with a median time to resolution of 3.9, 2.4, and 7.8 weeks in the IPI group, respectively. Objective response rates (ORR) were unchanged in the presence of any grade select GI AEs, or by using CS or CS+IFX (Table). **Conclusions:** NIVO+IPI or IPI alone is associated with a high incidence of GI select AEs, but most are effectively managed by IMMs, which do not appear to inhibit tumor response. Clinical trial information: NCT01844505; NCT01927419.

9524 Poster Session (Board #132), Sat, 1:15 PM-4:45 PM

Efficacy and safety of nivolumab (NIVO) in patients with advanced melanoma (MEL) and poor prognostic factors who progressed on or after ipilimumab (IPI): Results from a phase II study (CheckMate 172). *First Author: Dirk Schadendorf, University Hospital Essen, Essen, Germany*

Background: In the phase III CheckMate 037 study, NIVO improved the objective response rate and progression-free survival with less toxicity vs chemotherapy in patients (pts) with MEL who progressed after prior IPI treatment. We report the first efficacy and updated safety data from pts with MEL in CheckMate 172, including those with rare melanoma subtypes (uveal, mucosal), brain metastases, or an ECOG performance status (PS) of 2. **Methods:** In this ongoing phase II, single-arm, open-label, multicenter study, pts with MEL who progressed on or after IPI were treated with NIVO 3 mg/kg Q2W for up to 2 years until progression or unacceptable toxicity (NCT02156804). We report efficacy and updated safety data from 734 treated pts with ≥1 year of follow-up (database lock: November 2016). **Results:** Of 734 pts, 50% had LDH>ULN, 7% ECOG PS 2, 66% M1c disease, 15% a history of brain metastases, and 23% received ≥3 prior therapies. Overall, 593 pts (81%) received more than 4 doses of NIVO. Overall, response rate at 12 weeks was 32%, with a complete response in 1% (Table). The 1-year overall survival (OS) rate was 63%. Any grade and grade 3/4 treatment-related adverse events (AEs) occurred in 66% and 17% of pts, respectively. Discontinuations due to treatment-related AEs occurred in 4% of pts. The most common treatment-related select (potentially immune-related) AEs were diarrhea (12%), hypothyroidism (9%), and pruritus (7%). **Conclusions:** CheckMate 172 is the largest study of NIVO efficacy and safety in pts with MEL who progressed on or after IPI. NIVO demonstrated a safety profile consistent with that of prior clinical trials. Efficacy outcomes were encouraging in some difficult-to-treat subgroups of pts with poor prognostic factors, such as mucosal melanoma and brain metastases. Clinical trial information: NCT02156804.

	Total pts (N=734)	ECOG PS 2(n=48)	Uveal (n=75)	Mucosal (n=52)	CNS (n=112)

9525 Poster Session (Board #133), Sat, 1:15 PM-4:45 PM

Glycemic disorders in melanoma patients treated with anti-PD1. *First Author: Quentin Magis, Dermatology and Skin Cancers Department, UMR911 CRO2 Timone Hospital, Aix-Marseille University, Marseille, France*

Background: Anti-PD1 are now the backbone of immunotherapy (IT) of metastatic melanoma (MM). Although they are overall well- tolerated, a number of severe immune-related adverse events (IRAE) have been described, among which type 1 diabetes. We observed 3 cases of fulminant diabetes (FD) in our center, and also had the impression that diabetics patients became more difficult to manage when receiving anti-PD1. **Methods:** Retrospective analysis of blood glucose samples collected before, during and after anti-PD1 treatment (trt) in all mm patients (pts) receiving anti-PD1 in our department over a 36-month period. Study of FD cases observed. **Results:** A total of 163 pts were treated with 1920 cures of anti-PD1 including 27 treated within clinical trials. Anti-PD1 was the 1st line of IT in 70% of cases. As a whole, 1470 glycaemia were available. There was no significant difference between the median pre and post-trt glycaemia (5.37 +/-1.6 vs 5.6 +/-1.3 mmol/L (p = 0.033)). In the 28 pts with a type I (n = 0) or II (n = 28) diabetes prior to trt, there was very slight drift toward an increase of glycaemia along with the successive trt infusions (+0.05mmol/L/Cure, p = 0.004 with linear regression tendency test). Three pts (1.84%) developed a FD revealed by a severe episode of ketosis with acute polyuria polydipsia, hyperglycaemia until 50mmol/L and weight loss. Two additional cases of FD were observed in pts treated within clinical trial comparing anti-PD1 with anti-CTLA4 in adjuvant and metastatic situation (imputability of anti-PD1 likely but uncertain until unblinding). None of these pts had any glucose increase in weeks prior to FD diagnosis. Four out of 5 FD cases had an HLA group at risk for type 1 diabetes development (HLA DRB3/4), a rare group in general population (1%). **Conclusions:** We could not document any systematic tendency to glycemic disorder in mm pts treated by anti-PD1. In diabetic pts prior to trt, a slight drift toward increase of glycaemia may be explained by other interfering factors (diet, metastatic disease itself, corticosteroids, anxiety etc). FD is not exceptional (2% of patients in our series) and does not seem to be announced by any minor preliminary glycemic disorder. Despite apparently stochastic onset, FD may be associated with HLA DRB3/4 subgroup.

9526 Poster Session (Board #134), Sat, 1:15 PM-4:45 PM

Updated 5-y landmark analyses of phase 2 (BREAK-2) and phase 3 (BREAK-3) studies evaluating dabrafenib monotherapy in patients with *BRAF* V600–mutant melanoma. *First Author: Paul B. Chapman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prior analyses of phase 2 (BREAK-2; NCT01153763) and phase 3 (BREAK-3; NCT01227889) trials showed that durable clinical benefit and tolerability lasting ≥ 3 y are achievable with the BRAF inhibitor dabrafenib in some patients (pts) with *BRAF*V600–mutant metastatic melanoma. Here, we report 5-y landmark analyses for BREAK-2 and BREAK-3. **Methods:** BREAK-2, a single-arm, phase 2 study, evaluated dabrafenib 150 mg twice daily in pts with stage IV *BRAF* V600E/K–mutant MM. BREAK-3, an open-label, randomized (3:1), phase 3 study, assessed dabrafenib 150 mg twice daily vs dacarbazine 1000 mg/m^2 every 3 weeks in pts with previously untreated *BRAF*V600E–mutant unresectable stage III or stage IV MM. Updated analyses were performed to describe ≥ 5-y outcomes in each study. **Results:** BREAK-2 enrolled 92 pts (V600E, n = 76; V600K, n = 16), of whom most (90%) had prior systemic anticancer therapy. At data cutoff (17 Jun 2016), all pts had discontinued, mostly due to progression (84%). In V600E pts, 5-y progression-free survival (PFS) was 11%, and 5-y overall survival (OS) was 20%. Post-progression immunotherapy was received by 22% of enrolled pts. In BREAK-3 (data cutoff, 16 Sep 2016), median follow-up was 18.6 mo for the dabrafenib arm (n = 187) and 12.8 mo for the dacarbazine arm (n = 63). Follow-up for the 37 dacarbazine-arm pts (59%) who crossed over to receive dabrafenib was based on the initial assignment of dacarbazine. The 5-y PFS was 12% vs 3% and 5-y OS was 24% vs 22% for the dabrafenib and dacarbazine arms, respectively. A subset of pts in each respective arm received postprogression anti–CTLA-4 (24% vs 24%) and/or anti–PD-1 (8% vs 2%) therapy, whereas 31% vs 17% did not receive any further therapy following study treatment. No new safety signals were observed in either study with long-term follow-up. Additional characterization of pts using cfDNA analysis will be presented. **Conclusions:** These data provide the longest reported PFS and OS follow-up for BRAF inhibitor monotherapy in BRAF V600–mutant MM. Both BREAK-2 and BREAK-3 showed that 11%-12% of pts initially treated with single-agent dabrafenib remained progression free at 5 y. Clinical trial information: NCT01153763; NCT01227889.

9527 Poster Session (Board #135), Sat, 1:15 PM-4:45 PM

PD-L1 and CD8 expression and association with outcomes in patients (pts) with *BRAF* V600E/K-mutant metastatic melanoma (MM) who received dabrafenib + trametinib (D+T) in the randomized phase 3 COMBI-v study. *First Author: Dirk Schadendorf, University Hospital of Essen, Essen, Germany*

Background: The phase 3 COMBI-v study (NCT01597908) showed that D+T significantly improved outcomes vs vemurafenib inpts with *BRAF*V600E/K–mutant MM. Checkpoint inhibitors also provide clinical benefit in some pts with MM. To date, characterization of markers associated with response to anti–PD-1 therapy has identified positive associations with PD-L1 expression and immune cell infiltration. Here we describe expression of PD-L1 and the T-cell marker CD8 in tumor samples from pts randomized to receive D+T in COMBI-v and associations with clinical outcomes. **Methods:** Biopsies from 74 of 352 D+T pts (21%) in COMBI-v were assessed for expression of PD-L1 (PD-L1 IHC 22C3 pharmDx assay; Dako) and CD8 (anti-CD8 antibody, clone C8/144B; Dako). PD-L1 positivity was determined as a percentage of stained tumor cells and MEL score (staining on both tumor and mononuclear inflammatory cells; 0 or 1 [negative]: < 1% staining; 2-5 [positive]: ≥ 1% staining; Daud et al. *J Clin Oncol*. 2016). **Results:** Of 74 pts analyzed, 54 (73%) had PD-L1–positive tumors, and the largest MEL score subgroup was 2 (45%). A significant association ($P < .0001$) was observed between PD-L1 and CD8 expression. Overall response rate, tumor shrinkage, progression-free survival, overall survival (OS), and duration of response with D+T were not associated with PD-L1 (MEL score of ≥ 2) or CD8 positivity. However, a significant association ($P = .04$) with improved OS was observed in tumors with high PD-L1 expression (≥ 20% of cells PD-L1 positive), and a trend ($P = .06$) was seen in pts with a MEL score of ≥ 3. Among PD-L1–negative pts, improved OS was seen in those with high CD8 positivity ($P = .03$), particularly in the stromal compartment. **Conclusions:** These data, representing PD-L1 and CD8 expression profiles for a *BRAF*-mutant mm population in the context of outcomes following D+T, showed that clinical benefit was maintained regardless of immune phenotype. The results also suggest that an immune component has an impact on outcomes following targeted therapy. Clinical trial information: NCT01597908.

9528 Poster Session (Board #136), Sat, 1:15 PM-4:45 PM

Association of improved survival (OS) and tumor control (TC) with interleukin-2 (IL2) with development of immune-related events (IREs): Data from the PROCLAIM^{SM} registry. *First Author: Brendan D. Curti, Providence Cancer Center and Earle A. Chiles Research Institute, Portland, OR*

Background: IREs are associated with immunotherapy (IT) for cancer and while reports suggest improvement in TC and OS with induced IREs, the long-term impact is unclear. IL2 has been the major IT for patients (pts) with renal cell carcinoma (RCC) and melanoma (MM) since 1992. We evaluated IREs reports in the PROCLAIM^{SM} data base (2008-2016) of IL2-treated pts. **Methods:** Reports on 614 (MM) and 843 (RCC) pts were queried for IREs. IREs were categorized as occurring before, during, or after IL-2 and related to any checkpoint inhibitor (CPI). TC (CR+PR+SD) was compared between no IRE and IRE, using Fisher's exact test. OS curves were estimated by Kaplan-Meier method, and comparison of no IRE/before IL2 with during/after IL2, was analyzed by log-rank test. **Results:** With a median (med) follow-up of 3.5+ years (range 1-8+ year), 140 IREs were reported in 118 pts (9.6% of all PROCLAIM^{SM} pts): 93 (15%) in MM; 47 (5.6%) in RCC. 25 IREs were prior to IL2; 13 IREs were during IL2; 102 were after IL2. Of the latter 102, 31 were after IL2 and after subsequent CPI; 71 were attributed to IL2 only; and in 13, IREs were due to either IL2 or CPI. TC was 73% for IRE group vs 56% for no IRE group ($p = 0.0054$). OS was significantly greater for IRE group during/after IL2 compared to no IRE/before IL2 in MM, med 46 months (mo) vs 18 mo ($p = 0.0001$) and in RCC, med 61 mo vs 43 mo ($p = 0.0196$), independent of CPI IREs. Med # of IL2 doses was 19 in no IRE group, 39 in IRE during IL2 group, and 25 in IRE after IL2 group. IL2-related IREs were primarily vitiligo and thyroid dysfunction (70% of IL2 IREs), with limited further impact, while CPI-related IREs were often serious, requiring intervention (hypophysitis, colitis, hepatitis, uveitis) (52% of CPI IREs) and possibly chronic management. **Conclusions:** IREs following IL2 are associated with improved TC and OS. IREs resulting from IL2 and from CPIs are qualitatively different and likely reflect different mechanisms of action of immune activation and response.

9529 Poster Session (Board #137), Sat, 1:15 PM-4:45 PM

ENCORE 601: A phase II study of entinostat (ENT) in combination with pembrolizumab (PEMBRO) in patients with melanoma. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Entinostat is an oral, class I selective histone deacetylase inhibitor shown preclinically to enhance immune checkpoint inhibitor activity by regulation of immune suppressor cells in the tumor microenvironment. ENCORE 601 is designed to evaluate safety and efficacy of ENT in combination with PEMBRO. Phase 1b identified ENT 5 mg PO weekly and PEMBRO 200 mg IV every 3 weeks as the recommended Phase 2 dose for further investigation. **Methods:** Phase 2 of ENCORE 601 employs a Simon 2-stage design to assess activity across 3 cohorts: 1) NSCLC not previously treated with a PD-1/L1 blocking antibody, 2&3) NSCLC & melanoma previously progressing on or after a PD-1/L1 blocking antibody. Patients were enrolled irrespective of PD-L1 expression levels. The primary endpoint is ORR as assessed by irRECIST. Results of the first stage of Cohort 3 are reported. Criteria for advancing to Stage 2 are $\geq$2 responses out of 13 evaluable patients. **Results:** Stage 1 enrollment has been completed (n = 13). All patients received a prior PD-1 inhibitor; in addition, 7 patients received prior ipilimumab and 2 patients received a prior BRAF inhibitor. 9 patients are still on treatment; 4 patients have discontinued due to progression. To date, 1 confirmed and 1 unconfirmed objective response have been observed. The confirmed response (PR) was in a patient who was previously treated with ipilimumab/nivolumab for 6 months (best response of SD with subsequent progression on therapy). Treatment-related AEs occurred in 5 patients (most common being nausea and fatigue occurring in 2 patients); one patient experienced Gr3/4 events (fatigue and rash). Blood samples and pre-treatment biopsies were obtained in all patients along with paired post-treatment biopsies in 8 patients. Evaluation of PD-L1 expression, gene expression, myeloid and lymphoid compartments in blood and tumor samples is in progress. Of note, the patient with a confirmed PR converted from a PD-L1 negative, non-inflamed gene signature to PD-L1 positive, inflamed after 2 weeks of treatment. **Conclusions:** ENT combined with PEMBRO demonstrates acceptable safety and encouraging preliminary activity in melanoma patients refractory to checkpoint inhibitors. Clinical trial information: NCT02437136.

9530 Poster Session (Board #138), Sat, 1:15 PM-4:45 PM

First-line (1L) avelumab treatment in patients (pts) with metastatic Merkel cell carcinoma (mMCC): Preliminary data from an ongoing study. *First Author: Sandra P. D'Angelo, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MCC is a rare, aggressive skin cancer. Avelumab is a fully human anti–PD-L1 antibody. In a phase 2 study in pts with distant mMCC who progressed after prior chemotherapy (JAVELIN Merkel 200; NCT02155647), avelumab showed a manageable safety profile and durable responses, including an objective response rate (ORR) of 31.8%, estimated 6-month durable response rate of 29%, and 6-month overall survival rate of 69%. Here, we report preliminary results from a separate cohort of pts with chemotherapy-naïve mMCC enrolled in the same study. **Methods:** Eligible pts with mMCC and no prior systemic treatment for metastatic disease received avelumab 10 mg/kg Q2W until confirmed progression, unacceptable toxicity, or withdrawal. Tumors were assessed every 6 weeks (RECIST v1.1). Adverse events (AEs) were assessed by NCI CTCAE v4.0. **Results:** As of Dec 30, 2016, 29/112 planned pts had been enrolled. Median age was 75.0 years (range 47–87). Median treatment duration was 8.1 weeks (range 2.0–37.9). Of 16 pts with $\geq$3 months of follow-up, unconfirmed ORR was 68.8% (95% CI 41.3–89.0) with CR in 18.8%; confirmed ORR was 56.3% (95% CI 29.9–80.2; 1 unconfirmed PR with discontinuation). Of 25 pts with $\geq$6 weeks of follow-up, unconfirmed ORR was 64.0% (95% CI 42.5–82.0). All responses were ongoing at last follow-up, including in 5/5 pts with $\geq$6 months of follow-up (potential to confirm responses). 20/29 pts (69.0%) had a treatment-related AE (TRAE), including grade 3–4 TRAE in 5 pts (17.2%). TRAEs led to discontinuation in 5 pts (17.2%): 2 pts with infusion-related reaction, and 1 pt each with elevated AST and ALT, cholangitis, and paraneoplastic syndrome. There were no treatment-related deaths. 21/29 pts (72.4%) remain on treatment. **Conclusions:** In initial results from a cohort of chemotherapy-naïve pts with mMCC, avelumab was associated with early responses and a manageable safety profile, consistent with findings for second-line or later avelumab treatment in a previous cohort. These results suggest that responses mature to become durable and the use of 1L avelumab may increase the probability of response vs later-line treatment. Enrollment and follow-up in this 1L cohort are ongoing. Clinical trial information: NCT02155647.

9531 Poster Session (Board #139), Sat, 1:15 PM-4:45 PM

Intra-patient escalation dosing strategy with IMCgp100 results in mitigation of T-cell based toxicity and preliminary efficacy in advanced uveal melanoma. *First Author: Takami Sato, Department of Medical Oncology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: IMCgp100 is a bispecific biologic capable of redirecting T cells against the melanocyte-associated antigen gp100. In the first-in-human (FIH) clinical trial,preliminary efficacy of IMCgp100 in advanced uveal melanoma (UM) was observed; however, cases of severe T cell-mediated toxicities with the first 2 doses limited dosing to 50 mcg QW. This phase 1 study was designed to implement intra-patient escalation to mitigate toxicity and maximize exposure of IMCgp100. **Methods:** Using a 3+3 design, HLA-A2+ pts with metastatic UM were treated with low weekly (QW) dosing of IMCgp100 *iv* at Cycle 1, Day 1 (C1D1) (20 mcg) and C1D8 (30 mcg), followed by the escalated cohort dose administered at C1D15 and beyond. **Results:** Nineteen metastatic UM pts with a median of 3 prior lines of therapy (range 0 - 8) were treated across 4 target dose cohorts (60, 70, 80, and 75 mcg). Fifteen of 19 pts remain on treatment at the data cutoff (25Nov16). Enrollment completed 15Sep16. DLT was observed in 1 of 6 pts in the 70-mcg cohort (LFT elevation), and 2 of 4 pts treated at 80 mcg QW (LFT and bilirubin elevation). The 80 mcg dose level was not tolerated and a 75 mcg cohort was enrolled. Six pts were treated at 75 mcg without DLT; this dose was identified as the MTD and RP2D. All 3 DLT resolved without corticosteroids and all pts resumed IMCgp100. Frequent related AE included pruritus (84%), pyrexia (84%), fatigue (74%), hypotension (74%) and peripheral edema (63%). Gr 3/4 drug-related AE include AST increased (15%), erythema (15%) and hypotension (15%). Preliminary efficacy data (RECIST v1.1) from 17 evaluable pts (2 pts had insufficient follow-up) showed no objective responses; 12 pts had a BOR of SD (63%) including 4 pts (24%) with a $\geq$10% reduction in target lesions. With median follow-up of 1.8 mo, the disease control rate (16 wks) was 32%. **Conclusions:** The intra-patient escalation regimen of IMCgp100 results in a 50% increase in dose above the FIH Phase 1, acceptable safety profile, and preliminary efficacy in UM pts. Considering the dismal prognosis of metastatic UM, the PFS observed in this study is encouraging. A Phase 2 expansion cohort and separate pivotal trial of IMCgp100 in advanced UM are ongoing. Clinical trial information: NCT02570308.

9532 Poster Session (Board #140), Sat, 1:15 PM-4:45 PM

Incidence, patterns of progression and outcomes of melanoma brain metastasis (MBM) during programmed-death 1 inhibitor (PD1i) therapy. *First Author: Gustavo Schvartsman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MBM are common in patients (pts) with metastatic melanoma (MM) and represent a frequent site of treatment failure with current therapies. Little is known, however, about the incidence, patterns of progression and outcomes of MBM pts treated with PD1i and in conjunction with central nervous system (CNS) focused therapy. **Methods:** Outcomes of mm pts treated with PD1i at MD Anderson from 01/12 to 07/16 were reviewed. The association between clinical variables and development of MBM and overall survival (OS) were assessed using logistic regression and Cox regression analyses. **Results:** We identified 324 mm pts, including 77 pts (24%) who had MBM prior to first dose of PD1i. Median follow-up from start of therapy was 16.3 months, median OS for pts without MBM at the start of PD1i 3.37 years, as compared to 2.85 years in pts with prior MBM (p = 0.268). Of the 247 pts without prior MBM, 64 (26%) developed MBM after exposure to PD1i. Of those, 21 pts (8.5%) developed MBM during therapy or within 30 days of discontinuation, with 12 (4.5%) having CNS-only progression, while 9 (3.6%) had both systemic and CNS progression. Pts with MBM prior to PD1i (n = 77) had CNS-only progression in 22 pts (28.6%) during therapy. Progression occurred in systemic and systemic plus CNS in 12 pts (15.6%) and 19 pts (24.7%), respectively. 24 pts (31.2%) had stable disease (SD). On multivariate analysis, pts with lung metastases (OR, 2.16; 95% CI, 1.25 - 3.78; p = 0.006) and NRAS-mutated tumors (OR, 2.17; 95% CI, 1.14 - 4.18; p = 0.02) were more likely to develop MBM; pts who had liver metastases at the start of PD1i (HR, 1.77; 95% CI, 1.09 - 2.87; p = 0.002) and those who developed MBM during PD1i (HR, 4.81; 95% CI, 3.00 - 7.71; p < 0.0001) had increased risk of death. **Conclusions:** We found a 26% incidence of MBM after PD1i exposure. Pts that develop MBM are still at higher risk of death despite advances in systemic and local CNS therapy. CNS-only progression was substantially higher in patients with MBM prior to PD1i, supporting a change in the natural history of the disease after PD1i. These findings support the use of CNS imaging to monitor disease during PD1i therapy.

9533 Poster Session (Board #141), Sat, 1:15 PM-4:45 PM

Phase II multicenter, single arm, open label study of nivolumab (NIVO) in combination with ipilimumab (IPI) as first line in adult patients (pts) with metastatic uveal melanoma (MUM): GEM1402 NCT02626962. *First Author: Josep M. Piulats, Catalan Institute of Oncology, Barcelona, Spain*

Background: Uveal melanoma is the most common primary intraocular malignant tumor in adults. Overall Survival (OS) at 5 years(y) is 62% due high incidence of liver metastasis, fatal within 4-9 months(m) from diagnosis. No standard treatment exists for MUM. NIVO+IPI combination has shown efficacy in metastatic cutaneous melanoma. However, MUM pts were excluded in these trials. **Methods:** GEM1402 is a phase-2 trial evaluating NIVO+IPI in untreated adult pts with MUM; is being conducted in 10 centers in Spain, leading by the Spanish Melanoma Group. Eligible pts had histologically-confirmed MUM, ECOG-PS 0/1, and no prior systemic treatment for MUM. Treatment consisted in NIVO (1mg/kg, iv, q3 weeks [wk]) and 4 doses of IPI (3mg/kg iv q3wk) followed by NIVO (3mg/kg q2wk) until progressive disease (PD), toxicity or withdrawal. Primary endpoint is OS and secondary progression free survival (PFS), Overall Response Rate (ORR) (per RECIST 1.1) and safety. Radiologic evaluations q6wk. Interim analysis (n = 19) was planned per protocol to assess safety and ORR. Intention to treat analysis includes pts with PD at first radiological evaluation. Safety population includes all pts receiving at least one dose of study treatment. **Results:**19 pts enrolled from April to July 2016: Median age 62y (43y-82y), 63% male, liver M1 84% pts and extra-liver M1 42% pts, 31% elevated baseline LDH. 11 pts completed cycle 2 and 8 pts stopped after 1 dose (6 PD, 2 toxicity). Treatment-related adverse events were reported in 12 pts and lead to end of treatment in 2 pts. Grade ≥3 toxicities were seen in 7 pts (36.8%): diarrhea, transaminitis, dermatological events, anemia, acute thyroiditis. All G3/4 were resolved following the toxicity guideline. One G5 acute thyroiditis related to NIVO+IPI was reported. ORR was observed in 15.8% and disease stabilization in 47.4%. With a median follow-up of 4.6m, PFS was 4.99m. Median OS was not reached at time of this analysis. **Conclusions:** Combination of NIVO+IPI is feasible for MUM. In this INTERIM ANALYSIS, ORR did not reach yet 20%, but PFS seems promising. The clinical trial is ongoing. Final results will be updated. Clinical trial information: 2015-004429-15.

9534 Poster Session (Board #142), Sat, 1:15 PM-4:45 PM

Targeting EZH2 in acral lentiginous melanoma (ALM). *First Author: Allison Izsak, New York University School of Medicine, New York, NY*

Background: Efforts to identify targeted therapies that can improve treatment outcome in metastatic ALM have been unsuccessful. In a previous genomic screening, we identified copy number amplification of the histone methyltransferase EZH2 in 47% of ALM cases, a higher frequency than previously reported in cutaneous melanomas (CM) (5%). Here, we tested the hypothesis that increased EZH2 expression contributes to ALM progression and may confer selective sensitivity to EZH2 inhibition. **Methods:** EZH2 expression was examined by immunohistochemistry (IHC) in 51 primary (21 stage I, 13 Stage II and 17 Stage III) and 23 metastatic (11 in transit, 8 nodal and 4 visceral) ALM cases with extensive clinicopathological data and protocol-driven follow up. Colony formation and cell proliferation was assessed following treatment of ALM and CM cell lines with three EZH2 inhibitors, including GSK126, currently in clinical trials. The effect of GSK126 on H3K27me3 and downstream EZH2 targets was analyzed by western blotting. **Results:** EZH2 is commonly overexpressed in both primary (30/51; 65%) and metastatic (20/23; 87%) ALM cases, with a significant increase in mean IHC score between primary and metastatic tumors (1.9 vs. 2.7, respectively, p = 0.047). EZH2 expression increased in 6/10 metastatic ALM tumors compared to their matched primary tumors. ALM tumors with EZH2 gene amplification showed increased EZH2 protein expression; however more cases showed overexpression with no amplification suggesting a potential epigenetic component of EZH2 regulation. GSK126 significantly suppressed ALM colony formation at lower doses compared to CM (1 μM vs. 5 μM, respectively). EZH2 inhibition also increased expression of the downstream tumor suppressor E-cadherin in ALM but not in CM cell lines. Finally, ALM cell lines had significantly lower basal H3K27me3 levels than CM cell lines, suggesting an additional, histone methyltransferase-independent function of EZH2 in ALM. **Conclusions:** Our data demonstrate thatEZH2 upregulation is common in ALM, and suggest that it may play a role in ALM's metastatic progression that requires further investigation. Selective sensitivity of ALM cell lines to EZH2 inhibitors supports the therapeutic potential of EZH2-targeted therapy in ALM.

9535 Poster Session (Board #143), Sat, 1:15 PM-4:45 PM

Follow-up of patients with complete remission of locally advanced basal cell carcinoma treated with vismodegib after treatment discontinuation: A retrospective multicentric French study. *First Author: Florian Herms, CHU Saint Louis, Paris, France*

Background: Vismodegib is a Hedgehog Pathway inhibitor (HPI) indicated for treatment of inoperable locally advanced basal-cell carcinoma (laBCC). Previous studies showed an objective response (OR) rate of 67%, including 34% of complete response (CR). Discontinuation of vismodegib is very frequent, mostly due to intolerable side-effects. Long-term response and predictive factors of relapse after suspension of vismodegib have not yet been evaluated, but should play a crucial role in the management of laBCC patients. **Methods:** We conducted an observational retrospective study in 9 onco-dermatological French units. Medical charts of laBCC patients treated with vismodegib from March 2012 until June 2016 were reviewed and patients with CR who stopped treatment were selected. Relapse was diagnosed clinically and/or histologically. A survival analysis was conducted, and predictive factors, characterization and management of relapse were studied. **Results:** 119 laBCC patients achieved CR and stopped treatment. 21 were lost to follow-up and 6 died before relapse. Event-free survival median was 18.4 months (12.1 – 24.1) and cumulative incidence of relapse at 36 months was 59.04% (48.05 - 70.04), implying that more than 40% of patients do not relapse. Multiple BCC and BCC not localized on the head and neck were associated with a higher risk of relapse, independently of the existence of Gorlin syndrome (HR = 3.3 (IC95 = 1.6 - 6.7) and 2.01 (IC95 = 1.05 - 3.87) respectively). Total duration of treatment was not associated with relapse. 50% (n = 27) of patients who relapsed during follow-up were retreated with vismodegib, with an OR of 85.2% (n = 23). 42% (n = 24) were eligible to surgery only and other patients received local treatments. **Conclusions:** Long term responders after vismodegib treatment discontinuation are frequent independently of the time exposure to the drug before and after CR. Most patients who relapse are still responder to vismodegib rechallenge. Patients with multiple or laBCC not localized on the head and neck are more at risk of relapse after discontinuation. This study emphasizes the interest of treatment of laBCC with HPI.

9536 Poster Session (Board #144), Sat, 1:15 PM-4:45 PM

Landscape of genomic alterations (GA) and tumor mutational burden (TMB) in different metastatic melanoma (MM) subtypes. *First Author: Douglas Buckner Johnson, Vanderbilt University Ingram Cancer Center, Nashville, TN*

Background: MM is a highly targetable malignancy, with both kinase inhibitors and immunotherapies providing meaningful survival benefit. Different subtypes of mm harbor distinct GA that suggest targeted and immunotherapy options. **Methods:** Comprehensive genomic profiling was performed in 2,197 MMs for up to 315 cancer-related genes plus introns from 28 genes commonly rearranged in cancer on hybrid-capture, adaptor ligation-based libraries (mean coverage depth > 600X). TMB was calculated from ≥1.11 Mb sequenced DNA. We assessed base substitutions, insertions and deletions (short variants; SV), rearrangements, and copy number changes. **Results:** We assessed 6 subtypes: routine cutaneous (CT; 90%), desmoplastic (DM: 1%), acral lentiginous (AL; 1%), Spitzoid (SP; 1%), mucosal (MC; 2%) and ocular (OC; 5%). Each group harbored characteristic genomic signatures (Table). *BRAF* was mutated in 38% of CT of which 92% were SV GA and 8% were amplifications, fusions or cases with > 1 *BRAF* GA. High TMB in CT and DM is highly prevalent (42% and 83% with > 20 mut/Mb). *BRAF* GA were less common in AL (18%), MC (15%), and OC (2%). SP GA were dominated by fusions in *BRAF* (60%) and other kinases. *KIT* GA were prominent in MC and AL. TMB for MC and OC mm were very low. Key findings include novel drivers of BRAF inhibitor resistance including *BRAF* internal rearrangements and kinase domain duplications. **Conclusions:** In the largest cohort of mm with NGS to date, genomic profiles and TMB differ across mm subtypes. Highly prevalent BRAF GA (including in the SP variant) and high TMB in CT and DM mm permit effective use of targeted and immunotherapies. Although MC and OC have lower BRAF GA frequency and lower TMB, targetable GA can be present. Novel BRAF inhibitor resistance mechanisms were observed.

Outcomes following progression on BRAF/MEK inhibition in metastatic melanoma. *First Author: Robert Mason, Princess Alexandra Hospital, Brisbane, Australia*

Background: Restrictions in Australia dictate the prescription of BRAF/MEK inhibitors prior to immunotherapy in BRAF mutant metastatic melanoma (BRMM). We analysed patients (pts) with advanced BRMM after treatment with a BRAF/MEK inhibitor and use of second line immunotherapy (PD-1 inhibitor or CTLA4 inhibitor). **Methods:** Patients (pts) with BRMM from Princess Alexandra Hospital treated between June 2013 to June 2016 were identified retrospectively. Demographics, treatment pattern and survival were analysed. **Results:** 92 pts were identified. 50% had an elevated LDH at diagnosis. 30 pts had brain metastasis at diagnosis, of these pts 11 had cerebral progression on BRAF/MEK. 41 pts had radiotherapy, 50% had stereotactic/gamma knife and 50% WBRT. 68 pts progressed giving a median progression free survival (PFS) of 9 months (95% CI 6.4 – 11.6 m). The median PFS for pts with normal LDH was 14 months, opposed to 9 months if elevated. On progression 31 pts (36.5%) were not offered second line immunotherapy due to rapid deterioration or declining performance status. 26 (30.6%) were treated with PD-1 inhibitor; 7 (8.2%) had Ipilimumab, of these, 4 then had PD-1; 1 had combination therapy; 23.5% of pts continued on BRAF/MEK at analysis. Of the patients exposed to immunotherapy, 27 pts experienced disease progression, giving a median PFS survival of 2.5 months (95% CI 1.2 –3.6m). **Conclusions:** After BRAF/MEK inhibition, due to rapid disease progression and poor performance status a significant proportion of patients do not receive immunotherapy and received best supportive care. Disease control with single agent PD-1 is short after BRAF/MEK inhibitors. These patients may have benefited from first line immunotherapy. This cohort, while small, suggests further data is needed about optimal sequencing of targeted and immunotherapy.

9538 Poster Session (Board #146), Sat, 1:15 PM-4:45 PM

Micro- and macro-metastatic disease kinetics: Results from the French cohort Melbase. *First Author: Anais Vallet, Dermatology, Hôpital Saint-Louis, Paris, France*

Background: In the past decade, the prognosis of advanced melanoma has been greatly improved by new therapeutic agents such as immune and targeted therapies, which are now being evaluated as adjuvant therapies. Although the kinetic of metastatic disease is correlated to patient survival, the unfolding of the dormant disease remains hardly predictable and data from the literature on the topic is controversial (Karakousis, Francken). We hypothesized that the course of the advanced disease could be predicted from time to distant recurrence. **Methods:** Melbase is a French multicentric cohort dedicated to the prospective follow-up of adults with unresectable stage III or IV melanoma. Date of primary excision, time to recurrence, progression free survival (PFS) and overall survival (OS) of 298 patients treated in first line by immune therapies (IT, n = 148), targeted therapies (TT, n = 68) or within clinical trials (n = 73) were collected on September 5th, 2016. Patients with unknown primary or *de novo* metastatic melanoma were not included. Time to distant recurrence was analyzed as a continuous variable and as a categorical variable (< 12 months; 12 to 24 months; ≥ 24 months). **Results:** Patients' characteristics at baseline are: mean age 62 years, PS 0-1 84%, elevated LDH 32%, BRAF mutated 39%, brain metastases 18%. Time to recurrence studied as a continuous variable was not correlated to PFS (HR = 0.96; 95%CI: 0.85-1.07) or OS (HR = 0.89; 95%CI: 0.77-1.03). These results remained insignificant after stratification upon treatment or even when time to recurrence was analyzed as a categorized variable. **Conclusions:** Our data showed no correlation between the time from primary to distant recurrence and PFS or OS in patients treated with TT or IT. Therefore, kinetics of advanced disease cannot be predicted by the history of dormant disease. Dormancy and metastasis proliferation are thus probably driven by different molecular and cellular mechanisms.

9539 Poster Session (Board #147), Sat, 1:15 PM-4:45 PM

Real life outcome of advanced melanoma patients who discontinue pembrolizumab (PEMBRO) in the absence of disease progression. *First Author: Yanina Jansen, Vrije Universiteit Brussel (VUB), Brussels, Belgium*

Background: PEMBRO improves survival of patients (pts) with advanced melanoma. Optimal duration of treatment in responding pts hasn't been established. **Methods:** 12 European hospitals collected data from 509 pts treated with PEMBRO outside an interventional clinical trial. Outcome was evaluated for pts who discontinued PEMBRO in the absence of progressive disease [PD]. **Results:** After a median follow up of 56 wks [range 1-135], median PFS was 22 wks [95% CI 18-26] and median OS was 70 wks [95% CI 59-81] for the total population. PEMBRO is ongoing in 66 [13%] pts, 344 [68%] pts stopped PEMBRO because of PD, and 99 [19%] pts discontinued PEMBRO without evidence of PD (of which 65 [13%] pts upon pt/MD decision, 26 [5%] pts due to a PEMBRO-related AE of grade < 4 and 8 [2%] pts due to a grade 5 PEMBRO-unrelated AE). Pts discontinuing PEMBRO without PD had a significant [P <.005] better ECOG PS, less advanced tumor stage, less frequent brain metastases and more often a normal LDH at baseline. There was no significant difference between pts stopping due to AE or upon pt/MD decision. The median time on treatment for the 65 pts who stopped PEMBRO upon pt/MD decision was 55 wks [range 9-112].Their best objective response rate [BORR] was 80% [31 [48%] CR, 21 [32%] PR, 12 [18%]SD, 1[2%]NE]. After a median follow-up of 26 wks [range 1-75] after the last PEMBRO dose, 3 [5%] pts progressed (after 9, 14 and 15 wks). PEMBRO was reintroduced in 1 patient resulting in a CR. The median time on treatment of the 26 pts who stopped PEMBRO due to an AE in the absence of PD was 27 wks [range 1-103]. Their BORR was 77% [9 [35%] CR, 11 [42%] PR, 5 [19%] SD, 1 [4 %] NE]. After a median follow-up of 50 wks [range 12-109] following the last PEMBRO dose, 9 [35 %] pts progressed. Median time to PD was 26 wks [range 7-108]. PD was not correlated with BOR. PEMBRO was reintroduced in 4 pts resulting in 1 CR, 1 PD, 1 SD and 1 NE. **Conclusions:** In this real life experience, advanced melanoma pts who discontinue PEMBRO treatment upon pt/MD decision, in the absence of PD or AE, were at low risk for short-term recurrence. Pts stopping PEMBRO due to an AE in the absence of PD (having a shorter exposure to PEMBRO and longer FU after discontinuing treatment) seem to have a higher risk for subsequent PD.

9540 Poster Session (Board #148), Sat, 1:15 PM-4:45 PM

Association of concomitant use of acid reducing agents in full-dose vemurafenib users with risk of progression in BRAF V600 mutation-positive unresectable or metastatic melanoma patients: A retrospective cohort study. *First Author: Lotte Marieke Knapen, Department of Clinical Pharmacy and Toxicology, Care And Public Health Research Institute, Maastricht University Medical Center+ and Department of Pharmacoepidemiology and Clinical Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Maastricht, Netherlands*

Background: Vemurafenib is used for the treatment of adult patients with *BRAF* V600 mutation-positive unresectable or metastatic melanoma. The approved fixed vemurafenib dose of 960 mg twice daily may result in overexposure. Concomitant use of acid reducing agents (ARAs) may result in underexposure. Both situations are likely to affect treatment outcome. Therefore, the aim of this study was to determine the association between the use of vemurafenib (full-dose versus reduced dose) and/or concomitant ARA use (yes versus no) and the risk of disease progression. **Methods:** A retrospective cohort study was conducted using data from the electronic health record software of the Radboudumc pharmacy and medical records of the Radboudumc (March 17th 2012 to March 17th 2016). Patients (N = 112) using vemurafenib as first line treatment for melanoma were included. Multivariable cox regression estimated adjusted hazard ratios (HRa) and 95% confidence intervals (CI) of progression in vemurafenib users (full-dose N = 67 versus reduced dose N = 45) and/or concomitant ARA users (N = 38). Adjustments were made for age and sex. **Results:** The mean follow-up time was 3.5 months and 41 patients (36.6%) developed progression on first line vemurafenib. Co-treatment of ARAs in patients using full-dose vemurafenib was associated with a 4.6-fold increased risk of progression (HRa 4.56; 95% CI 1.51-13.75) as compared to full-dose vemurafenib users not co-treated with ARAs. No increased risk was found for users of vemurafenib in a reduced dose, regardless of concomitant ARA use. **Conclusions:** Concomitant use of ARAs in full-dose vemurafenib users was associated with an increased risk of progression. Physicians should be cautious to prescribe ARAs to patients tolerating full-dose vemurafenib. The presence of considerable confounding by disease severity, the small number of events and the hypothesis generating character of this study emphasize the need to prospective validate these results.

9541 Poster Session (Board #149), Sat, 1:15 PM-4:45 PM

Distinct gene expression, mutational profile and clinical outcomes of V600E and V600K/R BRAF-mutant metastatic melanoma (MM). *First Author: Ines Esteves Domingues Pires Da Silva, Melanoma Institute Australia, Sydney, Australia*

Background: BRAF V600E and V600K/R mm have distinct clinicopathologic features suggesting different etiology. V600K/R mm appears less responsive to MAPK inhibitors (MAPKi) compared to V600E MM. We investigated potential mechanisms for this by comparing the gene expression and mutation profiles of these two melanoma subgroups. **Methods:** BRAF V600 mutant mm patients (pts) treated with MAPKi (BRAFi +/- MEKi) between July/2009 and July/2013 were selected. Demographics, clinicopathologic features and clinical outcomes were examined. Pre-treatment FFPE tumors underwent RNA expression profiling (795-gene nanostring panel) and DNA sequencing (239 gene NGS panel). Molecular results were validated using an independent cohort from the The Cancer Genome Atlas (TCGA). **Results:** 95 mm pts were included (78 V600E, 17 V600K/R), with median (med) follow-up of 18.4 months (mo). 74 (78%) had BRAFi, 21 (22%) had BRAF/MEKi. At MAPKi start, there were no differences between subgroups regarding age, gender, ECOG, AJCC stage or LDH level. V600K/R pts had a trend to less tumour regression by RECIST (med 30% vs 51%, $p = 0.08$) and shorter PFS (med 5.1 vs 7.1mo, $p = 0.08$) than V600E, with no difference in OS (20.8mo vs 17.9mo, $p = 0.64$). V600K/R had lower expression of the MAPK-pathway feedback regulator DUSP6 and glycosyltransferase GCNT1, compared to V600E ($p < 0.05$). Analysis of TCGA data (122 V600E, 21 V600K/R) confirmed these findings. There was a trend toward higher mutational load in V600K/R than V600E, confirmed with TCGA data ($p < 0.05$). V600K/R had a higher proportion of mutations in PIK3CA and several tumour suppressor genes (FBXW7, NF2, RB1 and SMAD4), with only FBXW7 confirmed using TCGA data. **Conclusions:** V600K/R mm has inferior response and shorter survival with MAPKi than V600E, potentially due to less reliance on MAPK pathway activation (lower DUSP6 expression) and greater use of alternative drivers of oncogenesis (higher mutational load, particularly in tumor suppressor genes). Further analyses will be performed, including comparison of MAPK and additional pathway signalling in cell models. Response to immunotherapy will also be examined.

9542 Poster Session (Board #150), Sat, 1:15 PM-4:45 PM

A randomized phase II study of ipilimumab at 3 (ipi3) or 10 mg/kg (ipi10) alone or in combination with high dose interferon-alfa (HDI) in advanced melanoma (E3611). *First Author: Ahmad A. Tarhini, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Interferon-α (IFN) favors a Th1 shift in immunity. Combining CTLA4 blockade with IFN may downregulate CTLA4 suppressive elements. Prior data from a phase II of tremelimumab and HDI showed promising efficacy supporting the current study. **Methods:** E3611 had a 2x2 factorial design (A: ipi10 + HDI; B: ipi10; C: ipi3 + HDI; D: ipi3) to evaluate (i) no HDI vs. HDI (across ipi doses) and (ii) ipi3 vs. ipi10 (across HDI status). We hypothesized that median progression free survival (PFS) would improve from 3 to 6 months (mos) with HDI vs. no HDI and with ipi10 vs. ipi3. Based on the log-rank test for 80 patients (pts) these comparisons would have 82% power at 2-sided type I error of 0.10. **Results:** Median follow up 26.4 mos. PFS and overall survival (OS) (eligible and treated pts; N = 80: 18 III/M1a, 24 M1b, 38 M1c) are shown in Table 1. There were no significant differences in PFS or OS when evaluating HDI vs. no HDI or ipi10 vs. ipi3 (Table 1). Response (RECIST) among response evaluable pts (and 4 pts with early death) (N = 76) is shown in Table 1. Stable disease (SD) in 7 (A), 6 (B), 8 (C) and 6 (D). Adverse events (AEs) were consistent with the toxicity profiles of ipi and HDI and included 3 grade 5 AEs considered at least possibly related: 1 in A (suicide), 1 in B (lung infection and hemorrhage) and 1 in C (adult respiratory distress syndrome). One patient in B died of gastrointestinal bleed and cardiac arrest while on corticosteroids to treat temporal arteritis and vision loss. **Conclusions:** Within the limitations of the sample size, there were no significant differences in PFS with HDI vs. no HDI or ipi10 vs. ipi3. Response and PFS with ipi10 were superior to historical controls and similar to the combination. Correlative studies are ongoing. Clinical trial information: NCT01708941.

PFS (top) and OS: Median (95% CI) months.

	Ipi10	Ipi3
HDI	A 8.0 (2.8, 20.1) 20.1 (5.1, -)	C 5.7 (1.5, 11.1) 20.2 (1.9, -)
No HDI	B 6.2 (2.7, 25.7) 19.6 (6.5, 31.4)	D 2.8 (2.6, 5.7) 24.7 (12.1, -)
RR HDI	A 5/15 (33.3%)	C 3/18 (16.7%)
No HDI	B 7/22 (31.8%)	D 3/21 (14.3%)
HDI vs. no HDI	PFS: 6.7 (5.1, 11.0) vs. 5.0 (2.7, 8.2) OS: 20.1 (8.5, 33.6) vs. 23.5 (12.2, 35.6)	
Ipi10 vs. Ipi3	PFS: 6.5 (5.1, 13.5) vs. 4.1 (2.6, 7.5) OS: 20.1 (10.4, 31.4) vs. 23.5 (11.7,35.7)	

9543 Poster Session (Board #151), Sat, 1:15 PM-4:45 PM

Efficacy and safety of single agent pan-HER inhibitor dacomitinib in locally advanced unresectable or metastatic skin squamous cell cancer (sSCC). *First Author: Paolo Bossi, Head and Neck Cancer Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In recurrent/metastatic skin squamous cell cancer (sSCC) not amenable to radiotherapy (RT) or surgery, chemotherapy (CT) has a palliative intent and limited clinical responses. We investigated the role of pan-HER inhibitor dacomitinib within a phase II trial in this setting. **Methods:** Patients (pts) with diagnosis of sSCC not amenable to curative approaches were included. Oral dacomitinib was started at a dose of 30 mg daily for 15 days, followed by 45 mg daily. Primary endpoint was response rate (RR). Tumor samples were analyzed through Next Generation Sequencing methods (pgm, Ion torrent) using a custom panel targeting 36 genes associated with sSCC. **Results:** Forty-two pts (33 M, 9 F; median age 77 years, range 45-92) were treated. ECOG PS was 0 in 58%, 1 in 40% and 2 in 2%. One fifth of the pts had distant metastasis. Most pts (86%) received previous treatments consisting in surgery (86%), RT (50%) and CT (14%). Among evaluable pts, overall RR was 28% (complete response CR 2%, partial response PR 26%), disease control rate 86%. Median duration of response was 11 months (range 1-26+). Median treatment duration was 4 months (range 1-26+). Reason for discontinuation were disease progression in 69%, adverse events (AEs) in 19%, non drug-related death in 5%; 3 pts are still on treatment. Median PFS and OS were 6 and 12 months, respectively. Most pts (93%) had at least one AE, mainly consisting in diarrhea and skin rash (71% each), fatigue (36%) and stomatitis (31%). G3/G4 AEs occurred in 36% of pts (diarrhea and skin rash 17% each). Tumor material was available from 7 responding (R: 6 PR, 1 CR) and 15 non-responding (NR: 13SD, 2PD) pts. Frequent TP53 (60%), NOTCH1/2 (60%) and FAT1 (40%) mutations were observed. NR pts showed a higher occurrence of HRAS/BRAF/NRAS mutations (40%) than R ones (28%). Moreover, HER3 (27%) CASP8 (27%), KMT2C (33%) and DCLK1 (27%) mutations were restricted to NR pts. **Conclusions:** In sSCC dacomitinib showed activity, similar to what observed with anti-EGFR monoclonal antibody cetuximab and panitumumab (RR 28% and 31%); safety profile was comparable to previous experiences in other diseases. Molecular pt selection could improve therapeutic ratio. Clinical trial information: NCT02268747.

9544 Poster Session (Board #152), Sat, 1:15 PM-4:45 PM

Safety of resuming anti-PD-1 (aPD1) in patients (pts) with immune-related adverse events (irAEs) during combined anti-CTLA-4 (aCTLA4) and aPD1 in metastatic melanoma (MM). *First Author: Megan Pollack, Vanderbilt University Medical Center, Nashville, TN*

Background: Combination aPD1 and aCTLA4 has demonstrated greater response rates (RR) than aPD1 alone in MM. However, aPD1 + aCTLA4 also leads to more frequent and severe irAEs compared to aPD1. The safety of resuming aPD1 following these irAEs is not known. We characterized the safety and efficacy of resuming aPD1 following severe irAEs during aPD1 + aCTLA4 in pts with MM. **Methods:** We retrospectively reviewed mm pts from 3 academic centers who had a severe irAE with aPD1 + aCTLA4 (defined as CTCAE v4.03 G3-4 or leading to early discontinuation of aPD1 + aCTLA4) and who resumed aPD1 thereafter. We assessed for frequency, timing, and spectrum of irAEs as well as RR, progression free survival (PFS) and overall survival (OS). **Results:** We identified 64 pts who received aPD1 + aCTLA4 for a median of 2 doses (range, 1-4). The most frequent irAEs that led to aPD1 + aCTLA4 discontinuation were: colitis (36%), hepatitis (23%), hypophysitis (8%), pneumonitis (5%), nephritis (3%), neurologic complications (3%), and pancreatitis (3%); eight pts (13%) had >1 concurrent severe irAEs. aPD1 was resumed at a median of 55 days after last dose of aCTLA4 + aPD1 (range, 17-289); 23% experienced recurrence of the same irAE with aPD1 monotherapy, 16% experienced a distinct irAE, and 60% did not experience any severe irAE after resuming aPD1. Hepatitis recurred in 6 of 18 pts, pancreatitis in 2 of 2, dermatitis in 1 of 4, nephritis in 1 of 2, pneumonitis in 1 of 3, hypophysitis in 1 of 5, and colitis in 1 of 27; the grade of these recurrent irAEs was: 46% grade 1-2, 33% grade 3, 13% grade 4, and 7% grade 5 (n = 1). One death from irAEs occurred related to Toxic Epidermal Necrolysis (TEN). No difference was observed in time prior to resuming aPD1 in those that had recurrent irAEs vs. those without (median 56 days each). The RR in this cohort was 73% (30% CR; 44% PR); median PFS (range, 2.2-not reached (NR)) and OS (range, 2.4-NR) were not reached. **Conclusions:** In our experience, pts who resume aPD1 following irAEs with aPD1 + aCTLA4 exhibit variable toxicity profiles with most experiencing no irAEs, but a minority experiencing severe or life-threatening irAEs. We observed excellent efficacy in this cohort.

9545 Poster Session (Board #153), Sat, 1:15 PM-4:45 PM

KEYNOTE-029: Efficacy and safety of pembrolizumab (pembro) plus ipilimumab (ipi) for advanced melanoma. *First Author: Matteo S. Carlino, Westmead and Blacktown Hospitals and Melanoma Institute Australia, Sydney, Australia*

Background: We previously showed that standard-dose pembro plus reduced-dose ipi has manageable safety and robust antitumor activity in patients (pts) with advanced melanoma. Here, we present more mature data, including 1-y landmark PFS and OS estimates. **Methods:** In the phase 1 KEYNOTE-029 expansion cohort (NCT02089685), pts with advanced melanoma, ECOG PS 0-1, no active brain metastases, and no prior immune checkpoint inhibitor therapy received pembro 2 mg/kg Q3W + ipi 1 mg/kg Q3W for 4 doses, then pembro alone for up to 2 y. Primary end point was safety. Efficacy end points were ORR, PFS, and DOR per RECIST v1.1 by independent central review and OS. **Results:** 153 pts were enrolled between Jan 13, 2015, and Sep 17, 2015. Median age was 60 y, 66% were male, 25% had elevated LDH, 56% had stage M1c disease, 36% were $BRAF^{V600}$mutant, and 13% received ≥ 1 prior therapy. As of Oct 17, 2016, median follow-up was 17 mo, and 64 (42%) pts remained on pembro. 110 (72%) pts received all 4 ipi doses. There were no treatment-related (TR) deaths. TRAEs occurred in all pts, were grade 3/4 in 69 (45%), and led to discontinuation of pembro and ipi in 17 (11%), ipi alone in 11 (7%), and pembro alone after ipi completion or discontinuation in 19 (12%). PD occurred in 1/11 pts who discontinued ipi alone and 4/17 pts who discontinued ipi and pembro. Of the 11 pts who discontinued ipi alone for a TRAE, 0 experienced recurrence of the same TRAE during pembro monotherapy and 2 discontinued pembro for a different TRAE (both elevated lipase). Immune-mediated AEs occurred in 90 (59%) pts and were grade 3/4 in 39 (25%). With 7 mo additional follow-up, there were 6 additional responses for an ORR of 61% (95% CI, 53%-69%); the CR rate increased from 10% to 15%. Median DOR was not reached (range, 1.6+ to 18.1+ mo), with 86/93 responders (92%), including 23/23 (100%) with CR, alive and without subsequent PD at cutoff. Median PFS and OS were not reached; 1-y estimates were 69% for PFS and 89% for OS. **Conclusions:** Pembro 2 mg/kg plus 4 doses of ipi 1 mg/kg has a manageable toxicity profile and provides robust, durable antitumor activity in pts with advanced melanoma. Clinical trial information: NCT02089685.

9546 Poster Session (Board #154), Sat, 1:15 PM-4:45 PM

Analysis of circulating tumor DNA (ctDNA) in pseudoprogression in anti-PD1 treated metastatic melanoma (MM). *First Author: Jenny HJ Lee, Macquarie University, Sydney, Australia*

Background: We have previously shown that undetectable ctDNA either at baseline or during therapy predicted response in mm patients (pts) treated with anti-PD1 antibodies (aPD1). Pseudoprogression, defined as radiological progression prior to response, occurs in 8% of pts treated with aPD1. We sought to determine if ctDNA could differentiate pseudoprogression from true progression, defined as continued clinical or radiological disease progression. **Methods:** Between July 2014 and May 2016, pts receiving aPD1 had serial bloods for ctDNA. Included pts either had RECIST PD at first restaging or early clinical progression. Those with untreated brain metastases were excluded from the analysis. ctDNA was quantified using digital droplet PCR for mutations (BRAF/NRAS) at baseline and during the first 12 wks of treatment. Based on our prior studies, ctDNA results were grouped in to 'favorable' and 'unfavorable' ctDNA profiles (see Table), and these were compared in pts with true and pseudoprogression. **Results:** 29 pts were included, 28 with RECIST PD at first restaging and one with early clinical progression. 9 (31%) pts had a subsequent RECIST PR or SD and were considered pseudoprogression and 20 (69%) had true progression. Of the pseudoprogressors, 7/9 pts remained in response with a median follow-up of 20 months (mths). 2/9 pts had disease progression at 7 and 18 mths, with ctDNA that remained detectable with a >10-fold decrease during treatment in both patients. Of those with true progression and a favourable profile, 1 had a >10-fold decrease in ctDNA by wk 12 and was switched to MAPK therapy prior to further imaging, and the other had an undetectable ctDNA at wk 6 which increased again at wk 12. The latter pt had a new lesion on first restaging CT scan despite PR in all existing lesions with true PD on second restaging at wk 24. **Conclusions:** ctDNA in patients with mm at baseline and early on aPD1 treatment differentiates pseudo from true progression.

	ctDNA profile			
	Favorable (n = 11)			Unfavorable (n = 18)
ctDNA at baseline/ on treatment up to wk 12	Undetectable/ undetectable	Detectable/ undetectable	Detectable/ >10 fold decrease	Detectable/minimal change or increase
Pseudoprogression (n = 9)	2	4	3	0
True progression (n = 20)	0	1	1	18

9547 Poster Session (Board #155), Sat, 1:15 PM-4:45 PM

A phase I trial of panobinostat with ipilimumab in advanced melanoma. *First Author: Nikhil I. Khushalani, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Immune checkpoint blockade is standard therapy for advanced melanoma (MEL), yet not all patients (pts) benefit. Panobinostat (PAN), a pan inhibitor of class I, II, and IV histone deacetylases (HDAC) is immunomodulatory, decreases tumor associated inhibitory cytokines and inhibition of effector T-cells. This dose finding study aimed to determine the safety and efficacy of escalating doses of PAN combined with ipilimumab (IPI) in advanced MEL. **Methods:** Eligible pts with unresectable stage 3/4 MEL, up to 3 prior lines of therapy, and adequate laboratory values were treated with oral PAN 5mg thrice weekly (TIW) plus IPI at 3mg/kg IV every 3 weeks X 4 doses, followed by maintenance PAN until progression or intolerance. Using a modified Ji design, PAN dose escalation by 5mg was planned in 3-12 pt cohorts up to a maximum dose of 20mg TIW, without intra-pt dose escalation. Dose limiting toxicity (DLT) was assessed up to day 84 from start of therapy. **Results:** Seventeen pts (M/F: 13/4), median age 66 yrs (48, 80) were treated with a median of 4 cycles of IPI (1,4). Of 6 pts treated at PAN 5mg TIW, there was one DLT (G3 hydronephrosis). Eleven pts received PAN 10mg TIW; of 9 evaluable for DLT, there were 3 DLTs (G3 rash, G3 diarrhea, G4 thrombocytopenia) preventing further dose escalation. Other G3 toxicities included anemia, hypophysitis, diarrhea, fatigue (all n = 2); rash, colitis, nausea, dehydration, dizziness, hypotension, ↑ lipase, ↓ sodium, & ↑ glucose (all n = 1). Three pts had previous anti-PD1 therapy. The response rate was 12% (2 PRs) with 35% stable disease. One pt remains on PAN >24m since start of therapy. Median progression free- and overall survival was 2.23m (95% CI,1.57, 5.8) and 20.97m (95% CI, 8.97, NR) respectively. Biomarker analysis from peripheral blood and limited tumor biopsies pre-and on treatment examining immunoregulatory markers, including EOMES promoter acetylation in T-cells from PAN are ongoing. **Conclusions:** At tolerated doses, PAN does not appear to increase response to standard IPI in advanced MEL. Biomarker analyses will inform if immunomodulation by PAM improves efficacy of IPI. Combinations with selective HDAC inhibitors may be more appropriate for future study. Supported by grant P50 CA168536, Moffitt Skin Cancer SPORE. Clinical trial information: NCT02032810.

9548 Poster Session (Board #156), Sat, 1:15 PM-4:45 PM

Outcomes of patients with melanoma who discontinue immunotherapy. *First Author: Samuel Rosner, Albert Einstein College of Medicine, Bronx, NY*

Background: The question of when to discontinue (d/c) anti-program death-1 (PD-1) monotherapy (mono) or nivolumab in combination with ipilimumab (combo) immunotherapy (IT) is unknown. **Methods:** After IRB approval, a single center (Memorial Sloan Kettering Cancer Center), retrospective study was performed of 162 pts with unresectable stage III or IV melanoma treated with either mono (n = 106) or combo (n = 56) IT. Objective response rate (ORR), progression free survival (PFS), and overall survival (OS) were calculated for all pts from the 1st dose of IT. For pts (n = 40; mono and n = 40; combo) who d/c IT due to reasons (Table) other than progression or death, starting from the last date of IT, we then reported PFS, time to treatment failure (TTF) defined as any subsequent surgery/radiation/systemic therapy, and OS. **Results:** For pts that were alive at time of analysis, the median follow up was 28 mos. For all 162 pts (demographics in Table), ORR was 38.7% (mono) and 60.7% (combo); median PFS and OS were 12 months (mos) and 25 mos for mono; 34 mos and not reached (NR) for combo, respectively. From the last dose of IT, the PFS, TTF, and OS for 40 mono pts and 40 combo pts who d/c IT for reasons other than progression/death are shown in Table. Reasons included CR, toxicity, or other (most commonly protocol completion or prolonged PR). **Conclusions:** Outcomes in this cohort of pts with long follow-up treated with mono or combo IT are similar to results from other clinical trials. Pts who d/c IT for reasons other than progression/death were a highly selected group. Nonetheless, favorable PFS, TTF, and OS were seen after IT d/c, even in pts who did not obtain a CR.

	Mono (n = 106)	Combo (n = 56)
Age (years)	60	60
Sex (% Female)	45	41
Unresectable Stage III (%)	2	11
Stage M1A (%)	19	11
Stage M1B (%)	24	21
Stage M1C (%)	56	57

9549 Poster Session (Board #157), Sat, 1:15 PM-4:45 PM

A dose escalation phase 1 study of radiotherapy (RT) in combination with anti-cytotoxic-T-lymphocyte-associated antigen 4 (CTLA-4) monoclonal antibody ipilimumab in patients (pts) with metastatic melanoma. *First Author: Celine Boutros, Gustave Roussy, Villejuif, France*

Background: Preclinical findings have shown a synergy between RT and anti-CTLA-4 monoclonal antibody in several tumor animal models for both local tumor control and distant effects. Preliminary clinical data suggest that it could be due to an abscopal effect of RT. The Mel-Ipi-Rx phase 1 study aimed to determine the maximum tolerated dose (MTD) and safety profile of RT combined with ipilimumab in pts with metastatic melanoma. **Methods:** A 3+3 dose escalation design was used with 9, 15, 18 and 24 Gy dose of RT (in 3 fractions) at week 4 combined with 10 mg/kg ipilimumab (every 3 weeks for 4 doses). Pts with evidence of clinical benefit at week 12 were eligible for maintenance ipilimumab at 10 mg/kg every 12 weeks starting at week 24 until severe toxicity or disease progression based on immune-related response criteria (irRC). **Results:** 19 pts with advanced melanoma received ipilimumab between August 2011 and July 2015. Nine pts received the 4 doses of ipilimumab and 2 pts received maintenance ipilimumab (1 and 2 cycles respectively). All pts received the combined RT at week 4 in 3 fractions. All pts presented at least one AE of any grade. The most common AEs were asthenia, diarrhea, desease-related pain and fever. Grade 3 AEs occurred in 8 pts. They included colitis (n = 3), hepatitis (n = 2), anemia (n = 2), asthenia (n = 1), thyroid disorders (n = 1) and nausea/vomiting (n = 1). Nine pts discontinued the study owing to treatment-related adverse events including colitis (n = 6), hepatitis (n = 2) and DRESS (Drug Rash with Eosinophilia and systemic syndrome) (n = 1). DLT occurred in 2/6 pts in the cohort receiving 15 Gy. No drug-related death occurred. According to irRC, 4 partial responses (ORR: 21%) and 4 stable diseases were observed at week 24. The MTD was 9 Gy dose. One pt out of 12 treated in the 9 Gy cohort presented a DLT (grade 3 colitis). The median progression-free survival [95% CI] was 7.2 months [2.4 – 16.8]. The median overall survival [95% CI] was 14.4 months [7.2 – 20.4]. **Conclusions:** When combined with ipilimumab at 10 mg/kg, in the present design, the MTD of RT was 9 Gy. This combination appears to be associated with antitumor activity. Clinical trial information: 2010-020317-93.

9550 Poster Session (Board #158), Sat, 1:15 PM-4:45 PM

Phase 1b/2, open label, multicenter, study of intratumoral SD-101 in combination with pembrolizumab in anti-PD1 naïve & experienced metastatic melanoma patients. *First Author: Abraham C.F. Leung, Dynavax Technologies, Berkeley, CA*

Background: SD-101 is a synthetic CpG-ODN agonist of TLR 9 that stimulates dendritic cells to release IFN-alpha and mature into antigen presenting cells to activate T cell anti-tumor responses. Pembro is a PD-1 inhibitor approved for the treatment of metastatic melanoma. This study, MEL-01 (NCT02521870), assesses the safety and preliminary efficacy of SD-101 in combination with pembro in stage IIIC-IV melanoma. **Methods:** A modified 3+3 design was used for SD-101 dose escalation of 1, 2, 4, and 8 mg injected in a single tumor lesion Q1W x 4 then Q3W x 7 in combination with pembro (200 mg IV Q3W). Tumor responses were assessed per investigator using RECIST v1.1. **Results:** In phase Ib, 22 pts were enrolled: median age 64 y/o, male 68%, white 82%, Stage IV/IIIc 86%/14%, LDH $>$ 1 ULN 27%, $\geq$ 3 prior lines therapy 36%, anti-PD-1 naïve (n = 9) and experienced (n = 13). There has been no dose limiting toxicity (DLT) to date. The most common ($\geq$20%) treatment-related AEs (TRAEs) were transient low-grade fatigue, myalgia, headache, chills and injection site reactions. Grade $\geq$ 3 TRAEs were observed in 59.1% pts (most common: myalgia 13.6% and injection site pain 13.6%). Immune-related AEs occurred in 2 pts. One had a G2 pneumonitis on Day 23 resulting in drug withdrawal and the other G3 hypophysitis (85 days after last treatment). No deaths occurred. Responses were observed at all doses in PD-1 inhibitor naïve pts, both at the injected and non-injected lesions. A response was seen at the 8 mg dose in PD-1 inhibitor experienced pts. With median f/u of 97 days (max 382), the ORR was 66.7% in the PD-1 inhibitor naïve patients with best overall response of CR 22.2% (n = 2), PR 44.4% (n = 4), SD 11.1% (n = 1), PD 11.1% (n = 1), and NE 11.1% (n = 1). In the PD-1 inhibitor experienced pts: PR 7.7% (n = 1) and SD 38.5% (n = 5). **Conclusions:** The combination of SD-101 and pembro was well tolerated and demonstrates no worsening of the expected toxicities of each of the individual monotherapies. These interim data support enhanced activity of adding SD-101 to pembro in anti-PD-1 naive metastatic melanoma as well as potential activity in anti-PD-1 experienced pts. Additional follow up data through May 15, 2017 will be presented. Clinical trial information: NCT02521870.

9551 Poster Session (Board #159), Sat, 1:15 PM-4:45 PM

Role of time to switch from ipilimumab to anti-PD1 in anti-PD1 efficacy within the French national cohort, MelBase. *First Author: Clara Allayous, Dermatology, Hôpital Saint-Louis, Paris, France*

Background: With increasing armamentarium in advanced melanoma management, the impact of various strategies remains to be determined including the importance of time to switch from one treatment to another. We report the impact of time to IPI/APD non-planned switch on APD efficacy in real life patients within MelBase (MB). **Methods:** MB is a French multicentric biobank dedicated to the prospective follow-up (FU) of unresectable stage III or IV melanoma with 1102 patients included since March 2013. Data were collected (Sept.2016) and analyzed (demography, overall survival (OS), progression-free survival (PFS), response rate, multivariate analysis, safety). **Results:** 71 patients were treated with IPI/APD sequence. 72% received 4 IPI injections. The median time to switch was 1.7 months (0.36-3). The characteristics at the initiation of APD are: mean age 64 yrs, PS 0-1 80%, elevated LDH 34%, BRAF WT 90%, brain metastasis 25%, $\geq$ 3 metastatic organ sites (MOS) 49%, median FU 11.9 months, OS 20 months (95%CI:12.6-NR), PFS 3.5 months (95%CI:2.9-6.2). The best overall response was 25%, disease control rate was 54% with a low toxicity profile (17% grade 3/4). In a multivariable analysis, longer time to switch was significantly associated with better OS (adjusted HR 0.38 per 1 more month, 95%CI:0.14-0.93), as well as ECOG 0-1 (aHR 3.11, 95%CI:0.99-9.72) and LDH $<$ ULN (aHR 3.32, 95% CI:1.26-8.75). In addition, the association of time to switch with OS vary significantly according to the number of MOS ($<$ 3 MOS aHR 0.25, 95%CI: 0.10-0.62; $\geq$3 MOS aHR 0.99 95%CI:0.41-2.39) and AJCC stage (M0/1a/1b aHR 0.06, 95%CI:0.01-0.43 ; M1c aHR 0.77, 95%CI:0.39-1.54). **Conclusions:** In patients who failed IPI treatment, longer survival after APD was associated to time to switch only in patients with favorable baseline factors. Such results are probably more related to the slow kinetics of the disease than to the delay itself. Our results are different from Blank *et al.* (ESMO 2016) who tested a planned switch, immediately after 2 IPI perfusions, and showed overall response rate close to IPI+APD association. We are currently conducting a similar study on the reverse sequence (APD/IPI) and the role on IPI efficacy.

9552 Poster Session (Board #160), Sat, 1:15 PM-4:45 PM

Safety and results of anti-PD1 combined with radiosurgery for the treatment of melanoma brain metastases. *First Author: Caroline Gaudy Marqueste, Dermatology and Skin Cancers Department, UMR911 CRO2 Timone Hospital, Aix-Marseille University, Marseille, France*

Background: Anti-PD1 are now pivotal in the treatment of metastatic melanoma (MM). Some concerns have emerged regarding the risk/benefit ratio of their combination with stereotactic radiosurgery. **Methods:** Retrospective assessment of the interaction between Gamma-Knife radiosurgery (GKRS) and anti-PD1 in terms of toxicity and OS in mm patients (pts) with BM. Patients were included if they were under anti-PD1 (PRE) at time of GKRS, or if they had started anti-PD1 concomitantly with GKRS (CO), or had received anti-PD1 within 3 months after GKRS (POST). **Results:** Among 47 pts who received GKRS and anti-PD1 during their disease course, 35 fulfilled PRE or CO or POST criteria (anti PD1 1st line therapy in 10 pts and 2^{d} or more in 25 pts). One pt died before radiological evaluation. GKRS targeted a single BM in 10 pts and multiple BMs in 24 (max 19 BMs). Out of the 128 BMs treated, 6 cases of increase of preexisting edema (4.7%) and 8 hemorrhages (6.25%) occurred in 12 pts, but only 5 events (5%) were regarded as Adverse Radiation effects (ARE), being symptomatic in 3 pts (8% of pts). One BM had to be resected because of the occurrence of a symptomatic hemorrhage with hemiparesis 9 month after treatment. Median follow- up from GKRS was 13.7 mths. Median overall survival (OS) from GKRS and 1st BM were 14.8 and 26.5 mths respectively, with 6 and 12 mths OS rates from GKRS of 65.7% and 57%, respectively. Local failure was observed in 5 pt. Median time to new BM was 12.6 mths. There was no significant difference in outcomes in pts, depending on PRE, CO and POST conditions. **Conclusions:** In this series, the largest to date of pts with BMs treated by GKRS and anti-PD1,ARE were within the expected range and survival rates appear promising. Given the natural propensity of MM-BMs for bleeding and edema our data do not support an increased risk with the combination of GKRS and anti-PD1. Regarding the timing between anti-PD1 administration and GKRS our data do not support a higher efficacy or higher toxicity among the 3 following potential mechanisms: immuno- sensitization to radiation (PRE), immuno-radio direct synergy (CO) or radiosensitization to immunotherapy (POST).

9553 Poster Session (Board #161), Sat, 1:15 PM-4:45 PM

A phase Ib study of napabucasin plus weekly paclitaxel in patients with advanced melanoma. *First Author: William Jeffery Edenfield, Greenville Health System Cancer Institute, Greenville, SC*

Background: Napabucasin is a first-in-class cancer stemness inhibitor, identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al PNAS 112 (6):1839, 2015). Synergistic anti-tumor activity with paclitaxel was observed in pre-clinical testing, and a favorable clinical safety profile was established in a phase I/II trial in patients (pts) with advanced solid tumors. A phase 1b trial was established to evaluate the safety and preliminary signs of anti-cancer activity of the combination regimen in pts with advanced melanoma. **Methods:** Pts with melanoma were enrolled after failure of standard therapies for advanced disease. Napabucasin 480 or 500 mg orally twice daily was administered with paclitaxel 80 mg/m2 IV weekly for 3 of every 4 weeks. Adverse events were evaluated using CTCAE v4.03 and objective tumor assessments were obtained every 8 weeks and evaluated per RECIST 1.1 criteria. **Results:** A total of 12 pts with advanced melanoma were enrolled after a median 3 prior lines of therapy (including immune checkpoint inhibitors, BRAF-inhibitor if presence of BRAF V600E mutation). Protocol therapy was well tolerated with grade 3 AEs including diarrhea (n = 3), abdominal pain (n = 1), and fatigue (n = 1). Partial response (PR) was observed in 1 pt. Stable disease of at least 24 weeks or more was achieved by 33% of patients (n = 4) and the median progression-free survival (mPFS) was 3.7 months. Prolonged survival of 1 year or more was achieved by 33% of pts (n = 4), with a median overall survival (mOS) of 10.4 months. **Conclusions:** Napabucasin plus weekly paclitaxel has shown clinical safety and encouraging anti-tumor activity in a cohort of pts with previously treated advanced melanoma. The RP2D in combination with weekly paclitaxel was established to 480 mg orally bid. The data suggest that targeting stemness pathways with napabucasin may be a novel therapeutic strategy for melanoma. Clinical trial information: NCT01325441.

9554 Poster Session (Board #162), Sat, 1:15 PM-4:45 PM

The safety and early efficacy of high-dose ipilimumab (IPI) and the combination nivolumab plus ipilimumab (NIVO + IPI) in patients (pts) with uveal melanoma (UM). *First Author: Sapna Pradyuman Patel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: UM metastases occur in 50% of cases and high-risk pts are identified by a gene expression profile. High-dose IPI is approved for adjuvant (adj) treatment (tx) of cutaneous melanoma and NIVO + IPI for metastatic (met) melanoma, yet the safety and efficacy of high-dose IPI or NIVO + IPI has not been established in UM in the adj or met settings. **Methods:** We performed a phase I/II trial of IPI for the tx of high-risk & met UM (CA184-187). The study consisted of two arms: an adj arm (AA) & met arm (MA) with two dose levels, 3 mg/kg & 10 mg/kg. Dose-finding proceeded on each arm in a 3 + 3 fashion. Pts received IPI once every 3 weeks for four doses followed by maintenance IPI every 12 weeks (for up to one year in AA). The AA treated pts with a Class 2 gene expression profile. This score imparts a 3-year distant metastasis-free survival (DMFS) of 50%. The primary endpoint for the AA was maximum tolerated dose (MTD) and improvement in 3-year DMFS to 70%. The primary endpoint for the MA was MTD & overall survival. The study was later amended to include a cohort of UM pts treated with combination NIVO + IPI in the standard FDA approved schedule. **Results:** Ten pts were enrolled on AA, 18 on MA, and 20 on NIVO + IPI. Adverse events (AEs) of any Grade (Gr) related to tx occurred in 80% of pts on AA. Gr 3/4 related toxicities observed in more than one pt were: transaminitis (30%) & pruritus (20%). Of these, 10% of the elevated AST and ALT and 10% of the pruritus occurred during the dose-finding portion of the trial at 3 mg/kg. One pt developed biopsy-proven colitis, and one developed diarrhea. Both were treated with high-dose steroids. One pt developed vasculitis manifesting as temporal arteritis with resultant blindness. AEs of any Gr occurred in 44% of pts on MA. Gr 3/4 toxicities observed in more than one pt were: Fatigue (11%) and Hyperbilirubinemia (11%). Only 1 pt (5.6%) developed Gr 3/4 diarrhea, and this was at the 3 mg/kg dose. In the NIVO + IPI cohort, Gr 3 transaminitis & elevated TSH occurred in 10%. **Conclusions:** High-dose IPI in UM did not demonstrate new or unexpected toxicities. Similarly, the combination of NIVO + IPI was well-tolerated with no new toxicities. Efficacy data will be presented at the meeting. Clinical trial information: NCT01585194.

9555 Poster Session (Board #163), Sat, 1:15 PM-4:45 PM

Survival trends among patients with metastatic melanoma in the United States: A population based study. *First Author: Ranju Kunwor, MacNeal hospital, Berwyn, IL*

Background: Ipilimumab was approved by FDA in March 2011 for the treatment of Metastatic Melanoma. We conducted this study to compare survival outcome in patients with Metastatic Melanoma in pre- (1973-2010) and post- (2011-2013) ipilimumab era in the United States using U.S. Surveillance, Epidemiology, and End Result (SEER) registry database. **Methods:** We selected patients with metastatic melanoma age $\geq$ 20 years from the SEER database. We used SEER 18 registry database to evaluate relative survival (RS) rate during 1973-2010 and 2011-2013. The RS rate at 1year and 2 year were analyzed for cohorts by age (20-49 years, 50-74 and $\geq$75 years), race [White, African American (AA), and others] and gender. The RS rates (%) accompany standard error (SE). We used SEER Stat software for statistical analysis. **Results:** There were a total of 129,362 (106,516 and 22,846 in pre and post ipilimumab era) metastatic melanoma patients, male (n = 71,220), female (n = 58,142), white (n = 121,843), AA (n = 854) other (n = 1,315) reported in the registry. RS in pre vs post-ipilimumab era for age group 20-49 was: 96.50 $\pm$ 0.1% vs 97.20 $\pm$0.3%, P = 0.013; and 94.10 $\pm$ 0.1% to 95.60 $\pm$0.40, P = 0.0009; for age group 50-74 was: 94.10 $\pm$ 0.1% vs 95.30 $\pm$ 0.2%, P = 0.0001; and 90.70 $\pm$ 0.1%vs 92.90 $\pm$ 0.3%, P = 0.0001; and for age group $\geq$75 was 90.80 $\pm$ 0.3% vs 91.40 $\pm$ 0.7%, P = 0.23; and 85.0 $\pm$ 0.4% vs 88.10 $\pm$ 1.0%, P = 0.011 at 1 and 2 years respectively. Overall RS in pre and post ipilimumab era for white population was: 93.83 $\pm$ 0.16% vs 94.567 $\pm$ 0.4%, P = 0.017; and 90.0 $\pm$ 0.2% vs 92.033 $\pm$ 0.6%, P = 0.0008 at 1 and 2 years respectively. Similarly RS for AA was: 78.07 $\pm$ 2.93% vs 73.33 $\pm$ 8.23%, P = 0.37; and 65.87 $\pm$ 3.47% vs 65.33 $\pm$ 9.73%, P = 0.94; and for other race was: 85.2 $\pm$ 2.13% vs 77.97 $\pm$ 5.6%, P = 0.04; and 74.43 $\pm$ 5.2% vs 69.67 $\pm$ 6.7%, P = 0.1 at 1 year and 2 years. **Conclusions:** Our study showed that younger (20-74 years) patients with metastatic melanoma have improvement in 1 and 2-year RS rates in post ipilimumab era. Subgroup analysis by race showed no improvement in RS in AA and other races patients during this period. There was also no significant survival benefit seen in older ($\geq$ 75 years) patients of all races and gender in post ipilimumab era.

9556 Poster Session (Board #164), Sat, 1:15 PM-4:45 PM

Impact of gene expression profiles on clinical predictors of survival in patients (pts) with *BRAF*^{V600}-mutated metastatic melanoma (mM). *First Author: James M. G. Larkin, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Treatment of *BRAF*^{V600}-mutated mm with V and C+V has clinical benefit. Prior analyses established PFS/OS prognostic models in pts with mm based on clinical variables. This exploratory analysis evaluated the impact of immune and cell cycle gene signatures (GS) from baseline mm (Wongchenko et al, *Pigment Cell Melanoma Res*2015;28:822) on survival outcomes and associated prognostic models. **Methods:** Data from all eligible pts with GS data in the BRIM-2, -3, -7, and coBRIM studies were pooled for analysis. The independent effect of GS on PFS/OS outcomes was tested by multivariate Cox proportional hazards models. Recursive partitioning (RP) for censored response variables in a conditional inference framework was performed in the pooled dataset to model relationships between prespecified covariates, GS, and PFS/OS. Prognostic subgroups identified by the model for all pooled pts were applied to pooled treatment cohorts (dacarbazine [D], V, and C+V). **Results:** GS data were available for 608 pts across pooled studies. Immune GS was associated with improved survival vs cell cycle for PFS (HR = 0.75, 95% CI 0.62–0.89, *P*= 0.0015) and OS (HR = 0.74, 95% CI 0.61–0.90, *P*= 0.0024) in multivariate models. HR point estimates were consistent across treatment cohorts. PFS RP models identified baseline LDH, tumor size, and GS as prognostic factors, giving 4 groups with distinct outcomes. GS was not identified as a prognostic factor in OS RP models. C+V improved PFS/OS outcomes vs V across prognostic subgroups. Immune GS was significantly (one-sided Cochran-Armitage trend test) more prevalent in the favorable prognostic groups previously defined for PFS and OS for the V (*P*< 0.0001 for both) and C+V cohorts (*P*= 0.0240 and *P*= 0.0269, respectively), but not the D cohort. **Conclusions:** PFS/OS was significantly improved for pts with immune GS. RP modeling confirmed the importance of GS as an independent prognostic factor for PFS but not OS. The preferential association of immune GS with favorable prognostic subgroups in the C+V and V but not D cohorts and known effects of MAPK signaling on immune response merit further exploration in prospective studies.

9557 Poster Session (Board #165), Sat, 1:15 PM-4:45 PM

Exploratory biomarker analysis in avelumab-treated patients with metastatic Merkel cell carcinoma progressed after chemotherapy. *First Author: Irina Shapiro, EMD Serono, Inc., Billerica, MA*

Background: Merkel cell carcinoma (MCC) is a rare but aggressive skin cancer. Tumor oncogenesis is linked to Merkel cell polyomavirus (MCPyV) integration and UV exposure. PD-L1 is often expressed in MCC tumors, suggesting that patients with MCC could benefit from anti-PD-L1 therapy. Avelumab is a fully human anti-PD-L1 IgG1 monoclonal antibody that has demonstrated clinical efficacy in patients (pts) with metastatic MCC (mMCC) in a Phase 2 trial with an objective response rate (ORR) of 31.8% in the primary analysis. Assessment of candidate predictive biomarkers may help to identify patients with a greater probability of response to avelumab and to improve understanding of MCC biology. **Methods:** Patients in a Phase 2 trial (NCT02155647) with mMCC and tumor progression on prior chemotherapy received avelumab at 10 mg/kg Q2W. PD-L1 expression, MCPyV status and CD8+ T-cell infiltration in pretreatment tumor samples were evaluated by immunohistochemistry (IHC). MCPyV status was also evaluated by real-time PCR. **Results:** Tumor PD-L1 expression was evaluable in 74 of 88 (84.1%) pts with mMCC treated with avelumab, of which 58 (65.9%) and 19 (21.6%) pts were positive at 1% and 5% cut-offs. ORR was 34.5% and 18.8% for PD-L1 positive and negative pts at 1% cutoff, and 52.6% and 23.6% for PD-L1 positive and negative pts at 5% cutoff. MCPyV status was positive in 60% (46/77) pts evaluable by IHC and 63% (45/71) pts evaluable by PCR; of 66 pts tested by both IHC and PCR, concordance was 90.9%. MCPyV+ and MCPyV– pts had similar frequencies of PD-L1+ tumors (80% and 73%) with an ORR of 26.1% and 35.5% respectively. Baseline CD8+ T-cell infiltration was assessed at tumor invasive margin and tumor center in 53 pts, ORR was 44.4% vs 19.2% and 32.1% vs 28% for pts with high or low CD8+ T-cell density at respective locations. **Conclusions:** In an international cohort of pts with mMCC, avelumab had clinical activity among biomarker subgroups analyzed, including PD-L1 expression, MCPyV status and density of CD8+ tumor-infiltrating T-cells. The current biomarkers were not predictive of response but further research into understanding how avelumab mediates anti-tumor activity in MCC may identify novel biomarkers. Clinical trial information: NCT02155647.

9558 Poster Session (Board #166), Sat, 1:15 PM-4:45 PM

Analysis of mutational burden and adaptive immune response in desmoplastic melanomas treated with PD-1/L1 inhibitors. *First Author: Siwen Hu-Lieskovan, UCLA's Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Desmoplastic melanoma (DM) is a rare subtype of melanoma characterized by a dense fibrous stroma, resistance to chemotherapy and no actionable driver mutation for targeted therapy. We investigated the efficacy of PD-1/L1 inhibitors and correlation with genetic landscape and tumor immune microenvironment in DM. **Methods:** Retrospective analysis of 1054 pts with melanoma treated with anti-PD-1/L1, resulting in 57 pts with unresectable or metastatic DM. Available baseline biopsies were analysed by digital quantitative immunohistochemistry (IHC) for CD8 and PD-L1 and by whole exome sequencing (WES), compared to available tissue from non-DM pts treated with anti-PD1/L1 at UCLA. **Results:** At a median follow up of 20 mo, 40 pts (70%, 95% CI 57-82) had an objective response by RECIST 1.1 criteria, including 18 (45%) CRs with no relapse observed to date. Responses were similar in DM subsets (23 pure, 29 mixed and 5 indeterminate). Kaplan-Meier estimated 1-year and 2-year overall survival were 85% (95% CI 78-98) and 74% (95% CI 64-89). WES revealed a median of 1282 (interquartile range 517-1692) non-synonymous somatic mutations per tumor in DM tumors (n = 17), significantly higher (p = 0.02) than the median of 462 (interquartile range 230-1150) in non-DM (n = 23). Mutations in NF-1 were the most common (13/17) followed by loss-of-function TP53 and ARID2, and > 82% of single nucleotide mutations were UV damage signatures. IHC analysis from 19 DM and 13 non-DM revealed a strikingly higher percentage of PD-L1 positive cells in the tumor parenchyma in DM (p = 0.04), highly associated with CD8 density and PD-L1 expression in the tumor invasive margins, indicating an active adaptive immune response. No genetic mechanisms known to cause constitutive PD-L1 expression were detected in these samples. **Conclusions:** Patients with advanced DM derive significant clinical benefit from PD-1/L1 inhibitors, likely related to the high mutational burden and a highly active adaptive immune response as the main mechanism of immune escape prior to therapy. Our results challenge the general conception that dense fibrous stroma around the malignant cells interferes with immune cell infiltration and efficacy of immunotherapy.

9559 Poster Session (Board #167), Sat, 1:15 PM-4:45 PM

Predictive biomarkers of ipilimumab toxicity in metastatic melanoma. *First Author: Michael Gowen, The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY*

Background: There are no predictive biomarkers of ipilimumab (IPI) toxicity. Of metastatic melanoma (MM) patients (pts) receiving IPI (3mg/kg), 35% require systemic therapies to treat immune-related adverse events (irAEs) and 20% must terminate treatment (Horvat et al., JCO 2015). Here we tested the hypothesis that a pre-existing autoantibody (autoAb) profile is predictive of IPI irAEs. **Methods:** We measured autoAb levels in pre- and post-treatment sera from mm pts who received IPI (3mg/kg) monotherapy on a proteome microarray containing ~20,000 unique full-length human proteins (HuProt array, CDI Laboratories). Clinical data were prospectively collected with protocol-driven follow-up. IrAEs were categorized by CTCAE guidelines as none (grade 0), mild (grade 1-2), or severe (grade 3-4). AutoAb levels were standardized using median quantile normalization and considered positive hits if > 2-SD above the peak array signal and differed by ≥2 fold with $p < 0.05$ between toxicity groups (Non-parametric Analysis/Wilcox test). **Results:** Seventy-eight sera from 37 mm pts were analyzed. Antibodies against CTLA-4 were significantly elevated post IPI treatment ($p < 0.0001$), validating the assay. The pre-treatment levels of 190 IgG autoAbs were significantly different in pts who experienced irAEs (n = 28) compared to those with no irAEs (n = 9). Comparison of severe irAE (n = 9) and no irAE (n = 9) groups revealed 129 IgG autoAbs that significantly differed in pre-treatment sera. Localization and pathway analysis (UniProt, KEGG, Reactome) showed 81/190 (43%) of the autoAbs targeted nuclear and mitochondrial antigens and were enriched in metabolic pathways (p = 0.015). AutoAbs associated with irAEs did not correlate with treatment response. **Conclusions:** AutoAbs to antigens enriched in metabolic pathways prior to treatment may predict IPI-induced toxicity in MM. The subcellular localization of targeted antigens could explain the autoimmune toxicities associated with IPI. Studies in larger cohorts and in pts receiving other checkpoint inhibitors and/or combination therapies are essential to determine the validity of the data. If validated, our results would support the discovery of the first toxicity predictor in cancer immunotherapy.

9560 Poster Session (Board #168), Sat, 1:15 PM-4:45 PM

Validation, in silico and in vitro, of a gene-signature based risk score in cutaneous melanoma. *First Author: Georg Brunner, NeraCare GmbH, Bönen, Germany*

Background: Melanoma staging, as defined by the American Joint Committee on Cancer (AJCC), is limited in its ability to predict outcome. We have previously identified and validated a prognostic gene signature expressed in primary cutaneous melanoma and adjacent stroma. The signature comprises seven protective genes (down-regulated with tumor progression) and one risk-associated gene (up-regulated). A signature-based risk score independently predicts patient survival, across AJCC stages IA-IIIC, in formalin-fixed, paraffin-embedded (FFPE) melanomas (training cohort, n = 125; p = 0.0003, hazard ratio 1.85). The score has been validated in 206 melanomas, selected to be significantly mis-prognosticated by AJCC staging regarding patient survival (40.8% mis-prognostication). In this cohort, the score outperforms AJCC staging (p = 0.0005, hazard ratio 1.41 vs. p = n.s.), correcting 34.9% of AJCC-based mis-prognostications. **Methods:** Here, we report twofold external validation of the risk score, (i) prognostic performance *in silico* using the SurvExpress web tool (Aguirre-Gamboa et al., 2013), and (ii) technical performance *in vitro*(Dermatologikum Hamburg; IMGM Munich). **Results:** (i) Kaplan Meier analysis and log-rank testing demonstrated that all signature genes combined predicted survival in four different cohorts of metastatic melanoma (from GEO Expression Omnibus or Cancer Genome Atlas; cohorts dichotomized at the median): see table. (ii) The risk score was re-analyzed in melanomas of the training cohort (n=69). The overall concordance of duplicate determinations was 90% (average scores of 1.12 ± 0.14 and 0.97 ± 0.14). **Conclusions:** In conclusion, we have validated a signature-based FFPE melanoma risk score, complementary to AJCC staging in predicting outcome: (i) Signature genes predicted patient survival *in silico*(n=449) (ii) The risk score proved to be reproducible and technically robust *in vitro.* The score improves risk stratification and decision making in melanoma, particularly regarding new adjuvant therapies.

	TCGA (n=16)	GSE19234 (n=44)	GSE22153 (n=54)	TCGA (n=335)
p (log-rank test)	0.0016	0.0002	0.020	0.0002
HR	15.92	5.36	1.96	1.78

9561 Poster Session (Board #169), Sat, 1:15 PM-4:45 PM

Humanistic burden of disease in earlier stage metastatic (stage IIIb/c-IVM1a) versus late stage metastatic (IVM1b/c) melanoma patients in a real-world setting in the U.S. *First Author: Jacqueline Buchanan, Amgen, San Francisco, CA*

Background: To assess melanoma specific health-related quality of life (HRQoL) and health states in patients with earlier stage metastatic (IIIb/c-IVM1a) versus late stage metastatic (IVM1b/c) melanoma. **Methods:** Data were collected from the Adelphi Real World Advanced Melanoma Disease-Specific Programme, a cross-sectional survey of 112 physicians and their patients (N = 666). Data were collected between March and July 2016 in the US. A subset of 183 patients completed the Functional Assessment of Cancer Therapy Melanoma (FACT-M) and EuroQol-5D (EQ-5D) one time. Patients were classified by stage of melanoma at time of consultation. Descriptive analyses of HRQoL scores between earlier and late stage metastatic melanoma were assessed using Mann-Whitney U tests. **Results:** The mean age of the earlier stage and late stage metastatic patients was 62 and 64 respectively. More earlier stage metastatic patients had an ECOG status of 0 or 1 versus late stage metastatic patients (85%, 75% respectively). A total of 31% of late stage metastatic patients required caregiver support and had a median time since primary diagnosis of 5.0 months whereas earlier stage metastatic patients reported 14% and 5.2 months respectively. Patients with earlier stage metastatic melanoma had better mean EQ-5D index scores versus late stage metastatic melanoma patients (0.81 (n = 84), 0.76 (n = 93); p = 0.0103). Higher scores indicating better HRQoL were observed between earlier stage metastatic versus late stage metastatic melanoma patients for the FACT-M (120.7 (n = 81), 107.4 (n = 91); p = 0.0017) and subscales (except Social Well Being). Clinically meaningful differences between groups using published minimal important differences (MIDs) were observed in in 6/7 FACT-M subscales and EQ-5D VAS. **Conclusions:** Differences in HRQoL and health states were observed between earlier stage metastatic and late stage metastatic melanoma populations, highlighting the detrimental effect of developing metastatic disease. These results suggest that treatments that delay progression of the disease are important to conserve patients HRQoL

9563 Poster Session (Board #171), Sat, 1:15 PM-4:45 PM

Surveillance imaging with FDG-PET/CT in the post-operative follow-up of stage 3 melanoma. *First Author: Louise Sayers, Department of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: With the evolving treatment landscape in metastatic melanoma, approaches to disease surveillance post resection in stage 3 disease requires reconsideration. We previously reported the outcomes of sub-stage-specific schedules of combined fluorodeoxyglucose-positron emission and computerized tomography (PET/CT) surveillance at high risk of relapse following surgery. The aim of this study was to provide an update on our surveillance protocol with an extended sample size and longer duration of follow-up. **Methods:** From 2009, patients with AJCC stage 3 melanoma underwent PET/CT scans according to pre-specified schedules based on Bayesian probabilities of sub-stage-specific relapse. Schedules were stage 3A: 6, 18 mo; stage 3B: 6, 12, 18, 24, 36, 48, 60 months; stage 3C: 6, 12, 18, 24, 36 months. Contingency tables were used to evaluate the sensitivity, specificity and predictive values of these schedules. **Results:** In total, 171 patients (3A: 34; 3B: 93; 3C:44) underwent 553 PET/CT scans with a median follow up of 47 months. Relapses were identified in 65 (38%) patients of which (72%) were asymptomatic at the time of radiologically documented relapse. False positive results occurred in 8%. The positive predictive value (PPV) of an individual scan for diagnosing true recurrence was 77% (64-87%). Negative scans at 6 months had negative predictive values (NPV) between 57% in Stage 3A to 69% in Stage 3B for relapse. Sensitivity and specificity of the overall approach of sub-stage-specific PET/CT surveillance for detecting disease relapse were 70% and 89%, respectively. Evaluable predictive values for detecting disease relapse were: stage 3A: PPV:56%, NPV:76%; 3B: PPV 83%, NPV 86%; stage 3C: PPV 84%, NPV 84%. 32 of 65 patients (49%; 3A: 1; 3B: 7; 3C: 2) underwent resection of relapsed disease and 10 of these patients remained free of disease with a median follow-up of 24 months. **Conclusions:** Sub-stage-specific PET/CT is effective in detecting asymptomatic recurrence in stage 3 melanoma, and is associated with a high rate of disease resection at relapse.

9564 Poster Session (Board #172), Sat, 1:15 PM-4:45 PM

Circulating tumor DNA as a predictor for response to treatment in BRAF V600E mutant malignant melanoma. *First Author: Jan Braune, Department of Hematology and Oncology, University Medical Center, Freiburg, Germany*

Background: Available biomarkers LDH and S100B possess limited sensitivity and specificity to predict outcome in melanoma. In this pilot study we evaluated the use of circulating tumor (ct)DNA harboring BRAF and NRAS mutations as a predictive biomarker for treatment response and progression-free survival (PFS) in patients with locally advanced or metastatic melanoma. **Methods:** We analyzed 89 retrospective plasma samples from 32 unselected pts, and 158 samples from 12 pts included in a prospective trial (DRKS00009507). We included stage III disease with planned resection or stage IV disease before initiation or change of medical treatment. Blood samples were taken at baseline at d +8, d +28, and thereafter at 3 months intervals for up to two years. We developed a hydrolysis probe based, Locked Nucleic Acid assay to detect BRAF V600E and wild type ctDNA by droplet digital PCR. Results were correlated with LDH, S100B and PFS. **Results:** Sensitivity of BRAF V600E specific assay was 0.01% with a limit of Blank of 0.28 copies/well. Of 31 stage IV pts with retrospective samples, 23 were positive for BRAF V600E ctDNA at least once (74%). Positive pts had a mean of 9 (range: 1-17) and 483 (range: 0.1-16,388) BRAF V600E copies/mL for stage III and stage IV respectively. The presence of ctDNA at baseline predicted poor PFS (hazard ratio [HR] 1.487, 95% CI 0.34-6.45). A negative slope in BRAF V600E ctDNA was a favorable prognostic factor for PFS (hazard ratio [HR] 0.230, 95% CI 0.04-1.20) with a median PFS of 3.42 vs. 2.56 months (Range 1.87-8.9 vs. 0.89-5.02). Residual ctDNA at the first time point after initiation or change of treatment was related to a shorter PFS (hazard ratio [HR] 2.02, 95% CI 0.39-10.53). Based on 144 measurement pairs, BRAF ctDNA strongly correlated with S100 (r = 0.73) and LDH (r = 0.52). **Conclusions:** Residual ctDNA early after change or institution of treatment predicted tumor progression at first clinical response assessment. A positive to negative conversion or a decrease indicated a more favorable course. These data support the use of ctDNA as an early predictive marker for treatment response. We will examine whether two or more detected mutations indicate clonal heterogeneity and confer adverse prognosis. Clinical trial information: DRKS00009507.

9565 Poster Session (Board #173), Sat, 1:15 PM-4:45 PM

Evaluation of the Melanoma Tumor Burden Score (MTBS) in a real-world setting. *First Author: Michael Weichenthal, University Department of Dermatology, Kiel, Germany*

Background: Clinical cancer registration is increasingly important for healthcare delivery and outcome research in oncology. As compared to clinical trial data, information from clinical routine is often limited regarding the granularity and quality of measures for individual tumor load and distribution. **Methods:** In an effort to implement a robust and useful measure of tumor burden for patients with metastatic melanoma in a German national skin cancer registry (ADOReg) we evaluated the melanoma tumor burden score (MTBS), originally developed for analyzing chemotherapy data in melanoma patients. The MTBS contains a simple categorization of size, number an distribution of metastatic lesions in individual patients. It is aimed at being used on routine radiologic report allowing for a certain level of uncertainty and imprecise quantification of metastatic lesions. Basically, the lesions are categorized per affected organ with respect to number (solitary, few, multiple) and size (≤1cm, >1- 5cm, >5cm). For evaluation of prognostic significance the summary score was calculated and included in univariate and multivariate survival analysis. We performed extensive sensitivity analyses for a variety of different model settings. **Results:** In the primary analysis set we re-evaluated 898 radiologic reports in a total of 235 various chemotherapies in n=128 stage IV melanoma patients. The confirmatory data sets consisted of n=384 stage IV melanoma patients with various treatments including chemotherapy, BRAF inhibitor treatment, and immune checkpoint blockade. MTBS categorization could be applied on routine radiologic reports in the majority of cases (95.7 %). In a multivariate model MTBS remained significantly correlated with outcome when adjusted for age, sex, LDH, and number of metastatic sites. Moreover, change in MTBS correlated to a formal response evaluation according to RECIST. **Conclusions:** The MTBS appears to be a promising tool for meaninful quantification of metastatic tumor load in metastatic melanoma for real life data collection like in clinical cancer registries.

MTBS	n	PFS [months]	95%-CI	OS [months]	95%-CI
1-9	81	3.6	3.1 - 4.9	20.2	15.5 - 25.7
10-19	96	2.5	2.3 - 2.7	9.5	7.7 - 11.3
>19	59	2.2	1.9 - 2.5	4.7	3.7 - 6.2

9566 Poster Session (Board #174), Sat, 1:15 PM-4:45 PM

Clinical presentation of immune-related colitis associated with PD-1 inhibitor monotherapy (MONO) and combination PD-1/CTLA-4 inhibitors (COMBO) in melanoma. *First Author: Daniel Ying Wang, Vanderbilt University Ingram Cancer Center, Nashville, TN*

Background: Ipilimumab-related colitis has been well described, but the clinical presentation of colitis related to MONO or COMBO therapy has not. We aimed to characterize clinical features that define this serious adverse event. **Methods:** This retrospective study included melanoma pts with colitis screened from 6 academic centers treated with either MONO or COMBO therapy. Clinically relevant colitis was defined as diarrhea/colitis symptoms requiring systemic steroids. The onset, management, and outcomes related to colitis were summarized. **Results:** We screened 866 pts and identified 72 with clinically relevant colitis. For the MONO cohort, the incidence was 3.5% (23/657) and 23.4% (49/209) in the COMBO cohort. MONO-colitis occurred at a median 33 weeks (wks) into therapy, while median onset was 8 wks with COMBO therapy. One pt had grade 5 colitis from COMBO therapy. Despite the use of systemic steroids, COMBO-colitis needed more infliximab therapy (38.8% vs 26.1%). The median prednisone equivalent dose was higher for COMBO therapy (1.5 vs 1 mg/kg), and the median taper was shorter for MONO-colitis (4 vs 6 wks). Steroid dose-escalation for worsening symptoms during taper was more common with COMBO-colitis (42.9% vs 17.3%). Relapse was similar between cohorts (MONO: 26.1%, COMBO: 20.4%). Relapses occurred more frequently in COMBO therapy with tapers shorter than the median (38.1% vs 25.0%), and more frequently in MONO therapy with steroid doses lower than the median (60% vs 21.7%). MONO-colitis pts (17.4%) were less likely than COMBO-colitis pts (46.9%) to be restarted on PD-1 therapy. When restarted, only 13% with COMBO therapy relapsed as compared to 50% with MONO therapy. Objective response rates for MONO and COMBO cohorts were 72.7% and 56.1%, respectively. **Conclusions:** Colitis occurred with a much higher incidence in COMBO therapy. MONO-colitis was associated with a milder course with later onset, shorter duration and lower dose of steroids, fewer dose-escalations, and need for infliximab as compared to COMBO therapy. Relapse of colitis was generally associated with shorter steroid tapers for COMBO therapy and lower steroid doses for MONO therapy.

9567 Poster Session (Board #175), Sat, 1:15 PM-4:45 PM

Mutation burden as a potential prognostic marker of melanoma progression and survival. *First Author: Danny Simpson, New York University Medical Center, New York, NY*

Background: Recently, tumor mutation burden (TMB) has been shown to increase the presentation of neoantigens that stimulate immune tumor recognition, resulting in improved immunotherapy (IT) outcomes in melanoma and other cancers. As melanoma is highly immunogenic, here we tested whether TMB associates with immune recognition during tumor progression, hence impacting melanoma overall survival (OS), independently of IT treatment. **Methods:** We have generated somatic mutation data from 314 IT-naive metastatic melanomas from The Cancer Genome Atlas (TCGA). In the TCGA cohort, TMB has been calculated for 210 genes (200GS) previously established from TMB studies of anti-CTLA4 and anti-PD1/PD-L1 IT. For validation, we have sequenced exonic regions of 20 genes (20GS) with the highest TMB among 200GS in 89 IT-naive metastatic melanomas ascertained at New York University Langone Medical Center. The TMB was defined using total number of somatic, non-synonymous mutations in either 200GS (TCGA discovery) or 20GS (validation), respectively. For discovery and validation cohorts, OS from primary diagnosis of samples with high TMB was compared against low TMB, using thresholds established in previous studies. **Results:** We found that total TMB predicts better OS ($p = 0.03$, HR = 2.64) in TCGA melanomas. Restricting the analysis only to the established 200GS, this association became more significant in all patients ($p = 0.01$, HR = 2.67) as well as in patients without IT ($p = 0.01$, HR = 2.67). In the validation stage of 89 melanomas without prior IT treatment, a high TMB in a subset of 20GS accurately determined favorable OS ($p = 0.02$, HR = 2.69) and confirmed TCGA observations from the 200GS. **Conclusions:** Here we show, for the first time, that in addition to IT, high TMB predicts more favorable OS in patients that never received IT, potentially serving as a novel marker of prognosis of melanoma and likely other immunogenic tumors at early stages. In addition, our study suggests that TMB test can be robust when applied to only a small subset of genes that trigger significantly higher immunogenicity. This may also eventually assist with accurate sub-selection of early stage patients likely to respond to IT regimens.

9568 Poster Session (Board #176), Sat, 1:15 PM-4:45 PM

Clinicopathologic features and survival in immunocompromised vs. immunocompetent patients with Merkel cell carcinoma: An exploratory analysis of a series of consecutive patients. *First Author: Michael Del Rosario, Eisenhower Medical Center, Rancho Mirage, CA*

Background: Clinicopathologic characteristics and outcomes between immunocompromised and immunocompetent Merkel cell carcinoma (MCC) patients may differ. **Methods:** With approval of IRB, we conducted retrospective analysis in 40 consecutive patients with MCC treated at our institution in 2006-2016. 10 patients were immunocompromised and 30 immunocompetent. Immunosuppressed patients included patients with organ transplantation (n = 3), chronic lympocytic leukemia (n = 2), metastatic skin cancer post chemotherapy (n = 1), rheumatoid arthritis on azathioprine (n = 1), myasthenia gravis on mycophenolate mofetil (n = 1), follicular lymphoma post chemotherapy (n = 1) and human immunodeficiency virus infection (n = 1). Clinicopathologic features, therapy and survival were compared between two cohorts. Significance of associations was assessed via Fishers' exact test. Survival analysis was performed via Cox proportional model and 95% confidence intervals (CI). **Results:** Compared to immunocompetent MCC patients, the immunocompromised had an absolute male predominance (100% vs. 67%; $p < 0.01$), more TNM stage III disease (40% vs. 33%; $p = 0.021$) but less lymphovascular invasion (30% vs. 7%; $p < 0.01$). They received more chemotherapy (50% vs. 30%; $p < 0.01$) and radiation therapy (80% vs 57%; $p < 0.01$). Survival was worse in immunocompromised subjects (average time to death 290.13 days vs. 618.2 days ($p < 0.001$), and they were 5 times more likely to die (RR = 5.01, 95% CI = 1.49-16.86). **Conclusions:** Immunocompromised MCC patients displayed significantly shorter survival than their immunocompetent counterparts. They were all male, with more advanced disease but less lymphovascular invasion. They received more chemo- and radiotherapy presumably due to a more advanced stage. As our study is limited by sample size, larger studies are needed to confirm the significance of our findings.

9569 Poster Session (Board #177), Sat, 1:15 PM-4:45 PM

Multivariate analysis of prognostic factors among 706 mucosal melanoma patients. *First Author: Bin Lian, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Mucosal melanoma is rare and associated with extremely poor prognosis. Little is known about its outcome and prognostic analysis. In this study, we evaluated prognostic factors among mucosal melanomas. **Methods:** The survival rates, Relapse Free Survival (RFS), Overall Survival (OS) and prognostic factors were compared for 706 mucosal melanomas at different anatomical sites. **Results:** Mucosal melanoma from nasal pharyngeal and oral (268 pts), upper and lower gastrointestinal (GI) (221 pts), gynecological and urological (196 pts) had a similar survival with a 1-y survival rate (88%, 83%, 86%), 2-y survival rate (66%, 57%, 61%), 5-y survival rate (27%, 16%, 20%), respectively. Multivariate analysis revealed that Depth of Invasion ($p < 0.001$), Lymph node metastases ($p < 0.001$), Distant metastases ($p < 0.001$) were three independent prognostic factors for OS among 706 pts. Anatomical site ($p = 0.031$), Depth of Invasion ($p < 0.001$), Lymph node metastases ($p < 0.001$) were three independent prognostic factors for RFS among 543 pts. KPS status, Depth of Invasion, Lymph node metastases, Distant metastases were independent factors for OS among nasal pharyngeal and oral pts. Depth of Invasion, Lymph node metastases, CKIT Mutation were independent factors for RFS among nasal pharyngeal and oral pts. Gender, Lymph node metastases, Distant metastases were independent factors for OS among GI pts. Gender, Depth of Invasion, Lymph node metastases were independent factors for RFS among GI pts. Lymph node metastases, Distant metastases were independent factors for OS among Gynecological and Urological pts. Depth of Invasion, Lymph node metastases were independent factors for RFS among Gynecological and Urological pts. **Conclusions:** This is the first prognostic analysis for mucosal melanoma with the largest sample size for the first time. with few exceptions, It revealed that Depth of Invasion, Lymph node metastases, Distant metastases were independent prognostic factors for OS, Depth of Invasion and Lymph node metastases were independent prognostic factors for RFS. These results should be incorporated into the establishment of stage system and design of future clinical trials involving patients with mucosal melanoma.

9570 Poster Session (Board #178), Sat, 1:15 PM-4:45 PM

Investigation of the immune infiltrate of melanoma metastases under immune checkpoint inhibition. *First Author: Jessica Cecile Hassel, University Hospital Heidelberg, Heidelberg, Germany*

Background: Tumor infiltrating lymphocytes (TIL) play a crucial role in the therapeutic impact of immune checkpoint blockers. **Methods:** We investigated metastases from 56 melanoma patients before and during treatment with immune checkpoint blockers (i) immunohistochemically, (ii) with TCR repertoire profiling and (iii) analysis of the transcriptome. The patients were treated with ipilimumab (n = 25) or pembrolizumab (n = 23) or ipilimumab/nivolumab (n = 7); half of them had a disease control, the other half progressed as best response to treatment. **Results:** In contrast to previous reports immunohistochemical analysis of the immune infiltrate revealed no significant difference in the number of CD8+ TILs in pretreatment samples of responders and non-responders. Instead, the number of CD4 + TILs including regulatory T cells (Treg) and the number of PD-1 + cells was higher in responders especially when receiving pembrolizumab. Samples taken at least 6 weeks after start of the immune checkpoint blocker showed a significant higher number of immune cells in responders through all T cell subsets (CD3,4,8,FoxP3, PD-1), B cells (CD20) as well as macrophages (CD68, CD163). TCR repertoire profiling by deep TCR sequencing demonstrated that responders develop a more diverse repertoire under treatment ($p = 0.05$). Pretreatment samples as well as the size of the top 10 TCR clones posttreatment did not differ significantly in responders and non-responders. By RNA sequencing no differential expression profiles between responders and non-responders was found pretreatment. Posttreatment samples expressed different genes compared to pretreatment samples in responders including MHC molecules, CDK2/4, Myc, TNF family members and different apoptosis-inducing genes. There was no differential gene expression in non-responders pre- and posttreatment. **Conclusions:** Pretreatment metastases from responders and non-responders do not differ much. With treatment responding patients have significant higher numbers of immune cells including T- and B- cells as well as macrophages and develop a more diverse TCR repertoire. RNA sequencing revealed a differential expression pre- versus posttreatment only in responding patients.

Exploratory analysis of multiprotein serum predictors at baseline of progression-free survival of ipilimumab or ipilimumab and nivolumab in the Checkmate-069 study. *First Author: Krisztian Homicsko, University Hospital Lausanne, CHUV, Lausanne, Switzerland*

Background: Checkpoint inhibitors have revolutionized the treatment of stage IV melanoma patients. Selection of patients for PD-1 monotherapy or CTLA4/PD1 combination remains an important challenge. We set out to perform a discovery study of pretreatment serum protein biomarkers to identify predictors of progression free survival (PFS) for ipilimumab (IPI) or ipilimumab/nivolumab (IPI/NIVO)**. Methods:** We performed an exploratory analysis of baseline serum samples from 135 treatment-naive patients with metastatic melanoma included in the randomized phase II clinical trial, CheckMate 069 (NCT01927419). We used the RayBiotech 440 human cytokine array and evaluated the relationship of serum protein levels with 44 clinical parameters. R, Prism 7.0 and TensorFlow were used for analyses. **Results:** We focused on correlation of serum protein markers with PFS as a predictor of long-term benefit. In the IPI arm ($n = 46$), high FGF4 correlated with worse PFS outcome ($p = 0.0012$). However, FGF4 levels alone were unable to select responsive vs. non-responsive patients. In contrast, a set of three markers consisting of FGF4 ($<$ 760pg/ml), CCL15 ($>$ 2.7 ng/ml), and TACE ($>$ 600pg/ml) separated non-progressing versus progressing patients. Moreover a small group of FGF4-high patients who were concomitantly TIM-3-low also had longer PFS (combined of both: $p = 0.0004$, $HR_{logrank}$: 0.07, 95% CI: 0.03279 to 0.1533). The same markers did not discriminate between IPI/NIVO patients ($p = 0.467$, HR: 15). In the IPI/NIVO arm, three different markers could select patients. Patients either with low CCL2 ($<$ 72 pg/ml) or alternatively with high CCL2 combined with high PDGF-AA ($>$ 8.2 ng/ml) and low GASP-1 ($<$ 1.3 ng/ml) had longer PFS ($p < 0.0001$, HR: 0.115, 95% CI: 0.03848 to 0.3408). Conversely, these markers did not predict benefit for IPI-monotherapy. **Conclusions:** In this study we identified protein signatures in baseline serum that correlate with PFS for therapies with IPI or IPI/NIVO. The markers were exclusive for IPI or IPI/NIVO but not for both. Additional research is warranted to substantiate these results and evaluate the possibility of incorporating into clinical practice.

9572 Poster Session (Board #180), Sat, 1:15 PM-4:45 PM

Correlation between baseline parameters and overall survival in patients with advanced melanoma treated with ipilimumab. *First Author: Marnix Heimen Geukes Foppen, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Checkpoint inhibitors (IT) have revolutionized treatment options for patients (pts) with advanced melanoma. Recently, we proposed a framework of 7 parameters (PM) describing requirements for a sufficient anti-tumor immune response (the "cancer immunogram"). In a first analysis we tested pts from our ipi cohort for outcome. Using this framework pts benefitting the most from treatment with ipi might be selected upfront, and in the future also from other checkpoint inhibitors. **Methods:** Using Kaplan-Meier- and Cox-regression-analysis correlations between 6 of these PM at baseline and overall survival (OS) were investigated in a single center cohort of pts treated with 3 mg/kg ipi for metastatic melanoma. Results of the 7thPM are currently being finalized. **Results:** PM assessed were: LDH ($\leq$ULN vs $>$ ULN), erythrocyte sedimentation rate (ESR,$\leq$ULN vs $>$ ULN), absolute lymphocyte count (ALC, $<$ 1000/mm^3 vs $\geq$1000/mm^3) and IHC on tumor material for CD8+ T-cell infiltration ($<$ median vs $\geq$median), PD-L1 expression ($<$ 1% vs $\geq$1% positive cells) and MHC-class I expression (loss vs weak/positive). We analyzed 179 pts treated with ipi between 2010 and 2013. Median age was 55 years (19–88) and 61% of pts were male. Minimum follow-up of pts alive was 42 months(mo). Data were available as follows:177 cases LDH, 159 ALC/ESR, 118 PD-L1, 99 CD8 and 68 MHC-class I. Median OS was 7.1 mo. In univariable analysis LDH (HR 2.5, 95%CI 1.8-3.5), ALC (HR 1.6, 95%CI 1.1-2.4), ESR (HR 2.4, 95%CI 1.5-3.8) and CD8 (HR 1.8 95%CI 1.2-2.8) were significant for OS ($p < 0.01$). Pts with all 4 favorable PM had a median OS of 25.1mo(95%NR), pts with 3 PM 15.8 mo(95%CI 7.0-24.7), 2 PM 8.1 mo (95%CI 1.0-15.3), 1 PM 4.8 mo(95%CI 3.3-6.3) and no favorable PM 1.7 mo (95%CI 0–4.9). In multivariable analysis LDH(HR 2.4,95%CI 1.5-4.0) and CD8(HR 1.7,95%CI 1.1-2.8) were the only independent PM. Pts with a normal LDH and high CD8 had a median OS of 15.8 mo(95%CI 9.5-22.2) vs 3.8 mo (95%CI 1.8-5.7) for pts that did not ($p < 0.01$). **Conclusions:** In conclusion, low values of baseline LDH and high values of CD8 are the strongest PM associated with a favorable outcome in pts with advanced melanoma, treated with ipi. The other PM added low effect on the pts outcome upon ipi.

9573 Poster Session (Board #181), Sat, 1:15 PM-4:45 PM

Interim analysis of survival outcomes in a prospective cohort evaluating a prognostic 31-gene expression profile (GEP) test for melanoma. *First Author: Eddy C. Hsueh, Saint Louis University, St. Louis, MO*

Background: DecisionDx-Melanoma has been validated as an accurate prognosticator of cutaneous melanoma (CM) metastasis risk. The GEP test classifies CM pts as Class 1 (low risk) or Class 2 (high risk). Interim survival analysis from two clinical registry studies (NCT02355574/NCT02355587) designed to prospectively evaluate outcomes in pts for whom the GEP test was performed is described. **Methods:** Eleven US dermatologic and surgical centers participated in the IRB-approved protocols. Physicians enrolled CM pts who were ≥16 years old and had successful GEP test results. Endpoints of recurrence-free (RFS), distant metastasis-free (DMFS) and melanoma-specific survival (MSS) were assessed using Kaplan-Meier and Cox regression analysis. As an interim analysis at year 3 of an expected 5-year study, the critical alpha level (p-value) was 0.01. **Results:** At the time of data extraction, 322 pts were accrued and completed at least one follow-up visit. Median age was 58 years (range 18-87), median Breslow thickness (BT) was 1.2mm, 55% were male, 20% (58/296) were ulcerated, and 15% (36/237 biopsied) had a positive sentinel lymph node (SLN). Median follow-up time was 1.5 years for pts without a recurrence. Of 25 recurrent cases, 80% (20/25) were Class 2 and 40% (10/25) were SLN-positive. Two percent of Class 1 pts had a recurrence compared to 6% (12/201 biopsied) of SLN-negative pts. Of the SLN-negative pts who recurred, 75% (9/12) were called Class 2. Combined GEP and SLN risk prediction identified 88% (21/24) of recurrences. Kaplan-Meier event rates for each class are shown in the table. In Cox multivariate analysis, BT and GEP Class 2 were significant predictors of recurrence ($p<0.01$ for each). **Conclusions:** Results of this analysis show that the GEP test provides prognostic information that complements conventional staging and significantly enhances identification of high risk CM pts, consistent with reported validation studies.The results support use of the test for guiding surveillance decisions and enrollment of CM pts in clinical trials. Clinical trial information: NCT02355574, NCT02355587.

Clinical outcome rates at 1.5 years in prospective cohort.

	RFS	DMFS	MSS
Class 1 (n=259)	97%	99%	99%
Class 2 (n=76)	77%	89%	92%

$p<0.001$ for each endpoint

9574 Poster Session (Board #182), Sat, 1:15 PM-4:45 PM

Prognostic factors for overall survival (OS) in metastatic melanoma (MM) patients (pts) treated with immune checkpoint inhibitors: A single institution study of 696 pts. *First Author: Meredith Ann McKean, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Limited OS data, including prognostic and predictive factors of response, is available in mm pts treated with immune checkpoint inhibitors. **Methods:** A single-institution retrospective review was conducted on 696 mm pts treated with single-agent anti CTLA-4 or anti PD-1 on and off clinical trial between 2011-2015. Median OS was calculated from mm diagnosis. **Results:** Median age at mm diagnosis was 60 years old (range 15-86) and 65.2% were male. Subtypes were 63.2% non-acral cutaneous, 17.2% unknown primary, 7.8% mucosal, 6.5% acral, and 5.3% uveal. AJCC v7 staging at diagnosis was 7.9% M1a, 16.5% M1b, 33.0% M1c, and 42.5% not staged due to unknown LDH. LDH was elevated in 18.0% (400 pts). Mutation rates were 30.0% BRAF V600E/K (636 pts tested) and 24.5% NRAS (429 pts tested). First-line therapy for BRAF V600E/K mm pts included anti CTLA-4 (24.1%), BRAF/MEK targeted therapy (21.5%) and anti PD-1 (8.9%). First-line therapy for BRAF WT mm pts included anti CTLA-4 (28.1%) and anti PD-1 (12.8%). Median OS from mm for the cohort was 36.5 months (95% CI 33.3-44.9). Elevated LDH and staging correlated with OS ($p < 0.001$, $p < 0.001$, respectively) on univariate analysis. Age, gender, subtype and mutation status were not significantly associated with OS. Compared to BRAF WT, pts with BRAF V600E/K mutation were younger (median = 53 vs 62 yrs, $p < 0.001$), more likely to have non-acral cutaneous mm (83.2% vs 58.0%, $p < 0.001$) and have a diagnosis of brain metastasis during the disease course (57.0% vs 28.8%, $p < 0.001$). While adjusting for stage, there was no significant difference in OS based on first or second line therapy in pts with BRAF V600E/K mm or first line therapy in BRAF WT MM; however, BRAF WT pts treated second line with anti-PD1 were observed to have improved OS compared with pts receiving anti-CTLA 4 (HR 0.43 95% CI:0.23-0.84 p = 0.012). **Conclusions:** This study demonstrates that LDH and stage are prognostic of OS in all mm pts treated with single agent immune therapy. Second line therapy in BRAF WT pts treated with single agent immune therapy is also prognostic of OS thus prompting further investigation to determine advantageous therapy sequencing in MM.

9575 Poster Session (Board #183), Sat, 1:15 PM-4:45 PM

Multidimensional spatial characterization of the tumor microenvironment (TME) in synchronous melanoma metastases (SMM) to yield insights into mixed responses to therapy in metastatic melanoma (MM) patients (pts). *First Author: Alexandre Reuben, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although both targeted and immune therapies have significantly improved outcomes for mm pts, only a minority of pts experience durable responses with many pts with multiple SMM demonstrating differential responses to therapy. We performed multidimensional spatial characterization of immune markers in SMM from mm patients treated with targeted and immune therapies to improve our understanding of correlations and determinants of response. **Methods:** NanoString's Digital Spatial Profiling research platform was used on 6 SMM from 3 pts (treatment-naïve; BRAF + MEK targeted therapy treated; anti-PD-1 immunotherapy treated) for 30 immune and signaling proteins. For analysis, we selected and compared immune-rich (CD45+) and tumor-rich (S100B+) regions across SMM. Results were compared to lesion-specific clinical responses. **Results:** Striking differences in patterns of expression across SMM from individual pts were detected, including in Ki67, CD68 myeloid cells, and the potent immunosuppressor B7-H3. SMM progressing after targeted therapy demonstrated higher pAKT and PD-L1 expression, consistent with described resistance mechanisms. Large differences in expression of PD-L1 were noted following anti-PD-1 therapy, which could contribute to heterogeneous responses. Differential expression patterns in the TME associated with response were also detected, including in increases in CD4 and CD14 cells in progressing lesions. **Conclusions:** Striking differences in responding and non-responding SMM were observed, providing potential explanations for the heterogeneous clinical responses frequently observed in mm pts. Studies are ongoing to further characterize interactions and spatial distribution of cell types, as well as integrate these findings with previous molecular and immune profiling data (whole exome sequencing, gene expression profiling, flow cytometry, IHC, TCR sequencing) in these and additional SMM to identify actionable strategies to homogenize responses across metastases in mm pts.

9576 Poster Session (Board #184), Sat, 1:15 PM-4:45 PM

Performance of a 31-gene expression profile (GEP) test for metastatic risk prediction in cutaneous melanomas (CM) of the head and neck. *First Author: John T. Vetto, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: Accurate prognostication of distant metastatic risk using sentinel lymph node (SLN) biopsy for CM can be challenging in melanomas of the head and neck due to a higher false negative rate compared to other anatomical areas. A GEP signature that predicts metastatic risk based on primary tumor biology, providing a binary outcome of Class 1 (low risk of metastasis) or Class 2 (high risk), was previously described. The prognostic capabilities of the GEP independently and in combination with SLN status in a cohort of patients with primary head and neck CM are assessed here. **Methods:** All samples and clinical data were collected under an IRB-approved multicenter protocol. qPCR analysis was used to assess expression of the gene signature (Class 1 vs. Class 2). Distant metastasis-free survival (DMFS) and melanoma-specific survival (MSS) were assessed. **Results:** 157 subjects with primary CMs in the head and neck region were identified. 110 of 157 subjects had a SLN biopsy performed. Median age was 65 years (range 25-89) and median Breslow depth was 1.6 mm (range 0.2-15.0 mm). In 71 SLN-negative patients, 18 of 27 (67%) distant metastatic events were GEP Class 2. Overall, 73% (47 of 64) distant metastases, and 88% (22 of 25) deaths due to CM were called Class 2. By comparison, sensitivities for DMFS and MSS were 41% (26 of 64) and 52% (13 of 25), respectively, using SLN biopsy alone, and increased to 80% (51 of 64) and 88% (22 of 25), respectively, when combining the SLN status and GEP class. Kaplan-Meier 5-year DMFS and MSS rates based on SLN status alone or in combination with GEP are shown in the table. **Conclusions:** These data support the ability of the GEP test to accurately identify low- and high-risk cases of head and neck melanoma. The results strongly support the role of GEP testing to enhance current staging by better predicting the risk of distant metastasis and death for patients with melanoma in an anatomic region that is associated with a higher SLN biopsy false negative rate.

	5-year DMFS	5-year MSS
SLN– (n = 71)	64%	88%
SLN+ (n = 39)	28%	61%
Class 1 (n = 79)	81%	96%
Class 2 (n = 78)	37%	68%
Class 1/SLN- (n = 41)	80%	92%
Class 1/SLN+ (n = 7)	43%	100%
Class 2/SLN- (n = 30)	42%	82%
Class 2/SLN+ (n = 32)	24%	50%

9577 Poster Session (Board #185), Sat, 1:15 PM-4:45 PM

Primary melanoma histologic subtype (HS) impacts melanoma specific survival (MSS) and response to systemic therapy. *First Author: Michael Lattanzi, Department of Medicine, New York University School of Medicine, New York, NY*

Background: Unlike other solid tumors, the impact of primary HS on melanoma survival and response to systemic therapy is not well studied. Nodular melanoma (NM) has a worse prognosis than superficial spreading melanoma (SSM), which is usually attributed to thicker primary tumors. Herein, we examine the hypothesis that HS might have an impact on MSS independent of thickness and that NM and SSM exhibit different mutational landscapes that associate with response to checkpoint inhibitor immunotherapy (IT) and BRAF targeted therapy (TT) in the metastatic setting. **Methods:** Primary NM and SSM patients prospectively enrolled at NYU (2002 - 2016) were compared to the most recent SEER cohort (1973 - 2012) and analyzed with respect to MSS. Next-Generation Sequencing (NGS) was performed on a subset of matched tumor-germline pairs, allowing a comparison of the mutational landscape between NM and SSM. In the metastatic setting, survival analyses were used to compare outcomes and responses to treatment across HS. **Results:** The NYU cohort of 1,621 patients with either NM (n = 510) or SSM (n = 1,111) was representative of the analogous SEER cohort (21,339 NM, 97,169 SSM), with NM presenting as thicker, more ulcerated, and later stage (all $p < 0.001$). Among the NYU cohort, NM was found to have lower rates of TIL ($p = 0.047$), higher mitotic index ($p < 0.001$), and higher rates of NRAS mutation ($p < 0.001$). In multivariate Cox models, NM was a significant predictor of worse MSS, independent of thickness and stage ($p = 0.01$). NM had a significantly lower mutational burden across the exome ($p < 0.001$). Some of the most under-mutated genes noted in NM were NOTCH4, BCL2L12 and RPS6KA6 (all $p < 0.01$). Among patients treated with TT (n = 56), NM remained a significant predictor of worse MSS ($p = 0.004$). However, there was no difference in response to IT. **Conclusions:** NM and SSM show divergent mutational patterns which may contribute to their different clinical behaviors and responses to BRAF targeted therapy. More studies are needed to better understand the key molecular and cellular processes driving such differences. Integration of HS data into prospective clinical trial reporting is needed to better assess its impact on response to treatment.

9578 Poster Session (Board #186), Sat, 1:15 PM-4:45 PM

Performance of a prognostic 31-gene expression profile test in stage III cutaneous melanoma subjects. *First Author: Martin D. Fleming, University of Tennessee Health Sciences Center, Memphis, TN*

Background: The management of stage III cutaneous melanoma (CM) patients has changed significantly with the introduction of contemporary therapies. A 31-gene expression profile (GEP) test that provides a prediction of low or high risk of melanoma metastasis has been validated as an independent prognosticator of distant metastasis-free (DMFS) and melanoma-specific survival (MSS). We examine the prognostic accuracy of the test in a cohort of stage III, and particularly stage IIIA, subjects from a multicenter validation study. **Methods:** 207 primary CM tumors from 16 centers were analyzed as part of an IRB-approved study. Quantitative RT-PCR and predictive modeling were performed to classify metastasis and survival risk as Class 1 (low risk) or Class 2 (high risk). Results for Kaplan-Meier and Cox regression survival analysis are reported. **Results:** Of the 207 subjects with stage III melanoma, 76 were stage IIIA. The table shows 5-year DMFS and MSS rates for all stage III and stage IIIA groups. Patients with Class 2 GEP had significantly worse outcomes compared to Class 1. In univariate analyses, GEP was a significant predictor of DMFS and MSS with a hazard ratio for DMFS of 2.8 (95%-CI; 1.7-4.6) and for MSS of 4.0 (95%-CI; 1.7-9.4) for all stage III, while HR of 2.2 for DMFS (95%-CI; 1.0-4.7) and 4.3 for MSS (95%-CI; 1.2-15.2) were observed for the stage IIIA group. For all stage III cases, Breslow thickness and GEP were significant predictors of DMFS and MSS in multivariate models including ulceration and mitotic rate ($p < 0.05$). **Conclusions:** The results support the capability of the GEP to accurately predict stage III distant metastasis and survival, and that the test complements existing prognostic factors. GEP testing may be useful in identifying stage IIIA patients who are appropriate for adjuvant therapies and/or enrollment in clinical trials.

DMFS	Class	Event-free (95%CI)	p-value
Stage III (n = 207)	Class 1 (n = 63)	72% (61-85%)	< 0.0001
	Class 2 (n = 144)	42% (33-52%)	
Stage IIIA (n = 76)	Class 1 (n = 34)	75% (61-92%)	< 0.05
	Class 2 (n = 42)	53% (39-74%)	
MSS			
Stage III (n = 207)	Class 1 (n = 63)	92% (85-100%)	< 0.0001
	Class 2 (n = 144)	66% (56-76%)	
Stage IIIA (n = 76)	Class 1 (n = 34)	97% (91-100%)	< 0.02
	Class 2 (n = 42)	68% (53-86%)	

9579 Poster Session (Board #187), Sat, 1:15 PM-4:45 PM

Molecular and immune predictors of response and toxicity to combined CTLA-4 and PD-1 blockade in metastatic melanoma (MM) patients (pts). *First Author: Wei-Shen Chen, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Combined treatment with ipilimumab and nivolumab (Ipi/Nivo) achieves clinical responses in > 50% of mm pts. However, responses are not universal and toxicity may be limiting, thus biomarkers of response and toxicity are needed to optimize and personalize this therapy. **Methods:** Tumor biopsies were collected before (n = 29) and on treatment (n = 7) from mm pts (n = 40) treated with Ipi/Nivo. Whole exome sequencing (WES), gene expression profiling, TCR sequencing, and immunohistochemistry (IHC) were performed to define molecular and immune features of the tumors. Radiographic responses in patients were assessed via RECIST 1.1criteria, and patients were classified as responders (R) deriving clinical benefit (with SD, PR, CR) and non-responders (NR) not deriving clinical benefit (PD). Toxicity was also scored, with patients dichotomized into low toxicity (< grade 2) versus high toxicity (> grade 3) re: immune-related (IR) toxicities. **Results:** In this cohort, the response rate was 80%, with 53% of patients experiencing > grade 3 toxicity. There was no significant difference in baseline mutational load in responders (R) vs non-responders (NR) to Ipi/Nivo, but NR had a higher burden of copy number alterations (CNA; $p = 0.013$), with frequent alterations detected in *PTEN*, *JAK2*, and *B2M*. There were no significant differences in baseline CD8+ T cell density, expression of immune-related genes, or T cell clonality for R vs NR pts. Ipi/Nivo treatment increased intratumoral T cell clonality, but this did not correlate with response. A more diverse peripheral T cell repertoire at baseline was detected in pts who developed IR toxicity ($p < 0.05$). **Conclusions:** This data suggests that responses to Ipi/Nivo in mm may occur in the absence of high mutational load or brisk immune infiltrate at baseline. Putative mechanisms of resistance to Ipi/Nivo include high burden of CNA and alterations in *PTEN, JAK2, and B2M*. Together these studies identify candidate biomarkers of resistance and toxicity for Ipi/Nivo, though they need to be tested in larger cohorts and across cancer types.

9580 Poster Session (Board #188), Sat, 1:15 PM-4:45 PM

Characterizing the tumor microenvironment (TME) in primary melanomas using multiplex immunohistochemistry (mIHC). *First Author: Robyn Denise Gartrell, Columbia University Medical Center, New York, NY*

Background: Biomarkers are needed in primary melanoma to risk stratify for adjuvant trials. High levels of infiltrating cytotoxic (CD8+) T lymphocytes (CTLs) and low levels of CD68+ macrophages (MΦ) may correlate with prolonged survival but quantification methods are not standardized for clinical practice. HLA-DR is a marker of MΦ activation not expressed by suppressor myeloid cells. A novel pathology technique using mIHC allows for quantitative and spatial analysis of immune cell subsets. **Methods:** In a pilot set of stage II/III primary melanomas from Columbia University Medical Center (n = 94), clinical follow up is available for 51 cases. 32 had no evidence of recurrence at last follow up (minimum 2 years) while 19 died of melanoma. 5μm slides were stained using Opal multiplexed IHC (mIHC) for DAPI, CD3, CD8, CD68, SOX10, HLA-DR and Ki67. Tumor areas were pre-selected by a dermatopathologist, visualized using Mantra (Perkin Elmer) and analyzed using inForm (Perkin Elmer) and Spotfire (TIBCO). **Results:** In all patients (n = 94), CTLs are farther from tumor (SOX10+) cells when they are proliferating (Ki67+) ($p < 0.0001$***), while they are closer to MΦ when they are activated (HLA-DR+) ($p = 0.0002$***). Next, we evaluated impact on prognosis using disease specific survival (DSS) as an outcome based on median value (n = 51). In this exploratory study no correction for multiple comparisons was made. We find that CTL density correlates with prolonged DSS in tumor ($p = 0.0185$*) but not in stroma ($p = 0.1630$ ns). Ratio of density of CD8/CD68+HLA-DR- correlates with DSS in both tumor ($p = 0.027$*) and stroma ($p = 0.017$*). Finally, distance from CTLs to HLA-DR- MΦ was significantly greater in non-recurrent melanomas as compared to recurrent ones ($p = 0.0167$*). **Conclusions:** HLA-DR expression on MΦ and Ki67 expression on tumor cells correlate with position of CTLs in TME in primary melanoma. CTL density is a favorable prognostic marker while HLA-DR non-expressing MΦ may favor tumor progression. Quantitative mIHC allows for accurate spatial analysis of immune subsets within the TME and the development of novel, more accurate and potentially clinically relevant biomarkers.

9581 Poster Session (Board #189), Sat, 1:15 PM-4:45 PM

Preliminary results from the international neoadjuvant melanoma consortium (INMC). *First Author: Alexander M. Menzies, Melanoma Institute Australia, Royal North Shore Hospital, The University of Sydney, Sydney, Australia*

Background: For several cancers, response to neoadjuvant therapy (NAT) correlates with survival. Targeted and immune therapies achieve high response rates and durable survival in many patients with metastatic melanoma. Their role as NAT for stage III disease is not clear, and whether pathological response following NAT correlates with relapse-free (RFS) or overall survival (OS) in melanoma is unknown. **Methods:** Pooled clinical data from four ongoing NAT clinical trials (NCT02437279, NCT02231775, NCT02519322, NCT01972347) at three large melanoma centers participating in the INMC were examined. All trials included only patients with surgically resectable clinical stage III melanoma. NAT regimens included dabrafenib/trametinib (DT) and nivolumab (nivo) [single agent or in combination with ipilimumab (ipi/nivo)]. Patients who had undergone surgery prior to 27th January 2017 are included in this preliminary analysis. A pathological complete response (pCR) was defined as no viable melanoma cells in the resected specimen by hematoxylin and eosin evaluations by dedicated dermatopathologists. **Results:** 58 patients with clinical stage III melanoma (AJCCv7: 18 IIIB, 40 IIIC) have completed NAT and undergone surgery. 18 received neoadjuvant immunotherapy (IT): ipi/nivo x2 doses (N = 10), ipi/nivo x3 doses (N = 4) or nivo x4 doses (N = 4). 40 received neoadjuvant DT, either for two (N = 10) or three months (N = 30). Median age is 55 years (range 22-84). A pCR was observed in 50% of patients, 7 (39%) with IT and 22 (55%) with DT. Median follow-up is 10.2 months (95% CI 8.7-12.5). 14 (24%) patients have recurred (5 local, 8 distant, 1 both), 2 (11%) after IT, 12 (30%) after DT. For those with pCR, 14% have recurred, 0/7 (0%) after IT, 4/22 (18%) after DT. In contrast, for those without pCR, 34% have recurred, 2/11 (18%) after IT and 8/18 (44%) after DT. Two deaths have occurred, both after neoadjuvant TT. Early data suggests improved RFS in those with pCR. **Conclusions:** Neoadjuvant targeted and immunotherapy are active regimens in clinical stage III melanoma patients and are associated with high pCR rate. Preliminary data suggest pCR correlates with improved RFS. Updated data will be presented. Clinical trial information: NCT02437279, NCT02231775, NCT02519322, NCT01972347.

9582 Poster Session (Board #190), Sat, 1:15 PM-4:45 PM

A toll-like receptor agonist to drive melanoma regression as a vaccination adjuvant or by direct tumor application. *First Author: Richard Eldon Royal, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Toll like receptor (TLR) agonists may enhance vaccination or direct immune activation at the tumor microenvironment. This trial evaluates the biologic and clinical effects of Resiquimod, a TLR 7/8 agonist that can activate both myeloid (mDC, TLR 8) and plasmacytoid (pDC, TLR 7) dendritic cells, in patients with advanced stage melanoma. **Methods:** Class I HLA-A0201+ subjects with in-transit melanoma metastases or high risk for recurrence were vaccinated weekly with peptide vaccination (class I restricted peptide $GP100_{209\text{-}2m}$ and, if HLA-DP4+, also with class II restricted peptide MAGE-$3_{243\text{-}258}$). Subjects were randomized 1:1 to receive Resiquimod as an adjuvant applied to the GP100 vaccination site. Subjects with in-transit disease were thereafter treated with resiquimod topically on half of the target lesions. **Results:** All patients (n = 47) underwent $GP100_{209\text{-}2m}$ vaccination, a majority (39) also received the MAGE-$3_{243\text{-}258}$ peptide. The type I interferon-inducible genes (Mx A and IRF7), IFNg, and IP-10 RNA expression were up-regulated only in vaccination sites treated with Resiquimod (each $p < 0.01$) , demonstrating pDC activation (Type I interferon) and possibly T and NK cell activation (IFNg and IP-10). Nineteen subjects had in-transit disease at entry into the trial. In response to peptide vaccination alone, tumor regression was more likely in patients who received Resiquimod at the vaccination site (group A) compared to those who did not (group B). (4/9 vs 0/10, p = 0.033). In group A, 5 patients continued treatment with Resiquimod topically on the tumors, and all had tumor response (4PR, 1CR). In group B, 5 continued to tumoral resiquimod and 3 had regression (3 PR). **Conclusions:** Resiquimod increases Type I interferon and IFNg at the peptide vaccination site by activation of pDC/mDC and increases the antitumor response sufficiently to mediate regression of in-transit melanoma metastasis. Resiquimod on in-transit melanoma, in vaccinated hosts, drives regression of metastases, regardless of previous exposure at vaccination. Clinical trial information: NCT00960752.

9583 Poster Session (Board #191), Sat, 1:15 PM-4:45 PM

Use of circulating tumor DNA to predict survival in patients with resected high-risk stage II/III melanoma. *First Author: Rebecca Lee, Molecular Oncology Group, Cancer Research UK Manchester Institute, Manchester, United Kingdom*

Background: Patients with high-risk stage II/III resected melanoma commonly develop metastatic disease. Adjuvant high dose interferon and ipilimumab 10mg/kg are associated with survival benefit, but at the expense of toxicity. At present, we cannot differentiate between patients who will progress to stage IV disease or those cured by surgery. Circulating tumor DNA (ctDNA) is a biomarker of disease progression in many cancers including stage IV melanoma, however its utility in the adjuvant setting has not been investigated. **Methods:** We performed droplet digital polymerase chain reaction to detect *BRAF* and *NRAS* mutations in plasma of 161 stage IIB, IIC/III high-risk melanoma patients enrolled in AVAST-M; a randomized study of bevacizumab vs. observation. Baseline plasma samples were collected within 12 weeks of surgery for both arms. **Results:** Mutant *BRAF* or *NRAS*ctDNA was detectable (> 1 copy of mutant ctDNA) in 12% (19/161) of patients. Patients with detectable ctDNA had a decreased disease free interval (DFI; hazard ratio [HR] 3.12; 95% confidence interval [CI] 1.79-5.47; $p < 0.0001$) and distant metastasis-free interval (DMFI; HR 3.22; 95% CI 1.80-5.79; $p < 0.0001$) vs. those with undetectable ctDNA. One year DFI rate for patients with detectable ctDNA was 26% (95% CI 10-47%) vs. 74% (95% CI 66-81%) for those with undetectable ctDNA. One year DMFI rate for patients with detectable ctDNA was 37% (95% CI 17-57%) vs. 84% (95% CI 77-89%) with undetectable ctDNA. Detectable ctDNA remained a significant predictor after adjustment for N classification and performance status (PS) (DFI HR 3.48; 95% CI 1.95-6.19, $p < 0.0001$; DMFI HR 3.41, 95% CI 1.88-6.20, $p < 0.0001$). Five year overall survival (OS) rate for patients with detectable ctDNA was 33% (95% CI 14-55%) vs. 65% (95% CI 56-72%) for those with undetectable ctDNA. OS was significantly worse for patients with detectable ctDNA (HR 2.63; 95% CI 1.4-4.96); p = 0.003) and remained significant after adjustment for PS (HR 2.5, 95% CI 1.32-4.74, p = 0.005). **Conclusions:** CtDNA is predictive of relapse and survival in high-risk, resected melanoma and can potentially aid stratification of patients for adjuvant therapy.

9584 Poster Session (Board #192), Sat, 1:15 PM-4:45 PM

Patterns of histologic response to neoadjuvant targeted therapy in patients with BRAF mutant melanoma. *First Author: Zeynep Eroglu, Moffitt Cancer Center, Tampa, FL*

Background: While BRAF and MEK inhibitors are approved for patients with BRAF V600 + unresectable/metastatic melanoma, their role in the neoadjuvant setting is less well defined. Results from small trials have noted robust response rates, but less is known about histological patterns of response in resected tumor specimens and relation to outcome in these patients (pts). **Methods:** In a retrospective study, we analyzed the clinical and pathologic patterns of response to neoadjuvant BRAF ± MEK inhibitor therapy in pts with locally advanced melanoma subsequently rendered disease free with surgery. **Results:** Twenty pts were identified, nine with stage IIIC and 11 with stage IV melanoma. Seven patients received neoadjuvant vemurafenib (VEM), 12 received dabrafenib + trametinib (D+T), and one encorafenib + binimetinib. The median duration of treatment was 7.8 months. Seven patients (35%) had a pathologic complete response (pCR); six of them had received combination therapy, 5 with D+T, 1 VEM with an HSP90 inhibitor. Four distinct histologic patterns were observed in the resected tumor specimens: necrotic, fibrotic/melanotic (tumoral melanosis), hyalinized, or mixed. With median follow-up of 25 months (range 1-60), six pts (30%) had experienced recurrence; three developed CNS metastases. Four of the six patients had received neoadjuvant D+T; three were restarted on their prior targeted therapy at recurrence and all responded. All 6 pts with recurrence had residual disease in the surgical specimen; three had no necrosis identified. In contrast to the 13 pts with persistent tumor, none of the 7 pCR pts has relapsed (p = 0.05). There was a trend towards improved relapse-free-survival (RFS) with a pCR, with a 1 yr of RFS-rate of 50.4% vs 100% in pCR.(p = 0.08) Of the 14 patients without subsequent recurrence, 9 had either a pure necrotic histology, or a mixed histological pattern that included necrosis. **Conclusions:** In locally advanced or M1a BRAF mutant melanoma, attaining a pCR to neoadjuvant targeted therapy may correlate with improved patient outcomes and be more likely achieved with combination therapy. Presence of necrosis in the surgical specimen appears be a favorable prognostic factor.

9585 Poster Session (Board #193), Sat, 1:15 PM-4:45 PM

Clonality of T cell repertoire in the tumor (TME) and peripheral blood of regionally advanced melanoma patients (pts) treated with neoadjuvant ipilimumab (ipi) and high dose interferon-α (HDI). *First Author: Priyanka Vallabhaneni, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Pts with regionally advanced melanoma were treated with neoadjuvant ipi and HDI in a reported study (*Tarhini.J Clin Oncol suppl, 2016; abstr 9585*). Pathologic complete response (pCR) was found in 32% of pts. Clonality of T cell repertoire was investigated in TME and peripheral blood mononuclear cells (PBMC). **Methods:** Pts were randomized to neoadjuvant ipi 3 or 10 mg/kg combined with HDI. Tumor biopsies were evaluable for testing at pretreatment (N = 20 pts) and definitive surgery (week 6-8; N = 25). When available, primary (N = 24) and relapse tumors (N = 6) were tested. PBMC: pretreatment (N = 29), 6 weeks (wk) (N = 24), then 3 (N = 23), 6 (N = 21), 12 (N = 14) months. T cell receptor beta chain (TCRB) repertoire was immunosequenced in PBMC and TME to determine repertoire clonality and T cell fraction in blood and TME (TIL; fraction of all nucleated cells identified as T cells). **Results:** PBMC T cell fraction when measured early on-treatment (6 wks) was significantly higher in pts who had pCR or microscopic residual disease vs. gross disease at the 6-8 wks surgery (p = 0.047). PBMC clonality was significantly lower at 12 wks (p = 0.025) for pts who continued to be relapse free (NED) long term vs. those who eventually relapsed. In TME, except for trends no significant difference in clonality was seen, but in pts with pCR TIL fraction was significantly higher when measured in primary tumors (p = 0.033). The number of tumor-associated clones that were expanded in blood post-treatment was strongly correlated with both TIL fraction (Rho 0.7299, p = 0.0003) and TIL clone diversity (Rho 0.882, p = 2.7^{-7}). **Conclusions:** Higher T cell fraction and lower clonality in PBMC when measured early on-treatment, and higher TIL fraction in primary tumor constituted promising biomarkers of response. Pts with higher TIL fractions were more likely to have tumor-associated clones detectable in blood, suggesting these may be useful for tracking the immune response. These findings warrant validation in an independent cohort and exploration with other immunotherapeutics. Clinical trial information: NCT01608594.

9586 Poster Session (Board #194), Sat, 1:15 PM-4:45 PM

Neoadjuvant ipilimumab + nivolumab (IPI+NIVO) in palpable stage III melanoma: Updated data from the OpACIN trial and first immunological analyses. *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The combination of IPI+NIVO induces high response rates and improved overall survival in late stage melanoma. T cell checkpoint inhibition is of greatest value at the moment of TCR triggering and therefore dependent on the amount of antigen present, indicating that adjuvant immunotherapy may work most efficiently, when initiated prior to surgery. **Methods:** Two-arm Phase 1b feasibility trial of 20 high risk AJCC stage IIIB and IIIC melanoma patients with palpable nodal disease receiving the combination of IPI 3mg/kg and NIVO 1mg/kg, either adjuvant four courses after surgery, or split two courses neo-adjuvant and two courses adjuvant. **Results:** In this update all 20 patients are evaluable. Neo-adjuvant application of IPI+NIVO was feasible and no surgery-associated adverse events were attributed to (neo-)adjuvant therapy. 18/20 patients had to stop early due to grade 3/4 toxicities. Neo-adjuvant IPI+NIVO reduced tumor load in 8/10 patients (3 pCR, 4 near-pCRs [minimal remaining micrometastases], 1 pPR [75% reduction], 1 SD and 1 PD). To date, after a median follow-up of 45 weeks (range 13-74), none of the responders in the neoadjuvant arm has relapsed. Relapse was observed for both non-responders within the neoadjuvant arm and for 3 patients within the adjuvant arm. TCR sequencing and MHC tetramer-based analysis to compare the induction and expansion of tumor (neo-)antigen-specific T cell responses between both treatment arms are underway and will be presented. **Conclusions:** The combination of IPI +NIVO in the (neo-)adjuvant treatment setting for high risk stage III melanoma patients is feasible and induces very frequent responses. At the same time, severe grade 3/4 toxicity is more frequent than expected from stage IV melanoma patient study data. These results indicate that IPI+NIVO is a promising combination for neo-adjuvant treatment in stage III melanoma. Adjusted combination schemes are currently tested in the phase 2 OpACIN-neo trial, with the aim of reducing toxicity while preserving efficacy. Clinical trial information: NCT02437279.

9587 Poster Session (Board #195), Sat, 1:15 PM-4:45 PM

Relapse-free survial and target identification to enhance response with neoadjuvant and adjuvant dabrafenib + trametinib (D+T) treatment compared to standard-of-care (SOC) surgery in patients (pts) with high-risk resectable BRAF-mutant metastatic melanoma. *First Author: Jennifer Ann Wargo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Targeted and immune therapies have dramatically improved outcomes in stage IV metastatic melanoma pts. These agents are now being tested in earlier-stage disease. SOC surgery for high-risk resectable melanoma (AJCC stage IIIB/IIIC), with or without adjuvant therapy, is associated with a high risk of relapse (~70%). We hypothesized that neoadjuvant (neo) + adjuvant treatment with D+T improves RFS in these pts. Longitudinally collected biospecimens from pts receiving this treatment were analyzed to identify candidate strategies to further improve outcomes. **Methods:** A prospective single-institution randomized clinical trial (NCT02231775) was conducted in BRAF-mutant pts with resectable Stage IIIB/C or oligometastatic stage IV melanoma. Pts were randomized 1:2 to SOC (Arm A) versus neo + adjuvant D+T (Arm B; 8 wks neo + 44 wks adjuvant). The primary endpoint was RFS. Tumor biopsies were collected at baseline, week 3, and at surgery for molecular and immune profiling (whole exome sequencing, gene expression profiling, IHC, flow cytometry). **Results:** 21 of a planned 84 patients were enrolled (Arm A = 7, Arm B = 14). Arms were well balanced for standard prognostic factors, and toxicity was manageable. RECIST response rate with neo D+T was 77%, and the pathologic complete response rate (pCR) was 58%. First interim analysis revealed significantly improved RFS in the D+T arm over SOC (HR 62.5, p < 0.0001), leading to early closure to enrollment. Pts with a pCR at surgery had significantly improved RFS versus pts without pCR (p = 0.04) on neo D+T. Tumor profiling revealed incomplete MAPK pathway blockade and higher levels of CD8+ T cells expressing immunomodulators Tim-3 and Lag-3 in pts who did not achieve a pCR. **Conclusions:** Neo + adjuvant D+T is associated with a high pCR rate and markedly improved RFS over SOC in pts with high-risk resectable BRAF-mutant metastatic melanoma. pCR at surgery is associated with improved RFS. Tumor analyses reveal candidate targets for testing in future trials to enhance responses to neo D+T. Clinical trial information: NCT02231775.

9588 Poster Session (Board #196), Sat, 1:15 PM-4:45 PM

Financial toxicity and cancer-related distress among melanoma survivors. *First Author: Joanne S Buzaglo, Cancer Support Community, Research and Training Institute, Philadelphia, PA*

Background: Melanoma survivors are at risk for significant financial burden due to cancer care and out of pocket costs. We explored 1) the financial impact of melanoma and its relationship to cancer-related distress, and 2) survivors' experiences discussing financial burden with their health care team. **Methods:** Of 110 melanoma survivors enrolled in the Cancer Support Community's online Cancer Experience Registry, 56 completed questions about financial impact of cancer and cost of care communication. Participants rated concern (0 = not at all; 4 = very seriously) about 27 items encompassing psychological, emotional, physical and practical concerns; items were summed into a total distress score (mean = 33, SD = 21, range 0-88). Financial impact and overall distress were examined via regression analysis. **Results:** Participants were 71% female, 89% Caucasian, median age 54, and median time since diagnosis 2.5 years. Total annual income: 34% < $60K; 46% $60K+; 20% not reported. 24% spent $101-250/month on melanoma out of pocket costs; 20% spent $251-500; and 24% spent ≥$500. The top concern was health insurance/money worries (69% moderately to very seriously concerned). Due to medical costs, 57% depleted their savings, 20% borrowed against or used retirement money, 20% used pharmaceutical assistance programs, 13% skipped medicine dosages at least sometimes, and 17% postponed filling prescriptions. Only 28% reported that their health care team spoke to them about cost of care, and 28% were asked about financial distress; 42% desired financial assistance. Financial impact was associated with an increase in overall distress for those with income < $60K (p < .05; interaction p < 0.05). **Conclusions:** Substantial proportions of melanoma survivors experience financial burden that can impact quality of life, particularly lower income individuals. Although oncologists are encouraged to discuss treatment costs, most patients report they have not had these discussions with providers. These results support the development/evaluation of interventions to enhance doctor-patient communication, and financial counseling to minimize financial burden of melanoma and the risks it can confer for quality of life, course of cancer care, and health outcomes.

9589 Poster Session (Board #197), Sat, 1:15 PM-4:45 PM

Whole genome and RNA sequencing reveal the distinct genomic landscape of acral melanoma. *First Author: Yan Kong, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Acral melanoma is a common subtype of melanoma in Asians with extremely poor prognosis, and therapy strategy has not been clearly established for acral melanoma. The aim of this study is to perform genomic and RNA profiling of acral melanoma to obtain the comprehensive genomic view of this subtype of melanoma. **Methods:** Genomic DNA was extracted with Qiagen DNeasy Blood or Tissue Kit . DNA libraries were prepared using a CancerPROTM-P88 BOX library Prep kit and sequencing was performed using the Illumina HiSeq X10. RNA was isolated with Qiagen RNeasy mini-spin column. cDNA was synthesized from total RNA using the SuperScript III first-strand synthesis system . RNA libraries were prepared using the NEBNext Ultra II Directional RNA Library Prep Kit and sequencing was performed using the Illumina HiSeq X10. **Results:** To obtain a comprehensive genomic and functional genomic view of acral melanoma, we sequenced the genomes of 14 acral melanoma and transcriptomes of 11 of these melanoma samples. We found a new mutation in the V28 codon of BRAF in three patients. Furthermore, we identified recurrent non-synonymous single nucleotide variants in previously described oncogene NRAS, as well as in genes encoding keratin associated proteins (KRTAP4-7, KRTAP4-5) and mucin (MUC2, MUC21). Notably, a recurrent noncoding hotspot mutation was discovered in 4 of 11 cases. By analyzing the RNA sequencing data, we found significant divergence on transcriptome between patients with or without ulcer. In total, we identified 201 genes were significantly up-regulated and 386 genes significantly down-regulated in acral melanoma patients with ulcer. Differentially expressed genes were enriched in pathways associated with cancers, melanogenesis, cell death signaling, skin diseases, etc. **Conclusions:** Our study reveals potentially different driver mutations and distinct transcriptome in acral melanoma patients compared with cutaneous melanoma patients and sheds lights to the further personalized medicine for acral melanoma patients.

9590 Poster Session (Board #198), Sat, 1:15 PM-4:45 PM

Hyperproliferative keratinocytic cutaneous adverse events and inflammatory palmoplantar erythrodysesthesia in melanoma patients treated with encorafenib compared to other BRAF inhibitors. *First Author: Simone M. Goldinger, University Hospital Zurich, Zurich, Switzerland*

Background: BRAF inhibitor (BRAFi) an MEK inhibitor (MEKi) monotherapies have shown to cause more cutaneous adverse events (cuAEs) in monotherapy compared to combination therapy. Encorafenib in combination with binimetinib showed improved PFS in patients with BRAF mutant melanoma (14.9 months). Furthermore, encorafenib showed superiority over vemurafenib. Objective:The aim of this study was to investigate cuAEs of melanoma patients treated with encorafenib and/or binimetinib and compare them to other BRAFi and MEKi induced cuAEs reported in the literature and observed in our control population. **Methods:** Patients treated with encorafenib, binimetinib, and other BRAFi/MEKi within approved clinical trials at the University Hospital of Zurich were collected and analyzed. Clinical and histological assessments were performed. **Results:** In 111 patients treated with BRAFi and/or MEKi, 212 related or possibly related cuAEs were identified. The percentage of patients with at least one cuAE is shown in the table below. The most frequent cuAEs observed in patients treated with encorafenib where palmoplantar hyperkeratosis (PPH, 50%), palmoplantar erythrodysesthesia (PPD, 53.8%) and alopecia (42.3%), whereas acanthopapillomas (83%), maculopapular exanthemas (63.3%), PPH and PPD (each 50%) prevailed in patients treated with vemurafenib. The most frequent observed cuAE in patients with dabrafenib/trametinib combination therapy were maculopapular exanthemas (18.2%) and erythema-annulare-like eruptions (18.2%), with encorafenib/binimetinib combination therapy PPH (10.6%) respectivly. **Conclusions:** Encorafenib showed less hyperproliferative cuAEs as previous BRAFi. However, PPH and PPD seem to occur more often compared to the literature of other BRAFi. Both is supporting the argument that encorafenib is a second generation BRAFi with a longer dissociation time.

Substance (n)	% of patients with at least one cuAE
encorafenib (n=26)	73.1
vemurafenib (n=6)	100
encorafenib plus binimetinib (n=48)	31.9
dabrafenib plus trametinib (n=11)	45.4
trametinib (n= 8)	87.5
binimetinib (n=25)	92

TPS9591 Poster Session (Board #199a), Sat, 1:15 PM-4:45 PM

Phase 1 study to evaluate safety and efficacy of ipilimumab + nivolumab + external beam radiotherapy in patients with metastatic melanoma. *First Author: Michael Andrew Postow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immunotherapy (IMT) with checkpoint blocking antibodies has led to progress in metastatic melanoma with 3 FDA-approved drugs, including the combination of ipilimumab (IPI), a CTLA-4 antibody, and nivolumab (NIVO), a PD-1 antibody. Although radiotherapy (RT) is primarily used as local palliative therapy in metastatic melanoma, it also possibly affects systemic antitumor immunity. Preclinical data suggest RT alters the tumor microenvironment and renders tumor cells more susceptible to immunologically-mediated disease regression. These preclinical immunologic effects of RT have been shown to vary by RT dose and fractionation. We are now conducting the first clinical trial in patients to evaluate the triple combination of IPI + NIVO + RT using 2 different dose/fractionation schemes of RT. **Methods:** This ongoing Phase 1, open-label, multicenter study (NCT02659540) evaluates safety, efficacy, and immunologic effects of IPI + NIVO + RT in 18 patients with unresectable stage IV melanoma. Patients must have 1 melanoma metastasis that can be safely irradiated for palliative purposes and at least 1 measurable lesion that will not be irradiated. Patients receive concurrent IPI (3 mg/kg) and NIVO (1 mg/kg) every 3 weeks (Q3W) x 4, followed by NIVO monotherapy (240 mg Q2W), with RT initiated between the first and second doses of IPI + NIVO. In Cohort A, the irradiated metastasis receives a conventionally fractionated low dose of 30 Gy in 10 fractions of 3 Gy each over 2 weeks. If $\leq$7 of 9 patients (78%) in Cohort A have Grade 3/4 drug- or radiation-related adverse events, safety is deemed acceptable and Cohort B enrollment opens. In Cohort B, the irradiated metastasis receives a hypofractionated high dose of 27 Gy in 3 fractions of 9 Gy each over 2 weeks. The primary endpoint is safety. Secondary endpoints are objective response rate and disease control rate by RECIST and immune-related RECIST measured at Weeks 12 and 18, duration of response, progression-free survival, and overall survival. Exploratory endpoints include correlative studies of immunological effects. Enrollment opened on 05 Aug 2016. As of 31 Dec 2016, 4 patients are enrolled in Cohort A; enrollment is ongoing. Clinical trial information: NCT02659540.

TPS9592 Poster Session (Board #199b), Sat, 1:15 PM-4:45 PM

NCI 9922: Phase 2 study of ibrutinib in treatment-refractory distant metastatic cutaneous melanoma (DMCM). *First Author: Stergios J. Moschos, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: We have previously shown that the IL-2 inducible kinase (ITK) is highly expressed in primary melanomas compared with nevi due to promoter hypomethylation (Conway PCMR 2011). We have also shown using 2-color immunofluorescence (2CIF) that ITK protein expression is increased even more in metastatic compared to primary melanomas (S100+) and that molecular targeting (shRNA) or pharmacologic inhibition of ITK (BI 10N) in various melanoma cell lines, various melanoma xenografts and an immunocompetent melanoma mouse model suppresses cell proliferation and retards tumor growth without inducing cell death (Carson CCR 2015). We have also shown by intracellular stain of peripheral blood mononuclear cells (PBMC) that ITK is expressed in PBMC obtained from patients (pts) treated with MAPK or CTLA-4 inhibitors. Other groups have shown that ITK and BTK are expressed in Th2 cells, myeloid-derived suppressor cells, and tumor-associated macrophages. We have also shown that ibrutinib suppresses proliferation of various melanoma cell lines in low nM concentrations depending on tumoral expression of ITK. We hypothesize that targeting DMCM with ibrutinib alone will induce antitumor responses and/or prolong survival if DMCM expresses high levels of melanoma-associated ITK by 2CIF (S100/ITK). **Methods:** This is an open-label, single-arm, multicenter, phase II study of DMCM refractory to or ineligible for PD-1 and MAPK inhibitors. Ibrutinib will be dosed at 840 mg p.o. qd. The null hypothesis is that an ineffective drug will confer a 5% response rate (RR) and 18% 6-month PFS (6m PFS), whereas ibrutinib will confer $>=$ 20% RR and $>=$ 35% 6m PFS (KEYNOTE-002). This trial accrues in two stages; if either the RR and/or 6m PFS endpoint are met after 18 patients, then 14 additional pts will be accrued for a total of 32. The Simon's design will reject the null hypothesis if $>=$ 4 responses are observed or $>=$ 9 pts have PFS better than 6 months out of 32 patients. All pts are required to have baseline tumor tissue available for analysis of ITK expression by 2CIF. Immune monitoring will be performed on PBMC collected at baseline and various time points during treatment. Trial is currently recruiting pts (NCT02581930). Clinical trial information: NCT02581930.

TPS9593 Poster Session (Board #200a), Sat, 1:15 PM-4:45 PM

Pembrolizumab with or without vismodegib in treating metastatic or unresectable basal cell skin cancer. *First Author: Anne Lynn S. Chang, Stanford University School of Medicine, Stanford, CA*

Background: Basal cell carcinomas (BCCs) are the most common cancer in humans and have increased > 75% in the past two decades, with > 28,000 cases of advanced or metastatic diseases per year. Targeted therapy in the form of Smoothened inhibitors (SIs) are FDA approved for advanced BCC, however, over half of patients do not respond or become resistant to SI monotherapy after initial response. At this time, there are no other FDA approved drugs for advanced BCCs, however, emerging data indicates that a significant proportion of BCCs express programmed cell death ligand (PD-L)-1, suggesting potential response to PD-1 inhibition. In addition, BCCs are keratinocytic tumors, and our case series of PD-1 inhibitors against cutaneous squamous cell carcinomas, another keratinocytic tumor, have shown activity. Here, we present a proof-of-principle, phase 1b, open-label investigator initiated study of pembrolizumab for unresectable or metastatic BCC (NCT02690948). **Methods:** Following institutional review board approval, patients with locally advanced or metastatic BCCs who met all eligibility criteria were enrolled at a single academic center. Participants were allocated into either Arm 1 (pembrolizumab 200 mg IV every 3 weeks) or Arm 2 (pembrolizumab 200 mg IV every 3 weeks and concurrent vismodegib 150 mg by mouth daily) until disease progression or intolerable toxicity. Major inclusion criteria include individuals aged > or = 18 years with histologically verified unresectable and/or metastatic BCC, and with measurable disease by Response Evaluation Criteria for Solid Tumors version 1.1. Exclusion criteria include immunosuppresion, active infection, history of pneumonitis and autoimmune disease requiring systemic treatment. The primary outcome measures are the overall response rates in Arm 1 and 2. Secondary outcome measures include incidence and severity of adverse events (AEs) as defined by the Common Terminology Criteria for Adverse Events verson 4.0, and progression free survival. This study is currently enrolling, with 10 of 26 patients accrued to date (6 of 13 in Arm 1; 4 of 13 in Arm 2), and the study stopping rule (based on first 10 enrolled patients displaying progressive disease) did not need to be deployed. Clinical trial information: NCT02690948.

TPS9594 Poster Session (Board #200b), Sat, 1:15 PM-4:45 PM

A phase II study of oral azacitidine (CC-486) in combination with pembrolizumab (PEMBRO) in patients with metastatic melanoma (MM). *First Author: Emily Keung, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitors have impressive response rates and improved survival for many pts with MM, offering durable responses in up to 35% of pts while others have short-lived or no response (> 40%). A potentially targetable mechanism for immune escape is for cancers to subvert the cellular epigenetic machinery, affecting multiple aspects of the immune response from suppression of tumor antigen expression [such as Cancer Testis Antigens (CTA)] to antigen processing and presentation, thus allowing tumor proliferation to continue undetected. In preclinical models, decitabine (DAC), a DNA hypomethylating agent (HMA), has been able to revert heterogeneous CTA expression profiles, increasing cancer cell immunogenicity. HMAs also increased TH1-chemokine expression, T cell tumor infiltration, T cell-mediated tumor killing, and have been shown to be synergistic with checkpoint inhibitors in preclinical models. This suggests that epigenetic therapy with checkpoint inhibition is a rational combination to target MM. Clinical advantages of the HMA CC-486 over DAC include oral bioavailability and potential versatility in dosing and schedule. We hypothesize that CC-486 + PEMBRO will be tolerated at biologically relevant doses; enhance response to PEMBRO in pts with mm who are PD-1 naïve; and reverse resistance to immunotherapy in pts refractory/resistant to PD-1 directed therapy. **Methods:** This study will evaluate the safety and efficacy of CC-486 + PEMBRO defined by Objective Response Rate (ORR) by RECIST 1.1 in pts with MM. Pts who are PD-1 naïve (Arm A, n = 36) and pts who have progressed on prior PD-1 directed therapy (Arm B, n = 35) will be enrolled. Unlimited prior systemic therapies will be allowed. Pts will receive 300mg PO of CC-486 on days 1-14 and 200mg IV of PEMBRO every 3 weeks. Continuous monitoring for toxicity and futility will be performed and assumes an ORR of > 35% and > 15% for Arms A and B, respectively (95% power). Tumor biopsies at baseline and post treatment are required. Effects of CC-486 + PEMBRO on CTAs, MDSCs and Tregs, and correlation between mutation burden and response will be studied. This study is open for enrollment. Clinical trial information: NCT02816021.

TPS9595 Poster Session (Board #201a), Sat, 1:15 PM-4:45 PM

An open-label, uncontrolled, single arm phase II trial of the PI3K inhibitor buparlisib in patients with melanoma brain metastases. *First Author: Friedegund Elke Meier, Universitatsklinikum Carl Gustav Carus, Dresden, Germany*

Background: The approval of effective BRAF +/- MEK inhibitors and immune checkpoint inhibitors has revolutionized the treatment of metastatic melanoma. However, available therapies appear to be less effective on cerebral than extracerebral metastases. Hyperactivation of the PI3K-AKT survival pathway is a prominent feature of melanoma brain metastases (MBM). This trial aims to determine the activity and safety of the PI3K inhibitor buparlisib in patients (pts) with MBM. **Methods:** The study enrolls adults suffering from MBM not eligible for neurosurgery or/and radiosurgery. Patients must have failed prior treatment with BRAF +/- MEK Inhibitors (BRAF-V600E mutated population) and anti-PD-1 or/and anti-CTLA-4 antibodies (BRAF wild-type population), respectively. Patients are treated with buparlisib 100 mg PO daily until disease progression or unacceptable toxicity. The Simon-Two-Step design for phase 2 studies was used to determine sample size. Assuming a response rate of 12.5% in comparison to historical 10% for chemotherapy 22 (8/14) pts would be required. If there are one or fewer responses in the first 8 pts the study would stop. Prespecified activity goal for the first stage of accrual was met; currently 11/22 pts are enrolled. Clinical trial information: NCT02452294.

TPS9596 Poster Session (Board #201b), Sat, 1:15 PM-4:45 PM

CARSKIN: Pembrolizumab as first line therapy in patients with unresectable cutaneous squamous cell carcinoma (cSCC). *First Author: Eve Maubec, AP-HP, Hôpital Avicenne, Bobigny, France*

Background: Treatment options are limited for patients (pts) with locally advanced or metastatic cSCCs. Cisplatin-based combinations have some efficacy but their toxicity often prohibits their use, particularly for the elderly. New therapeutic options are needed. Tumors divert the programmed death receptor 1 (PD-1) pathway suppressing immune control. Pembrolizumab (MK-3475) is a high-affinity humanized monoclonal anti-PD-1 antibody. It leads to dual PD-1 ligand (PD-L1 and PD-L2) blockade that may reactivate the immune surveillance and elicit anti-tumor response. It has antitumor activity in several tumors including head and neck SCCs. Moreover, an efficacy of pembrolizumab in cSCCs has been reported recently in a series of 6 cases. **Methods:** CARSKIN (ClinicalTrials.gov, NCT02883556) is a French multicenter, open-label, nonrandomized phase 2 trial, designed to evaluate the efficacy and safety of pembrolizumab in 39 pts with unresectable and/or metastatic cSCCs, naive of chemotherapy and of EGFR inhibitors. Pembrolizumab is administered (200 mg IV Q3W) for up to 24 months or until disease progression or unacceptable toxicity. Eligible pts must undergo a baseline biopsy of the tumor prior to treatment for PD-L1 evaluation. Response is to be assessed at baseline, wk 9, 15 and 24, and thereafter Q12W by central radiology review per RECIST 1.1 and per modified RECIST v1.1. The primary objective is response rate (RR) at wk 15 per RECIST 1.1. Secondary efficacy objectives are to assess whether patients with PD-L1+ tumors have a better RR than the whole sample at wk 15 and to assess in the whole sample and in PD-L1+ pts, disease control rate (DCR) at wk15, RR at wk 24, best RR, overall survival (OS), progression free survival (PFS), duration of response / control and time to disease progression. A Simon optimal two-stage design will be used. Four responders among 19 pts will be needed in the 1st step to continue the trial. Overall 9 responses will be needed to conclude the effectiveness. Kaplan-Meier statistics will assess PFS and OS. Adverse events (AEs) will be assessed throughout the study and for 30 d thereafter (6 m for serious AEs) and graded per NCI CTCAE v4.0. Clinical trial information: NCT02883556.

TPS9597 **Poster Session (Board #202a), Sat, 1:15 PM-4:45 PM**

Multi-center phase Ib study of intermittent dosing of the MEK inhibitor, selumetinib, in patients with advanced uveal melanoma not previously treated with a MEK inhibitor. *First Author: Kimberly Mayumi Komatsubara, Columbia University Medical Center, New York, NY*

Background: Uveal melanoma (UM) is a rare subtype of melanoma with no effective therapy for advanced disease. UM is characterized by mutations in GNAQ and GNA11 leading to constitutive activation of the mitogen activated protein kinase (MAPK) pathway. We have previously shown that targeting the MAPK pathway though MEK inhibition with Selumetinib (AZD6244, ARRY-142886) using a continuous dosing schedule improved progression free survival (PFS) in a randomized Phase II study of Selumetininb versus chemotherapy in patients with metastatic UM; however, no PFS or overall survival (OS) benefit was observed in a subsequent randomized Phase III study of Selumetinib and chemotherapy versus chemotherapy alone. We hypothesize that an intermittent dosing schedule of Selumetinib may be more effective than continuous dosing by achieving higher dose levels, better drug tolerability, and more complete target inhibition. We propose a Phase Ib study of Selumetinib in UM using an intermittent dosing schedule. **Methods:** A total of 28 subjects will be enrolled using the time to event continual reassessment method (TITE-CRM). Key inclusion criteria include a diagnosis of advanced UM, measurable disease by RECIST v1.1, and no prior MEK inhibitor therapy. Eligible subjects will be treated with Selumetinib starting at a dose level of 125 mg orally twice a day, using a 3-days-on and 4-days-off per week schedule. The primary goal of this study is to estimate the maximum tolerated dose (MTD) of intermittently dosed Selumetinib. Secondary endpoints are response rate, PFS and OS. Responses will be evaluated every 8 weeks by a CT scan of the chest and CT or MRI of the abdomen/ pelvis using RECIST v1.1 criteria. Mandatory tumor biopsies will be obtained at baseline, cycle 1 day 3 (Selumetinib-on day), and between cycle 1 day 11-14 (Selumetinib-off day) in 20 subjects, and optionally at progression. Tumor tissue will be assessed for MAPK pathway inhibition and reactivation at each time point, as well as mechanisms of resistance. Recruitment is currently ongoing. Clinical trial information: NCT02768766.

TPS9598 **Poster Session (Board #202b), Sat, 1:15 PM-4:45 PM**

SECOMBIT (sequential combo immuno and target therapy study): A three arms prospective, randomized phase II study to evaluate the best sequential approach with combo immunotherapy [ipilimumab (I) /nivolumab (N)] and combo target therapy [encorafenib (E)/binimetinib (B)] in patients with metastatic melanoma and BRAF mutation. *First Author: Paolo Antonio Ascierto, Istituto Nazionale Tumori "Fondazione G.Pascale"- IRCCS, Naples, Italy*

Background: Treatment of BRAF-mutated metastatic melanoma has dramatically changed with the introduction of targeted therapy (BRAF and MEK inhibitors) and immune-checkpoint blockade (anti-CTLA4, anti-PD-1, and anti-PD-L1). Target therapy has been associated with high response rates, but short-term responses. Conversely, treatment with immune checkpoint inhibitors was found to present with lower response rates, but long-term responses. Synergism has been demonstrated when targeted therapy is combined with immunotherapy. The risk of a high rate of toxicity limits the simultaneous combination of all the four compounds (target agents and immunomodulating monoclonal antibodies). Sequencing of these different combinations seems to be more feasible; finding the right treatment sequence represents an important issue to be addressed. **Methods:** Approximately, 230 patients with untreated, histologically-confirmed advanced melanoma (measurable disease by RECIST v1.1) and carrying the *BRAF*^{V600} mutation will be randomized to Arm A [E+B until disease progression (PD), followed by I+N], or Arm B (I+N until PD, followed by E+B) or Arm C (E+B for 8 weeks, followed by I+N until PD, followed by E+B until PD). Patients will receive the combo treatments with the following schedules: target therapy, E 450mg p.o. od + B 45mg p.o. bid; immunotherapy, I 3mg/kg + N 1mg/kg Q3w x 4 cycles, followed by N 3mg/kg Q2w. The OS (time from the date of randomization until death from any cause) is primary efficacy endpoint of the study. Secondary endpoints include total PFS (time from randomization until the second progression), survival at 2 and 3 years, best overall response rate, duration of response. About 90 patients will take part in the ancillary study for the evaluation of biomarkers on the biological samples available (biopsies + blood samples). 30 Sites in Europe will concur to enroll the patients in the trial. This study is open and currently enrolling patients. Clinical trial information: NCT02631447.

TPS9599 **Poster Session (Board #203a), Sat, 1:15 PM-4:45 PM**

A randomized phase II study of vemurafenib plus cobimetinib continuous versus intermittent in previously untreated *BRAF V600*-mutation positive patients with unresectable locally advanced or metastatic melanoma. *First Author: Jose A. Lopez-Martin, Medical Oncology Department, Hospital 12 de Octubre, Madrid, Spain*

Background: Previous clinical trials have shown that vemurafenib significantly increases PFS and OS in untreated BRAFV600 mutant advanced melanoma patients. Nevertheless, disease progression occurs after a median of 6-7 months since start of vemurafenib. Several mechanisms of acquired resistance to vemurafenib result in reactivation of MAPK pathway. Upfront addition of a MEK inhibitor (MEKi) to vemurafenib delays secondary resistance to BRAFi. The combination of cobimetinib, a MEKi, plus vemurafenib as a continuous administration was approved by FDA in 2,015 in untreated metastatic BRAFV600 advanced melanoma patients based on an increase in PFS and OS achieved in a phase III trial (coBRIM trial). Preclinical models have shown that continuous vemurafenib dosing promotes the clonal expansion of drug-resistant cells, and intermittent dosing could serve to eliminate the fitness advantage of the resistant cells and delay the onset of drug-resistant disease (Das Thakur, Nature 2013). These observations and some clinical case reports support upfront evaluation of alternative dosing regimens of MAPK pathway inhibition. **Methods:** This is a randomized phase II study to explore the efficacy and safety of two schedules of administration of vemurafenib in combination with cobimetinib (continuous – 28-day cycles with vemurafenib 960 mg PO BID, Days 1-28, and cobimetinib 60 mg PO QD, Days 1-21 – and intermittent – same dose/schedule during first 12 weeks, and then, same doses with the following schedule: vemurafenib 4 *weeks on* /2 *weeks off*, and cobimetinib 3 *weeks on*/ 3 *weeks off*), in patients with untreated, BRAFV600 mutated, unresectable, measurable (RECIST 1.1), locally advanced or metastatic melanoma. Prior adjuvant immunotherapy is allowed. Primary endpoint is PFS. Secondary endpoints include: OS, ORR, pharmacokinetic and pharmacodynamic profiles and safety. Additional translational research to analyze predictive factors and mechanism of resistance will be explored. The trial is in progress; 56 of up to 116 planned pts have been recruited at the end of December 2016 (enrollment started in June 2015). Clinical trial information: NCT02583516.

TPS9600 **Poster Session (Board #203b), Sat, 1:15 PM-4:45 PM**

Multicenter phase 2 study to identify the optimal neo-adjuvant combination scheme of ipilimumab (IPI) and nivolumab (NIVO) (OpACIN-neo). *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The outcome of high risk stage IIIb and IIIc melanoma patients is poor, with a 5 year overall survival (OS) rate of $<$ 50%. Adjuvant high dose IPI significantly improves 5 year progression free survival (PFS) and OS. In stage IV patients the combination of IPI and NIVO improves response rates (RR) and PFS compared to monotherapy, but at cost of higher toxicity. Neo-adjuvant treatment may be a favorable approach as immune checkpoint inhibition (ICI) is of greatest value at the moment of TCR triggering and therefore dependent on the amount of antigen present. The phase Ib OpACIN study comparing neo-adjuvant and adjuvant IPI and NIVO showed that neo-adjuvant treatment is feasible as all patients underwent surgery on time. The neo-adjuvant pathological RR was 80%, although 18/20 patients (90%) stopped early due to $\geq$1 grade 3 or 4 immune-related adverse events (irAEs). To date (median follow-up 45 wks), none of the 8 responders in the neo-adjuvant arm have relapsed. This raises the question whether the neo-adjuvant IPI and NIVO schedule can be adjusted to reduce toxicity but preserve efficacy. **Methods:** The aim of the multi-center phase 2 OpACIN-neo trial is to identify an optimal neo-adjuvant combination scheme of IPI and NIVO. 90 patients with resectable stage III melanoma will be randomized 1:1:1 between three combination schemes of IPI and NIVO. Patients in arm A will receive 2 courses standard regimen IPI 3mg/kg + NIVO 1mg/kg q3wks, in arm B IPI 1mg/kg + NIVO 3mg/kg q3wks, and in arm C 2 courses of IPI 3mg/kg q3wks directly followed (2-24hr) by 2 courses NIVO 3mg/kg q2wks. All patients will undergo surgery at week 6. The primary endpoints are rate of grade 3/4 irAEs, pathological RR, and radiologic RECIST 1.1. An interim analysis is planned after 13 patients have been accrued to each arm (according to the Simon 2-stage design). Major inclusion criteria are: $\geq$1 measurable lymph node metastases (according to RECIST 1.1) that can be biopsied, no history of in-transit metastases in the last 6 months, and naïve for ICI. Baseline biopsies and blood samples (week 0, 6, 12) will be taken for translational research. The first center started inclusion in December 2016, until now 2 patients have been enrolled. Clinical trial information: NCT02977052.

10003 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

Lorazepam as an adjuvant to haloperidol for agitated delirium at the end of life: A double-blind randomized controlled trial. *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Agitated delirium is a highly distressing neuropsychiatric syndrome common in the last days of life. The use of benzodiazepines for agitated delirium is highly controversial. We compared the effect of lorazepam versus placebo as an adjuvant to haloperidol for persistent agitated delirium. **Methods:** In this double-blind trial, we randomly assigned patients with advanced cancer admitted to an acute palliative care unit with agitated delirium despite scheduled haloperidol to either lorazepam 3 mg IV or placebo, in addition to haloperidol 2 mg IV upon the onset of agitation. The primary outcome was the Richmond Agitation Sedation Scale (RASS) over the first 8 hours, ranging from -5 (unarousable) to +4 (combative). Secondary endpoints were rescue neuroleptic use, perceived comfort, delirium-related distress, adverse effects and overall survival. 26 patients per arm provided 80% power to detect a between arm difference of 0.5 effect size in mean RASS with a=5%. We used the Wilcoxon Rank Sum test for primary comparison. **Results:** 52 of 58 (90%) patients who received the medications completed 8 h of observation. RASS decreased significantly within 30 min of treatment in both arms (Table). The lorazepam arm was associated with significantly greater reduction of RASS (Table), less rescue neuroleptics (mean haloperidol equivalent dose 1 mg v. 3 mg, P=0.02), and greater comfort as perceived by blinded caregivers (84% v. 37%, P=0.007) and nurses (77% v. 30%, P=0.005) compared to placebo. We found no significant between-group differences in delirium-related distress, adverse effects and overall survival (median 68 v. 73 h, P=0.56). **Conclusions:** The combination of lorazepam/haloperidol resulted in rapid and significant reduction of agitation compared to haloperidol alone. Our study supports the judicious use of single dose lorazepam/haloperidol for persistent agitated delirium. Clinical trial information: NCT01670097.

RASS change.

	Mean difference (95% CI)			
	Lorazepam + haloperidol (n=29)	Placebo + haloperidol (n=29)	Difference between arms	P value

10005 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

Effect of inpatient palliative care during hematopoietic stem cell transplantation (HCT) hospitalization on psychological distress at six months post-HCT. *First Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

Background: Patients' experience during HCT hospitalization leads to significant psychological distress post-HCT. Inpatient palliative care integrated with transplant care improves patient-reported QOL and symptom burden during hospitalization for HCT. We assessed the impact of the inpatient palliative care intervention on patients' QOL, mood, and post-traumatic stress disorder (PTSD) at 6 months post-HCT. **Methods:** We randomized 160 patients with hematologic malignancies admitted for autologous or allogeneic HCT to an inpatient palliative care intervention (n=81) integrated with transplant care compared to transplant care alone (n=79). At baseline and 6 months post-HCT, we assessed QOL, mood, and PTSD symptoms using the Functional Assessment of Cancer Therapy-Bone Marrow Transplant (FACT-BMT), the Hospital Anxiety and Depression Scale (HADS) and Patient Health Questionnaire (PHQ-9), and the PTSD checklist, respectively. To assess symptom burden during HCT hospitalization, we used the Edmonton Symptom Assessment Scale. We utilized linear regression models controlling for baseline values to analyze the intervention effects on outcomes at 6 months. We conducted causal mediation analyses to examine whether symptom burden during HCT mediated the effect of the intervention on outcomes at 6 months. **Results:** Between 8/14 and 1/16, we enrolled 160/186 (86%) of potentially eligible patients. At 6 months post-HCT, the intervention led to improvements in depression and PTSD symptoms, but not QOL or anxiety [Table]. Improvement in symptom burden during HCT hospitalization partially mediated the effect of the intervention on patient-reported outcomes at six months post-HCT. **Conclusions:** Inpatient palliative care integrated with transplant care leads to improvements in depression and PTSD symptoms at 6 months post-HCT. Addressing symptom burden during HCT hospitalization partially accounts for the effect of the intervention on these long-term outcomes. Clinical trial information: NCT02207322.

10006 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

American Cancer Society (ACS) Nutrition and Physical Activity Guidelines after colon cancer diagnosis and disease-free (DFS), recurrence-free (RFS), and overall survival (OS) in CALGB 89803 (Alliance). *First Author: Erin Van Blarigan, University of California, San Francisco, San Francisco, CA*

Background: The ACS Nutrition and Physical Activity Guidelines for Cancer Survivors include: 1) healthy body weight; 2) physical activity; and 3) a diet high in vegetables, fruits, and whole grains. It is not known whether colon cancer patients who follow these guidelines have improved DFS, RFS, or OS. **Methods:** We conducted a prospective study among 992 stage III colon cancer patients enrolled in an adjuvant chemotherapy trial in 1999-2001. Lifestyle was assessed twice. We applied a score developed by McCullough ML et al. to quantify adherence to the ACS guidelines based on BMI; physical activity; and intake of vegetables, fruits, whole grains, and red/processed meats (range: 0-6; higher = more healthy behaviors). Alcohol is included in the ACS guidelines for cancer prevention, but not cancer survivors; we tested the score without and with alcohol using McCullough et al.'s cut points: 0 pts = >1/d for women, >2/d for men; 1 pt = no alcohol; 2 pts = >0-1/d for women, >0-2/d for men. We estimated hazard ratios (HR) and 95% confidence intervals (CI) for DFS, RFS, and OS adjusting for clinical, demographic, and lifestyle factors. **Results:** Over 7 y median follow-up, we observed 335 recurrences and 299 deaths (43 without recurrence). Compared to patients with 0-1 pt (262, 26%), patients with 5-6 pts (91, 9%) had 42% lower risk of death (HR: 0.58; 95% CI: 0.34, 0.99; p-trend: 0.01) and a trend toward improved DFS (HR: 0.69; 95% CI: 0.45, 1.06; p-trend: 0.03). When including alcohol in the score, the adjusted HR's comparing patients with 6-8 pts (162; 16%) to 0-2 pts (187; 91%) were: 0.49 for OS (95% CI: 0.32, 0.76; p-trend: 0.002), 0.58 for DFS (95% CI: 0.40, 0.84; p-trend: 0.01), and 0.64 for RFS (95% CI: 0.44, 0.94; p-trend: 0.05). **Conclusions:** Colon cancer patients with a healthy body weight who engaged in physical activity, ate a diet high in whole grains, vegetables, and fruits and low in red/processed meats, and drank moderate alcohol had longer DFS and OS than patients who did not engage in these behaviors. Support: U10CA180821, U10CA180882, U10CA180820, K07CA197077, R01CA118553, P50CA127003, R35CA197735. ClinicalTrials.gov: NCT00003835.

10007 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

The influence of yoga on mediational relationships between sleep and cancer-related fatigue: A URCC NCORP RCT in 321 cancer patients. *First Author: Po-Ju Lin, University of Rochester Medical Center, Rochester, NY*

Background: Cancer-related fatigue (CRF) is one of the most incapacitating adverse effects of cancer and its treatments. CRF co-occurs with impaired sleep quality in cancer survivors, increasing morbidity and mortality. We have previously shown that yoga significantly lowers CRF and improves sleep quality in survivors. However, it is not clear if the effect of yoga on CRF is mediated by improvements in sleep quality. This study assessed the mediating effects of changes in sleep quality stemming from YOCAS yoga on improvements in CRF. **Methods:** We conducted a secondary analysis on data collected from a multicenter phase III randomized controlled clinical trial with 2 arms (standard care and standard care + a 4-week YOCAS yoga intervention). 321 cancer patients (96% female; mean age, 54 years; 77% had breast cancer) reported both sleep quality, measured by the Pittsburgh Sleep Quality Index (PSQI), and CRF, evaluated by Multidimensional Fatigue Scale Inventory (MFSI). Causal mediation analyses were used to estimate effects of the changes in global PSQI scores and in each PSQI subscale on the relationship between yoga and CRF. **Results:** Yoga significantly improved both CRF ($p < 0.01$) and sleep quality ($p < 0.01$), compared to standard care, with total reduction in CRF by 6.5 points. Sleep quality significantly mediated the changes in CRF by 1.4 points ($p < 0.01$) in addition to the direct effect of yoga on CRF reduction (by 5.1 points; $p < 0.01$), suggesting that 22% (95% CI: 7%-54%) of the reduction in CRF was mediated through improving sleep quality. Among the PSQI subscales, daytime dysfunction had the most mediating effect of yoga on CRF. In this model, yoga directly improved CRF by 4.1 points ($p = 0.01$) and the mediating effect of yoga on CRF via daytime dysfunction was 2.4 points ($p < 0.01$), suggesting that 37% (95% CI: 23%-81%) of the improvements in CRF was mediated through decreasing daytime dysfunction. **Conclusions:** Between 22 and 37% of the improvements in CRF from yoga are due to improvements in sleep quality and reductions in daytime dysfunction. Clinicians should consider prescribing yoga for survivors experiencing CRF in combination with sleep disorders. Funding: NCI UGCA189961, R25 CA102618. Clinical trial information: NCT00397930.

10008 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Korean red ginseng to improve cancer-related fatigue in colorectal cancer patients with FOLFOX chemotherapy: A randomized, double-blind, placebo-controlled, parallel, multicenter trial, NCT02039635. *First Author: Yeul Hong Kim, Korea University College of Medicine, Seoul, Korea South*

Background: Cancer-related fatigue(CRF) is a common and severe symptom in patients with cancer. The purpose of this study is to evaluate the anti-fatigue effect of Korean Red Ginseng(Steamed *Panax ginseng* C.A. Meyer) on patients with colorectal cancer. **Methods:** 438 colorectal cancer patients in treatment with mFOLFOX-6 regimen were randomly assigned to either the Korean Red Ginseng[KRG](n = 219) or placebo(n = 219) group and received 2,000 mg/day test substances for 16 weeks. The primary endpoint was the Area Under Curve(AUC) of Brief Fatigue Inventory(BFI) over 16 weeks. The AUC and change from the baseline were calculated. The frequency and types of adverse events were determined by the National Cancer Institute's Common Terminology Criteria for Adverse Events, version 4.0. **Results:** 438 colorectal cancer patients were enrolled from 15 institutions. Changes from the baseline in the global BFI were 78.54(Standard deviation [SD] = 16.91) in KRG group vs. 75.89(SD = 16.85) in placebo group at 16 weeks(P = 0.0363). Changes from the baseline in the Usual Fatigue were 76.15 (SD = 17.08) in KRG group vs. 73.08(SD = 17.03) in placebo group at 16 weeks (P = 0.0454). Changes from the baseline in the Mood were 80.46(SD = 17.16) in KRG group vs. 77.88(SD = 17.59) in placebo group at 16 weeks (P = 0.0086). Changes from the baseline in the Relations with Others were 82.09(SD = 17.49) in KRG group vs. 78.67(SD = 17.90) in placebo group at 16 weeks(P = 0.0080). Changes from the baseline in the Walking ability were 82.70(SD = 17.28) in KRG group vs. 80.77(SD = 16.47) in placebo group at 16 weeks(P = 0.0090). Changes from the baseline in the Enjoyment of life were 79.53(SD = 19.53) in KRG group vs. 77.51(SD = 18.02) in placebo group at 16 weeks(P = 0.0150). Toxicities per self-report and CTCAE grading did not differ statistically significantly between the groups. **Conclusions:** The data supports benefits of consuming 2,000 mg KRG water extract powder daily on CRF over 16-week period. There were no discernible toxicities associated with the treatment. More studies on mechanisms of KRG to guide its role in CRF improvement are needed. Clinical trial information: NCT02039635.

FDA analysis of enrollment of older adults in clinical trials for cancer drug registration: A 10-year experience by the U.S. Food and Drug Administration. *First Author: Harpreet Singh, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Older adults are a growing segment of our oncology population, with an expected increase in cancer incidence of 67% from 2010 to 2030 in people age 65 and older. However, older adults have been proportionally underrepresented in clinical trials. We sought to analyze the age-related enrollment of cancer patients onto trials supporting registration of new drugs or new indications approved by the US Food and Drug Administration from 2005 to 2015. **Methods:** This study involved retrospective analyses of demographic data of cancer patients enrolled onto trials supporting registration from 2005-2015. The data on 224,766 cancer patients supporting 105 drug applications were analyzed according to age distributions of <65, 65-69, 70-74, 75-79, and ≥80 years. The rates of enrollment were compared with the corresponding rates in the US cancer population. The age distributions of the US cancer population were derived from the Surveillance, Epidemiology, and End Results Program of the National Cancer Institute for the year 2013 based on the 2010 US Census. **Conclusions:** Older adults were under-represented in the registration trials of new cancer therapies, especially those over age 75. Various strategies may be needed to evaluate cancer therapies for older adults in prospective clinical trials and to improve cancer care in adults over age 75. These include re-evaluating what may be considered restrictive eligibility criteria so as not to exclude older adults. Incorporating elements from geriatric assessment tools may help identify older adults most likely to benefit from treatment. More detailed labeling information that reflects the clinical experience with older adults could be considered. The FDA encourages drug sponsors as well as clinical trial cooperative groups to devise strategies to recruit patients that are reflective of their intended population.

	Clinical Trial Participants (2005-2015)	Cancer Incidence (2013)
<65	138077 (60%)	559949 (44%)
65-69	38664 (17%)	174886 (14%)
70-74	27578 (12%)	162483 (13%)
75-79	17544 (8%)	169510 (13%)
80+	9678 (4%)	209949 (16%)

10010 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Adherence to geriatric assessment (GA)-based recommendations in older patients (pts) with cancer. *First Author: Lore Decoster, UZ Brussel, Brussels, Belgium*

Background: In the general older population, GA-guided treatment plans improve overall survival, quality of life and functional status. In geriatric oncology, studies mainly focused on screening and assessment but not on geriatric interventions and follow-up. The aim of this study was to investigate the adherence to recommendations and subsequent interventions based on GA results in older pts with cancer. **Methods:** A prospective Belgian multicenter (n = 22) cohort study included pts ≥70 years with a malignant tumor when an oncological treatment decision had to be made. Pts with an abnormal G8 (≤14/17) underwent GA and were included in this study. Recommendations for interventions were formulated based on GA results. At follow-up adherence to GA-based recommendations was documented. **Results:** From 11-2012 till 2-2015, G8 screening was performed in 8451 pts. 5838 pts with an abnormal G8 were included in the study. Geriatric recommendations were given in 79.2% of pts with a median of 2/pt (range 0-10), most frequently consultation of a dietician (73%) for malnutrition, a social worker (54.8%) for social and functional status problems and a geriatrician (42.1%) for general geriatric problems. Follow-up data were available for 4167 pts. In the group of pts where recommendations were given, at least one intervention was performed in 69% with a median of 1/pt (range 0-6), most frequently dietician (43.4%), social worker (26.1%) and geriatrician (22.6%). A total of 7569 actions were undertaken for a total of 5725 geriatric recommendations. Recommendations were most frequently adhered to for malnutrition, social status and functional status problems. The most frequent actions undertaken were nutritional support and supplements, extended home care and psychological support. **Conclusions:** This large scale Belgian study focusses on the adherence to GA based interventions in older pts with cancer and contributes to the optimization of care for these pts. We identified the domains for which geriatric interventions are most frequently recommended and adhered to and which health care professionals and referrals are essential in the multidisciplinary approach of older pts with cancer.

10011 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

New-onset congestive heart failure (CHF) and cardiovascular disease (CVD) in older colorectal cancer (CRC) survivors: A population-based study. *First Author: Kelly Kenzik, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: CRC is primarily a disease of the elderly. The high burden of pre-existing comorbidities alone or in concert with cancer treatment place the older patients with CRC at increased risk of new-onset morbidities, specifically, CVD and CHF. However, the magnitude of risk of new-onset morbidity, and its association with pre-existing comorbidities or treatment remain unknown. **Methods:** Using SEER-Medicare data, we evaluated individuals diagnosed with incident stage I-III CRC at age ≥66y between 1/1/2000 and 12/31/2011 who had survived ≥2y after diagnosis (n = 57,256; 77% with colon cancer). We compared these to an age, sex-, and race-frequency matched comparison group of non-cancer Medicare patients (n = 104,731). We evaluated new-onset CHF and CVD using competing risk cumulative incidence functions and multivariable Cox regression models. **Results:** The median age at diagnosis was 77y (66-106y); 45% males; and 85% non-Hispanic white. Median follow-up was 8y (2-14y) from diagnosis of CRC. Treatment included surgery for 99%, chemotherapy for 31%, and radiation for 12%. *New-onset morbidity:* The 10y cumulative incidence of new-onset CHF and CVD were 43.6% and 58.9%, respectively. After controlling for pre-cancer comorbidities, CRC survivors were at increased risk of new-onset CHF (HR 1.29) and CVD (HR 1.74) (all $p < 0.001$) compared to controls. Patients receiving radiation (HR 1.29) or 5-FU+oxaliplatin (HR 1.09) were at increased risk of CVD compared to those without those therapies ($p < 0.001$). Pre-existing diabetes (HR 1.16) and CHF (HR 1.21) independently increased the risk of CVD ($p < 0.001$). While 5FU+oxaliplatin did not increase the risk of CHF independently (HR 0.97), diabetic patients treated with 5-FU+oxaliplatin were at 1.71-fold increased risk of developing CHF ($p < 0.001$) when compared with those without pre-existing diabetes. **Conclusions:** Older CRC survivors are at increased of developing CHF and CVD. Monitoring survivors with a history of exposure to 5FU+oxaliplatin or radiation, and improving management of pre-existing comorbidities may reduce the burden of long-term morbidity for older CRC survivors.

A multimodal intervention to enhance sexual function and quality of life (QOL) in hematopoietic stem cell transplant (HCT) survivors. *First Author: Sarah Fishman, Massachusetts General Hospital, Boston, MA*

Background: Although sexual dysfunction is a common long-term complication in allogeneic HCT survivors, interventions to address sexual dysfunction are lacking. **Methods:** We conducted a pilot study to assess the feasibility and preliminary efficacy of a multimodal sexual dysfunction intervention to improve sexual function in allogeneic HCT survivors. Transplant clinicians systematically screened all HCT survivors $\geq$ 3 months post-HCT for sexual dysfunction causing distress using the NCCN Survivorship Guidelines. Those who screened positive attended monthly intervention visits with trained study clinicians that focused on 1) assessing sexual dysfunction; 2) educating and empowering patients to address this topic; and 3) implementing therapeutic interventions. We used the PROMIS Sexual Function and Satisfaction Measure, Functional Assessment of Cancer Therapy-Bone Marrow Transplant (FACT-BMT), and Hospital Anxiety and Depression Scale (HADS) to assess sexual function, QOL, and mood at baseline and six months post-intervention, respectively. **Results:** 32.7% (49/150) of patients screened positive for sexual dysfunction causing distress. 95.9% (47/49) of patients who screened positive agreed to participate. We demonstrated significant improvement in patients' satisfaction and interest in sex as well as sexual function including orgasm, erectile function, lubrication, and vaginal discomfort [Table]. Six of ten patients who were not sexually active prior to the intervention became sexually active post-intervention (P = 0.031). Patients reported improvement in their QOL and a trend toward lower depression [Table]. **Conclusions:** The multimodal intervention to address sexual dysfunction appears feasible with encouraging preliminary efficacy for improving sexual function, QOL, and mood in allogeneic HCT survivors. Clinical trial information: NCT02492100.

Patient outcomes:	Pre-Intervention	Post-Intervention	P- Value
Satisfaction with sex	10.52	23.61	<0.0001
Interest in sex	11.30	13.74	0.039
Orgasm	1.57	2.78	0.011
Erectile function	17.3	29.2	0.002
Lubrication	9.38	22.85	0.005
Vaginal discomfort	41.69	27.15	0.004
QOL	105.43	116.03	0.036
Depression	4.35	3.04	0.134
Anxiety	3.88	4.34	0.431

Longitudinal assessment of cancer-related cognitive impairment (CRCI) up to six-months post-chemotherapy with multiple cognitive testing methods in 943 breast cancer (BC) patients and controls. *First Author: Michelle Christine Janelsins, University of Rochester Medical Center, Rochester, NY*

Background: Large nationwide studies are needed to assess CRCI. **Methods:** NCORPs recruited BC patients and age-matched non-cancer controls. Computerized ((CANTAB Delayed Match to Sample (DMS), Rapid Visual Processing (RVP), Verbal Recognition Memory (VRM)), paper-based ((Controlled Oral Word Association (COWA), and Trail Making Test (TMT)) , and phone-based (category fluency, word recall, backward counting and digits backward) cognitive assessments of memory, attention, and executive function at pre-chemotherapy, post-chemotherapy, and 6 months follow-up (or time-equivalent for controls) were completed. Longitudinal mixed model (LMM)s included group, time, time*group, and adjusted for age, education, reading, anxiety, and depression. **Results:** 580 BC patients (mean age = 54) and 363 controls (mean age = 53) were assessed. In all LMMs, there was a significant group*time interaction depicting lower scores in patients compared to controls ($p < 0.005$) except for TMT ($p = 0.09$). For longitudinal change on the DMS memory test (primary aim), we observed no significant difference between groups from pre- to post-chemotherapy but did observe a significant difference from pre-chemotherapy to follow-up ($p = 0.017$) where patients significantly declined ($p = 0.005$) and controls did not change. We observed similar results for RVP. For VRM, there was a significant pre- to post-chemotherapy group difference ($p = 0.003$). For COWA, patients significantly declined and controls significantly improved reflecting a significant between group difference ($p < 0.001$) from pre- to post-chemotherapy. For TMT, both groups significantly improved with patients improving less than controls reflected by a significant between group difference ($p = 0.04$) that remained a trend at follow-up ($p = 0.06$). On all phone tests, there was a significant between group effect from both pre- to post-chemotherapy and at follow-up with patients doing less well than controls (all $p < 0.001$). **Conclusions:** This nationwide study shows CRCI in BC patients persists in multiple cognitive domains up to 6 months post-chemotherapy compared to controls. Clinical trial information: NCT01382082.

New primary lung cancers after a head and neck cancer: The impact of radiation therapy and latency period on risk. *First Author: Chetan Jeurkar, Drexel University College of Medicine, Philadelphia, PA*

Background: Patients with head and neck cancer (HNC) have an increased risk of developing a new primary lung cancer (NPLC). Our objective was to assess the critical latency period after HNC when the risk for a NPLC was highest and to see if radiation therapy (XRT) had an impact on this risk. **Methods:** This was a population based study of patients with HNC in the Surveillance, Epidemiology, and End Results (SEER) database. The risk of NPLC was calculated using standardized incidence ratios (SIR) and from this, the number needed to screen (NNS) was extrapolated. The cohort was separated by delivery of XRT and latency period of the NPLC. **Results:** There were a total of 4,209 NPLC from the cohort of 85,154 HNC patients. The SIR, NNS, observed/expected number of NPLC for both the no XRT and XRT groups are shown in table 1. As compared to the no XRT group, the XRT group had higher SIR and lower NNS values across all latency periods. The highest SIR for both the no XRT and XRT groups came between 1 and 3 years. **Conclusions:** In patients with HNC, the risk of developing a NPLC is associated with receiving XRT. This risk is highest within 10 years of the initial HNC diagnosis. The NNS was especially low for the XRT group, less than 100 for most latency periods. Since low dose computed tomography scans for lung cancer screening in smokers has a NNS of 217, screening for these patients should be considered, especially within 10 years of the primary HNC diagnosis. This may contribute to better survivorship care in these patients.

SIR, observed/expected number of NPLC, and NNS for patients with a primary HNC separated by delivery of XRT.

XRT Delivery	Latency (Years)	SIR	Observed NPLC	Expected NPLC	NNS	Total Persons
No XRT	<1	2.18	142	65.04	472.0	36,327
	1-3	2.60	346	133.11	146.3	31,146
	3-5	2.41	274	113.85	153.9	24,642
	5-10	2.41	537	223.17	65.3	20,510
	10-15	1.88	278	148.01	100.0	12,997
	>15	1.80	334	186.07	52.7	7,794
	Total	2.20	1911	869.24	34.9	36,327
Beam XRT	<1	3.45	256	74.24	268.6	48,827
	1-3	5.86	694	118.44	65.6	37,744
	3-5	4.57	387	84.65	77.6	23,466

Impact of intensity of post-treatment surveillance on survival in colorectal cancer. *First Author: Rebecca A Snyder, Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The optimal strategy for CRC post-treatment surveillance is unknown. The frequency and type of testing remains controversial, and it is unclear whether surveillance impacts rates of detection or survival. The purpose of this study was to determine if the intensity of post-treatment surveillance is associated with time to recurrence detection, treatment, or overall survival (OS). **Methods:** Primary records of a random sample of 10,636 Stage I-III CRC patients from Commission on Cancer accredited hospitals (2006-2007) were abstracted, and detailed results of surveillance testing were reviewed. Data was merged with records in the National Cancer Database (NCDB). A predicted and observed number of imaging and CEA tests per patient were determined and clustered by hospital to categorize patients into high (HI, O/E $\geq$ 1) or low intensity (LI, O/E $<$ 1) categories. **Results:** 6,279 patients underwent imaging or CEA surveillance in the 3 years after CRC treatment. Patients with HI imaging (50.6%) or CEA (51.2%) had a mean of 2.9 imaging studies and 4.7 CEA tests. Patients with LI imaging underwent a mean of 1.4 imaging studies and 1.6 CEA tests. 5-year recurrence rates did not differ based on intensity of surveillance. Stage II and III patients who underwent HI imaging and CEA testing had a slightly higher resection rate, but this did not translate into an improvement in 5-year OS. **Conclusions:** High vs. low intensity surveillance was not associated with earlier detection of recurrent disease or improved OS. HI surveillance was associated with a slightly higher resection rate, but this did not result in a survival benefit. Our findings within a national hospital registry cohort failed to demonstrate a survival benefit of HI surveillance and suggest that an effective surveillance strategy may involve less frequent testing.

	Imaging			CEA		
	LI	HI	P-value	LI	HI	P-value
Observed # tests in 3 years Mean (SD) (n = 6279)	1.4 (1.46)	2.9 (2.4)	< .001	1.7 (2.6)	4.7 (4.4)	< .001
3-year recurrence rate (n = 8542)	17.7%	17.4%	0.673	17.7%	17.4%	0.816
Resection of recurrence in 3 years (n = 3393)	3.9%	4.8%	0.05	4.2%	4.5%	0.40

Receipt of recommended surveillance with imaging in survivors of early stage non-small cell lung cancer. *First Author: Jyoti Malhotra, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Lung cancer survivors have a high risk for recurrence and second cancers and a 5-year survival of only 50%. Imaging surveillance for early cancer detection in this group is recommended for life. We measured the rates and determinants of regular surveillance imaging in non-small cell lung cancer (NSCLC) survivors. **Methods:** Using the Surveillance Epidemiology and End Results (SEER)-Medicare linked database, we identified 10680 patients with stage I and II NSCLC, age $\geq$ 66 years diagnosed from 2001-2011 and treated with surgery. Patients were censored at the time of recurrence/second cancer, loss of insurance or 3 months before death. Receipt of a CT and/or PET scan during the surveillance periods of 7 to 18, 19 to 30, 31 to 42 and 43 to 60 months from the date of surgery was assessed. Percentage of patients' receiving regular imaging up to 18, 30 and 60 months of follow-up was determined. Adjusted cox regression was used to measure the effect of receiving recommended imaging on survival. **Results:** Overall, 79% and 40% survivors had follow-up information till the end of 30-month and 60-month surveillance periods respectively. Forty nine percent survivors were male and 86% were white. With a median follow-up of 7.6 years, 71% of the survivors received imaging in the first 18 months after surgery, but only 56% and 44% of survivors continued to receive regular imaging by 30-month and 60-month of follow-up periods respectively. Survivors were less likely to receive imaging if they were older ($\geq$80 years), black, not married, had rural residence, did not receive adjuvant therapy, had stage I disease (compared to stage II) and were diagnosed in 2006 or earlier. In adjusted analysis, survivors receiving recommended imaging up to 18 months from surgery had improved survival compared to survivors who did not (HR 0.86; 95% CI 0.81-0.92). Survival benefit was also observed in survivors who had regular imaging up to 5 years from surgery (HR 0.68; 95% CI 0.60-0.76). **Conclusions:** More than half the lung cancer survivors did not receive recommended long-term surveillance imaging especially if older, black or with rural residence. Adherence to regular surveillance even at 5 years from initial surgery is associated with improved survival.

Mitochondrial DNA content in peripheral blood as a biomarker for cancer-related fatigue in early-stage breast cancer patients: A prospective cohort study. *First Author: Jung-Woo Chae, Department of Pharmacy, National University of Singapore, Singapore, Singapore*

Background: Cancer-related fatigue (CRF) is reported to be associated with mitochondrial dysfunction. Hence, mitochondrial DNA (mtDNA) content, a biomarker of mitochondrial dysfunction, is hypothesized to correlate with the onset of CRF. This study aimed to evaluate the association between peripheral blood mtDNA content and CRF in patients receiving chemotherapy. **Methods:** This was a prospective cohort study. Early-stage breast cancer patients (Stages I to III) receiving anthracycline or taxane-based chemotherapy were recruited. CRF was assessed using the validated Multidimensional Fatigue Symptom Inventory-Short Form (MFSI-SF) at two time points: baseline (T1; prior to treatment) and 6 weeks after initiation of treatment (T2). Worsening of CRF was defined as $\geq$10% increase in the overall MFSI-SF score at T2. Peripheral blood mtDNA content was measured at both time points using real-time quantitative polymerase chain reaction. Multiple logistic regression was utilized to evaluate the association between mtDNA reduction and worsening of CRF, adjusting for age, anxiety, insomnia and other clinically important covariates. **Results:** A total of 91 patients [mean age ($\pm$SD): 51.3 (9.2) years; 81.3% Chinese; 63.3% receiving anthracycline-based chemotherapy] were recruited. Proportions of patients with worsening of CRF increased from the lower to the upper quartiles of mtDNA reduction (26.1%, 30.4%, 52.2%, and 59.1% in quartiles 1, 2, 3, and 4, respectively, $P = 0.010$ for trend). Reduction of mtDNA content was significantly greater among those with worsening of CRF compared to those without CRF [mean reduction ($\pm$SD): 16.3 (23.5) vs 6.0 (17.3), $P = 0.018$]. After adjusting for covariates, every 1-unit reduction of the mtDNA content was associated with a 4% increase risk for worsening of CRF (95% CI, 1%-8%; $P = 0.016$). **Conclusions:** This is the first study to show that reduction of mtDNA content in peripheral blood is associated with onset of CRF in patients receiving chemotherapy. Further validation studies are required to confirm the findings.

Effect of exercise on quality of life (QoL) in 198 older patients with cancer: A URCC NCORP nationwide RCT. *First Author: Kah Poh Loh, University of Rochester Medical Center, Rochester, NY*

Background: Cancer and its treatment frequently impact QoL in patients. In older cancer patients, a small decrement in QoL is associated with significant functional impairment, disability, treatment discontinuation and decreased survival. Little is known about the role of exercise in improving QoL in older cancer patients undergoing active chemotherapy and the mechanistic association between inflammation and QoL. We conducted a secondary analysis of a nationwide phase III RCT to assess the effect of exercise on QoL in older cancer patients. **Methods:** We included 198 older cancer patients (aged $\geq$60 years) who were randomized to receive chemotherapy alone (C) or with EXCAP (Exercise for Cancer Patients). EXCAP is a home–based progressive aerobic and resistance training program. We used ANCOVA to evaluate the effect of EXCAP on QoL (measured by the Functional Assessment of Cancer Therapy-General, FACT-G, and -Cognitive Function, FACT-Cog). Baseline values, gender and chemotherapy duration were adjusted. We assessed associations between changes in QoL and changes in inflammatory cytokines. **Results:** Median age was 66.7 $\pm$ 2.3 years, 92% were female and 77% had breast cancer. In terms of chemotherapy, 3-week and 2-week regimens were used for 72% and 28%, respectively. EXCAP group had better social (p=0.02), emotional (p=0.04) and physical (p=0.03) well-being post-intervention than the C group. There was also a positive trend for improvement in functional, cognitive and overall well-being (Table 1). In the EXCAP group, improved social well-being was associated with decreases in the pro-inflammatory cytokine, IL-8 (r=0.30, p=0.03). **Conclusions:** Our analysis showed that exercise improves QoL in older cancer patients receiving active chemotherapy. Improvement in social well-being may be mediated by reducing inflammation. Physicians should consider incorporating exercise when prescribing chemotherapy for older adults with cancer. Clinical trial information: NCT00924651.

QoL Domains		EXCAP (mean $\pm$ SD)	Control (mean $\pm$ SD)	P-value
FACT-G	Overall	85.5 $\pm$ 15.6	82.1 $\pm$ 17.2	0.46
	Social	25.4 $\pm$ 4.3	23.7 $\pm$ 5.5	0.02
	Emotional	20.5 $\pm$ 3.0	19.9 $\pm$ 3.7	0.04

Effect of exercise on novel biomarkers of muscle damage and cancer-related fatigue: A nationwide URCC NCORP RCT in 350 patients with cancer. *First Author: Karen Michelle Mustian, University of Rochester Medical Center, Rochester, NY*

Background: Chemotherapy may lead to systemic muscle damage. Up-regulation of developmental myosin light chain 5 (MYL5) and myosin heavy chain 8 (MYH8) genes is required for normal muscle regeneration in response to damage. However, secretion of MYL5 and MYH8 proteins into the serum suggest degradation of muscle, which, in turn, may lead to cancer-related-fatigue (CRF). In this study, we investigated (1) the effect of an exercise intervention, Exercise for Cancer Patients (EXCAP) on mRNA gene expression and serum protein levels of MYL5 and MYH8 and (2) the association of these novel biomarkers with CRF. **Methods:** Chemotherapy naïve cancer patients (N = 350; mean age = 55.7) from 39 community oncology practices throughout the U.S. affiliated with the URCC NCORP Research Base participated in this nationwide, multicenter, phase III RCT. Patients were randomized into 2 groups: (1) chemotherapy and (2) chemotherapy plus a 6-week aerobic and resistance exercise prescription-EXCAP. Gene expression and protein levels of MYL5 and MYH8, as well as CRF were assessed pre- and post-intervention from whole blood by qPCR, from serum by Luminex assays, and from patient-report by the Multidimensional Fatigue Symptom Inventory, respectively. **Results:** T-tests show MYL5, but not MYH8, mRNA levels were significantly up-regulated from pre- to post-intervention in exercisers and controls (all $p < 0.01$) with no significant group difference. Additionally, MYL5 and MYH8 serum protein levels significantly increased from pre to post in controls (all $p < 0.05$), but remained stable in exercisers. Significant group differences in these serum proteins ($p < 0.01$) suggest greater muscle degradation in non-exercisers. Pearson correlations revealed trends suggesting increases in MYL5 and MYH8 serum proteins are associated with increases in CRF ($r = 0.09$ and $r = 0.11$, respectively, all $p < 0.10$). **Conclusions:** Results suggest EXCAP exercise is protective from chemotherapy-induced muscle damage via its effects on MYL5 and MYH8, and changes in these novel biomarkers may mediate changes in CRF. Further research is needed to confirm these findings. NCI UGCA189961, R25 CA102618. Clinical trial information: NCT00924651.

Agreement about end-of-life (EOL) care among advanced cancer patients and their caregivers: Associations with care received. *First Author: Charles Stewart Kamen, University of Rochester Medical Center, Rochester, NY*

Background: Patients with advanced cancer and their caregivers often have different preferences regarding patients' EOL care. Disagreement in a patient-caregiver dyad can increase stress and result in suboptimal care. Understanding factors that promote agreement, as well as the effect of agreement on care received at EOL, can inform interventions to improve communication and EOL decision-making for patients and caregivers. **Methods:** 205 patients (Stage III or IV cancer plus limited prognosis) and their caregivers were recruited to a randomized controlled trial of a communication intervention for patients, caregivers, and providers (Cancer Communication Study, PI: Epstein). Before intervention, patients completed the Preferences for Life-Extending Treatment questionnaire, which asked their preference regarding experimental treatment, life support, and palliative care; caregivers were asked about patients' preferences. Binomial logistic regressions analyses modeled agreement in preferences as a function of patient and caregiver demographic characteristics and EOL care received as a function of patient-caregiver agreement. **Results:** The majority of patient-caregiver dyads agreed about experimental treatment (60.3%), life support (63.4%), and palliative care (70.7%). Dyads were more likely to agree about palliative care when patients were female (OR = 1.94, p = .03) and non-Hispanic white (OR = 2.10, p = .07) and when caregivers were college educated (OR = 2.04, p = .03). Of the 82 patients who died during study follow-up, 57 (69.5%) received EOL care congruent with their preferences. In 19 of the 38 (50%) cases where patient-caregiver dyads disagreed, caregivers' preferences predicted EOL care received. Dyadic agreement about life support was associated with increased odds of patients receiving/not receiving life support congruent with their preference (OR = 3.02, p = .02). **Conclusions:** Facilitating agreement between patients and caregivers could improve receipt of patient-centered care. A communication intervention designed to increase dyadic agreement by helping patients and caregivers discuss challenging EOL decisions might improve EOL care delivery. Clinical trial information: NCT01485627.

Randomized trial of a cognitive-behavioral therapy mobile app for anxiety in patients with incurable cancer. *First Author: Joseph Greer, Massachusetts General Hospital, Boston, MA*

Background: Patients with incurable cancer often experience marked anxiety that is associated with poor quality of life (QOL), high symptom burden, and complications with medical treatment. The aim of this study was to test the efficacy of a mobile app-based cognitive-behavioral therapy (CBT) intervention to treat anxiety symptoms in patients with incurable cancer. **Methods:** From 2/15 to 8/16, 145 patients with incurable cancers (e.g., advanced lung, breast, GI/GU, sarcoma, melanoma) who screened positive for at least mild anxiety symptoms (Hospital Anxiety & Depression Scale-Anxiety subscale, HADS-A > 7) were randomized 1:1 at two cancer centers to receive either the CBT mobile app for anxiety or a mobile health education program (control), delivered via tablet computers. The CBT app included 7 modules teaching skills to relax the body, reduce worry, stay present-focused, improve communication, and plan/pace activities, which patients completed over 12 weeks. To assess anxiety, mood, and QOL, we administered the Hamilton Anxiety Rating Scale (HAM-A), Clinical Global Impression Scale (CGI), HADS, and Functional Assessment of Cancer Therapy-General at baseline and 12 weeks. General linear models were used to assess the effect of the intervention on patient outcomes over time. **Results:** The sample was predominantly female (73.8%) and white (91.7%), with a mean age of 56.45 (*SD*= 11.30) years. Both study groups reported significant improvements in anxiety, depression, and QOL from baseline to post-assessment (all *p*-values≤002), with no differences in the improved outcomes between groups. Secondary analyses showed interaction effects on anxiety between the intervention and baseline HAM-A scores. Among patients with higher baseline anxiety, those randomized to the CBT app had greater improvements on the HAM-A (*p*= .043), CGI (*p*= .048), and HADS-A (*p*= .001) compared to the health education control group. **Conclusions:** Patients with incurable cancer who received either a CBT mobile app intervention or mobile health education program reported improvements in anxiety, depression, and QOL. However, the CBT mobile app had better outcomes than health education for patients with higher baseline anxiety. Clinical trial information: NCT02286466.

Improved coping to mediate the positive effects of integrated palliative care on quality of life and depression. *First Author: Jamie M. Jacobs, Massachusetts General Hospital, Boston, MA*

Background: In a recent trial, early integrated palliative care (PC) improved quality of life (QOL) and reduced depression symptoms in patients with newly-diagnosed incurable lung and gastrointestinal (GI) cancer. The mechanisms by which PC benefits these outcomes are unclear. Therefore, we examined whether early integrated PC improved patients' coping strategies and the degree to which changes in coping mediated intervention effects on patient-reported QOL and depression symptoms. **Methods:** From 5/2011 to 7/2015, we enrolled 350 patients with newly diagnosed incurable lung or non-colorectal GI cancer in a randomized trial of early PC integrated with oncology care vs. oncology care alone at Massachusetts General Hospital. Patients completed self-report measures of QOL (Functional Assessment of Cancer Therapy-General), depression symptoms (Patient Health Questionnaire-9), and use of active and avoidant coping strategies (Brief Cope) at baseline, 12, and 24 weeks. Linear regression was used to assess the effects of the early PC intervention on active and avoidant coping strategies. A multiple mediation regression with bias-corrected bootstrapping was modeled to examine whether changes in use of coping strategies mediated intervention effects on QOL and depression symptoms. **Results:** Compared to oncology care, early integrated PC improved patients' use of active coping and reduced use of avoidant coping strategies. Improvements in 24-week QOL in patients assigned to PC were mediated by increased use of active coping strategies (indirect effect = 1.27, bootstrapped SE = 0.65, 95% CI [0.31, 2.86]), but not by decreased use of avoidant coping. Similarly, PC-related reductions in 24-week depression symptoms were mediated by increased use of active coping strategies (indirect effect = -0.39, bootstrapped SE = 0.20, 95% CI [-0.89, -0.08] but not by decreased use of avoidant coping. **Conclusions:** Patients with newly diagnosed incurable cancer who received early integrated PC showed increased use of active coping strategies, which led to improved QOL and depression symptoms. PC may improve QOL and mood by providing patients with the skills to cope effectively with life-threatening illness. Clinical trial information: NCT01401907.

10024 Poster Session (Board #13), Sat, 1:15 PM-4:45 PM

The PULSES project: Teaching the vital elements of code status discussions to oncology residents. *First Author: Oren Hannun Levine, McMaster University, Hamilton, ON, Canada*

Background: Discussions with cancer patients around cardiopulmonary resuscitation (CPR), or 'code status,' are often led by trainees in oncology, but formal education for this competency is lacking. In this study, we developed and tested a novel communication tool, the PULSES framework, for informed code status decision-making (a six-step approach summarized by the PULSES acronym [Table 1]), through an educational workshop. **Methods:** A multicentre randomized controlled trial was carried out at 3 academic cancer centres in Ontario, Canada. Residents in medical oncology (MO) and radiation oncology (RO) programs completed a workshop and an observed structured clinical exam (OSCE). Participants were randomized to complete the training before the OSCE (experimental arm) or after the OSCE (control arm). Randomization was stratified for centre and oncology discipline. Expert raters evaluated communication with two rating tools: the novel PULSES scale and the communication skills assessment form (CSAF), a validated benchmark tool that is not specific to oncology content. The primary outcome was improvement in PULSES scores. **Results:** Forty-six residents consented to participate (28 RO and 18 MO). Groups were well balanced for program and year of training. Participants in the experimental group had higher mean PULSES score than those in the control group (80.4±13.5 vs 63.4±9.7; $p < .001$; maximum score = 108). There was no significant effect for program and no significant interaction between program and training condition. Scores for the PULSES and CSAF scales were highly correlated (R = 0.864). **Conclusions:** The PULSES training improved performance among oncology residents for code status discussions. Improved communication scores were not scale-specific. The PULSES framework offers a standardized approach and can be incorporated into competency-based curricula for postgraduate oncology programs. Future work will explore whether communication training in this area impacts patient-level outcomes.

Six steps for code status communication.

Predictive value of the patient reported outcome "living with cancer" instrument on overall survival in advanced cancer patients: A tool for guiding timing of palliative care consultations. *First Author: Stuart L. Goldberg, COTA, New York, NY*

Background: The Living with Cancer (LWC) patient reported outcome (PRO) instrument evaluates distress from the point of view of the advanced cancer pt. The 7-item Likert survey measures 4 personhood domains (performance status, pain, burden [financial and family], depression) with scores ranging 0-112. In a pilot study of 433 cancer pts at a single center a score of >28 was associated with an increased likelihood of physician's (blinded) opinion of need for end-of-life care discussions (*J Palliative Med* 2016). **Methods:** The LWC instrument is a statistically validated PRO (ASCO Palliative Care Symposium 2016). LWC was administered to 1024 cancer pts receiving non-curative therapy at 7 centers (Regional Cancer Care Associates, NJ) from Sept 2015 - Oct 2016. LWC surveys were linked to the Cota database, which extracts and enriches data from EHRs. Date of survey was used as the start point in time-to-event analysis. **Results:** 290 (28%) pts expired during the study (median f/u 9.9 months). 267 (26%) pts exceeded the threshold score of 28 defined in the pilot set (28 was also independently this study's optimal cut point). Pts with an LWC score >28 had inferior 6 and 12 mo overall survival (69% and 54%) vs pts with scores <29 (88% and 73%) (log rank $p<0.001$). A Cox model demonstrated that LWC score and cancer type were significant (LWC: $p<0.001$, cancer types (compared to B): GI $p<0.001$, GU: p=0.013, T: $p<0.001$, M: p=0.334) A one point score increase in LWC resulted in a 1.8% increase in expected hazard. Among solid tumor pts with LWC >28, 20% died within the next 3 mo and 35% died within the next 6 mo, indicating appropriate timing for hospice and palliative care consults, respectively. **Conclusions:** Pt responses to the LWC instrument predict survival among advanced cancer pts and may be useful in guiding timing of palliative care consultations.

Cancer type	N	<29 6mo OS	<29 12mo OS	>28 6mo OS	>28 12mo OS	Log rank p-value
Gastrointestinal (GI)	331	84.7 %	66.0 %	60.5 %	41.0 %	<0.001
Thoracic (T)	143	74.6 %	52.3 %	52.3 %	37.6 %	0.007
Genitourinary (GU)	140	86.6 %	72.6 %	68.8 %	48.6 %	0.008
Myeloma (M)	239	96.0 %	86.0 %	87.0 %	76.2 %	0.040
Breast (B)	171	92.9 %	82.7 %	84.6 %	71.6 %	0.105

10026 Poster Session (Board #15), Sat, 1:15 PM-4:45 PM

Early specialist palliative care for all hospitalized, advanced cancer patients (ACP)? Better outcomes with "up-front" versus "on-demand" palliative care. *First Author: Monica Malec, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: Palliative care improves outcomes for cancer patients, especially those with advanced disease. Optimal timing for initiation of specialist palliative care remains undetermined. We created a Supportive Oncology inpatient service that integrates immediate "up-front" palliative care (IPC) consultation for selected ACP to supplement our usual oncologic care (UOC) service, which continued to utilize "on-demand" palliative care consultation. Here, we compare ACP populations and selected outcomes between these two versions of in-patient cancer care. **Methods:** A retrospective cohort analysis of ACP receiving either IPC or UOC between Jan 2015-Dec 2015 (N = 809). ACP were compared for age, gender, race, and ethnicity. Disease severity was determined by APR DRG weight, Risk of Mortality (ROM), and Severity score. Outcomes included examining differences between groups for: Length of stay (LOS), Cost, and 30 day readmission rate. Univariate and multivariate analysis were employed. **Results:** 468 ACP were admitted to IPC and 341 to UOC. Compared with UOC, ACP assigned to IPC were significantly younger (61.1±13.2 vs 63.3±13.0, p = 0.02); more likely female (50% vs 40%, P = 0.005); and more likely to be AA (47% vs 35%, P = 0.005). After adjusting for gender, age, race, and encounter type, ACP receiving IPC had higher ROM (52% v 47%, p = 0.03). There were no differences in APR DRG weight (p = 0.30) or Severity scores (p = 0.34). IPC had significantly lower costs ($12,050 vs $15,990, p = 0.003), less 30-day readmissions (16% vs 23%, p = 0.03), and a trend toward shorter LOS (5.6 ± 4.9 vs 6.2 ± 6.5, p = 0.10). **Conclusions:** Our data provides additional evidence for the benefits of earlier specialist palliative care consultation services, including patients traditionally identified as underserved.

10027 Poster Session (Board #16), Sat, 1:15 PM-4:45 PM

Anti-dementia and anti-hyperlipidemic medication use at end of life in elderly lung cancer patients: Analysis of SEER-Medicare data. *First Author: Min Ji Kim, MD Anderson Cancer Center, Houston, TX*

Background: Despite risk for polypharmacy, elderly cancer patients may receive drugs whose time to benefit likely exceeds life expectancy. This study aims to describe use of drugs considered potentially unnecessary, namely anti-hyperlipidemics and anti-dementia drugs, and to identify factors associated with their use in Stage 3 or 4 non-small cell lung cancer (NSCLC) patients approaching end of life. **Methods:** We identified all patients older than 65 diagnosed with primary Stage 3 or 4 NSCLC between 2006 and 2011 in the Surveillance, Epidemiology and End Results (SEER)-Medicare database. Information on drug prescriptions was extracted from Medicare Part D files. First-time hospice enrollment or death date was used as the final endpoint in analysis. The primary outcome was use of drugs of interest at 4 months before NSCLC diagnosis, 6 months and 3 months before death or hospice. Associations with demographic or other factors were tested using the Pearson $\chi 2$ test. **Results:** Of all 7983 patients, 45.1% were taking statins before diagnosis, while 40.7% and 30.9% were still taking statins at 6 and 3 months before death or hospice. Use of bile acid sequestrants, fibric acid derivatives, and cholesterol absorption inhibitors were found to decrease toward death or hospice. In contrast, anti-dementia drug use did not decrease, with 3.4% before diagnosis and 4.2% and 3.5% at 6 and 3 months before death or hospice. Approximately 30% of anti-dementia medications were newly prescribed at 6 and 3 months before study endpoint. Having a higher number of prescriptions at 3 months before death or hospice was associated with higher rates of drug use both before and after cancer diagnosis. Having a higher Charlson comorbidity index correlated with greater anti-dementia drug use before diagnosis. Demographic, socioeconomic, and treatment factors were not found to be correlated with drug use. **Conclusions:** A high prevalence of statin use persists while a notable proportion of anti-dementia drugs are newly prescribed toward death or hospice. Our findings suggest an opportunity for clinicians to re-evaluate risks and benefits of potentially unnecessary medications in elderly patients nearing end of life.

10028 Poster Session (Board #17), Sat, 1:15 PM-4:45 PM

Latino ethnicity, immigrant status, and preference for life-extending end-of-life cancer care. *First Author: Ana Isabel Tergas, Columbia University College of Physicians and Surgeons and New York-Presbyterian Hospital, New York, NY*

Background: Latino advanced cancer patients are less likely to engage in advance care planning, use hospice services, and receive end-of-life (EOL) care in line with their preferences compared to non-Latino advanced cancer patients. Little is known about how immigration status influences preference for life-extending care (LEC) at the EOL. **Methods:** Data were derived from two sequential multi-institutional, longitudinal cohort studies of patients with advanced cancer recruited from 2002 – 2008 (Coping with Cancer I [CwC-1]) and 2010 – 2015 (Coping with Cancer II [CwC-2]). Multiple logistic regression analysis was used to estimate effects of immigrant status and CwC cohort among Latinos, and effects of ethnicity and CwC cohort among US-born Latinos and non-Latino whites, on preference for LEC at the EOL. **Results:** Of the 760 studied cancer patients, 661 were US-born non-Latino (US non-L), 34 were US-born Latino (USL) and 65 were Latino immigrants (LI). LI were less educated (mean years of education: 7.8 years) than USL (11.1 years), who were in turn less educated than US non-L (13.7 years). Far fewer LI had insurance compared to USL (18.5% vs. 64.7%, respectively; $p < 0.001$), and fewer USL had insurance compared to US non-L (64.7% vs. 81.4%, respectively; $p = 0.017$). Within CwC-2, LI had higher odds of preferring LEC over comfort care compared to USL (adjusted odds ratio [AOR] = 9.4; 95% CI: 1.2, 72.4), and USL had lower odds of preferring LEC compared to US non-L (AOR = 0.3; 95% CI: 0.1, 1.0). LI from CwC-2 had higher odds of preferring LEC compared to LI from CwC-1 (AOR = 11.4; 95% CI: 2.7, 48.4), but there was no difference between USL from CwC-2 and USL from CwC-1. US non-L from CwC-2 had higher odds of preferring LEC compared to US non-L from CwC-1 (AOR = 3.9; 95% CI: 2.6, 5.9). Within CwC-1, there was no difference in LEC preference between LI and USL, nor between USL and US non-L. **Conclusions:** Immigrant status has a strong effect on preference for life-extending care among the more recent cohort of Latino cancer patients. Preference for life-extending care appears to have increased significantly over time for Latino immigrants, but remained unchanged for US-born Latinos. Latino immigrants may increasingly want life-extending care near death.

10029 Poster Session (Board #18), Sat, 1:15 PM-4:45 PM

Do elderly and young patients derive similar relative survival benefits from novel oncology drugs? A systematic review and meta-analysis. *First Author: Vanessa Sarah Arciero, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Elderly patients are commonly believed to derive less benefit from cancer drugs, even if they fulfil clinical trial eligibility. We aim to examine if novel oncology drugs provide differential treatment outcomes for elderly and young patients on clinical trials. **Methods:** A systematic review of randomized control trials (RCTs) cited for clinical efficacy evidence in novel oncology drug approvals by the Food and Drug Administration, European Medicines Agency, and Health Canada between 2006 and 2015 was conducted. Studies reporting age-based subgroup analyses for overall or progression free survival (OS/PFS), were considered. Independent reviewers extracted survival hazard ratios (HRs) and confidence intervals (CIs) for age-based subgroups. Meta-analyses based on an inverse variance random effects model were performed to examine patient subgroups < 65 and ≥ 65 years separately, and pooled HRs were compared to examine if differences in relative survival benefits existed between patient subgroups. Sensitivity analyses were conducted specific to cancer type, primary endpoint, and the type of systemic treatment. **Results:** Eighty-five RCTs, including 55,512 patients, reported age-based survival outcomes and were included. One study reported age-based toxicity and no studies age-based quality of life results. Pooled HRs [95% CIs] for patients < 65 and ≥ 65 years were 0.60 [0.56-0.65] and 0.66 [0.61-0.72], respectively with no difference between the two subgroups ($P = 0.08$). All sensitivity analyses revealed similar results. **Conclusions:** Our results suggest that elderly and young patients derive similar relative survival benefits from novel oncology drugs. In settings where there is no other direct high-level evidence of elderly patients deriving less benefit than younger patients, it is reasonable to consider offering novel oncology drugs to elderly patients who fulfil trial eligibility. There is, however, a need to report age-based toxicity and quality of life results to support patient discussions regarding the balance of treatment benefit and harm, to encourage informed individualized decision-making.

10030 Poster Session (Board #19), Sat, 1:15 PM-4:45 PM

Chemotherapy toxicity risk score (CTRS) for treatment decision in older patients with advanced solid cancer. *First Author: Tomohiro F. Nishijima, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: The decision whether to treat older patients (pts) with advanced cancer with standard (ST) or reduced therapy (RT) is complicated by heterogeneity in aging. Currently, clinical impression based largely on age and performance status, determines whether a pt is fit or unfit for ST. We evaluated the potential utility of the CTRS (Hurria JCO 2011) for treatment decision in older cancer pts. **Methods:** This is a prospective observational study of older pts (+65) receiving first-line chemotherapy for locally advanced or metastatic cancer for which combination chemotherapy is the standard of care. CTRS was calculated before therapy initiation assuming the pts received ST (combination therapy at the standard dose). Pts were categorized as high risk (CTRS $\geq$10; RT (dose reduced combination or single agent chemotherapy) deemed appropriate) or non-high risk (CTRS $<$10; ST deemed appropriate) for grade 3-5 adverse events (gr3-5 AEs). Treatment decision was left to the treating physician who was blinded to the CTRS result. We estimated the agreement in chemotherapy choice (ST vs RT) between treating physician and CTRS using the kappa statistic. **Results:** 44 pts (median 71 years) with GI (68%), GU (14%), lung (14%) or HEENT (5%) cancer were enrolled. 29 pts received ST (11 had CTRS $\geq$10 and 18 had CTRS $<$10) and 15 pts received RT (10 had CTRS $\geq$10 and 5 had CTRS $<$10). The kappa statistic showed only modest agreement in chemotherapy choice (0.26, 95%CI = -0.01 to 0.54) between physician and CTRS. Gr3-4 AEs and hospitalization due to AE occurred in 50% and 29% of 42 pts with follow-up data, respectively. There was no fatal AE. Among pts receiving ST, pts with CTRS $\geq$10 had a significantly higher incidence of gr3-4 AEs and hospitalization than those with CTRS $<$10 using Fisher's exact test (Table). In the RT group, there was no significant difference in incidence of gr3-4 AEs or hospitalization between pts with CTRS $\geq$10 and CTRS $<$10. **Conclusions:** Incorporation of CTRS in treatment decision may increase the proportion of elderly pts with advanced cancer who receive tolerable treatment.

Chemotherapy choice	CTRS	Gr3-4 AEs (%)	P value	Hospitalization (%)	P value
ST	$\geq$10 (N=10)	90	0.01	70	0.004
	$<$10 (N=17)	35		12	
RT	$\geq$10 (N=10)	30	0.33	10	0.21
	$<$10 (N=5)	60		40	

10031 Poster Session (Board #20), Sat, 1:15 PM-4:45 PM

Accrual of older adults to Canadian Cancer Trials Group (CCTG) led trials: A retrospective analysis from 1990 to 2015. *First Author: Catalina Hernandez Torres, The Ottawa Hospital, Ottawa, ON, Canada*

Background: Older adults (OA) age 65+ make up to 60% of all newly diagnosed cancers. However, only 22-32% of patients accrued in cooperative group studies in the 1990s were age 65+. In 2003, several studies suggested that clinical trial design, in particular the presence of strict exclusion criteria, was a major barrier to accrual of OA. The objective of this study was to determine: 1) whether there has been an improvement in accrual of OA to clinical trials led by the Canadian Cancer Trials Group (CCTG) over time; 2) clinical trial features associated with accrual of OA to clinical trials 3) whether exclusion criteria in trials initiated 2003 or after have been relaxed. **Methods:** All completed randomized Phase II and III CCTG-led clinical trials initiated between 1990 or later were included. Trial characteristics including tumor type, stage, treatment type, and exclusion/inclusion criteria, as well as percentage of OA age 65+ accrued were recorded. Association between percentage of OA accrued and trial characteristics were compared using the Wilcoxin rank sum test. Assessment of exclusion criteria before and after 2003 was compared using the Chi Square test or Fisher exact test. **Results:** A total of 68 trials were included. Most trials were phase III (73%), chemotherapy trials (48%), opened before 2003 (70.6%), advanced disease (73%) and lung cancer was the most common tumour site (17.6%). OA accrual remains low compared to OA diagnosed with cancer in Canada (41% vs. 56%, $p < 0.001$). There was an improvement in accrual of OA after 2003 (47.1% vs. 34.9%, $p = 0.02$). Tumour site, early stage disease, more restrictive performance status, requiring a new biopsy, and having a longer consent form, were associated with lower accrual of OA ($p < 0.05$). There was no significant loosening of exclusion with time though patients with pulmonary comorbidities were more likely to be excluded in studies initiated in 2003 or later ($p = 0.006$). **Conclusions:** OA remain under-represented in clinical trials. There has been no relaxing of exclusion criteria; however, exclusion based on comorbidities was not significantly associated with under accrual of OA in our study.

10032 Poster Session (Board #21), Sat, 1:15 PM-4:45 PM

Pre-planned safety analysis of NORDIC 9: A randomized trial comparing full dose monotherapy (S-1) with reduced dose combination therapy (S-1/oxaliplatin) in older chemo-naive patients with metastatic colorectal cancer (mCRC). *First Author: Stine Brændegaard Winther, Department of Oncology, Odense University Hospital, Odense, Denmark*

Background: More than half of the patients (pts) diagnosed with mCRC are older, but they are underrepresented in clinical trials. Data about the best treatment strategy in pts who are not candidates for standard full-dose combination therapy is scanty. Here we present a preplanned safety analysis in the NORDIC 9 trial. **Methods:** NORDIC 9 explores treatment of older mCRC pts (≥70 years) who are not candidates for full-dose combination therapy. Pts receive full dose monotherapy (Arm A: S-1 30 mg/m^2 po bid day 1-14 q3w, followed by irinotecan upon progression or reduced dose (80%) combination therapy (Arm B: S-1 20 mg/m^2 po bid day 1-14 + oxaliplatin 100 mg/m^2 iv day 1 q3w, followed by reduced dose S-1 + irinotecan q3w). Bevacizumab (7.5 mg/kg iv day 1) may be added at the discretion of the treating clinician. Geriatric screening tools (eg G-8 and VES-13) and quality-of-life are evaluated at baseline. Blood samples and tumor tissue are prospectively collected. Primary endpoint is PFS. Secondary endpoints are correlations between the geriatric screening and safety but also efficacy. **Results:** The safety analysis was performed when 50 pts had received 3 cycles. 12 pts received bevacizumab. Median age was 79 (range 70-88) years, 26 pts were male, performance status was 0 (43%), 1 (38%) or 2 (19%). Five (10%) pts discontinued therapy after only 1 cycle due to toxicity (n = 2) or PD/clinical deterioration (n = 3); 45 pts (90%) continued therapy beyond 3 cycles. Pts receiving only 1 cycle had numerically a worse G-8 and VES-13 score. Grade 3-4 non-hematological toxicity was fatigue (6%), diarrhea (10%), nausea (4%) and vomiting (6%), and was experienced by 10 pts, 6 of them received ≥3 cycles of treatment. There was no hand-foot-syndrome, cardiac or hematological grade 3-4 toxicity. Dose intensity for S-1 was 0.98 (0.7-1.0) (arm A) and 0.93 (0.6-1.0) (Arm B), respectively, and for oxaliplatin 0.99 (0.4-1.0). **Conclusions:** The safety committee recommends to continue the trial without dose adjustments according to the original design. February 2017, 118 of planned 150 pts had been included. Clinical trial information: EudraCT no 2014-000394-39.

10033 Poster Session (Board #22), Sat, 1:15 PM-4:45 PM

Patient-reported comorbidity and survival in older adults with cancer. *First Author: Grant Richard Williams, University of Alabama at Birmingham, Birmingham, AL*

Background: Our ability to optimize the care of older adults with cancer and comorbid illnesses is insufficient as most clinical trials lack systematic measurement of comorbidities. The primary purpose of this study was to evaluate the prevalence and impact of patient-reported comorbidity on survival using various comorbidity scoring algorithms. **Methods:** We utilized a unique linkage of the Carolina Senior Registry, an institutional registry (NCT01137825) that contains geriatric assessment data, with the North Carolina Central Cancer Registry to obtain mortality data. Comorbidity was assessed using a patient-reported version of the Older Americans Resources and Services Questionnaire (OARS) Physical Health subscale that includes information regarding 13 specific comorbid conditions and the degree to which each impairs function ("not at all" to "a great deal"). Multivariable Cox proportional hazard regression models were used to evaluate the association between comorbidities and all-cause mortality. **Results:** 539 patients were successfully linked to mortality data. Median age 72, 72% female, 85% Caucasian, 47% breast cancer, and 12% lung cancer. 92% of participants reported at least one comorbid condition, mean of 2.7 conditions (range 0-10), with arthritis and hypertension the most common (52 and 50%, respectively). 62% of patients with a comorbid illness reported a functional limitation related to comorbidity. Both the presence of 3 or more total comorbidities (hazard ratio (HR) 1.44, CI 1.08-1.92) and 2 or more comorbidities impacting function (HR 1.46, CI 1.09-1.95) increased mortality. After adjusting for age, cancer type, and stage, the risk of death increased 12% for each comorbid condition impacting function (HR 1.12, CI 1.02-1.24), but did not significantly increase for the number of comorbid conditions alone (HR 1.07, CI 0.99-1.15). **Conclusions:** Comorbid conditions in older adults with cancer are highly prevalent, frequently impair function, and impact survival. Comorbid conditions that impair function have a greater impact on survival than the presence of comorbidity alone. Comorbidity assessment should be incorporated in clinical trials and can be measured via a simple one-page patient-reported questionnaire.

10034 Poster Session (Board #23), Sat, 1:15 PM-4:45 PM

Immuno-oncology and the elderly: A comparative analysis of participation and toxicities of senior adults aged 65 years and above vs mid age and adolescent/young adult patients on immunotherapy-based phase I clinical trials. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Senior adults ≥ 65 yrs remain underrepresented in early phase clinical trials in particular trials with novel immunotherapies. One general limitation to enrollment is the concern for immune-related toxicities in the context of older age and comorbidities. We analyzed the enrollment and incidence of toxicities of seniors in comparison to mid age and adolescent/young adult (AYA) pts enrolled in phase 1 immunotherapy trials. **Methods:** We identified 422 consecutive pts w advanced cancer treated on immunotherapy-based phase I trials bw 04/2009-09/2015. We divided pts into 3 cohorts based on age at start of trial (AYA 15-39y, mid age 40-64y, seniors 65y+) and collected pt/disease characteristics and immune-related adverse events (irAE) including endocrinopathies, diarrhea/colitis, pneumonitis, constitutional (eg fatigue, fever, anorexia), myalgia, and dermatitis. **Results:** Of 422 patients treated, 116 were seniors (27%, median 70y), 50 AYA (12%, median 30y), 256 mid age (61%, median 56y). Most common cancers were GI (n = 108, 26%), thoracic/head/neck (n = 84, 20%), GU (n = 54, 13%), and GYN (n = 47, 11%). Median PFS was comparable in all 3 cohorts (2.4m seniors, 2.1m AYA, 2.1m mid age). The incidence of irAE was higher in elderly than mid age or AYA (low grade [G1/2] 49% vs 34% vs 34%, p 0.02; high grade [G3/4] 19% vs 11% vs 12%. p 0.14). When comparing irAE rates of seniors to AYA and mid age pts, the odds ratio of high grade events was 1.81 (95% CI 1.01, 3.24; p 0.05) and low grade events was 1.85 (95% CI 1.20, 2.85; p 0.0055). Most common G1/2 irAE among all cohorts was fatigue (n = 76, 18%), dermatitis (n = 59, 14%), fever (n = 29, 7%) and anorexia (n = 28, 7%) with seniors having a greater incidence of low grade fatigue (25% vs 15%, OR 1.84, 95% CI 1.09, 3.10, p 0.025). **Conclusions:** Senior adults accounted for < 1/3 of pts on immunotherapy-based phase I trials. When compared to mid age and AYA pts, seniors had a higher likelihood of experiencing a toxicity. Early phase immunotherapy trials may be an option for older adults but with a particular vigilance for adverse events in this population.

10035 Poster Session (Board #24), Sat, 1:15 PM-4:45 PM

A phase II trial of older adults with metastatic breast cancer (MBC) receiving nab-paclitaxel: Melding the fields of geriatrics and oncology. *First Author: Enrique Soto Perez De Celis, City of Hope, Duarte, CA*

Background: The Institute of Medicine and ASCO identified key research priorities to improve the evidence base of older adults with cancer, including the need for therapeutic phase II trials. Here we present a phase II study of *nab*-paclitaxel in older patients (pts) with MBC, incorporating geriatric oncology principles in the study design. **Methods:** Pts age ≥65 years with MBC and 0-1 chemotherapy (CT) lines received *nab*-paclitaxel (100 mg/m^2, 3 wks on, 1 wk off). Pts completed a geriatric assessment (GA) pre-CT including measures of function, comorbidity, cognition, nutrition, and psychosocial status. A CT toxicity (tox) risk score was calculated for each pt (Hurria et al. JCO 2011 and 2016). Relationships between tolerability (no. courses, hospitalizations, dose reductions, and grade (G) ≥3 tox attributed to CT) and risk score were assessed using generalized linear models, Student's t tests, and Fisher's exact test. Response rate (RR) and progression free survival (PFS) were evaluated. **Results:** 40 pts (mean age 73 [65-87]) were accrued from 06/12 to 01/16. Median no. of cycles was 6 [0-33], RR was 35% (95% CI 21-52%) and PFS was 6.5 months (95% CI 5.5-NR). 58% (n = 23) of pts had G ≥ 3 tox and 30% (n = 12) were hospitalized due to CT. G 2/3 neuropathy and G 3/4 neutropenia occurred in 10% of pts (n = 4), with no cases of febrile neutropenia. Based on the CT tox risk score, 53% (n = 21), 38% (n = 15), and 10% (n = 4) were low, intermediate, and high risk. As a continuous variable, doubling in the risk score was associated with a reduction in courses completed of 4.5 (se = 1.4, p = 0.003). Lower mean $\log_2$ risk scores were found in pts that did not require hospitalization (diff = -0.59, 95% CI -1.00, -0.18; p = 0.007), or did not have a dose reduction (diff = -0.46, 95% CI -0.85, -0.06; p = 0.02). G ≥ 3 tox was found in 38% of low, 73% of intermediate and 100% of high risk pts, with combined intermediate/high risk pts experiencing significantly more G ≥ 3 tox (OR 5.8, 95% CI 1.3-33.1; p = 0.01). **Conclusions:** This phase II trial of older pts with MBC receiving *nab*-paclitaxel incorporated geriatric principles in an oncology trial. Incorporating the GA and CT tox risk score can help weigh the risks and benefits of therapy in older adults. Clinical trial information: NCT01463072.

10036 Poster Session (Board #25), Sat, 1:15 PM-4:45 PM

Impact of hearing and visual impairment in older adults with cancer. *First Author: Enrique Soto Perez De Celis, City of Hope, Duarte, CA*

Background: Hearing and visual impairment increase the risk of psychological, functional, and cognitive deficits in older adults. However, little is known about their impact in older patients (pts) with cancer. **Methods:** This is a cross-sectional analysis of 2 prospective studies of pts ≥65 with cancer (Hurria et al. *JCO* 2011 & 2016) which identified risk factors for chemotherapy (CT) toxicity. Relationships between self-reported hearing/visual impairment (fair, poor or deaf/blind) and the need for assistance in instrumental activities of daily living (IADL, i.e. shopping), or activities of daily living (ADL, i.e. bathing); anxiety; depression and cognitive deficit (>11 on Blessed OMC test) were assessed (adjusted for age, sex, race, education, cancer type/stage, comorbidity, falls & medication). **Results:** Among 750 pts (median age 72, range 65-94) with solid tumors (28% lung, 27% GI, 30% breast/GYN; 58% stage IV), 28% (n = 213) reported 1 impairment (61% hearing, 39% visual) and 7% (n = 55) both. On multivariate analysis, impaired hearing was associated with IADL dependency, anxiety and depression. Visual impairment was associated with IADL dependency, ADL limitation and depression. Impairment in both was associated with IADL dependency, anxiety, depression and cognitive deficit. **Conclusions:** Older pts with cancer and hearing/visual impairment are at higher risk of functional, psychological and cognitive deficits. Interventions aimed at improving vision and hearing of older adults with cancer should be studied.

Outcomes for patients ≥75 years with localized gastroesophageal cancer: Experience from the Princess Margaret Cancer Centre. *First Author: Akina Natori, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The optimal treatment and outcome for elderly patients (pts) with localized gastroesophageal (GE) cancer remains unclear as they are underrepresented in clinical trials. We aimed to assess survival in pts ≥75 years according to treatment received. **Methods:** A retrospective analysis was performed for all pts aged ≥75 years with GE cancer treated in 2012-2014. Frailty was measured using the Charlson comorbidity index (CCI) and ECOG performance status (PS). Overall survival (OS) and disease-free survival (DFS) were assessed via uni- and multivariable Cox proportional hazards regression, adjusting for demographics. Logistic regression analyses were used to examine factors impacting treatment choices. **Results:** Of 105 pts, median age was 81 years (range: 75-99), primary sites were esophageal (55%, with 43% squamous histology) and gastric (45%). Baseline characteristics included: PS: 0 (31%), 1 (42%), 2 (16%), 3 (10%), 4 (1%); and CCI: 0 (34%), 1 (25%), 2 (19%), ≥3 (22%). Treatment received included radiotherapy alone (RT) (31%); surgery alone (29%); surgery plus adjuvant chemotherapy (chemo) and/or RT (14%); chemoradiation alone (7%) and supportive care (18%). In univariable analyses; age < 85 (p = 0.003), PS < 2 (p = 0.03) and surgery (p < 0.001) were associated with improved OS. Chemo and RT, either alone or in combination, did not significantly improve OS. In multivariable analyses; surgery (HR 0.38, 95% CI 0.21-0.70, p = 0.002) was the only independent predictor for improved OS. Patients with good PS (p = 0.01), gastric disease site (p = 0.01) and adenocarcinoma histology (p = 0.02) were more likely to undergo surgery. **Conclusions:** At our institution, relatively few pts ≥75 years received multimodality therapy for localized GE cancers. Those pts ≥75 years who underwent surgery had excellent outcomes, but they were well-selected. Comprehensive assessment should be considered for pts ≥75 years with localized GE cancer to ensure optimal treatment selection, particularly given the potential benefit of surgery.

10038 Poster Session (Board #27), Sat, 1:15 PM-4:45 PM

A randomized control trial of outpatient occupational and physical therapy for older adults with cancer: The CARE program. *First Author: Mackenzi Pergolotti, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Limitations in functional status and reduced health status are common among older adults with cancer, yet occupational and physical therapy (OT/PT) remain underutilized (Pergolotti, et.al. *JGO,*2015). For this population, we evaluated an outpatient CAncer REhabilitation (CARE) program and compared it to usual care (UC). **Methods:** We recruited adults 65 years and older who had a diagnosis of cancer or recurrence within 5 years and had at least one functional limitation as measured by a geriatric assessment (GA). Participants were then randomized to OT/PT (CARE) or UC. CARE delivered individualized outpatient intervention; OT addressed functional activities, and PT strength/endurance needs. UC participants received a brochure on supportive care services. Primary outcome was functional status (Nottingham Extended Activities of Daily Living Scale [NEADL] (range 0-22)) and secondary outcomes were global Mental and Physical Health, and ability to participate in Social Roles (SR) and activities (Patient-Reported Outcomes Measurement Information System [PROMIS] (range 0-100)), for all measures, higher scores indicate better health. We used t-tests to compare groups. **Results:** 51 adults were randomized: median age 73 years, 55% male, 92% White, 33% with Leukemia/lymphoma, 26% Breast, 22% Colorectal, 67% in active treatment, and 37% with Stage 3 or 4. After 3 months, both groups experienced a significant decline in functional status ($p = .046$; $p = .005$), but change in functional status (-1.5 UC, -1.1 CARE, $p = .637$) , physical health status (0.0 UC, 2.4 CARE, $p = .121$) and participation in SR (.11 in UC, 3.71 CARE, $p = .088$) between UC and CARE were not significant. However, change in mental health (-1.0 in UC, 3.0 CARE, $p = .032$) significantly different between groups. **Conclusions:** CARE was associated with a significant improvement in participant's mental health status compared to a decline in UC. Results suggest CARE may influence ability to participate in social roles and activities and physical health, but further study is needed with larger sample sizes. We demonstrated that for older adults with cancer, OT/PT are promising interventions to improve mental health. Clinical trial information: NCT02306252.

10039 Poster Session (Board #28), Sat, 1:15 PM-4:45 PM

Polypharmacy and potentially inappropriate medication use in older patients with aggressive non-Hodgkin lymphoma (NHL) leads to inferior survival and increased treatment-related toxicities. *First Author: Richard Jirui Lin, NYU Langone Medical Center, New York, NY*

Background: Survival outcomes for older patients with aggressive NHL are disproportionally inferior to those of younger patients. While differences in tumor biology may play a role, older patients are often frail with comorbidities, polypharmacy, and use potentially inappropriate medications (PIM) such as anticholinergics and benzodiazepines. **Methods:** Using Cox proportional hazard and logistic regression models, we analyzed all aggressive NHL patients age ≥60 treated at our two affiliated hospitals from 2009-2014 to examine the association of polypharmacy and PIM use with progression-free survival (PFS), overall survival (OS), and treatment-related toxicities. **Results:** In this updated and final analysis, we included 171 patients with complete records from these two hospitals. They share similar demographic, clinical, and laboratory characteristics except for higher International Prognostic Index (IPI) in patients from one hospital. The median age was 70 years (range 65-77). At the time of diagnosis, 46% of patients used more than 4 medications (polypharmacy) and 47% used at least one PIM. Only 43% of patients received first-line chemotherapy of adequate relative dose intensity (>85% dosage), and 65% experienced ≥grade 3 toxicities. Polypharmacy and PIM use were associated with shortened PFS and OS by log-rank test. Most importantly, PIM use remained an independent predictor of PFS, OS, and ≥ grade 3 toxicities in multivariable analyses (Table). **Conclusions:** This is the first report of significantly adverse survival impacts of polypharmacy and PIM use in older patients with aggressive NHL, presumably from drug-drug interactions that increase toxicities and impair the delivery of adequate chemotherapy dosage. Our findings support the use of evidence-based geriatric principles to guide meticulous medication management to improve outcome disparity for these patients.

Multivariable analyses estimating the association between PIM and clinical outcomes.

Clinical outcomes	HR/OR	95% CI	P
PFS	2.81 (HR)	1.36 to 5.81	0.005
OS	3.12 (HR)	1.49 to 6.52	0.003
Toxicities ≥Grade 3	2.91 (OR)	1.42 to 5.97	0.004

10040 Poster Session (Board #29), Sat, 1:15 PM-4:45 PM

Unmet supportive care needs of older adults with advanced cancer. *First Author: Brandon Temel, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Cancer disproportionately affects older adults, yet research defining the supportive care needs of these patients is lacking. We sought to examine associations between geriatric impairments, quality of life (QOL), and physical and psychological symptom burden in older adults with newly diagnosed incurable gastrointestinal (GI) cancer. **Methods:** We prospectively enrolled patients age ≥70 within 8 weeks of diagnosis of incurable GI cancer at Massachusetts General Hospital from 10/2015-11/2016. We used surveys to assess geriatric impairments (Vulnerable Elders Survey-13 [range 0-10, scores ≥3 identify patients with impairments), QOL (EORTC QLQ-C30 [range 0-100, higher scores indicate better QOL]), physical symptoms (Edmonton Symptom Assessment System [range 0-10, higher scores indicate greater symptom burden]) and psychological symptoms (Geriatric Depression Scale, [range 0-15, higher scores indicate greater depression symptoms]). We used descriptive statistics to determine differences in patient characteristics by the presence or absence of geriatric impairments. We used linear regression adjusted for age, employment, cancer type, and comorbidity to examine associations between geriatric impairments, QOL, and physical and psychological symptom burden. **Results:** We enrolled 50 of 58 (86%) patients approached (mean age = 78.7; 52% with pancreatic cancer). Nearly half (46%) screened positive for geriatric impairments; these patients were older (81.7 vs 76.1, $p < .01$) and had more comorbid conditions (2.4 vs 1.2, $p = .01$). On linear regression, patients with geriatric impairments reported worse QOL across all domains (General QOL: B = -28.3, $p < .01$; Physical: B = -36.8, $p < .01$; Role: B = -36.8, $p < .01$; Emotional: B = -30.1, $p < .01$; Cognitive: B = -17.8, $p = .03$; Social: B = -39.7, $p < .01$), higher depression scores (B = 5.1, $p < .01$) and worse fatigue (B = 4.6, $p < .01$), drowsiness (B = 4.0, $p < .01$), appetite (B = 3.8, $p < .01$), and pain (B = 2.7, $p = .02$). **Conclusions:** Older adults with advanced cancer experience considerable unmet supportive care needs, particularly those with geriatric impairments. Future research is needed to assess older patients for geriatric impairments and address their unique palliative and supportive care needs.

10041 Poster Session (Board #30), Sat, 1:15 PM-4:45 PM

Serum frailty biomarkers to predict overall survival in older patients with metastatic solid tumors: A substudy of prospective multi-center cohort study (KCSG PC13-09). *First Author: Se Hyun Kim, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea*

Background: To determine individualized cancer treatment for older patients, easily measurable markers that predict functional decline and mortality are needed. The purpose of this study was to confirm prognostic value of potential biomarkers of frailty in older patients with metastatic solid tumors. **Methods:** Serum samples were prospectively collected before first line chemotherapy at 11 academic centers in Korea. All patients were participants in a prospective cohort study of older patients with metastatic solid tumors (KCSG PC13-09, WHO ICTRP number: KCT0001071). Serum levels of C-reactive protein (CRP), CXCL10, SIRT1, VEGF-A, Activin A, C-terminal telopeptide of type I collagen (CTx), total 25-hydroxyvitamin D (vitD) were measured by ELISA and IL-6, Myostatin, Irisin, FGF-19, FGF-21, FGF-23 by luminex mutiplex assay. Overall survival (OS) was studied by means of Kaplan-Meier, Log Rank and Cox methods. **Results:** Serum samples from 138 patients (median age: 75, range: 70-92) were collected from Feb 2014 to Dec 2016. During a median follow up time of 13.8 months, 72 (52.6%) patients had died. Among 13 serum markers, CRP (log-rank, P=0.006), Activin A (P=0.003), and Myostatin (P=0.043) were significantly correlated with OS in univariate analyses. In a Cox regression analysis, Activin A (HR 2.36, 95% CI 1.41-3.96; P=0.001) and Myostatin (HR 2.70, 95% CI 1.24-5.84; P=0.012) were significantly associated with OS after adjustment of other clinical factors (Age, Gender, ECOG PS, BMI, Geriatric assessment, Chemotherapy response, WBC, Albumin). **Conclusions:** In older cancer patients, high serum concentration of Activin A and Myostatin are predictive of poor OS.

Multivariate analysis of prognostic factors for survival.

Factor	HR for OS (95%CI)	P-value§
ECOG PS (0-1 vs. 2-3)	2.70 (1.47-4.95)	0.001
Activin A (< 17.5 pg/mL vs. > 17.5 pg/mL)	2.36 (1.41-3.96)	0.001
Myostatin (< 480 pg/mL vs. > 480 pg/mL)	2.70 (1.24-5.84)	0.012
Chemotherapy response (CR/PR/SD vs. PD/UA)	1.87 (1.13-3.12)	0.016

§: Forward stepwise (conditional likelihood ratio) method of Cox proportional hazard regression model.

10042 Poster Session (Board #31), Sat, 1:15 PM-4:45 PM

The emotional toll of caregiving for older patients with advanced cancer: Baseline data from a multicenter geriatric assessment (GA) intervention study in the University of Rochester NCI Community Oncology Research Program (UR NCORP). *First Author: Supriya Gupta Mohile, University of Rochester Medical Center, Rochester, NY*

Background: Depression is common in caregivers (cgs) of patients (pts) with cancer. However, little is known about the association of health status of older pts with cancer with cg emotional health. **Methods:** Baseline data from a GA intervention study conducted at 68 oncology practices in the UR NCORP were analyzed. Pts aged ≥ 70 with an advanced solid tumor cancer or lymphoma with ≥ 1 GA impairment were enrolled; pts could enroll with 1 cg. Relationships between pt GA impairments (using 12 validated measures) and cg (spouses or live-in partners) emotional health including anxiety (≥ 5 on Generalized Anxiety Disorder-7 (GAD-7)), depression (≥ 2 on Patient Health Questionnaire-2), and distress (≥ 4 on distress thermometer) were evaluated in separate multivariate logistic models adjusted for pt (cancer type, treatment status) and cg (age, sex, race, education, income, comorbidity) characteristics. **Results:** Among 213 pts (mean age 76, 70-89), >50% had ≥ 5 impaired GA measures. Of the 213 cg (mean age 73, 52-91), 23% screened positive for anxiety, 16% for depression, and 40% for distress. In bivariate analyses, number of GA impairments, ≥ 1 fall, pt anxiety (≥ 5 on GAD-7) and depression (≥ 5 on Geriatric Depression Scale (GDS)) were associated with all 3 cg outcomes; pt activities of daily living (ADL) deficits were associated with cg depression and distress. In multivariate analysis, number of GA impairments was associated with cg distress. In separate models, pt ADL deficit and depression were associated with cg distress, and pt ADL deficit was associated with cg depression. GA variables were not associated with cg anxiety in multivariate analysis. **Conclusions:** A high proportion of cg of older pts with cancer report distress. GA can help identify cg at risk for poor emotional health. Interventions for cgs should address the health status of older pts with cancer.

	Cg depression		Cg distress	
Pt factors	**OR (95% CI)**	**p**	**OR (95% CI)**	**p**
Number of GA impairments	1.14 (0.92-1.41)	0.22	1.19 (1.03-1.38)	0.02
ADL deficit	3.21 (1.04-9.96)	0.04	2.75 (1.15-6.60)	0.02

10043 Poster Session (Board #32), Sat, 1:15 PM-4:45 PM

Association between glycemic control, age, and outcomes among intensively treated patients with acute myeloid leukemia (AML). *First Author: Patrick Kuhlman, Wake Forest Baptist School of Medicine, Winston-Salem, NC*

Background: Hyperglycemia and increased glycemic variability are associated with infection and increased mortality. We evaluated the relationship between glycemic control during AML induction and outcomes by age. **Methods:** We retrospectively evaluated outcomes in 262 consecutive patients (pts) with newly diagnosed AML hospitalized for intensive induction at Wake Forest Baptist Hospital (2002-2009). Data on mean blood glucose (BG) (mg/dL) during hospitalization and standard deviation (SD) of BG (measure of glycemic variability, GV), complete remission ± incomplete count recovery (CR+CRi), and overall survival (OS) were collected. Modified Charlson Comorbidity Index (CCI), diabetes, age, gender, race, cytogenetics, hemoglobin, WBC, LDH, body mass index, and insurance were used in uni- and multi-variate models. We used logistic regression to evaluate CR+CRi, and Cox proportional hazard models for OS, stratified by age (< 60 vs ≥60 yrs). **Results:** 124 pts were < 60 (median age 47, median OS 23.1 months), 138 were ≥60 yrs (median age 70, median OS 7.9 months). Older pts had higher baseline comorbidity (CCI > 1 60.1% vs 25.8%) and a higher prevalence of diabetes (20.3% vs 7.3%). The mean ±SD number of BG values obtained per patient during hospitalization was 61±71. The mean ±SD of each individual s mean BG during hospitalization was 111.6± 16.4 in younger versus 121.7±25.9 older pts. The mean SD of BG values [GV] was 26.8±18.6 in younger versus 33±22.8 in older pts. In multivariable analysis higher mean BG was associated with lower odds of CR+CRi in younger (odds ratio (OR) 0.67, 95% CI 0.48-0.93) and older pts (OR 0.78, 95% CI 0.65-0.93) per 10 mg/dL BG increase. Higher mean BG was associated with shorter OS in older adults (HR 1.12, 95% CI 1.04-1.21). Higher GV was associated with lower odds of CR+CRi in younger (OR 0.73, 95% CI 0.56-0.96) and older (OR 0.71, 95% CI 0.57-0.88), as well as shorter OS in older pts (HR 1.17, 95% CI 1.08-1.26) for each 10 mg/dL SD increase in GV. **Conclusions:** Hyperglycemia and GV during intensive induction are associated with lower CR+CRi rates (all ages) and shorter OS among older adults.Glycemic control during induction may be a modifiable factor to improve AML outcomes.

10044 Poster Session (Board #33), Sat, 1:15 PM-4:45 PM

Autologous stem cell transplant (ASCT) in myeloma to improve patient reported physical function and fatigue. *First Author: Geetika Bhatt, Ohio State University Wexner Medical Center, Columbus, OH*

Background: Patients with Multiple Myeloma (MM) report some of the poorest Health-related quality of life (HRQoL). Few studies show how ASCT influences global health outcomes as measured by a Geriatric Assessment (GA). We performed a prospective GA evaluating the dynamic changes in health pre- and post-ASCT. **Methods:** 100 pts with plasma cell dyscrasia (median (m) = 60 yrs, range (r) = 36-75 yrs) underwent GA pre-ASCT, 90 days and 1-yr post-ASCT. GA included nutritional survey, Hospital Anxiety and Depression Scale (HADS), Brief Fatigue Inventory (BFI), Medical Outcomes Study-Social Support Survey (MOS-SSS), Short Physical Performance Battery (SPPB), handgrip strength, self-reported Human Activity Profile (HAP) Maximum Activity Score (MAS) and Adjusted Activity Score (AAS). Data were analyzed using paired t-test ($p < 0.05$). **Results:** Pts reported moderate fatigue pre-ASCT (m = 4.6, r: 0-9.8) which normalized at 1-yr (m = 2.5, r: 0-7.3; p = 0.008). Self-reported pre-ASCT physical function (MAS) (m = 73, r = 20-94) improved at 1-yr (m = 75.5, r = 52-94; p = 0.014); AAS (m = 64, r = 18-94) also improved at 1-yr (m = 70.5, r = 38-91; p = 0.025). In contrast, MD-reported KPS decreased. Screens for deficits in anxiety, depression, social support, objective physical function, handgrip strength and wt loss did not change significantly at 1-yr. **Conclusions:** Our data indicate that ASCT significantly improves patient-reported fatigue and physical function, unlike MD-reported KPS.

		PRE-ASCT (n = 100)	PRE VS 90-DAY POST-ASCT (n = 36)		PRE VS. 365-DAY POST-ASCT (n = 36)

Cancer-related fatigue in breast cancer survivors: A longitudinal analysis compared to matched controls. *First Author: AnnaLynn Williams, University of Rochester Medical Center, Rochester, NY*

Background: Cancer related fatigue (CRF) is commonly reported among breast cancer survivors and can negatively impact quality of life and treatment adherence. Large, prospective, longitudinal studies assessing CRF in breast cancer survivors compared to matched non-cancer controls are rare. **Methods:** Breast cancer survivors (n = 581, stage I-IIIBC, mean age 53.4) from community oncology clinics and age-matched controls (n = 364, mean age 52.6) completed the Multidimensional Fatigue Symptom Inventory-Short Form (MFSI, scores range -24 to 96) prior to chemotherapy (T1), at chemotherapy completion (T2) and six-months after chemotherapy (T3). Linear mixed models compared trajectories of CRF over time in survivors compared to controls, adjusting for age, education, race, BMI, marital status, menopausal status, and depressive symptoms. **Results:** Survivors reported greater CRF compared to controls at all time points (mean total score T1 9.4 vs. -3.7, T2 17.0 vs. -3.3, and T3 8.5 vs. -3.1, all $p < 0.001$; all subscales $p < 0.001$). From T1 to T2 survivors experienced a significant increase in CRF as shown in the total score (mean change (MC) = 8.3; effect size (ES) = 0.4 , $p < 0.001$), and general, mental, and physical sub-scales (MC = 4.3, 2.1, 3.2 , ES = 0.7, 0.5, 0.7, respectively, all $p < 0.001$), while controls experience minimal changes (MC = 0.1-0.3, ES < 0.09, $p > 0.05$). At T3 survivors total score returned to T1 values (MC = -0.1, ES = 0.01, p = 0.461), which was, however, still greater than controls ($p < 0.001$), while general, mental, and physical CRF subscale scores remained significantly higher than T1 values (MC = 1.2, 1.7, 1.9, ES = 0.2, 0.4, 0.3, respectively, all $p < 0.001$; controls no change). Group by time interactions indicated changes over time were greater in the survivors than controls ($p < 0.001$). In multivariate analyses of survivors, age, BMI, performance status, and baseline depression significantly predicted change in CRF. **Conclusions:** These results from the largest well-controlled study to date showed that breast cancer survivors experience significantly more CRF prior to and after chemotherapy compared to healthy controls. Further research should aim to identify subgroups of survivors most susceptible to CRF.

10046 Poster Session (Board #35), Sat, 1:15 PM-4:45 PM

Utility of the Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) in hematopoietic stem cell transplantation (HSCT). *First Author: Patricia B. Mumby, Loyola University Medical Center, Maywood, IL*

Background: The SIPAT is used to assess psychosocial risk in solid organ transplants but data in HSCT is lacking. We examined if pre-HSCT SIPAT scores predict mortality, morbidity, length of stay (LOS) and number of hospitalizations over a 1 year period. **Methods:** 89 adult HSCT (59% autologous, 38% allogeneic) pts from an academic medical center underwent the SIPAT pre-HSCT. Additional data were obtained on Day 0, and 3-, 6-, and 12-months. Univariable Cox proportional hazards models assessed the instantaneous risk of mortality at any given time after Day 0 as a function of baseline pt characteristics and the SIPAT score. **Results:** TheSIPAT categorized 28%, 66% and 5.7% respectively of the pts as excellent (E), good (G), and high risk (HR) candidates. One year post HSCT, 76% of E, 72% of G, and 40% of HR candidates were alive. Higher SIPAT scores were a significant predictor of mortality. Compared to E candidates, the HR candidates were 5.94 (95% CI: 1.31-26.81) times more likely to die any time after Day 0 – even after controlling for pts' comorbidity index ($p = .02$). Similarly, compared to G candidates, HR pts were 4.81 (95% CI: 1.33-17.47) times more likely to die even after controlling for pts' comorbidity index ($p = .01$). There was no difference between the G and E candidates on univariable ($p = .75$) or multivariable analysis controlling for comorbidity index score ($p = .72$). For every 1 point increase in pts' adherence score, the risk of death was expected to decline by approximately 14% ($HR = 0.86$, 95% CI: 0.78 – 0.96; $p = .01$). SIPAT items that predicted mortality were depression ($p = .02$), deceptive behavior ($p < .001$) and moderate alcohol abuse ($p < .001$). In linear regression analysis, higher SIPAT score was associated with longer LOS ($p = .04$) but not infection ($p = .23$), GVHD ($p = .40$), or number of hospitalizations ($p = .73$). Because there were only 18 mortality events, multivariable analyses were limited. Future research will examine the effect of SIPAT on time to death controlling for other pt comorbidities. **Conclusions:** We found the SIPAT was able to predict mortality and LOS in HSCT pts. This finding if validated in a multi-center manner could be an important tool for HSCT pt selection.

10047 Poster Session (Board #36), Sat, 1:15 PM-4:45 PM

Evaluation of adolescents and young adults (AYA) attitudes towards participation in cancer clinical trials. *First Author: Abha A. Gupta, Department of Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Participation in clinical trials (CT) for AYA (< 39 years) remain the lowest of any patient group with cancer. Little is known about the personal barriers to AYA accrual. The aim of this study was to explore AYA attitudes that influence CT participation. **Methods:** A mixed methods approach included 1) qualitative: interpretive descriptive methodology guided individual semi-structured interviews with 21 AYA for factors influencing CT enrollment and 2) quantitative: AYA and non-AYA (≥ 40) matched for histology completed Cancer Treatment subscale of Attitudes toward Cancer Trials Scales (ACTS-CT) (Schuber, 2008) and 9 supplementary questions formed from interview analysis. Differences between AYA and non-AYA cohorts were analyzed using the Mann-Whitney U test and ordered logistic regression models were constructed for prediction of the effect of baseline demographics. **Results:** The major themes influencing CT participation were: (1) family/peer group opinion (2) CT impact on daily/future life (e.g. school; starting a family) and (3) illness severity/psychological readiness for CT information. Surveys were distributed to 61 AYA (median age: 29 years (17-39)); 74 non-AYA (55 (40-88)). Compared with non-AYA, AYA perceived CT to be unsafe/more difficult (Personal Barrier/Safety domain; p = 0.01). AYA were also more concerned with CT interference in their long term goals (p = 0.04). Logistic regression identified participants who had previously been offered a CT (p = 0.01) or who spoke English as their first language (80% of cohort)(p = 0.01) reported less barriers to CT. There were no differences based on age in other domains (Personal Benefits; Personal/Social Value; Trust in CT). In all participants, differences were seen in the Personal Benefits domain if respondents had children (p = 0.05) or were currently working (p = 0.04). **Conclusions:** Age-related differences in attitudes towards CT suggest that tailored approaches to CT accrual of different patient groups may be warranted. Patient-centered delivery of information regarding CT, particularly for those in whom English is a second language and who are trial-naïve, may improve accrual and warrants further prospective, randomized study.

10048 Poster Session (Board #37), Sat, 1:15 PM-4:45 PM

Prevalence of depression and anxiety in older patients with multiple myeloma in North Carolina: A population-based, claims-based assessment. *First Author: Anureet Copeland, University of North Carolina, Chapel Hill, NC*

Background: Patients (pts) with multiple myeloma (MM) experience physical symptoms and complications from disease or treatment that include bone pain, fatigue, anorexia, and insomnia. However, the prevalence of psychiatric comorbidities and their impact on short and long-term outcomes has been understudied. The aim of this analysis was to identify the prevalence of anxiety and depression in older pts with MM in the state of North Carolina. We also sought to evaluate if comorbid depression and anxiety impacted short and long-term outcomes in these patients. **Methods:** Using the University of North Carolina Integrated Cancer Information and Surveillance System (ICISS), we retrospectively identified a statewide cohort of 536 pts (ages 65-80) diagnosed with MM from 2006-2012 who had continuous enrollment in Medicare or Medicaid. Patients were identified through insurance claims by ICD-9 diagnosis codes for anxiety or depression or antidepressant medications filed at any time from 6 months prior to MM diagnosis to 12 months after MM diagnosis. **Results:** The mean age of pts in the cohort was 72 years. Pts were 68% non-Hispanic white, 42% rural, and 51% male. Of the 536 pts, 200 (37%) had a diagnosis of anxiety or depression and/or were being treated with an antidepressant. 54% of those with psychiatric comorbidity had a relevant diagnosis or medication in the 6 months prior to MM diagnosis. Of those with psychiatric comorbidities, 70% were diagnosed with fatigue and 57% were diagnosed with pain. In multivariate analysis, there was no association of psychiatric comorbidity with mortality (HR, 1.03; 95% CI, 0.83-1.28), but psychiatric comorbidity was associated with an increased likelihood of hospitalization or ER visit (RR, 1.17; 95% CI, 1.05-1.30) and increased opiate use within 1 year after diagnosis (RR, 1.66; 95% CI, 1.27-2.16). **Conclusions:** The presence of psychiatric comorbidity identifies a subset of older MM pts at risk for high symptom burden and increased health care utilization. The association of psychiatric comorbidity with increased opiate use in cancer pts may also have public health implications.

10049 Poster Session (Board #38), Sat, 1:15 PM-4:45 PM

Psychological and educational outcomes among adolescent survivors of wilms tumor: A report from the Childhood Cancer Survivor study. *First Author: Rebecca Hope Foster, St. Louis Children's Hospital, St. Louis, MO*

Background: Little is known about psychological and educational problems experienced by adolescent survivors of Wilms tumor (WT), including the impact of treatment exposures and chronic health conditions. **Methods:** Parent-reports from the Childhood Cancer Survivor Study were analyzed for 666 adolescent survivors of WT (Mean[SD] age at survey = 15.3[1.65] years; age at diagnosis = 2.8[1.77] years) and 698 siblings (15.4[1.66] years). Adjusting for race and household income, survivors were compared to siblings on the Behavior Problem Inventory and educational services. Among survivors, therapeutic exposures and chronic medical conditions (CTCAE 4.03 coding) were examined via multivariable log binomial regression adjusting for sex, race, income and age at diagnosis to calculate adjusted Relative Risk (aRR) and 95% confidence intervals (CI). **Results:** Compared to siblings, survivors were more likely to use psychoactive medication (9.4 vs. 5.1%, $p = .0002$) or be in special education for learning problems, inattention, and/or low test scores (19.1 vs. 11.1%, $p = .003$) but had similar rates of depression/anxiety, headstrong behavior, inattention, social withdrawal, and antisocial behavior (p's $> .05$). Survivors who received radiation therapy (RT) to the abdomen (aRR 1.64, CI 1.03-2.61) or abdomen and chest (aRR 1.95, CI 1.16-3.26) were more likely to be in special education for any reason than those without RT. Those with grade 2-4 cardiovascular conditions were more likely to have anxiety/depression (aRR 2.04, CI 1.26-3.30), headstrong behavior (aRR 1.95, CI 1.30-2.93), or inattention (aRR 1.58, CI 1.04-2.42) compared to survivors with grade 0/1 conditions. Survivors were more likely to be in special education if they had problems with antisocial behavior, anxiety/depression, headstrong behavior, inattention or social withdrawal (p's $< .05$). **Conclusions:** Psychological intervention may be needed for adolescent survivors of WT treated with RT to the abdomen or abdomen and chest or with higher grade cardiovascular conditions. These survivors are more likely to experience behavioral and emotional problems, which in turn increases risk for placement in special education.

10050 Poster Session (Board #39), Sat, 1:15 PM-4:45 PM

The importance of recognizing and addressing depression in patients with advanced cancer. *First Author: Risa Wong, Massachusetts General Hospital, Boston, MA*

Background: Patients with cancer often experience depression, which is associated with worse outcomes, including longer hospital length of stay (LOS). Although antidepressant medication can improve depressive symptoms in patients with cancer, it is unclear whether their use translates into better outcomes. We sought to clarify the relationship between depressive symptoms, antidepressant medication, and hospital LOS in patients with advanced cancer. **Methods:** We enrolled hospitalized patients with advanced cancer from 9/2014 to 4/2016 as part of a longitudinal data repository. We examined patients' medical records to obtain information about documented depressive symptoms in the 3 months prior to admission and use of antidepressant medication at the time of admission. Using descriptive statistics, we compared differences in patient characteristics and hospital LOS across these groups. We used linear regression to examine associations and moderation effects between depressive symptoms, use of antidepressant medication, and hospital LOS. **Results:** Of 1,036 enrolled patients (89.9% of approached), 126 (12.2%) had documented depressive symptoms in the 3 months prior to admission and 288 (27.8%) were taking an antidepressant medication at the time of admission. Patients with depressive symptoms were more likely to be on antidepressant medication at admission than those without depressive symptoms (48.4% vs 24.9%, $p < .001$). Patients taking antidepressant medication were younger (62.4 vs 64.4 years, $p = .026$) and more likely to be female (55.2% vs 47.2%, $p = .021$). Depressive symptoms were associated with longer hospital LOS (7.3 vs 6.1 days, $p = .036$), and antidepressant medication was a moderator of this relationship. Among patients not on antidepressant medication, depressive symptoms were associated with longer hospital LOS (7.9 vs 6.1 days, $p = .025$), but among those on antidepressant medication, depressive symptoms were not associated with hospital LOS (6.6 vs 6.2 days, $p = .588$). **Conclusions:** Antidepressant medication moderated the relationship between depressive symptoms and longer hospital LOS. Our results support the need to recognize and address depressive symptoms in patients with advanced cancer.

10051 Poster Session (Board #40), Sat, 1:15 PM-4:45 PM

Psychosocial effects of the relaxation response resiliency program (SMART-3RP) in patients with MGUS and smoldering multiple myeloma: A waitlist controlled randomized clinical trial. *First Author: John W. Denninger, The Benson-Henry Institute for Mind Body Medicine at Massachusetts General Hospital, Boston, MA*

Background: Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are asymptomatic clonal precursors to multiple myeloma, a hematological malignancy. Because observation is currently the standard of care, a diagnosis of MGUS or SMM can be associated with stress and worry about progression. We evaluated the efficacy of the evidence-based mind-body intervention, the Stress Management and Resiliency Training: Relaxation Response Resiliency Program (SMART-3RP) in reducing distress and stress reactivity in patients with MGUS and SMM. **Methods:** In participants diagnosed with intermediate or high risk MGUS or SMM, this randomized, waitlist controlled trial (Oct 2013 – Sep 2016) assessed distress (10-point scale) as the primary outcome and perceived stress (PSS-10), stress reactivity (MOCS-A), and mindfulness (FFMQ) as secondary outcomes and hypothesized mediators of distress reduction. We collected self-report measures at enrollment (T1), 3 months (T2), and 6 months (T3). The immediate treatment arm received the 8-session, 1.5 hour/week SMART-3RP group intervention from T1 to T2 and continued practicing skills from T2 to T3; the waitlist arm received the intervention from T2 to T3. **Results:** 93 participants (59% women) diagnosed with MGUS (n = 49) or SMM (n = 44) were randomized to immediate treatment (n = 45) or waitlist (n = 48). In an ITT analysis of immediate SMART-3RP vs. waitlist (T1-T2), we found significantly greater improvement in distress (-1.4 vs. -0.3, $p = .04$) and stress reactivity (0.39 vs. 0.02, $p < .001$), but not perceived stress (-3.9 vs. -2.2, $p = .12$) or mindfulness (2.4 vs. -0.1, $p = .17$). Improvements in stress reactivity were maintained for the immediate treatment group (T2-T3), but only partially for distress. **Conclusions:** The SMART-3RP, compared to waitlist, reduced distress in participants with intermediate or high-risk MGUS and SMM, with improvements in stress reactivity as a primary mediator of distress reduction. Participants strongly endorsed the intervention's ability to enhance coping and reduce distress. Clinical trial information: NCT01955395.

10052 Poster Session (Board #41), Sat, 1:15 PM-4:45 PM

Treatment decisions and employment of breast cancer patients: Results of a population-based survey. *First Author: Reshma Jagsi, University of Michigan Health System, Ann Arbor, MI*

Background: Many patients with breast cancer work for pay at time of diagnosis, and the treatment plan may threaten their livelihood. Given rapidly evolving policies, evidence, and treatment options, we evaluated work experiences in a contemporary population-based sample of breast cancer patients to inform initiatives to reduce the burden of cancer care. **Methods:** We surveyed women aged 20-79 years diagnosed with stages 0-II breast cancer as reported to the SEER registries of Georgia and Los Angeles in 2014-15. Of 3672 eligible women, 2502 responded (68%); we analyzed 1006 who reported working prior to diagnosis. Multivariable models evaluated correlates of missing $>$ 1 month and stopping work altogether vs missing $\leq$1 month. **Results:** In this diverse sample (48% white, 19% black, 20% Latina, 11% Asian), most pts (62%) received lumpectomy; 16% had unilateral mastectomy (8% with reconstruction); 23% had bilateral mastectomy (19% with reconstruction). One third (33%) received chemotherapy. The vast majority (84%) worked full time at diagnosis, but only 50% had paid sick leave, 39% disability benefits, and 38% flexible work schedules. Surgical treatment was strongly associated with missing $>$ 1 month of work (OR 7.8 for bilateral mastectomy with reconstruction vs lumpectomy) and with stopping altogether (OR 3.1 for bilateral mastectomy with reconstruction vs lumpectomy). Chemotherapy receipt (OR 1.3 for missing $>$ 1 month; OR 3.9 for stopping altogether) and race (OR 2.0 for missing $>$ 1 month and OR 1.7 for stopping altogether, blacks vs whites) also correlated. Those with paid sick leave were less likely to stop working (OR 0.5), as were those with flexible schedules (OR 0.3). Those with disability benefits were more likely to stop working (OR 1.6) or miss $>$ 1 month of work (OR 2.7). **Conclusions:** Working patients who received more aggressive treatments, particularly surgery, were much more likely to experience substantial employment disruptions. Given the growing choice of bilateral mastectomy by patients seeking peace of mind, particularly among young women with years of potential employment ahead, these findings suggest the importance of discussing impact of treatment decisions on employment. Funded by NCI P01CA163233.

10053 Poster Session (Board #42), Sat, 1:15 PM-4:45 PM

Fear of recurrence among cancer survivors. *First Author: Rachel B Jimenez, Massachusetts General Hospital, Boston, MA*

Background: Fear of cancer recurrence (FoCR) following definitive cancer therapy is often reported by patients, but little is known about who is most likely to be impacted, how FoCR influences emotional distress, and what interventions may mitigate patients' FoCR. We sought to determine the prevalence of FoCR among cancer survivors and to evaluate potential predictors of FoCR in this population. **Methods:** As part of a comprehensive supportive care needs assessment, we evaluated the prevalence of FoCR among patients receiving follow-up cancer care at our institution as well as factors associated with FoCR. Elevated FoCR was measured with a single item: "I worry about my cancer coming back" rated on a 4-point Likert scale (1 = "not at all" to 4 = "very much"); responses of 3 or 4 were considered positive for FoCR. Descriptive statistics were used to characterize patterns of FoCR. Chi-square and Fisher's exact tests compared differences in emotional, clinical, and demographic characteristics between participants with and without FoCR, as well as interest in and knowledge of survivorship services. **Results:** Of 636 patients who completed the survey, 318/636 (50.0%) patients had curable cancer and had either completed cancer therapy or were completing maintenance treatment. On inquiry, 167/318 (53%) reported FoCR. Those with FoCR were more likely to be female ($p < 0.002$) and under the age of 70 ($p < 0.003$). They were also more likely to be sad (25% vs. 14%, $p < 0.015$), anxious (40% vs. 21% $p < 0.0005$), feel uncertain about the future (30% vs. 14%, $p < 0.0005$), have problems managing stress (26% vs. 13%, $p < 0.003$), and were more likely to worry about dying (55% vs. 8%, $p < 0.0001$) and to fear another cancer (74% vs. 8% $p < 0.0001$). Education level, cancer type, knowledge of and interest in support services, and survivorship care plan receipt were not associated with FoCR. **Conclusions:** Patient FoCR is prevalent among more than half of survivors of cancer and is associated with emotional distress that is insufficiently addressed by survivor care planning and supportive services. Clinicians can and should screen for and address this issue. Future research is needed to develop and test interventions, beyond care plans, to address FoCR in both low risk and high risk patient populations.

10054 Poster Session (Board #43), Sat, 1:15 PM-4:45 PM

Risk tolerance and attitudes toward chemotherapy: Who chooses palliative treatment when cure is possible? *First Author: Thomas William LeBlanc, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Many patients with acute myeloid leukemia (AML) face a difficult choice about whether to receive palliative chemotherapy or high-dose, potentially-curative chemotherapy that poses a risk of early death. How people weigh these factors in decision-making is unknown. We hypothesized that the possibility of cure primarily drives decision-making, regardless of treatment risk. **Methods:** We designed an electronic survey describing two treatment paths: (1) high-dose chemotherapy with possibility of cure but a 10% risk of early death, and (2) palliative chemotherapy with no chance of cure but no risk of early death. We recruited respondents via Amazon MTurk and presented 7 scenarios in random order, varying only the likelihood of cure associated with high-dose chemotherapy. Subjects rated their preferred treatment on a 4-point Likert scale. We assessed numeracy and attitudes toward chemotherapy using validated scales, and employed attention checks for quality assurance. **Results:** 100 subjects completed the survey (median age 30.5; 52 female, 85 Caucasian). 46 (46%) had at least a bachelor's degree and numeracy was generally high (median 4.75 out of 6). Respondents' preferences for intensive chemotherapy varied with likelihood of cure, however some displayed a fixed preference for either curative or palliative treatment throughout, regardless of benefit level. For example, given a 50% likelihood of cure 20 respondents (20%) still preferred palliative therapy; similarly, with only a 1% likelihood of cure 28 respondents (28%) still preferred high-dose chemotherapy. In a multivariable model, preference for palliative chemotherapy was significantly predicted by subjects' scores on the attitudes toward chemotherapy scale ($p < 0.001$), controlling for age, education, and numeracy. **Conclusions:** Contrary to our hypothesis, a significant proportion of subjects preferred palliative chemotherapy, even in scenarios where high-dose chemotherapy confers a high likelihood of cure. Pre-existing attitudes toward chemotherapy appear to drive patients' decision-making, even when treatments are potentially curative. This finding may have significant implications for risk communication in oncology.

10055 Poster Session (Board #44), Sat, 1:15 PM-4:45 PM

Randomized trial of a smartphone mobile app for adherence to oral chemotherapy. *First Author: Joseph Greer, Massachusetts General Hospital, Boston, MA*

Background: As patients with cancer are increasingly prescribed oral chemotherapy, they share greater responsibility for ensuring adherence and monitoring side effects. The aim of this study was to test the effect of a smartphone mobile app to improve adherence and symptom management in patients prescribed oral chemotherapy. **Methods:** From 2/15 to 12/16, 181 patients with diverse cancers prescribed oral chemotherapy were randomized to receive either the smartphone mobile app or standard care. The mobile app included a medication treatment plan with alerts, symptom reporting module, education library, and cancer-specific resources. The primary outcome was adherence, measured by electronic pill cap (MEMS) and self-report (Morisky Medication Adherence Scale; MMAS). To assess symptoms, mood, and satisfaction with care, participants completed the MD Anderson Symptom Inventory, Hospital Anxiety & Depression Scale (HADS); and Functional Assessment of Chronic Illness Therapy-Treatment Satisfaction (FACIT-TS) at baseline and 12 weeks. General linear models were used to assess intervention effects on patient outcomes. **Results:** Study groups did not differ across outcome measures from baseline to week 12. Secondary analyses showed that baseline adherence (MMAS) and anxiety (HADS) were moderators of intervention effects on adherence and treatment satisfaction. Among patients who reported adherence problems, those assigned to the mobile app had better average MEMS adherence (Mean Diff = 19.30, 95% CI = 0.09-38.51, p = .05) and satisfaction with clinician explanations per the FACIT-TS (Mean Diff = 1.69, 95% CI = 0.25-3.13, p = .02) compared to standard care. Also, among patients with higher anxiety, those in the mobile app group reported better adherence on the 12-week MMAS (95.2% vs. 68.0%, OR = 0.11, 95% CI = 0.01, 0.94, p = .04) and satisfaction with interpersonal treatment per the FACIT-TS (Mean Diff = 0.76, 95% CI = 0.13-1.39, p = .02) compared to standard care. **Conclusions:** Although potentially not for everyone taking oral chemotherapy, a smartphone mobile app to improve adherence and treatment satisfaction may be useful for patients with certain risk factors, such as those struggling with adherence or anxiety. Clinical trial information: NCT02157519.

10056 Poster Session (Board #45), Sat, 1:15 PM-4:45 PM

Patterns of osteoporosis (OP) in survivors of colorectal cancer (CRC) enrolled on SWOG trials. *First Author: Afsaneh Barzi, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: There are currently 1.5 million CRC survivors in US and this number will continue to rise with advancements in treatment. The risk of OP in CRC survivors has not been well described. **Methods:** We used data from 3 SWOG CRC treatment trials, all of which were phase III and had long term follow-up. Enrollees were linked to Medicare claim files for identification of OP and fractures using HCPCS and ICD9 codes. First, we compared patterns of osteoperosis and fracture risk by sex in colorectal cancer patients. To assess whether patterns of fracture risk by sex differed between patients with vs. without colorectal cancer, we compared the difference in fracture risk by sex in colorectal cancer patients to the difference in fracture risk by sex in the general U.S. population, using data from the National Health Interview Survey (NHIS) and the National Hospital Discharge Survey (NHDS). Finally, we assessed whether absolute estimates of osteoperosis and fracture risk differed between men with colorectal cancer and men without colorectal cancer. Comparison data for men without colorectal cancer were obtained from the placebo arm of the Prostate Cancer Prevention trial (PCPT). **Results:** We linked 1233 CRC cases with Medicare claims. The median age at CRC diagnosis was marginally higher for women (65 vs 64 ys, $p = 0.03$). 47% of females, 15% of men with CRC, and 19% of men without CRC had a OP diagnosis. The female to male ratio of osteoporotic fracture in general U.S. population was 1.67, while the same ratio in CRC survivors was 2.84, an increase of 70% (p-value < 0.001). **Conclusions:** Our study indicates that the risk disparity for OP fracture for females is much greater in CRC survivors than in the general U.S. population. This may be due to more OP diagnoses for female CRC survivors, but not for male CRC survivors.

10057 Poster Session (Board #46), Sat, 1:15 PM-4:45 PM

Cardiac autonomic dysfunction in breast cancer survivors. *First Author: David Payne, Brigham and Women's Hospital Heart and Vascular Center, Boston, MA*

Background: Cardiac autonomic dysfunction (AD) has been associated with increased cardiovascular (CV) and all-cause mortality in several diseases. We evaluated the prevalence, functional and prognostic significance of cardiac AD in a cohort of breast cancer (BC) survivors referred for exercise treadmill testing (ETT). **Methods:** Cardiac AD was defined as the presence of both an elevated resting heart rate (HR $\geq$ 80 beats per minute) and abnormal HR recovery (HRR $\leq$ 12 beats per minute if active cool down, or $\leq$ 18 beats per minute if passive recovery) at 1 minute after peak exercise. Presence of cardiac AD, exercise capacity, and all-cause mortality were assessed in 448 women (age 62.6$\pm$10.0 years), 8.7 [range 4.5, 14.3] years from BC diagnosis, compared to 448 cancer-free, age- and sex-matched controls, all of whom were clinically referred for ETT. **Results:** Elevated resting HR (23.7% vs. 17.0%, $p = 0.013$), abnormal HRR (25.9% vs. 20.3%, $p = 0.048$), and cardiac AD (8.0% vs. 4.2%, $p = 0.025$) were more prevalent in BC survivors than controls. BC survivors with cardiac AD had reduced exercise capacity compared to those without AD (Table). Among controls, cardiac AD was not associated with decreased exercise capacity. Among BC survivors (age-adjusted hazard ratio 1.90 (95% CI 0.78-4.62) and controls (age-adjusted hazard ratio 4.09 (95% CI 0.49-34.18), cardiac AD was not associated with increased all-cause mortality. **Conclusions:** Among patients referred for ETT, BC survivors have an increased prevalence of cardiac AD relative to controls. Cardiac AD is associated with decreased exercise capacity, but not increased all-cause mortality, in BC survivors. Available strategies to modulate cardiac AD may improve functional capacity in BC survivors. Table: Impact of markers of cardiac AD on exercise capacity.

	Breast cancer		Controls		
	Adjusted* mean reduction (SE) in METs achieved	p value	Adjusted* mean reduction (SE) in METs achieved	p value	Interaction p value

Temporal treatments and outcomes following acute myocardial infarction among cancer survivors: A population-based study, 1995-2013. *First Author: Inna Y. Gong, University of Toronto, Toronto, ON, Canada*

Background: There is little contemporary information regarding cardiac care and mortality differences following an acute myocardial infarction (AMI) between cancer survivors (CS) and non-cancer patients (NCP). **Methods:** All patients with AMI (1995-2013) in Ontario, Canada were identified through administrative databases and stratified into CS (solid or hematologic) and NCP. Those with cancer within 1 year of AMI were excluded. We used inverse probability treatment weight of propensity scores to balance confounders. Coronary intervention use and survival following index AMI were compared between CS and NCP using Modified Poisson and Cox modeling, and their temporal trends were examined. **Results:** Of 270,089 AMI patients (62.1% men; 87.8% >65 yrs old for CS vs. 56.2% for NCP), 22,907 were CS (prostate 26%, colorectal 17%, breast 16%) and 247,182 NCP. From 1995-2013, coronary interventions usage increased similarly for both groups (Table). The overall 30-day use did not differ between CS and NCP (angiogram unadjusted 36% vs. 50%, adjusted RR 0.96, 95% CI 0.96-1.00, p=.21; percutaneous coronary interventions unadjusted 21% vs. 31%, adjusted RR 0.98, 95% CI 0.94-1.01, p=.21; bypass surgery unadjusted 5% vs. 7%, adjusted RR 0.95, 95% CI 0.87-1.04, p=.25). Unadjusted 30-day mortality following AMI decreased similarly for CS and NCP (Table). However, adjusted 30-day mortality was worse in CS (HR 1.09, 95% CI 1.04-1.15, p<0.001). Over median follow-up of 11 yrs, CS had worse survival than NCP (HR 1.22, 95% CI 1.18-1.26, p<0.0001). CS had higher risk of heart failure than NCP (HR 1.10, 95% CI 1.05-1.15, p<0.0001), while myocardial (re)-infarction and stroke were similar (HR 0.99, 95% CI 0.96-1.02, p=.46; HR 1.09, 95% CI 1.00-1.18, p=.052). **Conclusions:** Following AMI, coronary intervention use increased and early mortality decreased comparably between CS and NCP over time. However, CS had worse short-term and long-term survival, suggesting that continued emphasis on cancer and cardiovascular care is needed to improve outcomes.

10059 Poster Session (Board #48), Sat, 1:15 PM-4:45 PM

Multicenter, randomized phase II trial of physical activity (PA), metformin (Met), or the combination on metabolic biomarkers in stage I-III colorectal (CRC) and breast cancer (BC) survivors. *First Author: Jeffrey A. Meyerhardt, Dana-Farber Cancer Institute/Partners CancerCare, Boston, MA*

Background: Observational data demonstrate an inverse relationship between PA and Met to disease outcomes in CRC & BC pts. A mechanism that these could impact cancer recurrence and mortality is hypothesized to involve insulin and related growth factors. We investigated the effects of PA, Met or the combination on metabolic biomarkers in CRC & BC pts. **Methods:** In a phase 2 RCT, stage I-III CRC & BC survivors at least 2 months from completing standard therapy (excluding hormone rx or trastuzumab) were randomized to PA, Met, PA + Met or control. Major eligibility included absence of recurrence or diabetes (glucose $<$ 160 (random) or $<$ 126 (fasting) mg/dl) and exercising $<$ 120 min/wk. The PA intervention consisted of supervised aerobic training at least 2 x /wk. Metformin dosing was 850 mg 1x/day titrated to 850 mg 2x/day after 2 wks if tolerated. Interventions were 12 weeks in duration. Fasting bloods at baseline & 12 wks were analyzed for insulin (1^{o}endpoint), leptin, IGF1, IGFBP1 & IGFBP3. **Results:** 139 pts were enrolled: 62% BC/38% CRC; 83% female; median BMI 28.3; median 2 yrs from dx; median age 56 (range 34-79). 107 pts completed assigned therapy. Pts in PA and PA + Met arms increased PA by 166 and 140 min/wk vs 30 min/wk in controls (both P<0.0001). Pts in the Met and PA + Met arms lost weight vs controls (-1.41 and -0.91 kg vs + 1.97 kg, both P <0.0001). Both interventions had impact on metabolic biomarkers (Table). **Conclusions:** PA and Met both led to significant changes in insulin and other biomarkers in CRC & BC survivors with potential synergistic effect on leptin with dual intervention. Clinical trial information: NCT01340300.

10060 Poster Session (Board #49), Sat, 1:15 PM-4:45 PM

Changes in p16INK4a (p16) expression, a biomarker of aging, in peripheral blood T-cells (PBTC) in patients receiving anthracycline (A) vs non-anthracycline (NoA) chemotherapy (CRx) for early-stage breast cancer (EBC). *First Author: Shlomit Strulov Shachar, Rambam Health Care Campus, Haifa, Israel*

Background: Age-related accumulation of senescent cells plays a causal role in some aspects of mammalian aging. We have shown that the total-body burden of senescent cells can be estimated by measuring the expression of the *p16* tumor suppressor, a canonical effector of senescence, in human CD3+ PBTC (Liu et al, *Aging Cell*, 2009). Expression of *p16* increases more than 10-fold over an adult human lifespan, and this rate of accumulation is accelerated by age-promoting exposures such as CRx or stem cell transplant (Sanoff et al, *JNCI* 2014; Wood et al, *EbioMed* 2016). Increased molecular age as evidenced by increased expression of p16 prior to CRx predicts a patient's risk of CRx toxicity independently of chronological age (DeMaria et al, Cancer Discovery, 2017).This study investigates the impact of different types of CRx (A vs NoA) regimens on PBTC *p16*expression in pts with EBC. **Methods:** EBC pts who received neoAdj or Adj CRx had blood samples drawn for *p16* assay prior to CRx initiation and again between 2 months and 1.5 years after the end of CRx. Expression of *p16* mRNA in PBTC was determined using TaqMan real-time quantitative reverse transcription PCR. T-test compared *p16*change between A and NA groups. **Results:** 70 pts were evaluable. Pt. characteristics: median age 49 (range 32-76); 52 (74%) White, 14 (20%) black, 4 unknown; 39 (56%) ER or PR+ and HER2 neg, 18 (26%) triple negative, 13 (19%) HER-2 pos (all received trastuzumab). 53 pts (76%) had A (47 AC + taxane, 6 AC no taxane) and 17 (24%) NoA (all TC). Expression of *p16* increased 2.0-fold in patients who received A-based CRx compared to 1.2-fold in NoA CRx ($p = 0.04$). There was no relationship of race, ER, PR or HER-2 status on change in *p16*expression. **Conclusions:** This study is ongoing and further results will be presented at the ASCO meeting. In this sample of EBC patients treated with A vs. NoA CRx regimens, A-based CRx is more strongly associated with increased biologic aging of T-cells compared to NoA CRx. These changes are equivalent of increased biologic aging of PBTC of 11 years (A) vs.6 years (NoA) and may have major consequences on the long-term survival of these pts.

10061 Poster Session (Board #50), Sat, 1:15 PM-4:45 PM

NeuroCog-FX study: A multicenter cohort study on cognitive dysfunction in patients with early breast cancer. *First Author: Oliver Rick, Klinik Reinhardshoehe, Bad Wildungen, Germany*

Background: Many breast cancer patients complain about cognitive dysfunction (CD) with mnestic and attentional deficits. These complaints persist even after completion of therapy in approximately one third of the patients and affects both social life and working capacity. The exact nature and genesis of CD in breast cancer patients is still not fully understood and risk factors are not yet described. **Methods:** To determine CD and risk factors, we used the computer-based neuropsychological test NeuroCog-FX during a three weeks oncological rehabilitation in breast cancer patients. Eight subtests addressed attention, working memory, verbal and figural memory, and language. Test duration was < 30 minutes. A cognitive deficit was diagnosed if at least one subtest was clearly below average (score $<$ M - 1.5 SD) of the normative age group. The data on cognitive function were correlated with the level of depression (PHQ-9 test), QoL (EORTC QLQ-30) and clinical parameters (nodal status, chemo-/radiotherapy and endocrine therapy). **Results:** From February 2013 to December 2014 a total of 476 patients were recruited in 9 oncological rehabilitation centers in Germany. NeuroCog-FX was used to examine 439 patients. Median age was 50 years (range: 24-62 years); 93% of patients had early tumor stage (T0-T2) and 67% were node-negative. Sixty-one percent of the patients received chemotherapy while 84% of the subjects underwent radiotherapy. CD was found in 59% and a moderate to severe depression in 38% of the patients. The severity of depression was correlated with slower reaction times and reduced verbal memory performance. These two cognitive parameters were also associated with a reduced global health status and a reduced physical function score on the EORTC-QLQ30 questionnaire suggesting an impact of cognitive deficits on quality of life. Cognitive function was not associated with type of treatment or node status. **Conclusions:** In this large and homogeneous cohort of breast cancer patients, CD has been shown in most of the subjects using a valid test method. CD was associated with depression and reduced quality of life. Neither tumor therapy nor other clinical parameters had a significant impact on development of CD.

10062 Poster Session (Board #51), Sat, 1:15 PM-4:45 PM

Survivorship needs after head and neck cancer treatment. *First Author: Callie Berkowitz, Duke University Medical Center, Durham, NC*

Background: Head and neck cancer (HNC) survivors experience significant sequelae of treatment, including long-term physical side effects and ongoing surveillance for recurrence and secondary malignancy. Given the complicated trajectory of HNC survivors, survivorship care plans educating patients and their caregivers about treatment and recovery may be beneficial. However, little is known about patients' knowledge gaps related to survivor issues. **Methods:** Through a prospective anonymous self-administered survey, we evaluated the baseline knowledge of HNC survivors regarding common post-treatment issues and mediating factors. Forty-one HNC patients within 3 months of completing treatment participated between July-November 2016. Descriptive statistics were used to characterize patient responses. **Results:** Patients had undergone a variety of treatment modalities: radiation (97%), chemotherapy (71%), and surgery (39%). 85% of patients had primary care providers, 56% had regular dental care, and 44% had dental insurance. 78% had caregivers. HNC survivors' correct responses to side-effect (SE) knowledge questions were lowest for items regarding hearing loss (15%), sleep (33%), tiredness (38%), and anxiety (49%). Only 28% correctly identified cancer risk with alcohol intake. 87% correctly linked tobacco products to cancer recurrence. Patients were most interested in learning via discussions with nurse or doctor (76%) followed by reading written materials (61%), and researching online (32%). Most patients desired to learn more about their cancer (73%), short-term SE (80%), and long-term SE (77%). **Conclusions:** Our study demonstrated clear gaps in knowledge and healthcare access that may inform targeted, individualized survivorship care plans. Patients had the largest knowledge deficits for alcohol use and recurrence, hearing loss after treatment, and a variety of emotional effects of cancer treatment. These topics should be addressed during delivery of survivorship care plans and surveillance encounters to improve survivorship knowledge.

10063 Poster Session (Board #52), Sat, 1:15 PM-4:45 PM

What do social media-savvy cancer survivors tell us about the completeness of survivorship care plans? *First Author: Diane Mary Radford, Cleveland Clinic, Cleveland, OH*

Background: The Commission on Cancer (CoC) standard 3.3 became effective in 1/2015 requiring the delivery of a survivorship care plan (SCP) at the completion of curative treatment. Both the CoC and ASCO have recommended minimum requirements for SCPs, which should include both a treatment summary and follow up care plan. Many cancer patients use social media (SM) as a way to obtain support and information. We have shown previously that the majority of SM savvy cancer survivors (88.2%) do not receive SCPs (*J Clin Oncol* 35, 2017 suppl 5S; abstr 104). We sought to determine the contents of the SCPs received. **Methods:** An IRB-approved survey was conducted via the online tool SurveyMonkey from 3/21/2016 to 4/2/2016. Patients were invited to participate via SM outlets reaching cancer-related communities including Twitter chats, Facebook groups, blogs, and targeted emails. **Results:** A total of 312 patients responded. 63% (194) had completed curative treatment (excluding endocrine therapy). Of these 11.8% (23) reported receiving an SCP at the end of treatment. Of 22 patients who responded, 9/22 (40.9%) found the SCP helpful, 11/22 (50.0%) somewhat helpful, and 2/22 (9.1%) not helpful. The table below shows the components of those SCPs received. **Conclusions:** Not only did a small percentage of patients receive SCPs but also no patient received a complete SCP per the CoC and ASCO recommendations. Particularly deficient was a description of late/long-term effects of treatment—only 36% received such information. Challenges exist in the delivery of complete SCPs.

Neurocognitive functions and psychological distress in young adults with cancer (YAC): A prospective, longitudinal study. *First Author: Kim Edelstein, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Non-CNS cancer and treatments are associated with neurocognitive sequelae in older adults; whether YAC (age 18-39 yrs) are protected from these effects is unknown. In YAC, cancer interferes with education and occupational attainment and is associated with psychological distress. This prospective, inception-cohort study characterizes neurocognitive functions and psychological distress in YAC. **Methods:** YAC completed a 2-hr battery of standardized neurocognitive tests and questionnaires 1.7 ± 1 months after diagnosis prior to chemotherapy (mean ± SD, T1) and 8.2 ± 1.2 (T2) and 14.2 ± 1.6 (T3) months later. Healthy YA with no cancer history (HYA) were tested at similar time points. Tests were scored using published norms, transformed to T-scores, and grouped into neurocognitive domains. **Results:** YAC (n = 108; lymphoma, breast, gyne, GI, GU, sarcoma) were grouped according to whether they required chemotherapy (n = 70) or not (n = 38), and compared to 63 HYA. At baseline, there were no group differences in neurocognitive performance, number of impaired tests, or neurocognitive complaints (Kruskal Wallis, all p-values $> .4$). About 70% of each group completed assessments at T2 and T3. Mean performance improved over time (random effects models, all p-values $< .01$), but there were no group differences or interactions between group and time. There were also no differences in proportions of participants in each group whose test scores improved (> 10 points) or declined (< 10 points) from T1 to T2 or T3. Adjusting for psychological distress, fatigue, or neurocognitive complaints did not change these results, despite higher symptoms of somatic distress, anxiety and fatigue in YAC compared to healthy YA over time (all p-values $< .03$). **Conclusions:** Before chemotherapy and up to about 14 months later, YAC have elevated distress and fatigue, but do not demonstrate the cognitive decline reported in older cancer patients. Our findings are consistent with research suggesting that aging brains are more vulnerable to neurotoxic insult. Whether the effects of cancer treatment emerge later in YAC, placing them at risk for accelerated aging as reported in older patients, remains to be examined.

10065 **Poster Session (Board #54), Sat, 1:15 PM-4:45 PM**

Pregnancy after breast cancer: Results from a prospective cohort study. *First Author: Philip Daniel Poorvu, Dana-Farber Cancer Institute, Boston, MA*

Background: Prospective data regarding fertility and pregnancy after breast cancer are limited. Many young survivors are interested future fertility, but pregnancy rates among women attempting and not attempting pregnancy have not been studied prospectively. **Methods:** As part of a multicenter cohort study, women diagnosed age ≤40 with stage 0-3 breast cancer are surveyed at baseline then annually regarding fertility interest, attempts, and pregnancies. Chi-square tests were used to compare proportions attempting and achieving pregnancy. **Results:** At least once in the 5 years (yrs) after Dx, 334/959 (35%) women reported interest in future biologic children. The percent interested was stable in the first 3 yrs then declined: 256 (27%, baseline), 244 (27%, 1 year), 209 (25%, 2 yrs), 176 (25%, 3 yrs), 106 (18%, 4 yrs), and 72 (16%, 5 yrs). Pregnancy was attempted by 104/334 (31%) of women who reported interest and 4/625 (1%) who did not. Pregnancy occurred in 118 women (12%), including 76/108 (70%) who attempted and 42/851 (5%) who did not. Attempts and achieving pregnancy were associated with younger age, partnered status, and not having children prior to Dx (table). Lower stage was associated with attempting pregnancy and ER negative disease with achieving pregnancy. **Conclusions:** A substantial number of young women become pregnant in the 5 years after a breast cancer diagnosis. Given that over 1/3 of pregnancies were among women who did not report attempting, additional attention to contraception counseling should be considered. Further evaluation of assisted reproductive technology use, pregnancy and disease outcomes in this cohort, and the POSITIVE Trial (NCT02308085) will shed light on the feasibility and safety of pregnancy after breast cancer.

Can exercise influence survival following breast cancer: Results from a randomised, controlled trial. *First Author: Sandra Christine Hayes, Queensland University of Technology, Institute of Health and Biomedical Innovation, Brisbane, Australia*

Background: Exercise for Health was a randomised, controlled trial designed to evaluate an 8-month translational exercise intervention, commencing 6-weeks post-surgery for newly diagnosed breast cancer. Outcomes for this follow-up exploratory analysis were overall- and disease-free survival. **Methods:** Consenting urban-based women (n = 194) were randomized to one of two exercise groups (intervention delivered either face-to-face or over the telephone) or a usual care group, while consenting rural/regional women (n = 143) were randomised to either the telephone-delivered exercise group or usual care group. For the purposes of these analyses, exercise groups and usual care groups were combined (exercise group, n = 207; usual care group, n = 130). Analyses were done on an intention-to-treat basis and trials were registered with the Australian New Zealand Clinical Trials Registry (ACTRN12606000233527; 12609000809235). **Results:** Participant disease and treatment characteristics were similar to the wider breast cancer population in Queensland, Australia, and 42% of the sample resided in rural or regional areas. After a median follow-up of 101 months, there were 15/130 (11.5%) survival events in the usual care group, compared with 11/207 (5.3%) events in the exercise group. Disease-free events for the usual care versus exercise group were 23/130 (17.7%) and 25/207 (12.1%), respectively. The corresponding unadjusted hazard ratio for the exercise group for overall survival was 0.45 (95% CI = 0.21-0.97; p = 0.037), and for disease-free survival was 0.66 (95% CI = 0.38-1.17; p = 0.155). **Conclusions:** Epidemiological evidence consistently shows a positive relationship between physical activity and survival post-breast cancer, but is unable to establish causality. These exploratory findings suggest that an exercise intervention delivered during and beyond conventional treatment for breast cancer and that was designed to cater for all women, irrespective of place of residence and access to medical services, has clear potential to influence survival. Clinical trial information: ACTRN12606000233527; 12609000809235.

10068 Poster Session (Board #57), Sat, 1:15 PM-4:45 PM

Chemotherapy-induced ovarian failure (CIOF) in young women with early breast cancer (EBC). *First Author: Jenny Furlanetto, German Breast Group (GBG), Neu-Isenburg, Germany*

Background: Women ≤45 years (yrs) treated with chemotherapy (CT) for EBC have a high risk of developing CIOF. Awareness of CIOF is essential for young women. **Methods:** 740 patients (pts) aged ≤45yrs treated with anthracycline or taxane-based CT for EBC from 4 German neoadjuvant/adjuvant trials were included. Blood samples were collected at baseline (N=740), end of treatment (EOT n=740), 6 (n=177), 12 (n=113), 18 (n=69), 24 (n=47) months (m) after EOT. Only samples collected in a time sequence were included. Estradiol (E2), Follicle-Stimulating Hormone (FSH) and Anti-Müllerian Hormone (AMH) were centrally assessed. CIOF was defined as FSH >12.4IU/l and E2 <52.2ng/ml and was analysed per timepoint and according to clinical and treatment-related variables. **Results:** Median age was 40yrs (range 21-45); 57.2% had BMI 18.5-<25, 41.1% ≥25; 32% had luminal, 35.9% HER2+, 32.0% triple-negative BC. Median hormone levels at baseline for pts <30yrs vs 30-40yrs vs ≥40yrs were: FSH 5.2IU/l vs 5.6IU/l vs 6.4IU/l; E2 101ng/l vs 86ng/l vs 88ng/l; AMH 2.14ng/ml vs 1.58ng/ml vs 0.53ng/ml. 85.7% of pts had CIOF at EOT, 62.2% at 6m, 54.0% at 12m, 43.5% at 18m, 38.3% at 24m. Similar results were observed in 47 pts with all timepoint samples available. Older vs younger pts had more frequently CIOF at EOT (≥40yrs 94.6%, 30-40yrs 82.0%, <30yrs 50.0%, p<0.001). CIOF at EOT was not influenced by BMI. CT agents impacted the rate of CIOF (p<0.001; Table 1). Higher rate of CIOF was associated with longer CT duration (12w 58.3%, 16-18w 94.5%, 24w 82.1%; p<0.001) and with dose-dense (ddEC-ddD, weekly PM(Cb), intense-dd (idd) EnPC) vs conventional dosed CT (P/nP-EC q3w, P, Cz) (94.5% vs 78.6%; p<0.001). **Conclusions:** The majority of young women experienced CIOF after CT for EBC. After 2 yrs 62% of the pts returned to premenopausal hormone levels. Age, CT regimen, duration and density influenced the rate of CIOF and should be taken into account when counseling young women who desire to maintain ovarian function.

CIOF according to treatment at EOT.

CT Regimen	ddEC-ddD	PMCb	iddEnPC	PM	P	nP-EC	P-EC	Cz
CIOF %	95.6	95.2	94.6	93.1	89.7	82.9	81.3	29.0

10069 Poster Session (Board #58), Sat, 1:15 PM-4:45 PM

Fatigue and health behaviors in cancer survivors: A cross-sectional population based study. *First Author: Margarida Matias, Gustave Roussy, Université Paris-Saclay, Villejuif, France*

Background: A substantial proportion of breast, colo-rectal and prostate cancer patients (pts) can expect long term disease free survival after their primary treatment. Among those, fatigue commonly persists after diagnosis (dx) and can be debilitating. In this study, we evaluated the incidence of fatigue 2 years (y) after cancer dx and its association with health behaviors. **Methods:** We used a French population based cross-sectional study, which included a representative sample of pts from 12 cancer types (VICAN2). VICAN2 surveyed 4347 pts 2 y after dx. There is a 99% completion rate of fatigue related questions. For this study, we included 2017 pts with breast (1237), colo-rectal (348) and prostate (432) cancer without evidence of metastases at dx or relapse 2y after dx and with fatigue information. Severe fatigue was defined as average score of EORTC QLQC30 fatigue subscale ≥40 at 2y after dx. There were <1% of missing values in the evaluated covariates. Multivariate logistic regression models looked at associations of fatigue with heatlh behaviors (Δ in exercise since dx, exercise at diagnosis, body mass index (BMI), Δ since dx, smoking), age, gender, comorbidities, education, employment, cancer type, radiation, chemotherapy, hormonal therapy. **Results:** 52% of pts reported severe fatigue at 2 y after dx (median fatique score: 44, range: 0-100). 2 y after dx, 47% of pts either stopped or decrease exercise and 16% had a ≥ 10% change in BMI. Factors associated with fatigue included health behaviors (Table), but also age (adjusted odds ratio [*a*OR] for severe fatigue, 95% confidence interval [95% CI]: 0.97, 0.96-0.98), gender (*a*OR, 95 CI male vs. female: 0.5, 0.3-0.8), comorbidities (*a*OR, 95 CI yes vs. no: 2.0, 1.6-2.4) and treatment type (*a*OR, 95 CI radiation vs. no: 1.5, 1.1-2.0). **Conclusions:** Fatigue continues to be a substantial problem for cancer survivors 2 y after dx. Some factors that may contribute to persistent fatigue (health behaviors) may be amenable to interventions.

	N	% Fatigue	Adjusted odds ratio for severe Fatigue (95% confidence interval)
Δ in exercise since dx			
No	760	36	1
>than before	296	55	1.6 (1.2-2.1)
<than before or stopped	946	65	3.4 (2.7-4.3)
BMI Δ since dx			
Stable	1674	48	1
≥ or ≤10%	326	72	1.7 (1.3-2.3)

10070 Poster Session (Board #59), Sat, 1:15 PM-4:45 PM

The effect of loneliness on cancer mortality. *First Author: Simona D'ippolito, Department of Oncology, Santa Maria del Prato Hospital ULSS 1 Dolomiti, Feltre, Italy*

Background: Convergent findings indicate the need of broadening the vision of cancer beyond known prognostic factors, as many variables of different nature equally affect the course of disease. Loneliness has been found to be associated with various health outcomes, but its relationship with cancer remains unclear. Here we aimed to investigate the specific effect of loneliness and other demographic, psychological, and clinical variables on cancer mortality and to validate the Italian UCLA Loneliness Scale in cancer patients. **Methods:** This descriptive and correlational study was conducted at the Veneto Institute of Oncology in Padua. 400 patients undergoing chemotherapy from 01/2014 to 06/2015 were enrolled. The sample was stratified by sex and age (4 groups, 40-80 y). We collected demographic, clinical (site and stage of cancer, type of chemotherapy, death date), and psychosocial [self-esteem (RSE), perceived social support (MSPSS), social interaction anxiety (SIAS), personality (EPQR), and depression (BDI)] data. **Results:** GLM analyses: loneliness was higher in women than men ($F(1,398) = 7.5$, $p = .006$) and it linearly increased with age ($F(1,398) = 10.9$, $p = .001$). Loneliness was also influenced by marital status ($F(3,396) = 2.9$, $p = .037$), cohabitant offspring ($F(1,398) = 7$, $p = .008$), and educational level ($F(3,396) = 4.7$, $p = .003$), but not by clinical variables (all $ps > .05$). Correlation analyses: loneliness was inversely related to RSE ($r = -.51$), MSPSS ($r = -.52$), and extroversion ($r = -.32$), and directly related to SIAS ($r = .46$), neuroticism ($r = .43$), and BDI ($r = .44$). More importantly, a hierarchical binomial logistic regression revealed that patients' mortality was reliably predicted by gender, stage of cancer at diagnosis, time from diagnosis to UCLA collection, BDI, and UCLA (HL $\chi^2(8) = 3.53$, $p = .90$). In particular, high BDI predicted higher mortality (Wald = 11.6, $p < .001$); surprisingly, after controlling for BDI and other effects, high loneliness predicted lower mortality (Wald = 7, $p = .008$). **Conclusions:** Our results replicate prior research and reveal a surprising association between loneliness and mortality risk after partialling out the impact of, especially, depression. This suggests the role of loneliness on cancer course as an important health concern.

10071 Poster Session (Board #60), Sat, 1:15 PM-4:45 PM

Influence of patient characteristics on provider surveillance for colorectal cancer. *First Author: Joanna M. Brell, MetroHealth Medical Center Case Western Reserve University, Cleveland, OH*

Background: The majority of colorectal cancer (CRC) patients present with resectable disease and benefit from future resection of second primary CRC, local recurrence, and oligometastases. Therefore, in addition to colonoscopy one year after diagnosis, American Society of Clinical Oncology (ASCO) offers consensus recommendations to monitor serum CEA and CT scans for early detection. Limited adherence to guidelines has been reported; we explore the impact of specific patient factors related to CRC on provider prescribing in the first year. **Methods:** At a single urban safety-net hospital, electronic medical records of patients diagnosed with stages I-III CRC from 2002-2014 were reviewed with IRB approval. Chi-square tests determined extent of associations between categorical variables. Two sample t-tests compared means for continuous outcomes across groups. Cut-off for Type 1 error was alpha = 0.05. Due to minimal change in surveillance guidelines, we applied ASCO 2005 recommendations. **Results:** Records for 357 patients included 52% females and 40% African-Americans. Median age was 63 years, ever tobacco abuse was 69%. BMI > 30 found in 38%, median weight at diagnosis was 79 kg. Incidence of surveillance and associated variables are in the Table. **Conclusions:** The providers of this young, urban, almost 40% obese population were < 50% compliant with first year colonoscopy and < 60% compliant with CEA tests. Providers did significantly survey patients with co-morbidities, such as higher weight at diagnosis, in this small study. Most patients complied with orders and primary care providers were least compliant (data not shown). The data supports verification in larger study of safety-net hospitals and future comparison regarding influence of new Survivorship Care Plans on guideline adherence. To improve provider compliance, etiology of nonadherence must be addressed.

Surveillance Study	Number of Records % Completed	Variables P values < 0.05
Colonoscopy at 1st year	N = 329 46.5	Weight @ dx (0.001) Age < 55 (0.003) BMI > 30 (0.010) Ever tobacco (0.005) Hyperlipidemia (0.002)
CEA In 3-6 months of 1st year	N = 270 58.1	Weight @ dx (0.023) Stage III (0.007) Lymph nodes (0.004)
CT scan Within 1st year	N = 270 76.0	Weight @ dx (0.030) Age > 55 (0.006)

10072 Poster Session (Board #61), Sat, 1:15 PM-4:45 PM

The impact of the Affordable Care Act (ACA) on cancer survivorship. *First Author: Christine Leopold, Harvard Medical School and Harvard Pilgrim Heatlh Care Institute, Department of Population Medicine, Boston, MA*

Background: The ACA of 2010 has been recognized by the cancer community as an important step forward in insurance and payment reform, aiming to expand the number of insured patients, control costs and incentivize health care delivery system changes. In this review, we outline the ACA provisions relevant to cancer survivorship, provide available evidence for their impact, and offer insights for future research. **Methods:** We conducted a literature search in the PubMed database and grey literature. We searched the terms 'ACA and cancer survivors', which resulted in 17 articles and expanded the search to 'ACA and cancer' and found 213 articles, of which 75 were relevant for this review. We categorized the ACA provisions into three categories, 1) access to preventive care, 2) access to quality, coordinated care, and 3) coverage expansion and increased affordability. **Results:** Positive effects of the ACA were: an increased uptake of preventive services and cancer screening; a reduction in hospital admissions, increased guidelines concordance and generic prescribing through the implementation of cancer-specific Accountable Care Organizations; a reduction of unnecessary resource use (e.g. emergency visits) through the implementation of oncology patient-centered medical home models and decreases in costs though bundle payments. These results focus on the general population/cancer patients; specific studies targeting at the effects on cancer survivors are missing. In addition, evidence from literature showed that knowledge about the benefits of the ACA is low among childhood cancer survivors; while insurance coverage rates of cancer survivors, especially for childhood cancer survivors, increased. **Conclusions:** Evidence regarding the effects of the ACA on cancer survivorship care is limited, though point to greater access to preventive services and screening programs. Effects of provisions focusing on quality, coordinated care as well as coverage expansion and affordability may have beneficial effects. Whether the ACA remains or is reformed, it is critically important that decisions take into account the potential intended and unintended consequences of the ACA provisions on health outcomes and quality of life of this growing population.

10073 Poster Session (Board #62), Sat, 1:15 PM-4:45 PM

Genitourinary disease risks among 5-year ovarian cancer survivors in a population-based cohort study. *First Author: Mia Hashibe, Division of Public Health, Department of Family and Preventive Medicine, University of Utah, School of Medicine, Salt Lake City, UT*

Background: In the US, there are approximately 235,200 ovarian cancer survivors today. Five-year survival for ovarian cancer has increased from 36% for women who were diagnosed in 1975-1977 to 46% for women diagnosed between 2005-2011. Long term follow-up studies among ovarian cancer survivors are uncommon and late effects have not been well characterized in a population-based cohort. Although genitourinary complications during treatment are well known, long term impacts need to be investigated. **Methods:** A total of 602 first primary invasive ovarian cancer cases diagnosed between 1996-2012 who survived for $>$ 5 years were identified in the Utah Population Database and compared to a general population cohort of women. Genitourinary disease diagnoses were identified through ICD codes from hospital electronic medical records and statewide ambulatory surgery and inpatient data. Cox regression models were used to estimate hazard ratios for disease risks by time since cancer diagnosis with adjustments on matching factors, baseline BMI, baseline Charlson Comorbidity Index (CCI), and race. **Results:** The overall risk of genitourinary diseases for ovarian cancer patients in comparison to the general population cohort was 1.51 (95%CI = 1.30-1.74) 5-10 years after cancer diagnosis. Approximately 54.6% of ovarian cancer survivors were diagnosed with a genitourinary disease 5-10 years after cancer diagnosis. The most common genitourinary diseases among the ovarian cancer survivors were urinary tract infections (10.1%), acute renal failure (5.5%), and chronic kidney disease (4.4%). The greatest risks were observed for hydronephrosis (HR = 10.65, 95%CI = 3.68-30.80), pelvic peritoneal adhesions (HR = 5.81, 95%CI = 1.11-30.39), cystitis and urethritis (HR = 2.67, 95%CI = 1.21-6.38), and acute renal failure (HR = 2.30, 95%CI = 1.36-3.88). **Conclusions:** Ovarian cancer survivors experience increased risks of various genitourinary diseases in the 5-10 year period following cancer diagnosis. Understanding the multimorbidity trajectory among ovarian cancer survivors is of vital importance to improve their clinical care after cancer diagnosis and allow for increased attention to these potential late effects.

10074 Poster Session (Board #63), Sat, 1:15 PM-4:45 PM

Endocrine and metabolic diseases among colorectal cancer survivors in a population-based cohort. *First Author: Makenzie Hawkins, Division of Public Health, Department of Family and Preventive Medicine, University of Utah, School of Medicine, Salt Lake City, UT*

Background: Colorectal cancer is the third most common cancer among men and women in the United States. As of 2016, there were an estimated 1.4 million colorectal cancer survivors. Research on endocrine and metabolic diseases over the long term in colorectal cancer survivors is limited. Obesity is a risk factor for colorectal cancer, thus it is of interest to investigate diseases that may share this risk factor such as diabetes for long term health effects among survivors. **Methods:** A total of 7,077 colorectal cancer patients who were diagnosed between 1997 to 2012 were identified in the Utah Population Database. A general population cohort of 35,354 individuals was matched on birth year, sex, birth state and follow-up time as a comparison group. Late effects were identified using electronic medical records and statewide ambulatory and inpatient data and were assessed over three time periods of 1-5 years, 5-10 years, and $>$ 10 years. Cox proportional hazard models were used to estimate the risk of late effects after adjusting for matching factors, race, baseline body mass index, and the baseline Charlson Comorbidity Index. **Results:** Across all three time periods, late effects risk for endocrine diseases and metabolic disorders was significantly greater for colorectal cancer survivors compared to the general population cohort. Risk for diabetes mellitus with complications was significantly increased for survivors and risk was greatest for uncontrolled diabetes (HR = 5.04, 99%CI = 2.38, 10.67) and diabetes with neurological manifestations (HR = 4.10, 99%CI = 2.08, 8.26). Higher risk was also observed for thyroid disorders (HR = 3.09, 99%CI = 2.34, 4.08) and nutritional deficiencies (HR = 4.98, 99%CI = 3.47, 7.17). The risk of obesity in survivors was greatest 1-5 years post cancer diagnosis (HR = 5.04, 99%CI = 2.91, 8.75), but remained significantly increased at all follow-up time periods. **Conclusions:** Endocrine and metabolic diseases were significantly higher in colorectal cancer survivors across the follow-up periods. As the number of colorectal cancer survivors increases, understanding the long term multimorbidity trajectory is critical for improved survivorship care.

10075 Poster Session (Board #64), Sat, 1:15 PM-4:45 PM

Clinical, sociodemographic, and behavioral factors associated with cumulative burden of morbidity (CBM) among testicular cancer survivors (TCS) in the Platinum study. *First Author: Sarah L. Kerns, University of Rochester Medical Center, Rochester, NY*

Background: TCS are an important group in which to characterize late effects of cancer and its therapy given their young age at diagnosis and high cure rate. We comprehensively evaluated CBM and identified associated clinical, sociodemographic, and behavioral risk factors among TCS given cisplatin based chemotherapy in a multicenter study. **Methods:** TCS completed a comprehensive health questionnaire. Responses were grouped into 22 adverse health outcomes (AHO) and graded by severity. A CBM score was calculated based on AHO number and severity, following Geenen et al (JAMA 2007). Multivariable ordinal logistic regression examined the association of clinical, sociodemographic, and behavioral factors with CBM. Variable-based hierarchical clustering identified individual AHOs that co-occurred. **Results:** Among 1,215 TCS (median age at evaluation 38 y, range 19-68 y; time since chemotherapy 4.6 y), over 20% had a CBM score of high (17%), very high (4%) or severe (0.4%). Most TCS, however, had CBM scores of low (37%), medium (28%), very low (9%) or none (5%). In a multivariable model controlling for time since chemotherapy, older attained age (OR 1.2; 95% CI 1.1 - 1.3), being widowed/divorced/separated (OR 1.8; 95% CI 1.1 - 3.1), having less than college-level education (OR 1.7; 95% CI 1.3 - 2.2), being retired/on disability (OR 2.5; 95% CI 1.2 - 5.3), and receipt of 4 cycles of BEP vs. 4 cycles of EP or 3 cycles of BEP (OR 1.3; 95% CI 1.01 - 1.8) were associated with increased odds of a worse CBM score; vigorous exercise (OR 0.7; 95% CI 0.5 - 0.9) and non-white race (OR 0.6; 95% CI 0.4 - 0.9) were associated with decreased odds. A separate cluster analysis revealed five groups of AHOs: those known to be cisplatin-related (e.g. neuropathy, ototoxicity); metabolic abnormalities (e.g. hypercholesterolemia, diabetes); vascular damage (e.g. stroke); testicular cancer-related (e.g. hypogonadism); and other (e.g. thyroid disease). **Conclusions:** TCS with factors associated with worse CBM may be candidates for closer monitoring. If confirmed, our cluster analysis showing that groups of conditions tend to co-occur in TCS could provide guidance for survivorship care plans.

10076 Poster Session (Board #65), Sat, 1:15 PM-4:45 PM

Survivorship care plans: Recommended vs delivered care. *First Author: Karen L. Smith, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: The Committee on Cancer set a benchmark for the provision of survivorship care plans (SCP) to ≥50% of early cancer patients by the end of 2017 despite limited data indicating benefit. One hypothesis is that SCP will reduce overuse of medical care in survivors. **Methods:** We performed a retrospective review of all patients with early breast cancer (BC) who were seen by a single nurse practitioner (NP) for provision of SCP after completion of primary therapy (surgery, radiation +/- chemotherapy). We evaluated adherence to recommendations for follow-up (FU) care and testing in accordance with established guidelines. **Results:** Between August 2013 and December 2014, 152 patients received SCP after completion of primary therapy (median 2 months, range 0-27). 98% of SCP were given to patients, but only 38% were sent to primary care providers (PCP). Median FU was 23 months. Among 130 patients who did not undergo bilateral mastectomy for whom surveillance breast imaging (SBI) was recommended, 10 (8%) had 1st SBI ≥3 months earlier than time recommended (TR), 102 (78%) within 2 months of TR, 12 (9%) ≥3 months after TR, and 6 (5%) lacked confirmation of 1st SBI. Among 113 in whom 2nd SBI dates were specified, 25 (23%) had SBI ≥3 months earlier than TR, 62 (55%) within 2 months of TR, 7 (6%) ≥3 months after TR, and 18 (16%) lacked confirmation of 2nd SBI. Among 71 patients for whom first medical oncology (MO) FU visit dates are known, 64 (90%) occurred within 3 months of TR and among 81 patients for whom first radiation oncology (RO) FU visit dates are known, 67 (83%) occurred within 3 months of TR. However, among 47 patients for whom first FU visit dates with at least 2 types of providers (MO, RO and/or surgery) are known, 15 (32%) visited 2 providers within 2 months of one other. During the 1styear after completion of primary therapy, 22% underwent body imaging (CT, PET-CT, or bone scan) and 21% had liver function tests. **Conclusions:** Despite provision of a SCP to patients, PCP were often not notified and healthcare utilization exceeded recommendations. Nearly a third of patients had redundant visits, a fourth had SBI earlier than recommended, and a fifth had body imaging and lab testing. Ongoing efforts are needed to coordinate care and minimize unnecessary testing in BC survivors.

10078 Poster Session (Board #67), Sat, 1:15 PM-4:45 PM

Association of nutritional parameters and survival in parenteral nutrition-supported (PN) gastrointestinal cancer patients. *First Author: Wenli Liu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PN is a major tool in managing nutritional challenges in cancer patients. However, a clear set of clinical and biochemical indices to determine PN application in cancer patients has not been developed. We assessed the association between PN related nutritional parameters and survival in a large group of gastrointestinal (GI) cancer patients. **Methods:** 1197 consecutive GI cancer patients who received PN support between 08/01/08 – 08/01/13 were reviewed. Height, weight, plasma glucose (baseline and within 48 hours after PN initiation), surgical history, and pharmacy data including PN contents (dextrose, amino acids, and fat) and non-PN dextrose or fat in drug administration were recorded. Body mass index (BMI), Ideal body weight (IBW), PN and non-PN Calorie, and nitrogen were calculated for analysis. Data were entered into a multivariate analysis controlling for age, gender, cancer site, and medical comorbidities. **Results:** Median BMI was 25.4. 70% of the patients had unsteady weight (> 2.5% change) before PN initiation. The magnitude of weight change was inversely related to survival (HR 1.02), P < 0.001). Patients with BMI > 25 and < 7.5% weight change prior to PN initiation had the most favorable survival. Glycemic instability (maximum plasma glucose variation > 100mg/dL) was independently related to shorter survival (HR 1.53, P < 0.001). Total calorie by IBW (kcal/kg/day) (HR 0.97, P < 0.001), non-PN calorie % (HR 1.04, P < 0.001), and calorie to nitrogen ratio (kcal:g) (HR 1.02, P < 0.001) were all independently associated with overall survival. **Conclusions:** Lower BMI, weight instability, and glycemic instability were adversely associated with survival. Higher total PN calorie and amino acid support were associated with better survival. Higher non-PN calorie % was adversely related to survival. Future studies must focus on developing a set of indices incorporating independent prognostic clinical and biochemical factors in determining PN application and monitoring in cancer patients. Optimum calorie and amino acids in PN support for cancer patients also require further investigation.

10079 Poster Session (Board #68), Sat, 1:15 PM-4:45 PM

The association between mindfulness and post-operative pain in gynecologic oncology patients undergoing minimally invasive hysterectomy. *First Author: Erica Weston, Women and Infants Hospital in Rhode Island, Providence, RI*

Background: Studies demonstrate an inverse relationship between mindfulness and chronic pain. However, the relationship between mindfulness and acute post-operative pain has not yet been thoroughly investigated. The objective of this study is to determine if there is an association between pre-operative level of mindfulness and post-operative pain outcomes in women undergoing minimally invasive hysterectomy. **Methods:** For this prospective cohort study, women planning to undergo laparoscopic or robotic hysterectomy were prospectively recruited at the gynecologic oncology outpatient clinic at our institution. Baseline mindfulness was assessed at the pre-operative clinic visit using the Five Facet Mindfulness Questionnaire (FFMQ). Post-operative pain, using the Visual Numeric Rating Scale (VNRS-11), and opiate pain medication usage were evaluated via chart review and post-operative surveys completed at 1 to 2 week and 4 to 6 week post-operative clinic visits. **Results:** One hundred twenty four women completed the 6 week post-operative follow-up period, of which 80% were undergoing surgery for malignancy. Baseline mindfulness was inversely correlated with post-operative pain as measured by both the average and highest reported VNRS-11 values during the inpatient stay (r = -0.21, p = 0.019; r = -0.21, p = 0.016). At the 1 to 2 week post-operative visit, self-reported pain score was also inversely correlated with pre-operative mindfulness score (r = -0.24, p = 0.009). This relationship was not observed at the 4 to 6 week post-operative visit (r = -0.08, p = 0.403). Higher pre-operative mindfulness was also associated with lower opiate usage (r = -0.16, p = 0.077), though this relationship was not statistically significant. **Conclusions:** Higher pre-operative mindfulness is associated with more favorable post-operative pain outcomes, including lower reported numeric pain scores, in gynecologic oncology patients undergoing minimally invasive hysterectomy. This relationship provides an opportunity to target the modifiable personality characteristic of mindfulness, to improve post-operative pain in women planning gynecologic surgery.

10080 Poster Session (Board #69), Sat, 1:15 PM-4:45 PM

Exploration of risk factors for osteoporotic fracture following hematopoietic stem cell transplantation. *First Author: Huifang Lu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The incidence of fractures following hematopoietic stem cell transplantation (HSCT) ranges from 5% to 12% and the rates are up to 10 times greater than in the general population. The risk factors involved in osteoporotic fracture development following HSCT are incompletely understood. **Methods:** We conducted a retrospective cohort study of patients > 18 years that received a HSCT at MD Anderson Cancer Center, from January 1, 2001 to December 31, 2010. Patients were followed until December 31, 2013 for assessment of osteoporotic fracture occurrence using ICD-9 codes and confirmed by chart review. Cox regression model was used to identify independent risk factors for osteoporotic fractures. Factors included individual risk factors included in the World Health Organization Fracture Risk Assessment Tool FRAX and type of HSCT, type of preparatory regimen and underlying indication for HSCT. **Results:** A total of 5,170 patients received a HSCT during the 10-year study period, of which 527 (10%) patients developed an osteoporotic fracture. The median time of follow up was 3.2 years. A multivariate Cox regression model considering all clinical and malignancy specific risk factors was fitted. With the control of all other variables, the risk of developing fracture was 1.20 (95% confidence interval (CI):1.02-1.41) times higher for every 20 years increase in age at HSCT; female patients had a 1.24 (95% CI: 1.05-1.48) times higher risk compared to male patients; patients with a fracture prior to HSCT had a 2.01 (95% CI: 1.62-2.51) times higher risk compared to patients without a prior fracture; patients receiving an allogeneic HSCT had a 1.57 (95% CI: 1.20-2.05) times higher risk compared to patients receiving an autologous HSCT; and patients with multiple myeloma had a 2.62 (95% CI: 1.97-3.49) times higher risk compared to patients without multiple myeloma. **Conclusions:** Age at HSCT, gender, prior fracture status, type of HSCT, and underlying indication were identified to be statistically significantly associated with fracture. This is one of the first large scale studies assessing a comprehensive set of risk factors. To develop a risk model for fracture, we should consider these factors.

10081 Poster Session (Board #70), Sat, 1:15 PM-4:45 PM

Cardiovascular disease and preventive care among cancer survivors: A population-based study. *First Author: Kevin A. Pearlstein, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Cardiovascular disease (CVD) has been identified as a leading cause of mortality among cancer survivors, particularly long-term survivors. However, studies examining the prevalence of CVD risk factors and CVD-specific preventive care among US cancer survivors are lacking. We utilize the National Health Interview Survey (NHIS) data to address this knowledge gap. **Methods:** NHIS is an annual survey among roughly 88,000 individuals across the US, and its data are representative of US population-based estimates of health status, healthcare behavior, and healthcare utilization. 15,747 individuals surveyed from 2011 to 2015 who reported a history of cancer (except non-melanomatous skin cancer) were included in this study. Prevalence of CVD risk factors and preventive care received were calculated incorporating NHIS sample weights. A multivariable logistic regression model was used to evaluate factors associated with risk factor monitoring. **Results:** 55% of the cohort was ≥6 years out from cancer diagnosis and 53% were 65 years or older. CVD risk factors were prevalent across the entire cohort (Table). Among survivors < 50 years, 30% were active smokers, and 35% obese. Among survivors ≥65, 40% had known CVD. Among survivors with each risk factor, rates of monitoring and management of each is reported in Table. On multivariable analysis, seeing a generalist was strongly associated with monitoring of blood pressure (OR 18), cholesterol (OR 8), and fasting glucose (OR 3). **Conclusions:** This study provides the current status of preventive care among US cancer survivors, illustrating that CVD and its risk factors are common. Rates of monitoring of hypertension and hyperlipidemia are high, but there is room for improvement in interventions targeting obesity and smoking cessation.

Risk Factor	%	Management in Past Year Among Individuals with Risk Factor	%
Hypertension	53	Blood pressure check	98
Hyperlipidemia	48	Cholesterol check	94
Diabetes	18	Blood sugar check	86
Obesity	30	Moderate exercise (past month)	55
Smoking	14	Smoking cessation attempt	47

10082 Poster Session (Board #71), Sat, 1:15 PM-4:45 PM

The contribution of pre-existing cardiovascular (CV) risk factors to the risk of stroke or heart attack among non-Hodgkin lymphoma (NHL) survivors. *First Author: Talya Salz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Increased risk of myocardial infarction (MI) and cerebrovascular accident (CVA) among NHL survivors is commonly attributed to NHL treatment. The extent to which pre-existing CV risk factors also contribute to increased risk is unknown. We investigated this association among an entire national population of NHL survivors who have a full range of important CV risk factors. **Methods:** Using Danish population-based registries, we identified all adults diagnosed with primary aggressive NHL from 2000-2010 and followed them for MI and CVA from 9 months after diagnosis through 2012. MI and CVA diagnoses were ascertained from the nationwide Hospital Discharge Register and Cause of Death Register. CV risk factors (hypertension, dyslipidemia, and diabetes), vascular disease, and intrinsic heart disease prevalent at NHL diagnosis were ascertained algorithmically using the National Prescription Register and the Hospital Discharge Register. Cumulative anthracycline dose was coded continuously. Receipt of radiation was coded dichotomously for both chest and neck. Controlling for age, sex, treatment, and CV diseases, we used Cox multivariate regression to test the association between pre-existing CV risk factors and subsequent CVA or MI. **Results:** Among 2604 patients with NHL, median age was 62, and median follow-up time was 2.4 years. Overall, 131 patients were diagnosed with MI or CVA. Before NHL diagnosis, 40% of patients had at ≥1 CV risk factor, 13% had vascular disease, and 6% had intrinsic heart disease. 90% of the patients were treated with anthracyclines, 9% had received chest radiation, and 15% had received neck radiation. Patients with ≥1 CV risk factor had an increased risk of MI or CVA compared to patients with none (HR = 1.5 [95% CI = 1.1-2.2). Prevalent vascular disease, prevalent intrinsic heart disease, and NHL treatment were not associated with MI or CVA (p's > 0.05). **Conclusions:** In a large, well-characterized, and nationally representative cohort of NHL survivors, prevalent CV risk factors were associated with later CVA and MI. To prevent MI and CVA among survivors, decisions about post-treatment monitoring should take into account prevalent CV risk.

10083 Poster Session (Board #72), Sat, 1:15 PM-4:45 PM

Secondary solid tumors in patients younger than 55 with chronic lymphocytic leukemia (CLL). *First Author: Jordan Spencer Carter, Drexel University College of Medicine, Philadelphia, PA*

Background: Patients with CLL are at an increased risk of secondary solid tumors. Few studies have looked at this risk in patients < 55, despite research suggesting that this is a distinct cohort with a longer overall survival. What data does exist has yielded variable results in limited populations. In light of this, our study utilized the SEER registry to look at secondary solid tumors in patients < 55 with CLL. **Methods:** 4559 patients 15-54 years old with CLL were identified in the SEER registry between 1973 and 2013. Cancer risk was assessed using standardized incidence ratios (SIR) of observed (O) and expected (E) cancers. 95% confidence intervals (CI) were calculated assuming a Poisson distribution. Results where the CI = 1 were excluded. **Results:** 498 patients (O/E = 1.4) developed a secondary solid tumor after CLL with a mean age at diagnosis of 48.8 and 59.9 years for CLL and a second tumor, respectively. Higher than expected risk was seen in lip (O/E = 7.5), non-epithelial skin (O/E = 5.4), salivary (O/E = 4.8), mesothelioma (O/E = 4.4), melanoma (O/E = 3.1), lung (O/E = 2.4), and kidney (O/E = 1.7) cancers. Uterine cancer had a lower risk (O/E = 0.4). Stratifying the cohort by gender and race found that lip cancer in whites (O/E = 7.6) and men (O/E = 7.3), descending colon cancer (O/E = 13.3) in blacks and ureter cancer (O/E = 19.8) in women posed the highest risks. Lung cancer was the most prevalent among all groups. Secondary tumor risk was elevated in the < 1, 1-5, 5-10, and 10-15 years after diagnosis with CLL (O/E = 2.3, 1.4, 1.5, and 1.4, respectively). The cancers with the highest SIR in each period were thyroid (< 1 year, O/E = 9.2), lung (1-5 years, O/E = 3.1), nose/ear (5-10 years, O/E = 11.8), and lip (10-15 years, O/E = 15.6). In 4459 patients > 55 (O/E = 1.1), Kaposi sarcoma (O/E = 4.9), non-epithelial skin (O/E = 3.6), salivary (O/E = 2.8), melanoma (O/E = 2.1), nose/ear (O/E = 2.0), lip (O/E = 1.7), soft tissue (O/E = 1.6), lung (O/E = 1.4), kidney (O/E = 1.3), and colon cancers (O/E = 1.2) were significant. **Conclusions:** Patients < 55 have a unique tumor profile and greater risk of secondary solid tumors compared to patients > 55. This risk differs on the basis of gender, race, and survival time. Further research may help influence screening guidelines.

10084 Poster Session (Board #73), Sat, 1:15 PM-4:45 PM

Immediate-term chemotherapy-related cognitive impairment (CRCI) following administration of intravenous (IV) chemotherapy. *First Author: Omar Farooq Khan, Department of Oncology, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada*

Background: The acute impact of chemotherapy on cognition is unknown. This study utilized performance on the psychomotor vigilance task (PVT) and trail-making test B (TMT) to assess CRCI immediately following chemotherapy administration. **Methods:** Patients aged 18-80 years receiving first-line IV chemotherapy for any stage of breast or colorectal cancer were eligible. Patients with brain metastases, neurologic disorders or allergic reactions to chemotherapy were excluded. Patient symptoms, peripheral neuropathy and Stanford Sleepiness Scale were assessed. A five-minute PVT and TMT were completed on a tablet computer pre-chemotherapy and immediately post-chemotherapy. Paired Wilcoxon Rank Sum tests were used to assess change in median PVT reaction time, TMT completion time, TMT errors and PVT lapses. A priori, an increase in median PVT reaction times by over 20 ms (approximating reaction time changes with blood alcohol concentrations of 0.04 to 0.05 g%) was considered a clinically relevant change. **Results:** 144 patients (74 breast, 70 colorectal, median age 55.5 years) were tested. Post-chemotherapy, median PVT reaction time slowed by an average of 12.4 ms ($p = 0.01$). Post-chemotherapy median PVT times slowed by over 20 ms in 59 patients (40.9%). TMT completion post-chemotherapy was faster by an average of 6.1 seconds ($p < 0.001$). No differences were seen in TMT errors ($p = 0.417$) or PVT lapses ($p = 0.845$). Change in median PVT reaction time was not associated with age, gender, number of prior chemotherapy cycles, peripheral neuropathy grade, self-reported symptoms (anxiety, fatigue or depression). Change in median PVT reaction time was also not significantly associated with use of any specific chemotherapeutic drug or class, including paclitaxel (which includes ethanol as an excipient). **Conclusions:** Median PVT reaction time was significantly slower immediately after chemotherapy compared to a pre-chemotherapy baseline, and impairment correlating to effects of alcohol was seen in 41% of patients. This effect appears independent of age, self-reported symptoms or prior chemotherapy cycles. Further studies assessing functional impact of immediate-term CRCI are warranted.

10085 Poster Session (Board #74), Sat, 1:15 PM-4:45 PM

Effect of prophylactic fentanyl buccal tablet (FBT) on exertional dyspnea in patients with cancer: A pilot double-blind, placebo-controlled, randomized trial. *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Exertional dyspnea is one of the most common, debilitating and difficult-to-treat symptoms in cancer patients. Few clinical trials have been conducted. We tested the hypothesis that FBT, a rapid onset opioid, given prophylactically prior to exertion can improve exertional dyspnea. **Methods:** In this double-blind parallel (1:1) RCT, we asked cancer patients who were opioid-tolerant and had exertional dyspnea to complete a 6 minute walk test (6MWT) at baseline, and then randomly assigned them to either FBT proportional to 20-50% of daily dose or placebo 30 minutes before a second 6MWT. The primary outcome was a validated 11-point dyspnea NRS assessing dyspnea "now" (where 0 = none and 10 = worst possible) every minute during each 6MWT. Secondary outcomes included walk distance, vital signs and neurocognitive testing, adverse effects, and global impression. Ten evaluable patients in the FBT provided 80% power to detect an effect size as small as 1.0 using a two-sided paired t-test with a significance level of 5% to compare the change of dyspnea between the first and second walk tests. We compared the outcomes between the first and second 6MWTs using paired t-test. **Results:** Among 22 patients enrolled, 20 (91%) completed the study (9 FBT, 11 placebo). FBT was associated with a significant within-arm reduction in dyspnea NRS between 0 and 6 minutes (mean change -2.4, 95% confidence interval [CI] -3.5, -1.3) and respiratory rate (mean change -2.6, 95% CI -4.7, -0.4). Placebo was also associated with a non-statistically significant decrease in dyspnea (mean change -1.1). Between arm comparison of dyspnea scores in the second 6MWT favored FBT, albeit not statistically significant (estimate -0.25, P = 0.068). Global impression revealed more patients in the FBT group than placebo group reporting their dyspnea was at least "somewhat better" in the second 6MWT (4/9 vs. 0/11, P = 0.03). The other secondary outcomes did not differ significantly between arms. **Conclusions:** These data support our hypothesis that proportionally dosed FBT was associated with improvement in exertional dyspnea, and highlights the need for larger confirmatory trials. Clinical trial information: NCT01856114.

10086 Poster Session (Board #75), Sat, 1:15 PM-4:45 PM

Chemotherapy-induced neutropenia risk models to guide the use of myeloid stimulating factors in intermediate risk chemotherapy: A cost and practicality analysis. *First Author: Chetan Jeurkar, Drexel University College of Medicine, Philadelphia, PA*

Background: The National Comprehensive Cancer Network (NCCN) and the American Society of Clinical Oncology (ASCO) have published guidelines for use of prophylactic colony stimulating factors (CSF) for patients at risk for chemotherapy induced neutropenia (CIN). Both recommend CSF if the chemotherapy regimen has a >20% febrile neutropenia (FN) risk. If the regimen is of intermediate CIN risk, the guidelines are less definitive. In this study, we looked at lung cancer patients receiving intermediate CIN risk chemotherapy and applied two risk models developed by Hosmer et al and Bozcuk et al to see if they have adjunct value to the NCCN and ASCO guidelines to more accurately predict CIN. **Methods:** This was a retrospective study of 43 patients with a diagnosis of lung cancer who were treated with chemotherapy at Drexel University from 2005-2016. Risk models developed by Hosmer et al and Bozcuk et al along with the NCCN and ASCO guidelines were applied to the cohort of patients. **Results:** The Hosmer calculator recommended giving CSF to 26 patients, the Bozuk calculator for 22 patients, the NCCN guidelines for 25 patients and the ASCO guidelines for 38 patients. Sensitivities, specificities, and pricing information for one course of filgrastim are listed for each risk model in the Table. **Conclusions:** In lung cancer patients receiving intermediate CIN risk chemotherapy, the Hosmer calculator had the best combination of sensitivity, specificity, and ease of use. The Bozcuk calculator, while accurate, was more difficult to use. The NCCN guidelines missed more patients with severe CIN while the ASCO guidelines gave CSF to the greatest number of patients. The cost for using CSF would have been highest using the ASCO guidelines. Therefore, we recommend the Hosmer calculator for lung cancer patients receiving intermediate risk CIN chemotherapy as it lends to accurate but judicious use of CSF.

Risk model	Severe CIN sensitivity	Severe CIN patients not recommended CSF	FN sensitivity	Specificity	Pricing for one course of filgrastim ($)
Hosmer	89	1	100	44	94,705.00
Bozcuk	78	2	75	56	80,135.00
NCCN	67	3	50	45	91,062.50
ASCO	97	1	100	14	138,415.00

10087 Poster Session (Board #76), Sat, 1:15 PM-4:45 PM

Impact of skeletal muscle index (SMI) loss during palliative systemic treatment (Tx) on time to progression and overall survival (OS) in metastatic colorectal cancer (mCRC) patients. *First Author: Sophie Kurk, UMC Utrecht, Utrecht, Netherlands*

Background: Evidence for a strong link between skeletal muscle depletion and poor outcomes in mCRC is growing. However, the impact of SMI changes over time on progression and OS during palliative systemic Tx is not known. The CAIRO3 study *(Simkens et al. Lancet 2015)* randomized 556 mCRC patients after 6 cycles capecitabine+oxaliplatin+bevacizumab (CAPOX-B) to maintenance CAP-B Tx (Main) vs. observation (Obs). Upon 1st disease progression (PD1), CAPOX-B or other treatment was reintroduced until 2nddisease progression (PD2). This is the first analysis using scan data of multiple time-points to investigate SMI changes during palliative systemic treatment Tx and its association with survival. **Methods:** 1227 CT-scans of a random selection of 416 CAIRO3 patients (mean age 64±9 years, Main n = 206; Obs n = 210) were analyzed for SMI (skeletal muscle area at the L3 level in cm^2/m^2). Using mixed model analysis, SMI changes were analyzed for two intervals; interval 1: from randomization to PD1, and interval 2: from PD1 to PD2. Three Cox regression models were used to study the association between SMI loss and time to PD2 and death for interval 1, and time to death for interval 2. Main and Obs groups were combined in the analyses since the p-value for interaction was not significant. Hazard ratios (HR) were reported per 2 units change in SMI. **Results:** Median times from randomization to PD1, PD2 and death were 7.7, 13.5 and 24 months resp. During interval 1 (less intensive or no Tx) patients gained SMI on average (1.2 units; *95%CI 0.6-1.8*), but 23% of patients still lost SMI. SMI loss was associated with shorter time to PD2 (HR 0.88; 0.81-0.98, *p*= .01), but not with shorter OS (HR 0.94; *0.86-1.02*, *p*= .17). During interval 2 (more intensive Tx) average SMI loss was -2.2 units (*1.5-2.8)* and 63% of patients lost SMI. SMI loss was associated with shorter OS (HR 0.73; *0.62-0.*86, *p*< .00). **Conclusions:** Loss of SMI was related to shorter time to progression during first line less intensive main Tx or obs and shorter overall survival during more intensive reinduction Tx. This large longitudinal study suggests that SMI preservation may be a therapeutic goal. Clinical trial information: NCT00442637.

10088 Poster Session (Board #77), Sat, 1:15 PM-4:45 PM

Scalp Cooling Alopecia Prevention trial (SCALP) for patients with early stage breast cancer. *First Author: Julie R. Nangia, Baylor College of Medicine, Houston, TX*

Background: Adjuvant chemotherapy decreases the risk of recurrence. However, it has distressing side effects, including alopecia. There are no randomized trials assessing modern scalp cooling to prevent alopecia, and success rates in non-randomized trials have varied. **Methods:** We conducted a multi-center randomized trial to evaluate the safety and efficacy of the Orbis Paxman Hair Loss Prevention System (OPHLPS) in reducing chemotherapy-induced alopecia. Women with stage I-II breast cancer planned to receive anthracycline- or taxane- based chemotherapy for at least four cycles were eligible and randomized in a 2:1 ratio to scalp-cooling or control. Scalp-cooling was done with the OPHLPS 30 minutes prior to, during and 90 minutes after each chemotherapy. The primary efficacy endpoints were hair preservation and device safety. We planned to enroll 235 subjects to provide 85% power to detect a 20% difference in hair preservation. Secondary endpoints included wig/scarf use and quality of life assessed by the EORTC QLQ-30, HADS and BIS. Subjects will be followed for 5 years for recurrence, overall survival, and site of recurrence. One interim analysis was planned to allow the study to stop early for efficacy after 142 subjects were enrolled and evaluable for the primary endpoint. To maintain the overall type 1 error rate, an O'Brien-Fleming spending function was used (interim boundary p = 0.0061). **Results:** This is the first randomized trial with modern scalp cooling in the world. For the interim analysis, 142 subjects were evaluable. Among them, 48 (50.5%) out of 95 in the cooling group and 0 (0%) out of 47 in the control group had hair preservation. The one-tailed p-value from the Fisher's exact test is < 0.0001, which crosses the superiority boundary (p = 0.0061). Thus on 9/26/2016 the DSMB stopped the study early. The interim analysis was presented at SABCS 2016. There are 195 subjects enrolled on this clinical trial, and the final subject will be evaluable for the primary outcome February 2017. The final analysis will be presented. **Conclusions:** Our trial showed that scalp cooling using OPHLPS is highly effective in hair retention. Paxman Coolers has applied for FDA clearance for the OPHLPS based on the results of the interim analysis. Clinical trial information: NCT01986140.

10089 **Poster Session (Board #78), Sat, 1:15 PM-4:45 PM**

Factors influencing the analgesic response over time of the oxycodone-naloxone association in painful cancer patients: GREAT study. *First Author: Oscar Corli, IRCCS - Mario Negri Institute for Pharmacological Research, Milan, Italy*

Background: The prolonged use of opioids is usually associated with the appearance of adverse events as drowsiness, constipation, nausea/vomiting, and dizziness. Some effects are self-limiting over time for the onset of tolerance while others, as constipation, persist. Clinical studies demonstrated that the association oxycodone-naloxone (OXN), reduced the constipation in the presence of unchanged analgesic efficacy. Though, the variability of the analgesic response to OXN is not explained yet. The aim of this study was to evaluate the association between the clinical and genetics factors and analgesics response at OXN. **Methods:** In this study the cancer patients with moderate to severe pain received OXN and followed for 28 days. At each visit pain intensity modifications of therapy and adverse drug reactions (ADRs) were recorded. The primary efficacy endpoint was the proportion of responders, defined as patients with a decrease of the average pain intensity from baseline to last visit ≥30% and a final average pain score≤4, measured on 0-10 numerical rating scale. Genetic tests to identify SNPs related to opioid response were performed in each patient. **Results:** 14 centers participated in the study and recruited 206 patients. Among 176 patients analyzed for a primary endpoint the mean age was 68 (SD 10); 56% were male. Average and worst pain intensity decreased from baseline to last visit from 6.2 to 2.9 and from 8.3 to 4.6 respectively. 81% of patients were responders. Digestive system tumors (p = 0.05), concomitant thyroid endocrinopathy (p = 0.023), psychological irritability (p = 0.0029) and breakthrough pain at baseline were found to decrease the risk of positive response. None of the investigated polymorphisms influenced the analgesic response. Moderate to severe intensity ADRs were mainly constipation (26%), drowsiness (19%) and dry mouth (12%). **Conclusions:** In patients with moderate to severe cancer pain, OXN showed a strong analgesic effect (about 50% pain reduction). In comparison with other studies the induced constipation appears substantially lower. Some clinical factors influence the analgesic response while none genetic polymorphisms modulate the response. Clinical trial information: NCT02293785.

10090 **Poster Session (Board #79), Sat, 1:15 PM-4:45 PM**

Phase III study of NEPA, a fixed combination of netupitant and palonosetron, versus an aprepitant regimen for prevention of chemotherapy-induced nausea and vomiting (CINV). *First Author: Li Zhang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Co-administration of multiple antiemetics that inhibit several molecular pathways involved in emesis is required to optimize CINV control in patients receiving highly emetogenic chemotherapy (HEC). NEPA, a novel fixed combination of a highly selective NK_1 receptor antagonist (RA), netupitant (300 mg), and palonosetron (PALO 0.50 mg), a pharmacologically distinct 5-HT_3RA, has shown superior CINV prevention compared to PALO in cisplatin and AC-based settings. This study is the first head-to-head comparison of NEPA versus an aprepitant (APR)/granisetron (GRAN) regimen, with the primary objective being to demonstrate non-inferiority in preventing CINV. **Methods:** This randomized, double-blind, parallel group Phase III study conducted in an Asian population was designed to compare efficacy and safety of a single oral dose of NEPA with a 3-day oral APR/GRAN regimen in chemotherapy-naïve patients receiving cisplatin-based HEC. All patients also received oral dexamethasone (DEX) on days 1-4. The primary efficacy endpoint was complete response (CR: no emesis, no rescue medication) during the overall (0-120 h) phase. Non-inferiority was defined as a lower 95% CI greater than the non-inferiority margin set at -10%. Secondary efficacy endpoints included no emesis and no significant nausea (NSN: < 25mm on 100mm VAS). **Results:** Treatment groups were comparable for the 828 patients analyzed: predominantly male (71%); mean age 54.5 years; ECOG 0-1 (98%); lung cancer (58%). NEPA demonstrated non-inferiority to APR/GRAN for overall CR; no emesis and NSN rates favored NEPA. Most frequent study drug-related adverse events (AEs) for NEPA included constipation (8.0%) and hiccups (2.7%). The type/incidence/severity of AEs were similar for NEPA and APR/GRAN. **Conclusions:** In this first study comparing NK1RA regimens and 4 days of DEX, NEPA administered only on day 1 was non-inferior to a 3-day oral APR/GRAN regimen in preventing CINV associated with HEC.

Overall (0-120 h) % Patients	NEPA (N = 412)	APR/GRAN (N = 416)	Risk Difference % (95% CI)
CR	73.8	72.4	1.5 (-4.5, 7.5)
No Emesis	75.0	74.0	1.1 (-4.8, 6.9)
NSN	75.7	70.4	5.4 (-0.6, 11.4)

10091 **Poster Session (Board #80), Sat, 1:15 PM-4:45 PM**

Comprehensive study of risk factors for chemotherapy-induced nausea and vomiting in cancer patients receiving cisplatin-based chemotherapy: A TRIPLE pharmacogenomics study. *First Author: Hideaki Ayuhara, Tokyo Medical University Hospital, Tokyo, Japan*

Background: Chemotherapy-induced nausea and vomiting (CINV) is one of the most unpleasant adverse effects of chemotherapy. Resistance to prophylactic antiemetic treatment is problematic, with 30%–50% of patients experiencing unsatisfactory control. Younger age and female sex are well-known risk factors for CINV. Genetic polymorphisms are suggested to influence antiemetic treatment response. **Methods:** This study included a subset of patients previously enrolled in a randomised controlled trial. This study aimed to evaluate the role of pharmacogenomic polymorphisms relevant to antiemetic response in patients with cancer receiving cisplatin-based chemotherapy. The study's efficacy endpoint was the proportion of patients with complete response (CR). The study endpoint was evaluated separately in the acute ($CR_{0\text{-}24}$) and delayed ($CR_{24\text{-}120}$) phases. Thirteen polymorphisms were genotyped, and the association of these genotypes with the efficacy of prophylactic antiemetics was then investigated. Confounding variables for CR were identified using stepwise multivariate logistic regression analysis. Age and sex were included as independent variables by the forced-entry method, and the stepwise method was used to select the pharmacogenomic factors for inclusion as independent variables. **Results:** In this genetic polymorphism association study, 156 patients with solid cancer were evaluated. Multivariate logistic regression analysis revealed that *ERCC1* 8092AA (odd ratio [OR]: 11.251; 95% confidence interval [CI]: 1.741–72.712, P = 0.011) and female sex (OR = 3.630; 95% CI = 1.138–11.578, P = 0.029) were significant predictors of $CR_{0\text{-}24}$. No significant association of $CR_{24\text{-}120}$ with pharmacogenomic polymorphisms was found via multivariate logistic regression analysis. **Conclusions:** *ERCC1* polymorphism might be influenced the extent of CINV control in patients receiving cisplatin-based chemotherapy. Clinical trial information: 000009335.

10092 **Poster Session (Board #81), Sat, 1:15 PM-4:45 PM**

Morphological correlates of oxaliplatin induced peripheral neuropathy assessed by magnetic resonance neurography. *First Author: Leonidas Apostolidis, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany*

Background: Oxaliplatin induced peripheral neuropathy (OXA-PNP) is a frequent side effect of oxaliplatin containing chemotherapy protocols. It is commonly assessed clinically via physical examination and patient reported symptoms. Research has been impeded by the lack of objective tests to quantify OXA-PNP. Neurophysiological examination is time-consuming and can only cover a selected part of the examined nerve. The aim of this study was to investigate *in-vivo* morphological correlates of OXA-PNP by magnetic resonance neurography (MRN). **Methods:** 20 patients with mild to moderate OXA-PNP and 20 matched controls were prospectively enrolled. All patients underwent a detailed neurophysiology examination prior to neuroimaging. A standardized MRN imaging protocol at 3.0 Tesla with large-coverage included the lumbosacral plexus, as well as both sciatic nerves and their branches using T2-weighted fat-saturated sequences at high resolution. Qualitative evaluation of sciatic, tibial, and peroneal nerves were performed by two readers regarding the presence, degree, and distribution of nerve lesions. Quantitative assessment included volumetry of the dorsal root ganglia (DRG) and sciatic nerve normalized T2 (nT2) signal and caliber. **Results:** Significant DRG hypertrophy in OXA-PNP patients ($207.3 \pm 47.7 mm^3$ vs. $153.0 \pm 47.1 mm^3$ in controls, p = 0.001) was found as morphological correlate of the sensory neuronopathy. Peripheral nerves only exhibited slight morphological alterations qualitatively. Quantitatively, sciatic nerve caliber was unchanged ($26.0 \pm 5.1 mm^2$ vs. $27.4 \pm 7.4 mm^2$, p = 0.19) while sciatic nerve nT2 signal was slightly and non-significantly elevated in patients (1.32 ± 0.22 vs. 1.22 ± 0.26, p = 0.19). **Conclusions:** OXA-PNP leads to morphological correlates that can be detected *in-vivo* by MRN. Significant hypertrophy of the DRG was observed, a phenomenon which has not been described in OXA-PNP previously. DRG volume should be investigated as a biomarker in other sensory peripheral neuropathies and ganglionopathies as well as in studies evaluating neuroprotective strategies for OXA-PNP.

10093 Poster Session (Board #82), Sat, 1:15 PM-4:45 PM

Two-year trends of taxane-induced neuropathy in women enrolled in a randomized trial of acetyl-l-carnitine (SWOG S0715). *First Author: Dawn L. Hershman, Columbia University Medical Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and disabling side effect of taxanes that leads to suboptimal treatment and adversely affects quality of life. Acetyl-L-Carnitine (ALC) was unexpectedly found to increase CIPN in a randomized trial. We investigated the long-term patterns of CIPN among patients enrolled in this trial. **Methods:** S0715 was a randomized, double-blind, multi-center trial comparing ALC (1000 mg TID) versus placebo for 24 weeks in women with stage I-III breast cancer undergoing taxane-based chemotherapy. The primary objective was to determine if ALC prevents CIPN as measured by the 11-item neurotoxicity (NTX) component of the FACT-Taxane scale at 12 weeks. Additional assessments were conducted at weeks 24, 36, 52 and 104. We examined the reduction of NTX score over 2 years using linear mixed models for longitudinal data, adjusting for stratification factors and the baseline NTX score. Individual assessment time-points were examined using linear regression. **Results:** SWOG S0715 registered 437 patients, of whom 409 were eligible and evaluable, including 208 assigned to receive ALC and 201 to placebo. Patterns of evaluability were similar over time by arm. The results for the primary outcome of interest, NTX, show a statistically significant ($p = 0.01$) average difference of -1.39 (95% CI: -2.47 to -0.31) between treatment groups, with the ALC group having lower scores (worse CIPN) on average than the placebo group. These differences were particularly evident at Weeks 24 ($p = 0.02$), 36 ($p = 0.04$), and 52 ($p = 0.02$). A clinically meaningful ($\geq$5 points) reduction in NTX score over baseline was observed more frequently for the ALC vs. control arm (week 24, 41% vs. 34%; week 36, 41% vs. 28%; 1 year, 41% vs. 32%; 2 years, 40% vs. 34%). For both treatment groups 2 year NTX scores were significantly different compared to baseline ($p < 0.001$). **Conclusions:** For both groups NTX scores were reduced with taxane-therapy and remained persistently low 2-years following treatment. Twenty-four weeks of ALC therapy resulted in significantly worse CIPN at weeks 24 36 and 52. Understanding the mechanism of this persistent effect may inform prevention and treatment strategies. Clinical trial information: NCT00775645.

10094 Poster Session (Board #83), Sat, 1:15 PM-4:45 PM

RCT of brief behavioral therapy (BBT-CI) for cancer-related insomnia and circadian rhythm during chemotherapy in a community oncology setting (NCORP). *First Author: Oxana Palesh, Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background: Insomnia is experienced by up to 80% of cancer patients, and it frequently co-occurs with circadian rhythm disruption. The relationship is reciprocal in that disruption in circadian rhythm can cause or result from insomnia and vice versa. There are no effective brief behavioral interventions that can be delivered directly in infusion centers. We aimed to evaluate the efficacy of a novel intervention, BBT-CI, for improving sleep and circadian rhythm disruption in BC patients undergoing chemotherapy. **Methods:** In our phase II, two-arm, randomized clinical trial, 71 BC patients (mean age = 52.5) who reported moderate insomnia were randomized to: 1) BBT-CI or 2) a healthy eating behavioral control (HEAL). BBT-CI and HEAL were delivered over 6 weeks (2 face-to-face sessions + 4 phone calls) at 5 NCI-funded NCORP clinics by trained assistants. Sleep disruption was measured with the Insomnia Severity Index (ISI) and circadian rhythm with the Actiwatch-64 (Mesor, Amplitude, and Acrophase for 12- and 24-hour cycles). Participants completed the ISI at baseline and post-intervention and wore the Actiwatch for 7 days prior to each visit. **Results:** The study showed excellent feasibility and acceptability of BBT-CI as reflected by a recruitment rate of over 75% and an intervention adherence of 74%, with 75% of intervention components successfully delivered by trained community staff. ANCOVA results indicate that patients who received BBT-CI exhibited improvements in insomnia compared to HEAL at post-intervention ($p = .049$) and at 1-month follow-up ($p = .002$). Furthermore, results reveal a significant treatment effect in circadian rhythm at post-intervention for 24-hour amplitude ($p = .009$) and 12-hour Acrophase ($p = .012$) as well as a trend for Mesor in favor of BBT-CI ($p = .10$). **Conclusions:** BBT-CI demonstrated greater improvements in insomnia and circadian rhythm than HEAL. In addition, this novel intervention has shown efficacy in community oncology clinics. BBT-CI has the potential of changing clinical practice as it reduces patients' psychophysiological symptoms and burden due to its behavioral design and capacity to be delivered directly in infusion centers. Clinical trial information: NCT02002533.

10095 Poster Session (Board #84), Sat, 1:15 PM-4:45 PM

A longitudinal brain fMRI study of chemotherapy-induced peripheral neuropathy in 50 breast cancer patients. *First Author: Ian Kleckner, University of Rochester Medical Center, Rochester, NY*

Background: Over half of patients receiving taxane, platinum, and vinca alkaloid chemotherapy experience chemotherapy-induced peripheral neuropathy (CIPN), which involves numbness and neuropathic pain in the hands and feet. CIPN has no effective treatments partly because its etiology is poorly understood. We theorize that CIPN symptoms are partly caused by impairment of interoceptive brain circuitry, which processes bodily sensations via the posterior insula and anterior cingulate cortex (ACC). We investigated whether CIPN is associated with altered connectivity in interoceptive brain circuitry. **Methods:** Fifty women with breast cancer (50$\pm$9 years) reported CIPN symptoms (CIPN-20) and underwent resting fMRI one or more times: before surgery, one month after completion of chemotherapy, and one year after chemotherapy. We used an a priori seed-based investigation of connectivity between the posterior insula and ACC. We compared connectivity between 31 patients without CIPN symptoms ($\leq$10 CIPN-20-Sensory), 19 patients with CIPN symptoms ($>$ 10 CIPN-20-Sensory), and 280 healthy adults (174 women, 19.3 years) from another study. **Results:** Patients with CIPN symptoms had significantly reduced connectivity between the posterior insula and the ACC compared to patients without CIPN symptoms ($p = 0.01$, $d = 0.73$). Connectivity between the posterior insula and the ACC was negative in patients with CIPN symptoms but positive in both healthy adults and patients without CIPN symptoms. **Conclusions:** CIPN is characterized by reduced connectivity in interoceptive brain circuitry. Interoceptive networks may be a target for the development of therapies directed to prevent or treat CIPN. Future work will assess causal relationships between CIPN symptoms and reduced connectivity.

10096 Poster Session (Board #85), Sat, 1:15 PM-4:45 PM

A genome-wide association study (GWAS) meta-analysis of chemotherapy-associated cognitive impairment (CACI) in Asian early-stage breast cancer patients (ESBC). *First Author: Terence NG, Department of Pharmacy, National University of Singapore, Singapore, Singapore*

Background: Genetic variations among genes regulating neuronal function, neurotransmission and plasticity may contribute to varying risk of CACI. In order to fully elucidate the complex genetic structure underlying CACI, a GWAS meta-analysis was performed to identify genetic variants associated with CACI among ESBC patients. **Methods:** A GWAS meta-analysis of two independent cohorts totaling 266 chemotherapy-receiving ESBC patients (mean age: 51.0 $\pm$ 9.2 years; 80.8% Chinese) was performed. Patients' self-perceived cognitive function was assessed using the validated FACT-Cog (v.3). Genome-wide genotyping was performed using the Illumina HumanOmniExpress-24 version 1.1 BeadChips kits. Each beadchip contains over 700,000 genetic markers. Covariates included in the meta-analysis were the first two dimensions of the multi-dimensional scaling. **Results:** After applying stringent quality control measures and removing four population outliers, data from 546,399 SNPs were available for 84 cases and 170 controls. In the meta-analysis, two SNPs (rs6443264 and rs4686371) exceeded the suggestive threshold of $P < 1\times10^{-5}$ (Table). Following adjustment for the first two MDS dimensions in the meta-analysis, both SNPs remained as top two SNPs with $P < 1\times10^{-4}$. Both rs6443264 and rs4686371 are located in chromosome 3p25 and lie in the intronic regions encoding *OGG1* and *ARPC4* genes, respectively. Alteration of the *OGG1* gene could compromise the functions of downstream neuronal genes, and modification of the *ARPC4* gene could affect the formation of the actin-related protein 2/3 complex and impair memory formation. **Conclusions:** To the best of our knowledge, this is the first GWAS meta-analysis to identify two loci, namely rs6443264 and rs4686371 that are suggestive of genome-wide association with CACI among Asian ESBC patients.

SNP	Cohort	MAF cases	MAF controls	P	Per allele OR	95% CI
rs6443264	A	0.57	0.29	1.70×10^{-5}	3.26	1.89 to 5.64
	B	0.51	0.37	3.19×10^{-2}	1.79	1.05 to 3.08
	Meta-analysis			7.21×10^{-6}	2.41	1.64 to 3.53
rs4686371	A	0.59	0.31	1.18×10^{-5}	3.32	1.93 to 5.74
	B	0.53	0.39	4.18×10^{-2}	1.74	1.02 to 2.98
	Meta-analysis			7.99×10^{-6}	2.39	1.63 to 3.50

10097 **Poster Session (Board #86), Sat, 1:15 PM-4:45 PM**

Body weight response with anamorelin in advanced non-small cell lung cancer (NSCLC) patients with anorexia/cachexia: Pooled analysis of two phase III trials. *First Author: David Christopher Currow, IMPACT, Faculty of Health, University of Technology, Sydney, Australia*

Background: Anorexia/cachexia commonly occurs in patients with advanced NSCLC and is associated with increased morbidity and mortality. In two randomized, double-blind, placebo-controlled phase 3 trials in NSCLC patients with cachexia, the ghrelin receptor agonist anamorelin was well tolerated and significantly increased body weight, lean and fat mass, and anorexia/cachexia symptom burden over 12 weeks compared to placebo (Temel J. *Lancet Oncol*. 2016). Since an involuntary weight loss of $\geq$ 5% is an established diagnostic criterion for cancer anorexia/cachexia, an analysis was conducted to assess the proportion of patients with $\geq$ 5% increase in body weight. **Methods:** NSCLC patients [ROMANA 1 (NCT01387269; N = 484) and ROMANA 2 (NCT01387282; N = 495)] with stage III/IV disease and cachexia (BMI $<$ 20 kg/m^2 or $\geq$ 5% weight loss during prior 6 months) were randomized 2:1 to receive 100 mg once daily oral anamorelin or placebo up to 12 weeks. A pooled analysis was conducted post-hoc in the modified intent-to-treat population (N = 829) to measure the proportion of patients with $\geq$ 5% increase in body weight at the end of study (or last observation carried forward since week 6 or 9). **Results:** The percentage of patients with $\geq$ 5% increase in body weight at the end of study was significantly higher in the anamorelin arm (N = 188/552, 34.1%) compared to placebo (N = 37/277; 13.4%). Among patients with BMI $<$ 20kg/m^2 at baseline (N = 182), 47.3% (N = 53/112) of anamorelin patients had a weight increase of $\geq$ 5% compared to 17.4% (N = 12/69) in the placebo arm. In both cases the nominal p-value was lower than 0.0001. **Conclusions:** Data from two published large pivotal studies in advanced NSCLC patients with anorexia/cachexia suggest that anamorelin treatment effect size on body weight is clinically relevant, as shown by the higher response rate achieved when the stringent cut-off of $\geq$ 5% weight gain was applied. The proportion of patients with BMI $<$ 20kg/m^2 that benefited from anamorelin treatment was greater than the proportion of patients who benefited in the entire study sample, suggesting that patients with more advanced cachexia may still benefit from anamorelin treatment. Clinical trial information: ROMANA 1: NCT01387269; ROMANA 2: NCT01387282.

10098 **Poster Session (Board #87), Sat, 1:15 PM-4:45 PM**

Nutritional counseling with or without systematic use of oral nutritional supplements in head and neck cancer patients undergoing radiotherapy. *First Author: Paolo Pedrazzoli, Medical Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy*

Background: The benefit of systematic use of oral nutritional supplements (ONS) in addition to nutritional counseling in head and neck cancer (HNC) patients undergoing radiotherapy (RT) has not still been properly assessed. **Methods:** In a single-center, randomized, pragmatic, parallel-group controlled trial (ClinicalTrials.gov: NCT02055833; February 2014 - August 2016), 159 newly diagnosed HNC patients suitable for to RT regardless of previous surgery and induction chemotherapy were randomly assigned to nutritional counseling in combination with omega-3 enriched ONS (N = 78) or without ONS (N = 81) from the start of RT and continuing for up to 3 months after its end. The primary endpoint was the change in body weight at the end of RT. Secondary endpoints included changes in protein-calorie intake, muscle strength, body composition and quality of life (EORTC-QLQ-C30) over the study time points and anti-cancer treatment tolerance. **Results:** In patients in whom all the variables could be assessed, counseling plus ONS (N = 67) resulted in smaller loss of body weight than nutritional counseling alone (N = 69; mean difference, 1.6 kg [95%CI, 0.5 to 2.7]; P = 0.006). Imputation of missing outcomes provided consistent findings. In the ONS-supplemented group, higher protein-calorie intake and improvement in quality of life over time were also observed (P $<$ 0.001 for all). The use of ONS reduced the need for changes in scheduled anti-cancer treatments (i.e. for RT and/or systemic treatment dose reduction or complete suspension, HR = 0.40 [95%CI, 0.18 to 0.91], P = 0.029). Nine patients reported gastrointestinal intolerance to ONS. **Conclusions:** In HNC patients undergoing RT or RT plus systemic treatment, and receiving nutritional counseling, weight loss could not be completely prevented, but the use of ONS resulted in better weight maintenance, increased protein-calorie intake, improved quality of life and better anti-cancer treatment tolerance. Clinical trial information: NCT02055833.

10099 **Poster Session (Board #88), Sat, 1:15 PM-4:45 PM**

Use of heart rate variability (HRV) biofeedback for symptom management among cancer survivors. *First Author: Mark Allen O'Rourke, Center for Integrative Oncology and Survivorship, Greenville, SC*

Background: Late effects of cancer and its treatment include pain, fatigue, stress, and depression all mediated by autonomic dysfunction. Heart Rate Variability (HRV) coherence is an established measure of autonomic dysfunction. Cancer survivors have lower HRV coherence than normal controls. HRV biofeedback (HRV-B) training improves HRV coherence, restores autonomic health, and reduces the above symptoms. This report describes a feasibility study of HRV-B in symptomatic cancer survivors. **Methods:** In a randomized, waitlist controlled, clinical trial, 179 were screened, 34 enrolled and 31 completed the protocol. Participants in the intervention arm received weekly HRV-B training up to six weeks. Outcome measures assessed at baseline (pre) and after week six (post) included HRV coherence plus Insomnia Symptom Questionnaire (ISQ), Suscro Distress Inventory (SDI), Brief Pain Inventory (BPI), Multi-Dimensional Fatigue Inventory (MFI), Perceived Stress Scale (PSS) and Beck Depression Inventory II (BDI-II). **Results:** See table below. **Conclusions:** Delivering HRV Biofeedback training to cancer survivors is feasible at our Cancer Institute. This pilot study provides preliminary evidence that HRV-B for cancer survivors improves HRV coherence and reduces insomnia, pain, fatigue, depression, and stress. The intervention has great potential and further research is indicated.

Minocycline to reduce cancer pain in patients with multiple myeloma: A phase II randomized trial. *First Author: Xin Shelley Wang, Department of Symptom Research, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with multiple myeloma (MM) experience substantial pain that may be from disease and/or post autologous stem cell transplant condition, and exacerbated by maintenance therapy. Minocycline is a readily available, low-cost antibiotic with anti-inflammatory properties. We conducted a phase II randomized, double-blinded, placebo controlled clinical trial to investigate the effect of minocycline in reducing patient-reported symptoms during maintenance therapy. **Methods:** Adults with MM scheduled for maintenance therapy at a single-institution were consented and randomized to receive either minocycline (100 mg twice daily) or placebo over the first 3 cycles maintenance therapy. Feasibility, toxicity, and patient-reported outcome data were prospectively collected. The MD Anderson Symptom Inventory-MM (0–10 scale) was used to assess pain and other symptoms weekly during 3 months trial. The longitudinal analysis for pain was compared between the minocycline and control groups to examine minocycline's efficacy. **Results:** From April 2013 to Aug 2016, 88 patients were enrolled and 69 (78%) were evaluable: 33 were randomized to minocycline and 36 to placebo. There were no grade 3+ study medication-related adverse events. The worst 5 symptoms on MDASI-core during the trial were fatigue, pain, numbness/tinging, drowsiness, and disturbed sleep, followed by two MM module item bone aches and muscle weakness. Demographic and disease characteristics were not significantly different between groups. Longitudinal modelling of revealed a significant reduction on pain in minocycline group than placebo group (time and treatment group interaction, estimate=-0.068, *P*=.003). The favorite pain reduction in minocycline group vs placebo arm was represented by a moderate effect size (Cohen's *d* =0.48). **Conclusions:** Minocycline during maintenance therapy for MM was feasible, had a low toxicity profile, and yielded a statistically significant positive signal on pain reduction. These preliminary results are encouraging and warrant a Phase III trial to test its efficacy. Clinical trial information: NCT01793051.

10101 **Poster Session (Board #90), Sat, 1:15 PM-4:45 PM**

Elsiglutide in the primary prevention of chemotherapy (CT)-induced diarrhea in patients with colorectal cancer (CRC) receiving 5-fluorouracil (5-FU)-based CT: A multinational, randomized, double-blind, placebo-controlled study. *First Author: Meinolf Karthaus, Hematology and Onkology, Klinikum Neuperlach, Munich, Germany*

Background: Diarrhea is a burdensome toxicity of 5-FU-based regimens and may lead to CT dose intensity reduction. We investigated the efficacy of 3 subcutaneous (s.c.) doses of elsiglutide (a GLP-2 analog) vs. placebo and vs. each other, in the primary prevention of CT induced diarrhea in patients (pts) with CRC receiving FOLFOX or FOLFIRI. **Methods:** Pts were randomized equally to receive placebo or elsiglutide 10, 20, or 40 mg s.c. on days (d)1–4 of the first 2 CT cycles and were followed up in cycle 3 for safety only. Stratification factors were CT regimen and country. Primary endpoint was the proportion of pts with diarrhea of CTC grade ≥2 in cycle 1. Changes in plasma levels of citrulline, a marker of intestinal mass, from baseline to d5 and d14 of each cycle were analyzed. With 480 pts randomized, the study had 85% power to detect a 15% difference vs. placebo for each dose at an alpha level of 0.1, assuming a 20% frequency of diarrhea CTC grade ≥2 in the placebo arm. **Results:** Treatment groups were comparable for the 484 pts (142 receiving FOLFIRI) who were randomized to receive placebo (n = 123), elsiglutide 10 mg (n = 120), 20 mg (n = 121), or 40 mg (n = 120), respectively. The proportion of pts with diarrhea CTC grade ≥2 was higher with placebo (10%) than with elsiglutide 10 mg (3%), 20 mg (5%) and 40 mg (6%); differences were not statistically significant. A similar pattern was observed in cycle 2. Differences in diarrhea frequency between placebo and elsiglutide groups were pronounced in the FOLFIRI subgroup (cycle 1: 18% with placebo, 6% with 10 mg and 20 mg; 3% with 40 mg elsiglutide). Reduction of citrulline levels was smaller with elsiglutide compared with placebo. The safety profile of all elsiglutide doses was acceptable with few related injection site reactions, mostly at the highest dose. **Conclusions:** Although a lower frequency of diarrhea CTC grade ≥2 was observed with elsiglutide, this difference was not statistically significant in pts receiving FOLFOX or FOLFIRI for CRC. Interpretation must consider the unexpectedly low reported frequency of diarrhea of grade ≥2, particularly with FOLFOX regimens. Clinical trial information: 2014-000998-39.

10102 **Poster Session (Board #91), Sat, 1:15 PM-4:45 PM**

Genomic risk prediction of aromatase inhibitor-related arthralgias (AIA) in breast cancer (BC) patients using a novel analytical algorithm (NAA). *First Author: Raquel E. Reinbolt, The Ohio State University Comprehensive Cancer Center, Arthur G. James Cancer Hospital, Columbus, OH*

Background: Many BC patients treated with aromatase inhibitors (AIs) develop AIA; 20% have symptoms severe enough to effect treatment compliance. Results of candidate gene studies to identify AIA risk are limited in scope. In this case-controlled study, we evaluated the potential of a NAA to predict AIA using germline single nucleotide polymorphism (SNP) data obtained prior to treatment initiation. **Methods:** Systematic chart review of 700 AI-treated patients with stage I-III BC between 2003-2012 identified asymptomatic patients (n = 39) and those with clinically significant AIA resulting in AI termination or therapy switch (n = 123). Germline DNA was obtained from peripheral blood cells and SNP genotyping performed using the Affymetrix UK BioBank Axiom Array to yield 695,277 SNPs. The identity of the cluster of SNPs that most closely defined AIA risk was discovered using an NAA that sequentially combined statistical filtering and a machine learning algorithm. NCBI PhenGenI and Ensemble databases were used to define gene attribution of the 200 most discriminating SNPs. Phenotype, pathway, and ontologic analyses assessed functional and mechanistic validity. **Results:** Cases and controls were similar in demographic characteristics. A cluster of 70 SNPs, correlated to 57 genes (accounting for linkage disequilibrium), was identified. This SNP group predicted AIA occurrence with a maximum accuracy of 75.93%. Strong associations with arthralgia, breast cancer, and estrogen phenotypes were seen in 19/57 genes (33%) and were functionally and ontologically consistent. **Conclusions:** Using a NAA, we identified a 70 SNP cluster that predicted AIA risk with fair accuracy. Phenotype, functional, and pathway analysis of attributed genes was consistent with clinical phenotypes. This study is the first to link a specific SNP/gene cluster to AIA risk independent of candidate gene bias. An ongoing prospective companion study will be used to validate and to expand upon results.

10103 **Poster Session (Board #92), Sat, 1:15 PM-4:45 PM**

A double blind, randomised placebo controlled trial evaluating the effect of a pholyphenolic rich plant based nail bed balm on the severity of chemotherapy-induced onycholysis. *First Author: Robert J. Thomas, Addenbrooke's Hospital, Cambridge, United Kingdom*

Background: Nail damage is common amongst patients receiving chemotherapy, especially taxanes, causing pain, distress, disfigurement, infection and restricted daily activities. Cooling the nail beds helps but there has been no published evidence for the effectiveness of nail balms, despite their popular use. We investigated whether a topical nail bed balm containing bioactive polyphenolic rich African salvia officinalis, gaultheria procumbens in a natural base of olea europaea, butyrospermun parkii, cera alba and theobroma cacao protected the nail beds via their reported anti-inflammatory, analgesic, anti-oxidant and anti-microbial properties. **Methods:** 60 patients (23 male, 37 female) were randomized to apply to their nail bed (tds) the natural balm or a petroleum balm suitably scented for a placebo control. Demographics, type and number of chemotherapy cycles did not differ between the two groups, recruited between Sept 2016-Sept 2017. At baseline and at the end of chemotherapy both patients and physicians measured outcomes of nail health. Patients completed a *Dermatology Life Quality* questionnaire and a linear severity scale; physician completed a *Nail Psoriasis Index* (NPSI) and a linear severity scale based on clinical examination and photographs. Differences were analyzed using an unpaired t-test; significance level $\alpha = 0.05$ at 95% confidence intervals (CI); probability (p). **Results:** The mean change in nail health outcomes over the course of chemotherapy were: (see table). **Conclusions:** The polyphenolics rich essential oils and plant-based waxes in this nail bed balm profoundly reduced chemotherapy related nail damage and improved nail related quality of life compared to a plain petroleum based balm. A future evaluation combining nail bed cooling and this natural balm is planned. Clinical trial information: 015-001866-24.

Nail Health Outcome	Natural balm	Placebo	Difference	CI	P value
Dermatology Life Quality (Patient)	-0.034	-6.1	6.062	4.17 - 7.95	P<0.00001
Linear Severity Scale (Patient)	+2.63	-64.1	66.72	52.97 - 80.47	P<0.00001
NSPI (Physician)	0.0	-5.71	5.71	4.29 - 7.12	P<0.00001

Next-generation sequencing ordering trends in the cancer trajectory. *First Author: Joseph Ma, Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA*

Background: Next-generation sequencing (NGS) molecular tumor profiling is increasingly being ordered for advanced cancer patients to evaluate non-traditional therapeutic options. The timing of when NGS is ordered relative to date of diagnosis, palliative care (PC) consultation, and death remains unknown. The primary objective of this study was to examine NGS ordering patterns among cancer patients. **Methods:** This was a single center, retrospective data analysis in cancer patients at our institution between January 2011 and February 2016. Cancer patients ≥16 yrs of age were identified from a tumor registry and matched to an existing NGS tumor profiling database. Additional data were collected from an electronic medical record and compiled into a single database. Differences in the date of when NGS was ordered compared to date of diagnosis, PC consultation, and/or date of death were determined. A Mann-Whitney rank sum test examined differences in patients where NGS was ordered relative to the date of PC consultation. Logistic regression examined variables possibly associated with PC consultation. **Results:** Analysis included 1596 (807 women) cancer patients. Mean±SD age was 55.5±15.2 years, 30.8% (n = 492) of patients had metastatic disease, with breast and lung the most common cancers. The difference between date of cancer diagnosis and date of NGS order was 1053.6±1568.5 days (n = 1546). The difference between date of NGS order and date of death was 221.2.4±186.6 days. Two-hundred and fifty-one patients (15.7%) received a PC consultation, of which 82 patients had a NGS order before the PC consultation and 169 patients had a NGS order after the PC consultation. The mean difference in number of days between a NGS order before versus after a PC consultation was 147.3±216.8 vs. 179.8±169.7 days ($p < 0.005$). Four-hundred and sixty-six (29%) patients have died with 121 receiving a PC consultation. Metastatic disease, but not age and sex, was associated with PC completion (OR 1.7; 95%CI 1.27-2.21). **Conclusions:** NGS was frequently ordered near the time of death. PC consultations were completed in a minority of patients. NGS ordering in advanced cancer patients may serve as a trigger for PC consultation.

10105 Poster Session (Board #94), Sat, 1:15 PM-4:45 PM

Phase II study of the effect of the topical corticosteroid fluocinonide in patients on endocrine therapy for breast cancer or breast cancer prevention with symptoms of vaginal dryness and dyspareunia. *First Author: Evthokia A. Hobbs, Oregon Health & Science University, Portland, OR*

Background: Gynecologic symptoms and sexual dysfunction from endocrine therapy are troublesome side effects for a significant number of patients. This study explored amelioration of vaginal dryness and dyspareunia with fluocinonide cream, a strong topical corticosteroid. **Methods:** A single-arm, open-label phase II trial of topical fluocinonide 0.05% cream to improve vaginal symptoms in women on endocrine therapy in the adjuvant setting for early stage breast cancer was performed. Patients with vaginal symptoms applied topical vaginal fluocinonide 0.05% cream twice a day for two weeks then once daily for two weeks. Patients were assessed for symptoms by weekly completion of the Mayo/North Central Cancer Treatment Group Patient Pretreatment Questionnaire. The primary outcome was a change from baseline in patient-reported effects of vaginal dryness and dyspareunia on a scale from 0 (no symptoms) to 4 (very severe symptoms) from time of enrollment and at 4 weeks. Secondary outcomes were decrease in vaginal itching and total vaginal index score. Comparisons were made with Wilcoxon sign rank test with 2.5% significance level. **Results:** Thirty-four women were accrued. At 4 weeks compared with baseline, vaginal dryness improved from a median score of 2 (moderate symptoms) to 0 (no symptoms) ($P <$ .001) and dyspareunia from 3 (severe symptoms) compared with 1 (mild symptoms) (P = .002). Percentage of patients who had $>$ 2 point improvement in vaginal dryness and dyspareunia was 69.0% and 75% respectively. Secondary analysis showed decrease in vaginal itching score from 1 to 0 (P = .001) and vaginal index score of 6 to 1 (P = .002). Twenty-one patients experienced low-grade toxicities which were mostly limited to skin irritation. **Conclusions:** Fluocinonide 0.05% cream improves vaginal dryness and dyspareunia experienced by women receiving endocrine therapy and has the potential to improve quality of life of cancer survivors and compliance of endocrine therapy. Clinical trial information: NCT00297011.

10106 Poster Session (Board #95), Sat, 1:15 PM-4:45 PM

The impact of caregiver's role preference on decisional conflicts and psychiatric distresses in decision making to help caregiver's disclosure of terminal disease status. *First Author: Shin Hye Yoo, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea*

Background: A decision aid (DA) increases knowledge, decreases decisional conflicts and regrets and improves post-decision satisfaction, emotional distress. However, few DA trials have revealed whether decisional role preferences have an impact on patient-reported outcomes by decision making. The objective of this study was to investigate the impact of caregiver's decisional role preference on decisional conflicts and psychiatric distresses in decision making. **Methods:** 406 of 444 caregivers of terminally ill cancer patients enrolled onto a previous trial determining the efficacy of the decision aid about disclosure of terminal disease status were included in this analysis. The analysis outcomes were change score of decisional conflicts using the Decision Conflict Scale (DCS) and depression and anxiety using the Hospital Anxiety and Depression Scale (HADS) at 1 and 3 months from baseline. Participants were divided into 4 groups: active caregiver who received DA (active-DA), active caregiver in control group (active-control), passive caregiver who received DA (passive-DA), and passive caregiver in control group (passive-control). Linear mixed model was conducted to find out the impact of caregiver's decisional role preference on the DCS and the HADS. **Results:** Among 406 caregivers, 137 (33.7%) showed active role preference, and 269 (66.3%) showed passive role preference. In post-hoc analysis of adjusted differences of change scores between passive-DA and active-DA groups, non-significant differences were observed in DCS. However, at 3 months, change scores of HADS depression subscale increased as 4.43 (95% confidence interval (CI), 0.78-8.07; $P<$ 0.007; effect size (ES) 0.71) and those of HADS anxiety subscales increased as 4.14 (95% CI, 0.37-7.91; P= 0.021; ES 0.61) in passive-DA group than in active-DA group, showing moderate to large difference. **Conclusions:** These findings suggest that information about decision making might be provided with tailored format for how much individual wish to involve in decision making.

10107 Poster Session (Board #96), Sat, 1:15 PM-4:45 PM

The effect of pain self-management based on pain control diary on breakthrough pain. *First Author: Zu-Yan Fan, Department of Medical Oncology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Most patients suffer from cancer pain, especially breakthrough pain. The overall incidence of breakthrough pain is estimated to be 65%. Self-management makes patients actively participating in the use of drugs, transforming their roles and adjusting their moods in order to better cure their own diseases. Therefore, the aim of the study is to discuss the effect of reducing cancer pain patients' breakthrough pain through self-management based on pain control diary. **Methods:** From October, 2015 to October, 2016, a total of 200 patients treated with opioids for cancer pain were randomly divided into groups. Patients in the control group were given general management including the Standard "the three steps analgesic ladder treatment for cancer pain", the traditional form of health education and psychological care; While the intervention group in addition to conventional cancer pain management, self-management based on pain control diary was applied. Through repeated intensive training, patients learned how to do self-assessment, to master the feature of their own pain, problem-solving skills and formal report to their oncologists in charge. **Results:** After six weeks of intervention , 10% patients in the intervention group had suffer breakthrough pain compared with 54% patients in the control group ($P <$ 0.05). The whole processing management model is a whole process, specialization and humanization Care model for patients with advanced cancer pain management, can effectively improve patient medication compliance, reduce the cancer breakthrough pain's incidence, improve the patients,s life quality with cancer pain. The medication compliance of the intervention group was significantly higher than that of the control group(X^2= 46.606, P<0.001), and in intervention group the incidence of breakthrough pain was significantly lower than that of the control group (X^2= 44.148, P<0.001) **Conclusions:** The self management based on pain control diary is a whole process, specialization and humanization Care model for patients with advanced cancer pain management, can effectively improve patient medication compliance, reduce the cancer breakthrough pain's incidence, improve the patients's life quality with cancer pain.

10108 Poster Session (Board #97), Sat, 1:15 PM-4:45 PM

A prospective randomized controlled trial of hydrating nail solution for prevention or treatment of onycholysis in breast cancer patients who received neoadjuvant/adjuvant docetaxel chemotherapy. *First Author: Ji-Yeon Kim, Samsung Medical Center, Seoul, Republic of Korea*

Background: Onycholysis and other nail toxicities occur in approximately 20-30% of breast cancer(BC) patients receiving docetaxel(D) chemotherapy. Onycholysis, the separation of the nail plate from nail bed, is also often associated with painful paronychia decreasing patients' the efficacy of a hydrating nail solution (EVONAIL solution, Evaux Laboratories, France) for the prevention and treatment of D-induced onycholysis and nail toxicities. **Methods:** This study is a prospective randomized controlled study of hydrating nail solution for prevention or treatment of onycholysis in patients with BC receiving neo/adjuvant 3-weekly D after doxorubicin plus cyclophosphamide. In experimental arm, each patient painted hydrating nail solution on nails and periungual areas once a day till developing onycholysis grade 2 or more. After Gr 2 onycholysis development, patients painted EVONAIL twice a day regardless of treatment arms. The primary endpoint is the incidence of onycholysis Gr 2 or more and recovery rate from Gr2 onycholysis. The secondary endpoints include: the incidence of all grade onycholysis; duration from first docetaxel treatment until onycholysis symptom appearance; degree of pain from nail toxicities; the incidence of other nail toxicities. **Results:** Since Aug 2015 to May 2016, 103 patients were enrolled and completed this study (Experimental arm(E) : 51, control arm(C): 52). Of 103 patients, 25 cases of Gr1 and 22 of Gr2 onycholysis were observed (Gr1 and 2(n,(%)) : 8(15.7%) and 7(13.7%) in E, 17(32.7%) and 15(21.4%)in C, respectively). Hydrating nail solution resulted in statistically significant reduction of Gr2 onycholysis compared to C (HR = 0.39, 95% CI 0.16, 0.96; P = 0.041) and all grade onycholysis decreased in experimental arm with statistical significance (HR = 0.37, 95% CI 0.20-0.69, P = 0.002). However, the effect of onycholysis treatment was not observed. **Conclusions:** Hydrating nail solution significantly reduced the incidence of D induced onycholysis in BC patients (NCT02670603). Clinical trial information: NCT02670603.

10109 Poster Session (Board #98), Sat, 1:15 PM-4:45 PM

Chemotherapy induced nausea and vomiting in breast cancer treated with antiemetic prophylaxis as recommended by the ASCO antiemesis guidelines. *First Author: Ronda Copher, Eisai Co., Ltd., Woodcliff Lake, NJ*

Background: Current ASCO Antiemesis Guidelines recommend triple antiemetic therapy (a $5HT_3RA$, an NK1, and dexamethasone) to prevent chemotherapy (CT) induced nausea and vomiting (CINV) in patients undergoing highly emetogenic chemotherapy (HEC). This study evaluated whether this regimen resulted in reduced rates of CINV in patients diagnosed with breast cancer (BC) and initiated on HEC. The primary outcomes of interest were rates of acute and delayed CINV in patients whose antiemesis prophylaxis was or was not in accordance with the ASCO guideline (i.e., Per-guideline vs. Non-Guideline). Costs of treating CINV were also calculated. **Methods:** Patients were identified in the Premier Healthcare database, a complete geographically diverse census of inpatients and hospital-based outpatients. Adults treated for BC with HEC during the years 2012-14 were identified and stratified based on their antiemesis prophylaxis. Rates of acute (day of CT) and delayed CINV (days 2-7 post CT) were calculated following initiation of HEC. CINV was defined by ICD9 codes for nausea and vomiting or volume depletion/dehydration or use of a rescue antiemetic. Rates of CINV and health care costs were then compared between the two cohorts. **Results:** A total of 8,388 patients were included in the analysis. Of these, 5,447 (65%) had treatment Per-Guideline and 2,941 (35%) were Non-Guideline. For acute CINV, Per-Guideline patients had a significantly lower rate of CINV when compared to Non-Guideline patients (1.7% vs. 3.2%, respectively, $p < .001$). Similarly, in delayed CINV Per-Guideline patients had significantly lower rates of CINV when compared to Non-Guideline patients (15.4% vs. 19.1%, $p < .001$). Patients who experienced CINV also had significantly greater total health care costs versus those without CINV ($32,199 vs. $20,163, respectively, $p < .001$). **Conclusions:** The results showed adherence to the ASCO Antiemesis Guidelines led to lower rates of CINV and lower costs. Although defining CINV by claims may tell an incomplete story, this study suggests that following the ASCO Antiemesis Guidelines may help both patients and payers of health care costs.

10110 Poster Session (Board #99), Sat, 1:15 PM-4:45 PM

Efficacy of *Gastroplegia Patch* on treating postoperative gastroplegia: A multicenter, double-blind, randomized controlled trial. *First Author: Tian Zhou, Department of Medical Oncology, Dongfang Hospital, Beijing, China*

Background: Postoperative gastroplegia is common in digestive cancer patients and there were no effective treatments. *Gastroplegia Patch* is an external-used Chinese Herbal Medicine recipe. It has been applied clinically for more than ten years, which showed good effect. We conducted this study to verify its safety and efficacy on the symptoms of postoperative gastroplegia. **Methods:** This clinical trial was designed as a multi-center, double-blind, superior effect, randomized controlled trial. It has been registered in ISRCTN (No.18291857) before initiation and was monitored by the third party. Patient inclusion criteria: 1. Gastroenterological cancer patient who was diagnosed as post-surgery gastroplegia, could not eat and need tube feeding (parenteral nutrition or with Jejunum nutrient canal); 2. The local identification of abdomen is cold pattern, which means this kind of patient prefers heat to cold, likes hot food and hates cold ones. Eligible participants were randomized into two arms, placebo arm and *Patch* arm, respectively. Beside the basic treatments (nutrition support, gastrointestinal decompression, promoting gastric dynamics medicine), placebo or *Gastroplegia Patch* was applied in control group or *Patch* group, respectively. Placebos or the patches were allocated at two acupuncture points (*Zhongwan* and *Shenque*). The intervention course was 14 days or reached primary endpoint. The primary endpoint was able to eat without tube feeding. **Results:** All the 120 eligible participants (60 per arm) were recruited from four AAA hospitals in Beijing, China. Analysis was conducted based on intent-to-treat strategy. After the intervention, 68.33% of the participants in the Patch group were able to eat without tube feeding, which significantly higher than that of 41.67% in the control group ($p = 0.003$). It took 8 days on average in the *Patch* group to show effect, which significantly faster than that of 10 days in the control group ($p = 0.017$). The incidences of adverse events were compatible between the two arms ($p = 0.244$). **Conclusions:** *Gastroplegia Patch* is safe and effective in treating postoperative gastroplegia in gastroenterological cancer patients with cold syndrome. Clinical trial information: 18291857.

10111 Poster Session (Board #100), Sat, 1:15 PM-4:45 PM

Biomarker to cost-effectively harness the technical prowess of palliative radiation: Neutrophil lymphocyte ratio (NLR) and overall survival following palliative radiotherapy in an unselected real-world population of all tumor sites. *First Author: Santhanam Sundar, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom*

Background: Single fraction radiotherapy (RT) is standard of care for palliation of pain from bone metastases (ASTRO IJROBP 2011 79:965). But costly, complex, multi-fraction RT is quite often used for palliation of symptoms from various organs. Health care costs are burgeoning (ASCO JCO 2012 30: 1715). Costs can be constrained by judiciously reducing use of unnecessary multi-fraction RT in pts with limited life expectancy. But radiation oncologists' ability to predict survival is inaccurate. (Chow IJROBP 2005 61:870). Hence we assessed clinical utility of Neutrophil Lymphocyte ratio (NLR) - a routinely available biomarker. **Methods:** 233 patients (pts) undergoing palliative RT over a 3 month at Nottingham University Hospital. Predominant Tumour SITES: Lung 28% Breast 13% Prostate 13% Colorectal 9% Gastro-Oesophageal 5% Myeloma 5% Bladder 5%. Predominant HISTOLOGY: Adenocarcinoma 61% Squamous Cell 14%. NLR available for 158 pts. **Results:** A NLR of 4.5 was highly predictive of 90-day mortality & overall survival in an unselected real world population. (Table). No survival benefit seen for multi-fraction RT over single fraction RT across all tumour sites. On survival analysis by Cox regression, increased NLR was significant with a hazard ratio of 2.2 (95% CI 1.3 to 3.7) whereas total radiation dose, use of multiple fractions , age, serum haemoglobin, serum albumin & histology were not significant. **Conclusions:** In palliative care of advanced cancer, for pts with high NLR (>4.5), Single fraction RT should be the standard of care for palliation of symptoms.

	NLR <4.5	NLR <4.5	
Median Age	67.5	67.6	*P = 0.79 (ns)
Stage 4	94%	92%	# P = 0.63 (ns)
Site of palliative RT^x	15%	11%	# P= 0.48 (ns)
Brain	23%	31%

10112 Poster Session (Board #101), Sat, 1:15 PM-4:45 PM

Safety and efficacy of same-day administration of pegfilgrastim in patients (pts) receiving chemotherapy for gastrointestinal (GI) malignancies. *First Author: Robert M. Matera, Tufts University School of Medicine, Tufts Cancer Center, Boston, MA*

Background: Pegfilgrastim is typically administered 24 hours after chemotherapy per package insert; however some pts are unable or unwilling to return for this additional visit due to work or transportation especially with regimens consisting of infusional 5-FU. Same-day dosing eliminates need for this additional visit. Results from prior studies in other tumor types are inconclusive as few support same-day dosing whereas others show inferiority. Purpose of our study was to determine safety and efficacy of administering pegfilgrastim on same day as chemotherapy in pts with GI malignancies. **Methods:** A single-institution retrospective review was conducted of pts with GI malignancies who received chemotherapy and same-day pegfilgrastim (6 mg) within 1 hour of completion of chemotherapy from Jan 2014 through Jan 2017. Decision to administer pegfilgrastim was based on NCCN or ASCO recommendations. As per institutional guidelines, pts were counseled on risks of same-day pegfilgrastim prior to its administration. Data was collected on demographics, clinic notes and complete blood counts. Analyses included neutropenia, febrile neutropenia, hospitalization, use of antibiotics or bone pain. **Results:** A total of 536 chemotherapy cycles in 69 pts were analyzed. Median age was 60 years (range 32-87) with 46% of pts $\geq$ 65. Pts had an average of 4 risk factors for febrile neutropenia: advanced disease, gender, age $>$ 65 and chemotherapy regimen. Most common malignancy was colon (48%), pancreas (17%) and gastric (17%). Most commonly used regimens included mFOLFOX6 (42%), FOLFIRINOX (23%) and FOLFIRI (12%). Median absolute neutrophil count nadir for all cycles was 4538/uL (range: 1160-25168). Grade 1 and 2 neutropenia developed in 6 of 536 (1%) cycles. Bone pain reported in 3 pts (4%). There were no episodes of grade 3 or 4 neutropenia or febrile neutropenia. None had dose reductions, chemotherapy delays, hospitalizations, or antibiotic use due to neutropenia. **Conclusions:** We believe our study is the first in GI malignancies to report that same-day pegfilgrastim administration may be as effective and safe as next-day administration, benefiting pts and might reduce costs.

10113 Poster Session (Board #102), Sat, 1:15 PM-4:45 PM

A phase II RCT of high-dose vitamin D supplementation for androgen deprivation therapy (ADT)-induced bone loss among older prostate cancer (PCa) patients. *First Author: Luke Joseph Peppone, University of Rochester Medical Center, Rochester, NY*

Background: ADT is the most commonly used systemic therapy for treating locally advanced and metastatic PCa. ADT use causes hypogonadism, which can result in accelerated bone loss and fragility fractures. Vitamin D (VITD) may protect against bone loss; however it remains unclear if the recommended daily allowance (RDA) of VITD is sufficient to reduce bone loss or whether higher doses are needed. The aim of this phase II RCT was to collect preliminary data on the effect of high-dose VITD on bone mineral density (BMD) in ADT-treated PCa patients compared to the RDA of VITD. **Methods:** Older PCa patients (≥60 years old) with VITD insufficiency (< 32 ng/ml), within 6 months of starting ADT and with 6 more planned months of ADT were randomized 1:1 to high-dose VITD (hVITD; 600 IU/daily plus 50,000 IU/weekly) or RDA of VITD (rVITD; 600 IU/daily plus placebo weekly) for 24 weeks. All subjects received 100% of the RDA for calcium (1,000 mg/day). BMD was assessed at the total hip (TH) and lumbar spine (LS) via DXA at pre- and post-intervention. ANCOVA was used to test the change in BMD between groups. **Results:** 59 PCa patients were accrued (85% white; mean age = 67.6). Serum analyses confirmed high compliance in both groups (25-OH VITD change: hVITD = +32.0 ng/ml vs rVITD = +4.3 ng/ml; $p < 0.01$). The safety of hVITD was similar to rVITD (Grade I hypercalcemia: hVITD: n = 1 vs rVITD: n = 0). Bone loss was significantly reduced for the hVITD group compared to rVITD group for total hip (TH BMD% change: hVITD = −1.5% vs rVITD = −4.1%; p = 0.02), with a trend for the femoral neck (BMD% change: hVITD = −1.7% vs rVITD = −4.3%; p = 0.06) and trochanter (BMD% change: hVITD = −1.0% vs rVITD = −2.8%; p = 0.10). There was no difference between groups for LS bone loss (LS BMD% change: hVITD = −0.8% vs rVITD = −0.6%; p = 0.75). **Conclusions:** High-dose VITD supplementation produced significantly greater reductions in hip BMD loss among older PCa patients receiving ADT compared to rVITD. Clinically, higher doses of VITD may be necessary to effectively prevent ADT-induced bone loss. A definitive phase III RCT is needed to confirm these findings. Funding: NCI R21CA175793, K07CA168911 & UG1CA189961. Bio-Tech Pharmacal Inc. supplied all agents. Clinical trial information: NCT02064946.

10114 Poster Session (Board #103), Sat, 1:15 PM-4:45 PM

Multimodal therapy for cancer related fatigue in patients with prostate cancer receiving radiotherapy and androgen deprivation therapy. *First Author: Sriram Yennu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are limited studies to evaluate treatments that target causative mechanisms of Cancer-related-fatigue (CRF) using validated tools in a defined population. The objective is to determine the feasibility, and the preliminary estimates of the effects of various combinations of standardized exercise, cognitive behavioral therapy (CBT), and methylphenidate (multimodal therapy, or MMT) on CRF as measured by AUC of Functional Assessment of Chronic Illness Therapy- Fatigue (FACIT-F) subscale scores in Pts with prostate cancer receiving radiotherapy with androgen deprivation therapy. **Methods:** Prostate cancer Pts with CRF scheduled to receive radiotherapy with androgen deprivation therapy were eligible. Using a double blind (patient, investigators) randomized factorial study design, eligible Pts were randomized into 1 of the 8 arms, which included all possible combinations of the interventions (exercise, CBT, and methylphenidate) and/or their corresponding placebo treatments for a duration of 8 weeks. **Results:** 62/69 (89%) randomized Pts were evaluable. There were no differences in the demographics and baseline fatigue between groups. The adherence rates for pills, exercise and CBT were 96.5%, 67%, and 90% respectively. The study was feasible and there was no significant difference in adverse events by groups. Table 1 shows the comparison of AUC by treatment. For Pts receiving drug compared to placebo, the median FACIT-F AUC was 2328 vs 2095. The drug effect (estimate, 95% CI) in Pts who received Exercise was 596 (68.3, 1125); CBT was 354 (-121, 830); combined Exercise and CBT was -187 (-802,427); and control Exercise, control CBT was 294 (-192,781). **Conclusions:** Methylphenidate containing combinations were superior to no drug combinations. Methylphenidate + Exercise provided the best signal and should proceed to large randomized control trials. Clinical trial information: NCT01410942.

Comparison AUC (median scores and p-value) by treatment.

Interventions	AUC_ FACIT-F	AUC_ FACT-G
Methylphenidate vs Placebo	2328 vs. 2095 (p=0.0536)	4923 vs. 4532 (p=0.042)
Exercise vs control exercise	2143 vs 2285 (p=0.59)	4667 vs 4813 (p=0.37)
CBT vs control CBT	2247 vs 2197 (p=0.4)	4710 vs 4722 (p=0.84

10115 Poster Session (Board #104), Sat, 1:15 PM-4:45 PM

The impact of sleep disturbances (SD) on quality of life, psychological morbidity, and survival of advanced cancer patients (ACP) and caregivers (CG). *First Author: Fay J. Hlubocky, The University of Chicago Medicine, Chicago, IL*

Background: SD have been described as a significant symptom burden for cancer patients and their caregivers. However, in advanced cancer, the prevalence of SD and its impact on the quality of life (QOL) and psychological morbidity of ACP over time has not been described. **Methods:** A prospective cohort of ACP participating in phase I trials was assessed at baseline (T1) and one month (T2) using psychosocial instruments: cognition (MMSE); depression (CES-D), state anxiety (STAI-S), QOL(FACIT-Pal), global health (SF-36). Semi-structured interviews evaluated SD patterns including: quality/latency, habitual efficiency, daytime dysfunction. **Results:** To date,152 subjects (76 ACP and 76 CG) have been separately interviewed at T1 and T2. For the total population: median age 61 (28-78y); 51% male; 100% married; 90% Ca; 64% > HS educ; 52% GI dx; 51% income < $65,000 yr; ACP median survival 7.9 months (0.41-18.2). At T1, 57% of ACP reported experiencing SD within the past week including: 55.6% insomnia, 44% nonrestorative sleep, 49% low energy, 48% daytime somnolence. For CG, 72% reported experiencing SD: 68% insomnia, 64% nonrestorative sleep, 69% fatigue, 66% daytime somnolence. At T2, rates remained consistent over time for both ACP and CG across time with the exception of increased insomnia at 61% and 76% respectively. After controlling for pain, mood, and fatigue, ACP with self-reported SD had higher STAI-S (33 ±11 v 29 ±8 , p = 0.02) and poor global health (54 ± 19 v. 64 ± 21, p = 0.01) at T2. CG with SD had higher STAI-S anxiety (39 ± 17 v 35 ± 13, p = 0.03) and poor global health (75 ±26 v 88±16, p = .0002) at T2.Regression analyses revealed ACP with self-reported insomnia had poorer FACIT-Pal QOL (59 ± 9 v 63 ± 10, p = 0.01) over time. Prior chemotherapy was associated with ACP SD (70% v. 33%, p = 0.02). Regarding prognosis, ACP with insomnia had shorter median survival (5.5 v. 7.2 months, p = 0.01). **Conclusions:** SD are prevalent among ACP participating in clinical trials and were associated with disease progression, QOL, and anxiety. Multidisciplinary supportive care interventions designed to address SD are warranted.

10116 Poster Session (Board #105), Sat, 1:15 PM-4:45 PM

Safety and efficacy of alternating treatment with EP2006, a filgrastim biosimilar, and reference filgrastim for the prevention of severe neutropenia, in patients with breast cancer receiving myelosuppressive chemotherapy. *First Author: Andriy Krendyukov, HEXAL AG, Holzkirchen, Germany*

Background: In 2015, filgrastim EP2006 (Zarxio) became the first biosimilar approved by the FDA for commercial use in the US. This phase III randomized, double-blind registration study in patients with breast cancer receiving (neo)adjuvant myelosuppressive chemotherapy (TAC) compares US-licensed filgrastim, Neupogen (reference), with two groups who received alternating treatment with reference and biosimilar every other treatment cycle. **Methods:** A total of 218 patients receiving 5μg/kg/day filgrastim over 6 chemotherapy cycles were randomized 1:1:1:1 into 4 arms. Two arms received only 1 product, biosimilar or reference (unswitched), and 2 arms (switched) received alternating treatments every other cycle (biosimilar then reference or vice versa over cycles 1–6). Since the switch occurred from Cycle 2 onwards, this analysis compared pooled switched groups to the unswitched reference group for efficacy during Cycles 2–6. Safety was also assessed. Non-inferiority in febrile neutropenia (FN) rates between groups for Cycles 2–6 was shown if 95% confidence intervals (CIs) were within a predefined margin of -15%. **Results:** A total of107 patients switched treatment, and 51 patients received reference in all cycles. Baseline characteristics were similar between groups. Incidence of FN was 3.4% (switched) vs. 0% (reference) (95% CI: -9.65; 4.96), which is within the predefined non-inferiority margins. Infections occurred in 9.3% (switched) vs. 9.9% (reference). Hospitalization due to FN was low with 1 patient in Cycle 6 (switched). TEAEs related to filgrastim were reported in 42.1% (switched) vs. 39.2% (reference) (all cycles). Musculoskeletal/connective tissue disorders related to filgrastim occurred in 35.5% (switched) vs. 39.2% (reference) (all cycles), including bone pain (30.8% vs. 33.3%). No anti-drug antibodies were identified. **Conclusions:** There was no evidence of clinically meaningful differences when patients with breast cancer were switched from reference to biosimilar filgrastim, or from biosimilar to reference filgrastim. Clinical trial information: NCT01519700.

10117 Poster Session (Board #106), Sat, 1:15 PM-4:45 PM

Reducing chronic breast cancer related lymphedema utilizing a program of prospective surveillance with bioimpedance spectroscopy (BIS). *First Author: Pat W. Whitworth, Nashville Breast Center, Nashville, TN*

Background: Breast cancer related lymphedema (BCRL) represents a major side effect that can significantly impact quality of life. Current guidelines support prospective surveillance to allow for early diagnosis and treatment of BCRL at a subclinical, reversible stage. This current large, single institution experience evaluated the use of bioimpedance spectroscopy (BIS) to monitor patients for the development and treatment of BCRL. **Methods:** From April 2010 through Nov 2016, 596 patients (79.6% with high-risk features) were evaluated with BIS.Patients received a pre-operative baseline L-Dex measurement and post-operatively at regular intervals. Elevated L-Dex scores were defined as an increase of $\geq$10 points above baseline (considered subclinical BCRL). Intervention then consisted of applying an over the counter (OTC) sleeve for 4 weeks followed by re-evaluation. The need for complete decongestive physiotherapy (CDP) represented a surrogate for the development of clinically significant, chronic BCRL. **Results:** Median follow-up for all patients was 17 months. Seventy-three patients (12%) developed an elevated L-Dex score with axillary lymph node dissection (ALND) ($p < 0.001$), taxanes ($p = 0.008$), and (regional nodal irradiation (RNI) ($p < 0.001$) associated. At last follow-up, only 18 patients (3%) had unresolved clinically significant BCRL requiring CDP. Mastectomy ($p = 0.02$), ALND ($p < 0.001$), taxanes ($p = 0.05$), and RNI ($p < 0.001$) were associated with requiring CDP. **Conclusions:** Our results demonstrate that prospective monitoring using BIS, with intervention (using a simple OTC sleeve for 4 weeks) triggered by a $\geq$10-point L-Dex elevation, resulted in only a 3% rate of chronic, clinically significant BCRL. These results are lower than reported in contemporary studies and validate recent guidelines supporting prospective screening and intervention for BCRL.

10118 Poster Session (Board #107), Sat, 1:15 PM-4:45 PM

Frequency and factors predictive of aberrant drug behavior in patients presenting to outpatient supportive care center at a comprehensive cancer center. *First Author: Sriram Yennu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Opioid misuse is a growing crisis in cancer patients. Cancer patients at risk of aberrant drug behaviors (ADB) are frequently underdiagnosed in routine cancer care. The aim of this study was to determine the frequency and factors associated with ADB using the "Screener and Opioid Assessment for Patients tool" (SOAPP-14) in cancer patients seen at the outpatient supportive care center. We also examined the screening performance of Cut Down, Annoyed, Guilty, and Eye Opener (CAGE-AID) as compared to The SOAPP-14 as a gold standard. **Methods:** In this retrospective study, 1108 consecutive patients referred to supportive care clinic were reviewed. Patients were eligible if they were $\geq$18 yrs, have a diagnosis of cancer, and were on opioids for pain for atleast a week. Patients' demographics, the Edmonton Symptom Assessment Scale (ESAS), SOAPP-14, and CAGE-AID scores were analyzed. ADB+ was defined as SOAPP-14 score $\geq$7. Descriptive statistics, spearman correlation coefficient, multivariate, and ROC analysis were performed. **Results:** 703/1108 consults were eligible. A total of 153/703 (22%) were ADB +ve. SOAPP-14 scores were positively correlated with CAGE-AID $r = .38$, $p < 0.001$; male gender $r = 0.11$, $p = 0.003$; ESAS pain $r = 0.11$, $p = 0.005$; ESAS depression $r = 0.22$, $p < 0.001$; ESAS anxiety $r = 0.22$, $p < 0.001$, and ESAS financial distress $r = 0.23$, $p < 0.001$. Multivariate analysis indicated that the odds ratio for ADB +ve was 6.18 in patients with CAGE-AID+ ($p < 0.001$), 1.8 for male gender ($p = 0.007$), 1.1/pt. for ESAS anxiety ($p = 0.044$), and 1.1/pt. for ESAS financial distress ($p = 0.007$). A CAGE-AID score of 1/4 has a sensitivity of 47%, specificity of 89% positive predictive value 63.6% and negative predictive value 69.2%. **Conclusions:** Our study suggests that 22% of cancer patients on opioids presenting to supportive care center are at risk of aberrant drug behavior (ADB). Male patients with anxiety, financial distress, and prior alcoholism/illicit drug use are significant predictors of ADB's. A cut off score of $\geq$1 out 4 on CAGE-AID questionnaire allows better screening of ADB in outpatient advanced cancer patients. Further research to effectively manage these patients is needed.

10119 Poster Session (Board #108), Sat, 1:15 PM-4:45 PM

Effect of exercise on muscle immune response and mitochondrial damage and their relationship with cancer-related fatigue: A URCC NCORP study. *First Author: Anita Roselyn Peoples, University of Rochester Medical Center, Rochester, NY*

Background: Chemotherapy (CT) via inflammation and oxidative stress can cause muscle inflammatory injury, mitochondrial damage, and cancer-related fatigue (CRF). Following muscle and mitochondrial damage, various cytoplasmic and mitochondrial components are released into circulation. HLA-DQB1 gene encodes a protein involved in the activation of immune response, and is not expressed in normal muscle cells but is up-regulated under highly inflammatory states. Mitochondrial gene MT-CO2 encodes subunit 2 of complex IV, which plays a critical role in energy metabolism and mitochondrial function. We investigated the (i) influence of an exercise intervention, Exercise for Cancer Patients (EXCAP), on gene expression levels of muscle immune response and mitochondrial damage and (ii) the relationships of these genes with CRF. **Methods:** In this nationwide, multicenter, phase III RCT conducted through the URCC NCORP Research Base, cancer patients ($N = 350$; mean age = 55.7) were randomized to 2 groups: (i) CT and (ii) CT plus a 6-week individualized, home-based, aerobic and resistance exercise program (EXCAP). Gene expression and CRF were assessed pre- and post-intervention from whole blood by qPCR and from patient-report by MFSI, respectively. **Results:** T-tests revealed significant upregulation of peripheral HLA-DQB1 and MT-CO2 mRNA following CT in controls (both $p < 0.00001$) while there was less up-regulation in exercisers (both $p \leq 0.005$). ANCOVA showed a trend for significant differences between controls and exercisers for HLA-DQB1 (9.2% vs 5.4%; $p = 0.059$) and MT-CO2 (16.3% vs 12.7%; $p = 0.061$). Pearson correlations revealed that increases in HLA-DQB1 ($r = 0.21$; $p = 0.051$) and MT-CO2 ($r = 0.19$; $p = 0.025$) were significantly associated with concurrent increase in CRF in controls, but not in exercisers. **Conclusions:** CT alters muscle immune response and mitochondrial gene expression causing muscle and mitochondrial damage, which may be mediators for CRF. EXCAP is a promising intervention that may reduce both muscle and mitochondrial damage via its positive effects on HLA-DQB1 and MT-CO2. *Funding: NCI UGCA189961, R25 CA102618.* Clinical trial information: NCT00924651.

10120 Poster Session (Board #109), Sat, 1:15 PM-4:45 PM

Anticipative monitoring to improve chemotherapy induced nausea. *First Author: Reza Elaidi, Association for Innovative Therapies in Oncology, Paris, France*

Background: The PROCHE [Programme for optimisation of the chemotherapy network] initiative is an innovative oncology-monitoring program designed to reduce patient waiting time and chemotherapy wastage, ultimately improving patient care. **Methods:** Primary objective was to evaluate the incidence of nausea reported by grade (NCI-CTC AE: from 0 to 4) from 2008 to 2016. Association was quantified using Mantel-Haenszel khi^2 and exact *p-values*. Secondary objective compared the 2009-2016 patients with the control patients of 2008 period. **Results:** Between Oct 2008 and Oct 2016, 3012 patients participated in the program, representing 36 803 questionnaires completed over the whole period. Nausea was, clinically and statistically, significantly improved during the whole follow-up period with a decrease of grade 3-4 from 0.6% to 0.08% and a decrease of grade 1-2 from 29.3% to 8.2%. The already adapted nausea management in 2008 with 70% of questionnaires reported no nausea improved to 92% in 2016, with a 10% improvement the year after program initiation. As MASCC propose to change guidelines with an improvement above 10%, such an organization may impact new recommendations. **Conclusions:** Anticipating anti-cancer treatment adaptation and prevention, following guidelines and using adapted antiemetics, explain these positive results. The PROCHE initiative improves chemotherapy induced nausea.

	No adverse event (%)	Grade 1-2 (%)	Grade 3-4 (%)	
2008	70.08	29.32	0.6	p<0.0001

10121 Poster Session (Board #110), Sat, 1:15 PM-4:45 PM

Advanced cancer patients' self-reported perception of timeliness of their referral to outpatient supportive/palliative care and their survival data. *First Author: Angelique Wong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Palliative Care referral is often thought to be delayed as judged by health professionals and caregivers. However, no studies have ever examined patients' perception of timeliness of referral. The primary objective of this study was to determine patients' perception of the timeliness of their own referral to an outpatient palliative care clinic. We also examined the association between perceived timeliness and actual timing of referral. **Methods:** In this prospective survey, patients with advanced cancer were asked to rate their perceived timeliness of referral using a 5-point Likert scale ranging from much too early to much too late within 7-35 days after their first consultation visit at Supportive Care Center. They were also asked when they felt referral to Supportive Care should occur along 4 points in their disease trajectory. Actual timing of referral was assessed based on survival from the timing of completion of the survey. **Results:** 200 advanced cancer patients were surveyed. Median age was 64, 111 (55%) were female, and 35 (18%), 32 (16%) and 26 (13%) had gastrointestinal, lung and breast cancer, respectively. The median overall survival was 8.5 months. 144 (72%) patients perceived their referral was "just in time," 42 (21%) felt it was "late/much too late," and 14 (7%) felt it was much "too early/early." 76/193 (39%) felt the referral should occur at the time of diagnosis of cancer, 32 (17%) when they start first-line chemotherapy, 46 (24%) at diagnosis of recurrent disease, 14 (7%) when there are no further treatment options, and 4 (2%) reported never. We found no significant difference in survival among patients who reported their referral was early, just in time, and late (median 9.8 vs. 8.3 vs. 9.0 months, P=0.43). **Conclusions:** Patients with advanced cancer were referred to our outpatient Supportive Care clinic a median of 8.5 months before death. A vast majority of patients perceived the timing of referral was appropriate, and many agreed that referral should occur early in the disease trajectory. The lack of association between perceived timeliness of referral and survival may be related to the ceiling effect and the small number of patients who felt their referral was late.

10122 Poster Session (Board #111), Sat, 1:15 PM-4:45 PM

Radiation for bone metastases: Reconsidering the optimal timing. *First Author: Joanna C. Yang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Bone metastases impair function and decrease quality of life due to acute or chronic pain. The standard approach for patients with multiple bone metastases is systemic therapy and palliative radiation therapy (RT) when the metastases become symptomatic. This study aims to understand the characteristics and outcomes for inpatients admitted for painful bone metastases. **Methods:** An inpatient radiation oncology consult registry was created in 2015 to evaluate patterns of care for patients receiving RT in the inpatient setting. Of the 1151 consults requested between 7/2015 and 6/2016, 28% (n = 323) were for evaluation of symptomatic bone metastases in patients who were hospitalized for acute or chronic pain. Among this cohort, 64% (n = 208) went on to receive RT for 225 bone metastases. Sixty percent of RT courses were initiated while the patient was hospitalized. Clinical characteristics correlated with overall survival (OS) were evaluated through Cox regression analysis. **Results:** The median follow up for the 208 patients who received RT was 4 months (0.1-9 months). Patient median age was 61 (10-92 years), and the median KPS was 70 (20-90). The most common sites treated were spine (50%), joints such as hip and shoulder (11%), long bones including femur and humerus (11%), and pelvis (10%). Sixty-one percent (n = 138) of the treated metastases were diagnosed $\geq$4 months prior to RT. The median survival after receiving palliative RT was 4 months (0-19 months). Among the 141 patients who had died at the time of analysis, 92 (65%) died within 2 months, and 128 (91%) within 6 months. Eighteen patients (9%) discontinued RT to transition to hospice care. OS after RT is significantly correlated with KPS ($p < 0.0001$) at the time of consult but not with patient age or site of treated disease. **Conclusions:** In this select group of inpatients who were evaluated for palliation of symptomatic bone metastases, we found a short OS after RT. The majority of metastases were present for $\geq$4 months prior to RT. This study suggests that earlier RT for high-risk metastases should be considered to prevent development of symptomatic disease that requires hospitalization. Risk factors for development of painful bone metastases are being studied prospectively at our institution.

10123 Poster Session (Board #112), Sat, 1:15 PM-4:45 PM

Trastuzumab-related subclinical cardiotoxicity in patients with early stage HER2-positive breast cancer: A retrospective single-center cohort study. *First Author: Olexiy Aseyev, Ottawa Hospital Cancer Centre, University of Ottawa, Ottawa, ON, Canada*

Background: Trastuzumab-based therapy (TT) is standard treatment for HER2-positive breast cancer (HBC). Subclinical cardiotoxicity (SCTx), defined as asymptomatic decline in left ventricular ejection fraction (LVEF) > 10% to < 50%, has been reported in up to 30 % of HBC patients (pts) receiving TT. Objectives included: determine prevalence of SCTx; associated risk factors (RF); and completion rates of TT in pts with HBC referred to a cardio-oncology clinic (COC). **Methods:** HBC patients receiving TT referred to the Ottawa Hospital COC were included. Demographics, TNM staging, performance status, stage, cardio-vascular (CV) RF (history of heart disease, hypertension, smoking, dyslipidemia, and diabetes), cardiac medications (CM) (ACE-inhibitors, beta-blockers), baseline LVEF, previous cancer therapy, baseline anthracycline exposure, previous radiation therapy (RT) (including mediastinal RT) were collected. LVEF was evaluated by ECHO or MUGA. Rate of successful completion of TT among pts with SCTx was determined. Risk ratio (RR) and logistic regression analysis was performed. **Results:** 240/408 BC pts referred to the COC (2008-2016) had HBC and 163/240 (68%) were referred with SCTx while on TT. 139/163 (85 %) pts with SCTx recovered after COC assessment: 77/163 (47%) pts were prescribed CMs. A significantly higher proportion of recovery was observed in pts who did not require CM (0.92 vs 0.78, p = 0.012; RR = 0.85, 95%CI:0.74-0.91). A total of 129/163 (79%) pts who experienced SCTx finished a full course of TT. Regression analysis found baseline LVEF, diabetes, and diastolic blood pressure as significant RFs for SCTx. There were no independent predictors for recovery after asymptomatic drop in LVEF while on TT. Diabetes (OR:2.97, 95%CI:1.3-6.8) and left chest wall RT (OR:2.4, 95%CI:1.1-5.6) significantly increased risk of permanent TT interruption in pts with asymptomatic drop in LVEF. **Conclusions:** The majority of HBC pts who experience SCTx can safely complete a full course of TT; many without use of CMs. While CV RFs were associated with increased risk of SCTx, this did not impact CV recovery after asymptomatic drops in LVEF.

TPS10124 Poster Session (Board #113a), Sat, 1:15 PM-4:45 PM

A multicenter phase 4 geriatric assessment directed trial to evaluate gemcitabine +/- nab-paclitaxel in elderly pancreatic cancer patients (GrantPax). *First Author: Johannes Betge, Department of Medicine II, University Hospital Mannheim, Heidelberg University, Mannheim, Germany*

Background: *Nab*-paclitaxel/gemcitabine (*nab*-P/gem) is an effective 1st line regimen for metastatic pancreatic ductal adenocarcinoma (mPDAC). Elderly mPDAC patients (pts) may as well benefit from *nab*-P/gem. Geriatric assessments to evaluate the functional reserve of these pts may allow individualization of treatment. Therefore, the aim of this study is to determine whether comprehensive geriatric assessments (CGAs) can predict the benefit from combined *nab*-P/gem therapy for elderly mPDAC pts in 1st line. A stratified treatment approach shall result in patient groups with a stable or improving CGA performance during the 1st cycle of treatment. **Methods:** GrantPax (NCT02812992) is a multicenter, open label phase 4 interventional trial with stratified parallel treatment groups (n = 45 per arm). The hypothesis is that individualized assessment directed treatment algorithms identify elderly pts ($\geq$70 yrs), who benefit from combined *nab*-P/gem therapy. The study uses a CGA to stratify pts as GOGO, SLOWGO or FRAIL. Depending on test outcome, pts receive chemotherapy (GOGO: *nab*-P/gem; SLOWGO: gem mono) or best supportive care (FRAIL). After 1st cycle of chemotherapy (4 wks) a CGA and safety assessment will be performed to assign pts to their definite treatment arm. The primary objective is that CGA-stratified pts do not decline in their CGA performance in response to chemotherapy, measured as a loss of 5 points or less in Barthels activities of daily living (ADL1 vs. ADL2 during CGA core assessment). The expected proportion of pts with ADL decline in each treatment group is 6%. Under this assumption it shall be shown with 80% power at one-sided significance level alpha of 0.05 that the proportion of pts with functional decline is less than 20% (n = 43 per group; ADL decline: n = 2 per group). Secondary endpoints are CGA scores during the course of therapy (CGA1-4), response rates, safety, survival rates, duration of treatment, cumulative dose, quality of life and discrepancy between CGA strata estimation by the investigator and true CGA assessment. GrantPax is the first trial realizing a CGA-driven treatment to individualize cancer therapy for elderly pts. Clinical trial information: NCT02812992.

TPS10125 Poster Session (Board #113b), Sat, 1:15 PM-4:45 PM

UNICANCER: Prospective cohort study of treatment related chronic toxicities in patients with localized breast cancer (CANTO). *First Author: Ines Maria Vaz Duarte Luis, Gustave Roussy, Université Paris-Saclay, Villejuif, France*

Background: Corresponding with improved survival among breast cancer patients an awareness of the long term effects of cancer treatments has increased. There is now a call for better coordination of care and management of these patients to focus on their survivorship. This study will identify factors associated with the development and persistence of long term toxicities in patients treated for Stage I-III breast cancer. In addition, it will characterize their incidence as well as, psychological, social and economic impacts. **Methods:** This is a prospective cohort study enrolling newly diagnosed invasive cT0-cT3, cN0-3, M0 breast cancer patients of 26 French comprehensive cancer centers. All patients will be followed for a minimum of 5 years. Patients will be assessed at diagnosis, 3-6 (M0), 12 (M12), 36 (M36), 48 (M48), 60 (M60), months after treatment completion. Treatment completion is defined as completion of primary surgery, chemotherapy or radiotherapy, whichever comes last. Adjuvant trastuzumab, endocrine therapy or participation in clinical trials can be ongoing. CANTO collects an extensive list of clinical, treatment, and toxicity data including validated patient reported outcomes questionnaires *(Hospital Anxiety and Depression scale [HADS], Scheier et Carver's Questionnaire, Life Orientation Test-Revised [LOT-R], Beck Depression Inventory [BDI-SF], European Organization for Research and Treatment-QOL questionnaire for breast cancer [EORTC QLQC30-BR23], EORTC-FA13, 12 Item Short Form Survey [SF12], Global physical activity questionnaire [GPAQ]6, impact of cancer questionnaire [IOCv2], economic and social questionnaires).* Blood collection is available for all patients at diagnosis, M0, M12, M36 and M60. Genotyping will be performed in all samples. Biologic substudies are ongoing (e.g, microbiotic and cognitive substudy). CANTO aggregates a multidisciplinary team of French investigators and created a dedicated national network. Enrolment started in 2012 and by December 2016, 10030 patients were already enrolled, with a goal of 12.000 patients. Clinical trial information: NCT01993498.

TPS10126 Poster Session (Board #114a), Sat, 1:15 PM-4:45 PM

A phase II-III, multicenter, randomized, open study evaluating the feasibility and efficacy of a supervised home-based standard physical exercise program for metastatic cancer patients receiving oral targeted therapy: The UNICANCER SdS 01 QUALIOR study (ID-RCB: 2015-A01922-47). *First Author: Florence Joly Lobbedez, Centre François Baclesse, Caen, France*

Background: Fatigue is a frequent side effect with oral targeted therapies (OTT). Physical activity has been reported to improve fatigue and quality of life (QoL). However, few studies focused on metastatic cancer patients and mainly among patients treated with chemotherapy. Furthermore, recent guidelines recommend evaluation and optimization of standardized exercise programs. The aim of our study is to evaluate home-based standard physical exercise program (SPEP) for metastatic cancer patients treated with OTT. **Methods:** This phase II-III study will randomize (2:1) patients starting first-line OTT for metastatic cancer between an individualized SPEP supervised by a personal coach, and recommended physical exercises via a booklet. Eligible patients will have received $\leq$2 lines of metastatic chemotherapy, ECOG PS $\leq$2, controlled pain (VAS $<$ 3/10), and life expectancy $\geq$3 months. The phase II part (120 patients) will evaluate the feasibility of a 3-month SPEP using the rate of patients performing $\geq$50% of SPEP (2-stage Fleming: one-sided α = 5%; β = 85%). An interim analysis is planned after the phase II. The phase III will compare the efficacy of an SPEP as opposed to recommendations to reduce fatigue and/or improve physical well-being (PWB) dimensions of QoL (evaluated with FACT-G and FACT-F questionnaires). To show a difference of $\geq$5 points in PWB and 2.5 for fatigue (α = 2.5%; β = 80%), 312 patients are required in the phase III trial. . Secondary objectives include: PFS, OS, other dimensions of QoL, tolerability and observance of OTT, change in body composition, physical benefits, and a medico-economic study. The SPEP was developed by specialized coaches involved in physical activity and cancer. The study has Ethic committee approval and accrual is planned in 18 French centers in April 2017, for 30 months. This is the first randomized trial dedicated to patients with metastatic cancer treated with OTT evaluating the feasibility and the efficacy of a well design home based SPEP on fatigue and physical well-being.

TPS10127 Poster Session (Board #114b), Sat, 1:15 PM-4:45 PM

A pilot RCT of sarcopenia-focused prehabilitation in pancreas cancer. *First Author: Elizabeth Hile, Oklahoma University Health Sciences Center/ Stephenson Cancer Center, Oklahoma City, OK*

Background: Now the 3rd leading cause of US cancer deaths, pancreatic cancer (PanC) incidence is rising. Surgery is the only chance at cure, but sarcopenia (low muscle mass, strength, function) can eliminate surgical and chemotherapy options, and independently predicts poor outcomes. Strengthening (Str) with protein combats sarcopenia of aging, and pre-op exercise (prehab) benefits other cancer survivors. But the impact of Str in a brief pre-Whipple window, and a host with PanC-mediated catabolism, is unknown. We aim to quantify the post-op QoL impact of adding Str to our standard clinical aerobic instruction before Whipple for pancreatic head and related cancers. **Methods:** Pilot RCT of 130 PanC survivors age 30+ randomized (stratified by neo-chemo) to 2 home-based prehab arms: Standard/NPRE = aerobic + protein, or Sarcopenia/SPRE = Standard + Str. To explore PanC-sarcopenia as moderating Str's impact, a 3rd pre-malignancy Whipple group (p-mal, n=50) also receives SPRE. All participants get protein and exercise instruction personalized to baseline status, adherence diaries, actigraphy, and phone follow-up in pre-op period only. Endpoints are QoL (primary) as Functional Assessment of Cancer Therapy (FACT), performance as 6 Minute Walk (6MW) & Short Physical Performance Battery (SPPB); and self-reported symptoms & activities of daily living (ADL). Assessments at baseline, 1-3 days pre-op, and post-op week 4 & month 4 (primary) are blind. Sarcopenia measures are clinical (dynamometry, bioimpedance, CT body composition) and preclinical (ZIP4/ catabolic mediators in blood, muscle, tumor & duodenum). Analyses: QoL change at post-op month 4 will be compared across PanC arms (SPRE & NPRE) with mixed-models before Baron-Kenny and Preacher/Hayes' mediator analyses. To explore impact of PanC catabolic host environment on Str, outcomes will be compared by SPRE group (PanC & p-mal). To our knowledge, this is the first PanC prehab RCT with sarcopenia focus, comprehensive mechanistic approach, and high dose (60 min daily)/short duration (2-3 week) intervention. With local feasibility established, we continue to accrue (n=30), and seek multicenter collaboration to target NCI funding. Clinical trial information: pending - in submission.

TPS10128 Poster Session (Board #115a), Sat, 1:15 PM-4:45 PM

Testing a behavioral intervention to improve adherence to adjuvant endocrine therapy (AET). *First Author: Gretchen Genevieve Kimmick, Duke University Medical Center, Durham, NC*

Background: Adjuvant endocrine therapy (AET) is a crucial component of treatment used to prevent recurrence and reduce mortality for women with hormone receptor positive breast cancer. Poor adherence to AET is a significant problem, with rates of non-adherence ranging from 28% to 59%. Non-adherence to AET contributes to increased medical costs and increased mortality. Symptoms (e.g., pain, hot flashes, sleep problems, vaginal dryness) associated with AET are related to non-adherence and early discontinuation of treatment. Our goal is to test the efficacy of a novel self-management intervention (SMAET) that teaches patients skills for enhancing adherence to AET and coping with AET-related symptoms. **Methods:** Trial participants will be recruited from a tertiary care medical center and community clinics that are located in medically underserved areas. Target enrollment is 400 patients. Prospective participants must meet the following criteria: diagnosis of Stage I to III breast cancer; hormone receptor positive tumor; local definitive cancer treatment complete; within 12 months of beginning AET; have at least 18 months of AET recommended; and at least 21 years of age. We will test the effects of the SMAET intervention (n = 200) by comparing it to a general health education intervention (n = 200; attention control). The SMAET protocol includes 7 sessions providing systematic training in coping skills for managing symptoms that interfere with adherence and 3 maintenance calls delivered over 6 months by a nurse via the phone. The intervention also includes interactive voice messaging that is tailored based on real-time adherence data. The primary study outcome, adherence to AET, will be assessed in real-time for 18 months using wireless smart pill bottles (i.e., bottle opening and percent of pills remaining). Symptom interference will be examined as a secondary outcome and will be assessed over 18 months. If effective, the intervention may reduce the burden of AET use. Clinical trial information: NCT02707471.

TPS10129 Poster Session (Board #115b), Sat, 1:15 PM-4:45 PM

A randomized phase II/III study comparing stereotactic body radiotherapy (SBRT) versus conventional palliative radiotherapy (CRT) for patients with spinal metastases (NCT02512965). *First Author: Arjun Sahgal, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Innovative radiotherapy technology and modern imaging capabilities enable the use of Stereotactic Body Radiotherapy (SBRT) to treat patients with spinal metastases to optimize tumour control and palliation compared to standard conventional radiotherapy. No randomized clinical trial evidence exists directly comparing the two treatment strategies. **Methods:** SC.24 is a Canadian Cancer Trials Group randomized phase II/III study comparing standard conventional radiotherapy (20 Gy/5fr) to SBRT (24 Gy/2fr) in patients with solid tumours and MRI documented, painful spinal metastases suitable for RT. The primary accrual objective for the phase II portion of the study was met in January 2017 and the study continues as a randomized phase III study with a primary outcome measure of complete pain response at 3 months post radiotherapy. Secondary objectives include: measurement of complete pain response at 6 months; radiation site progression free survival at 3 and 6 months; adverse event profile, health related QOL and compliance with RT QA measures. Biobanking for future correlative studies is included in study design. Statistical design: The statistical assumptions for the phase III study include estimated complete pain response rates of 10% and 30% for the CRT and SBRT treatment arms respectively. Using a two sided alpha = 0.05 and power = 80% the sample size for the phase III study is 152, taking into account a 5% drop out rate. Conduct to Date: Study activation: July 2015. Accrual to date: 58. Supported by CCSRI grant 021039 Clinical trial information: NCT02512965.

Temporal trends in chronic disease among survivors of childhood cancer diagnosed across three decades: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Todd M. Gibson, St. Jude Children's Research Hospital, Memphis, TN*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 PM (EDT) on Friday, June 2, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

10501 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Age-associated vulnerability to treatment-related late cardiotoxicity: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: James Edward Bates, University of Florida, Gainesville, FL*

Background: Cardiovascular disease (CVD) is the most common non-cancer cause of death in long-term survivors of pediatric cancer. We investigated the role of age at diagnosis in modifying treatment-related late CVD risk in the CCSS population. **Methods:** We evaluated CTCAE grade 3 – 5 CVD events occurring ≥5 years after diagnosis in 23,465 5-year survivors of pediatric cancer diagnosed 1970-1999. We estimated the rates of developing any CVD, including coronary artery disease (CAD) or heart failure (HF). Modifications of treatment effects by age at diagnosis were analyzed using piecewise exponential models adjusting for current age, race, and smoking. **Results:** At a median age of 28.4 years (range 5.6 –58.3) and follow up of 20.2 years (5 – 39.3), 239 CAD and 359 HF events occurred. The cumulative incidence of CVD, CAD, and HF were 4.8% (95% CI: 4.3-5.3), 2.4% (95% CI: 2.2-2.9), and 2.5% (95% CI: 2.2-2.9) by 30 years from diagnosis. Mean cardiac radiotherapy (CRT) doses of ≥10 Gy were associated with a progressively increasing risk of CVD (10 - < 20 Gy: RR 3.6, 95% CI 2.1 – 6.2, $p < 0.01$; 20 - < 30 Gy: RR 4.4, 95% CI 2.7 – 7.2, $p < 0.01$; ≥30 Gy: RR 7.5, 95% CI 4.9 – 11.5, $p < 0.01$) relative to those receiving no CRT. In those receiving a low mean CRT dose (0.1 - < 10 Gy), younger children had higher rates of CVD (0 – 4 years: RR = 2.2, 95% CI = 1.0 – 4.6, $p = 0.04$; > 4 - ≤13 years: RR = 2.1, 95% CI = 1.1 – 4.1, $p = 0.03$) compared to those > 13 years, an effect not seen at higher doses. Among survivors exposed to anthracycline doses ≥250 mg/m2, those age 0 – 4 at diagnosis had increased risk of both CAD (RR = 4.9, 95% CI 1.5 – 16.3, $p = 0.01$) and HF (RR = 3.0, 95% CI 1.6 – 5.0, $p < 0.01$). Cisplatin exposure ≥300 mg/m2 was associated with increased risk of any CVD (RR = 1.8, CI = 1.2 – 2.6, $p < 0.01$), primarily attributable to increased risk of HF (RR = 2.3, 95% CI = 1.5 - 3.5, $p < 0.01$). **Conclusions:** Among long-term survivors of pediatric cancer, increasing CRT dose is associated with increased risk for CVD in a dose-response relationship. Young children are at higher risk for CVD after low-dose CRT or high-dose anthracycline exposure. Cisplatin exposure significantly increases risk for CVD. These findings should inform future treatment and surveillance protocols.

10502 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

A high-risk genetic profile for premature menopause (PM) in childhood cancer survivors (CCS) exposed to gonadotoxic therapy: A report from the St. Jude Lifetime Cohort (SJLIFE) and Childhood Cancer Survivor Study (CCSS). *First Author: Russell J Brooke, St. Jude Children's Research Hospital, Memphis, TN*

Background: CCS are at increased risk of therapy-related PM but contribution of genetic factors is unknown. **Methods:** Using Affymetrix 6.0 SNP array, treatment exposures [cumulative alkylating agents (AA), ovarian radiotherapy (RT) dose] and clinically-assessed PM status (menopause < 40 years), a genome-wide association analysis was conducted using logistic regression in SJLIFE. A cluster of most statistically significant SNPs on chr4 was further examined, stratifying by ovarian RT and AA. Replication was performed using self-reported PM in CCSS. **Results:** PM was diagnosed in 30 of 805 SJLIFE female survivors. A loci of 13 SNPs in 4 linkage disequilibrium blocks (mean $r^2 = 0.51$) in the upstream regulatory region of Neuropeptide Receptor 2 (*NPY2R*) was identified with a minimum p-value of 3.3×10^{-7} (all $< 10^{-5}$). ENCODE gene expression, motifs, and chromatin remodeling data suggest these SNPs alter transcription factor binding sites, potentially disrupting neuroendocrine events necessary for ovulation. Among CCS exposed to ovarian RT, homozygous carriers of a risk profile (RP) defined by 4 of the 13 SNPs, found in over half of the survivors with clinically-diagnosed PM and 1 in 7 in the general population, significantly increased PM risk (odds ratio (OR) 25.8, $p = 5.4 \times 10^{-5}$) (Table). This finding was replicated using self-reported PM status of 1644 survivors in CCSS (OR 4.2, $p = 4.6 \times 10^{-4}$). Prediction of clinically-diagnosed PM (in the SJLIFE discovery cohort) improved by adding the RP to the model with age and treatment (area under ROC curve 0.84 vs. 0.93, p=0.011). **Conclusions:** The common RP is associated with PM risk in pediatric cancer survivors and may have potential for clinical application.

SJLIFE discovery and CCSS replication.

Treatment		SJLIFE			CCSS		
Ovarian RT	AA≥8 g/m^2	N (Clinically-diagnosed PM %)	RP OR (95% CI)	Exact P-value	N (Self-reported PM %)	RP OR (95% CI)	Wald P-value

Molecular alterations to predict survival and response to chemotherapy of pediatric low-grade glioma. *First Author: Michal Zapotocky, The Hospital for Sick Children, Toronto, ON, Canada*

Background: RAS/MAPK pathway mutations have been identified as the major drivers of pediatric low-grade glioma (pLGG). The impact of these alterations on outcome and response to therapy is still unknown. **Methods:** We performed a large population based study of all pLGG diagnosed from 1985-2015. Detailed treatment and very long term outcome data was collected on all patients. Known pLGG-related alterations were detected using NanoString and QX200™Droplet Digital™PCR. Molecular data was correlated with outcome and response to chemotherapy. **Results:** In our cohort of 614 patients, BRAF was found to be altered in 57% and wild-type (WT) in 43% of patients without neurofibromatosis 1 (NF1). Among BRAF-WT we identified H3.3K27M, FGFR1-TACC1, MYBL1 and other alterations. Molecular alterations stratified pLGG into several risk groups. Ten-year progression free survival (PFS) was 72.3% for NF1, 69.5% for KIAA1549-BRAF, 53.5% for BRAF-WT, 30.3% for BRAF-V600E and 0% for H3.3K27M mutations ($p < 0.0001$). Similarly, overall survival (OS) at 10 years delineated difference between excellent survival of KIAA1549-BRAF and NF1 compared to BRAF-V600E and BRAF-WT ($p = 0.0005$). Interestingly, all patients with FGFR1-TACC1 and MYBL1 were alive despite observed progressions. Strikingly, response to chemotherapy determined by changes in tumor size at 6 months of therapy correlated with pLGG alteration. Objective response to first line chemotherapy was observed in 46% of patients with KIAA1549-BRAF and 35% of NF1. In contrast, only 15% BRAF-V600E and 18% BRAF-WT responded and 41% tumors grew after six months of chemotherapy. Moreover, 5-year PFS after chemotherapy was strikingly low for BRAF-V600E and BRAF-WT (25% and 31.9% respectively) compared to KIAA1549-BRAF (50%) and NF1 (76.7%) ($p = 0.001$). This translated to decreased OS for BRAFV600E and BRAF-WT patients ($p = 0.042$). **Conclusions:** Our study provides evidence that molecular alterations dictate the outcome of pLGG. KIAA1549-BRAF harbors excellent prognosis and choice of therapy should be made in favor of less toxic agents to minimize deleterious late effects. In contrast, poor prognosis is associated with lack of response to chemotherapy in BRAF-V600E and BRAF-WT tumors.

10504 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

A phase II prospective study of selumetinib in children with recurrent or refractory low-grade glioma (LGG): A Pediatric Brain Tumor Consortium (PBTC) study. *First Author: Jason R. Fangusaro, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Background: A greater understanding of the Ras-MAP kinase-signaling pathway in pediatric low-grade glioma (LGG) paired with the availability of potent selective inhibitors has enhanced the ability to target this pathway with therapeutic intent. **Methods:** The PBTC conducted a multi-institutional phase II study (NCT01089101) evaluating selumetinib (AZD6244, ARRY-142886), a MEK I/II inhibitor, in children with recurrent/refractory LGG assigned to 6 strata and treated at 25 mg/m^2/dose PO BID for up to two years. Here we present the data from three of these strata. The remaining strata are still accruing patients. **Results:** Stratum I included children with non-NF-1 and non-optic pathway recurrent/refractory pilocytic astrocytoma (PA) harboring BRAF aberrations (BRAF V600e mutation or the BRAF-KIAA 1549 fusion). Eight of 25 (32%) patients achieved a partial response (PR) with 2-year PFS of 66+/-11%. Two of 7 (29%) patient tumors with a BRAF V600e mutation and 6/18 (33%) with a BRAF KIAA-1549 fusion had a PR. Stratum 3 enrolled NF-1-associated LGG. Tissue for tumor BRAF evaluation was not required for eligibility. Ten of 25 (40%) achieved PR with a 2-year PFS of 96+/-4%. Only one patient progressed while on treatment. Stratum 4 included children with non-NF-1 optic pathway/hypothalamic LGG. Tissue for tumor BRAF evaluation was not required for eligibility. Two of 16 (12.5%) had a PR with a 2-year PFS of 65+/-13%. The BRAF aberration status of the responders in strata 3 and 4 is mostly unknown. All responses were confirmed centrally and seven patients remain on treatment. The most common toxicities were grade 1/2 CPK elevation, diarrhea, hypoalbuminemia, elevated AST and rash. Rare grade 3/4 toxicities included elevated CPK, rash, neutropenia, emesis and paronychia. **Conclusions:** Selumetinib was effective in treating children with recurrent/refractory LGG, including those with NF-1 associated LGG and PA harboring BRAF V600e mutation or BRAF-KIAA 1549 fusion. Larger prospective studies are necessary to determine the future, specific role of this agent in treating children with LGG harboring specific molecular aberrations. Clinical trial information: NCT01089101.

10505 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

ACNS1221: A phase II study for the treatment of non metastatic desmoplastic medulloblastoma in children less than 4 years of age—A report from the Children Oncology Group. *First Author: Lucie Lafay-Cousin, Alberta Children's Hospital, Calgary, AB, Canada*

Background: Nodular desmoplastic medulloblastoma and medulloblastoma with extensive nodularity (ND/MBEN) have been associated with a more favorable outcome in younger children. However, treatment-related neurotoxicity remains a significant concern in this vulnerable group of patients. **Methods:** We prospectively conducted a single-arm multicenter trial of conventional chemotherapy for non-metastatic ND/MBEN, based on a modified HIT SKK2000 regimen excluding the use of intraventricular methotrexate (MTX) injection, with the aim to achieve a similar outcome with reduced treatment related neurotoxicity. The design required 37 patients and targeted a 2-year PFS of $\geq$ 90%. Secondary objectives included evaluation of feasibility of timely central pathology review, prospective evaluation of the cohort's molecular profile and neurocognitive outcomes. **Results:** Between 12/2013 and 07/2016, 26 patients were enrolled, including 16 males and 10 females, diagnosed at a median age of 19.7 months (7.1-42.9 months). Four patients had residual disease at baseline. There were 19 ND and 7 MBEN medulloblastoma, confirmed by central pathology review. All cases were reviewed within 10 days by at least 2 of the 3 neuropathologists. The study was closed early following interim analysis due to a higher than expected relapse rate. At last follow-up, 7 patients had relapsed (3 local, 2 distant and 2 combined) at a median time of 9.7 months from diagnosis (range, 9.5-13.7 months). One patient subsequently died of disease. The current median follow-up for the 25 survivors is 1 year (range, 0.2-1.9 years) and the 1 year PFS rate is 66.2% (SE 12.2%). Based on the currently available information, older age ($p = 0.07$) and ND histology ($p = 0.009$) appear to be associated with worse PFS. To date none of the patients with MBEN histology have relapsed. **Conclusions:** The proposed modified regimen of chemotherapy without intraventricular MTX failed to achieve the desirable 2 y PFS of 90%, leading to premature closure of the study. Ongoing molecular characterization of the cohort may help uncover patients who may still benefit from this regimen. Clinical trial information: NCT02017964.

10506 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Intensive multi-modality therapy for extra-ocular retinoblastoma (RB): A Children's Oncology Group (COG) trial (ARET0321). *First Author: Ira J. Dunkel, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Metastatic RB is associated with a poor prognosis. Previous small series suggested that intensified systemic chemotherapy with or without radiation therapy (RT) may improve outcomes in this population. COG opened this prospective, multi-institutional, international trial to study the effectiveness of this approach. **Methods:** Patients with regional extra-ocular RB (stage 2 or 3) were treated with 4 cycles of intensive conventional chemotherapy (vincristine 0.05 mg/kg/day, cisplatin 3.5 mg/kg/day, cyclophosphamide 65 mg/kg x 2 days, etoposide 4 mg/kg x 2 days) followed by involved-field RT (4500 cGy). Two strata of patients with metastatic RB [stage 4a: distant metastases not involving the central nervous system involvement (CNS); and stage 4b (CNS metastases)/trilateral RB)] were treated with 4 cycles of the same chemotherapy. Patients with $\geq$ partial response then received 1 cycle of high-dose carboplatin (Calvert formula with AUC = 7/day, maximum 16.7 mg/kg/day) on days -8 to -6, thiotepa (10 mg/kg/day), & etoposide (8.3 mg/kg/day) on days -5 to -3 with autologous hematopoietic stem cell rescue on day 0. Patients with metastatic RB who did not achieve an adequate response to chemotherapy also received RT. **Results:** Sixty subjects (20 in each stratum) were enrolled; 57 were eligible and included in the analyses (based on data current to June 30, 2016). Toxicity was significant as expected and there were 2 therapy related deaths. Event-free survival (EFS) at 36 months was 87.7% (90% CI 65.4 to 96.0%) for subjects with stage 2 or 3 disease, 79.3% (90% CI 54.2 to 91.6%) for subjects with stage 4a disease and 8.0% (90% CI 1.0 to 25.1%) for subjects with stage 4b/trilateral disease. The observed results significantly improved the EFS in each stratum compared with historical results used for planning the study. **Conclusions:** This is the first prospective, multi-institutional, international study to show that intensive multi-modality therapy is highly effective for patients with regional extra-ocular RB and metastatic RB not involving the CNS. More effective therapy is required for patients with CNS RB. Clinical trial information: NCT00554788.

10507 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Effect of chimeric antigen receptor-modified T (CAR-T) cells on responses in children with non-CNS extramedullary relapse of CD19+ acute lymphoblastic leukemia (ALL). *First Author: Mala Kiran Talekar, Cancer Immunotherapy Program, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Anti-CD19 CAR-T cell therapies have shown high efficacy in inducing durable marrow responses in patients with relapsed/refractory CD19+ ALL. We now report on outcome of 10 patients with extramedullary (EM) involvement of ALL treated with CAR-T, including 5 patients who had EM disease at time of infusion. **Methods:** We identified patients treated on pediatric phase 1/2a trials of murine (CTL019) or humanized (CTL119) anti-CD19 CAR-T cells for isolated EM or BM/EM relapse of ALL. EM relapse was defined as involvement of non-CNS site by imaging +/- pathology within 12 months (mos) of infusion. Post infusion, patients had diagnostic imaging done at 1, 3, 6, 9, and 12 mos. **Results:** Among 97 patients receiving CAR-T, ten (CTL019, n=6; CTL119, n=4) were identified who had EM involvement on average 2.3 mos (range 0-9 mos) prior to infusion; including 5/10 at time of infusion. Sites of EM relapses included testes, sinus, parotid, bone, uterus, kidney and skin, and 5 patients had multiple sites of EM involvement. Patients ranged from 2-4 relapses of their ALL pre-CAR-T. Two had isolated EM relapse (sites were parotid and multifocal bony lesions in one; testis and sinus in second). All 10 patients had undergone hematopoietic stem cell transplantation prior to EM relapse, 2 had received radiation directed to the EM site prior to CAR-T. Five patients evaluated by serial imaging had objective responses: 2 had resolution of EM disease by day 28; 2 had resolution by 3 mos; 1 had continued decrease in size of uterine mass at 3 and 6 mos and underwent hysterectomy at 8 mos with no evidence of disease on pathology. In the 4 patients with prior history of skin or testicular involvement, there was no evidence by exam at day 28. One patient had progressive EM disease within 2 weeks of CAR-T cell infusion and died at 6 weeks. Three relapsed with CD19+ disease [1 skin/medullary- died at 38 mos post CAR-T; 2 medullary (1 died at 17 mos, 1 alive at 28 mos)]. The remaining 6 are alive and well at median follow-up of 10 mos (range 3-16 mos) without recurrence of disease. **Conclusions:** Single agent CAR-T immunotherapy can induce potent and durable responses in patients with EM relapse of their ALL. Clinical trial information: NCT01626495, NCT02374333.

10508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Expansion of HER2-CAR T cells after lymphodepletion and clinical responses in patients with advanced sarcoma. *First Author: Meenakshi Hegde, Texas Children's Cancer Center, Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX*

Background: Outcome for patients with advanced sarcoma is extremely poor and treatment options are limited. Encouragingly, in our phase 1 dose-escalation trial (Ahmed et al, JCO 2015), systemic administration of up to $1x10^8/m^2$ autologous HER2-CAR T cells in patient with HER2+ sarcoma was safe. While T cells did not expand, 4/19 evaluable patients are alive 37-61 months post infusion without evidence of disease. The goal of this study was to evaluate if lympohodepleting chemotherapy can safely induce the expansion of HER2-CAR T cells. **Methods:** In a phase 1 clinical study, NCT00902044, we administered $1x10^8/m^2$ autologous HER2-CAR (with a CD28.zeta signaling domain) T cells to patients with refractory/metastatic HER2+ sarcoma after lymphodepletion. **Results:** Six patients with refractory/metastatic HER2+ sarcoma (4 osteosarcoma, 1 rhabdomyosarcoma, 1 synovial sarcoma) with a median age of 16 (range: 4 to 55) received up to 3 infusions of $1x10^8$ cells/m^2 CAR T cells after lymphodepletion with either fludarabine (Flu; n = 3) or Flu and cyclophosphamide (Flu/Cy; n = 3). Flu and Flu/Cy induced lymphopenia with an absolute lymphocyte count (ALC) of $<$ 100/ml at the day of the T-cell infusion. Only Flu/Cy induced neutropenia (absolute neutrophil count [ANC] $<$ 500/ml) for up to 14 days. 4/6 patients developed grade 1-2 cytokine release syndrome (CRS) within 24 hours of CAR T-cell infusion that resolved completely with supportive care within 3 days of onset. T cells expanded in 5/6 patients (median 89-fold (range: 41 to 2,893) with a median peak expansion on day 7 (range: 5 to 28). CAR T cells could be detected by qPCR in 6/6 patients at 6 weeks post infusion. One patient with rhabdomyosarcoma metastatic to the bone marrow had a complete responses (CR), 2 had stable disease (SD), and 3 had progressive disease (PD). Two patients are alive with a median overall survival of 14.2 months. **Conclusions:** Infusion of autologous HER2-CAR T cells after lymphodepletion is safe, and can be associated with objective clinical benefit in patients with advanced HER2+ sarcoma. These findings warrant further evaluation in a phase 2b study as a single agent or in combination with other approaches. Clinical trial information: NCT00902044.

10509 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

The INFORM personalized medicine study for high-risk pediatric cancer patients. *First Author: Barbara Christine Worst, German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: Relapses from high-risk tumors pose a major clinical challenge in pediatric oncology. The German INFORM registry (INdividualized therapy FOr Relapsed Malignancies in children) addresses this problem using integrated next-generation sequencing to rapidly identify patient-specific therapeutic targets. **Methods:** Whole-exome, low-coverage whole-genome and RNA sequencing is complemented with microarray-based DNA methylation profiling. Identified alterations are discussed and prioritized according to biological significance and potential druggability in a weekly molecular tumor board. **Results:** To date, 214 tumor samples of high-risk pediatric cancer patients have been profiled from 47 German centers, with 39% being sarcomas, 30% brain tumors, 13% neuroblastoma and 18% hematological or other malignancies. Turnaround time from tissue arrival to molecular results was 21 calendar days on average. In 14/214 patients (7%) we identified an underlying germline predisposition syndrome. In several cases there were discrepancies between the original histological diagnosis and our molecular findings, especially in brain tumors. We detected one or more potentially druggable alterations in 147/214 (69%) cases. Tyrosine kinases, the PI3K/mTOR pathway, MAPK pathway, and cell-cycle as well as transcriptional regulators were commonly affected. Based on these findings, targeted therapeutics were incorporated into the therapy regime in one-third of patients, with anecdotal reports of marked responses, including a patient with a pleomorphic sarcoma, where we detected a previously undescribed RAF-fusion, showing a partial remission upon RAF-inhibition. **Conclusions:** In summary, real-time comprehensive profiling of pediatric tumors provides valuable diagnostic information and identifies potential therapeutic targets. In parallel, the implementation of a systematic program for reverse-translational evaluation is ongoing. Recently, this nationwide effort has expanded to include patients from other countries. We will also recruit patients to the complementary eSMART and INFORM2 biomarker-driven, phase I/II combination trial series, to provide unprecedented access to targeted therapies in Europe.

10510 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A pediatric phase I study of larotrectinib, a highly selective inhibitor of the tropomyosin receptor kinase (TRK) family. *First Author: Theodore Willis Laetsch, The University of Texas Southwestern, Children's Health, Dallas, TX*

Background: Larotrectinib is the first selective small-molecule inhibitor of TRKA, B, and C in clinical development. Data from the adult phase I trial demonstrate prolonged responses in patients (pts) with TRK fusions and a favorable tolerability profile. **Methods:** This multicenter, rolling 6 phase I study enrolled pts with refractory solid or CNS tumors aged $\geq$ 1 month – 21 years. Pts were dosed orally BID on a continuous 28-day schedule either by capsule or solution. Pharmacokinetic (PK)-directed intra-subject dose escalation was permitted, with exposures targeting the adult recommended Phase II dose (RP2D) of 100 mg BID. The primary objective was to define the MTD / RP2D; secondary objectives included PK and efficacy using RECIST v1.1. **Results:** As of December 31, 2016, 17 pts (12 with TRK fusions, 5 without TRK fusions) with a median age of 5.2 years (0.4 – 18.3) were enrolled to 3 dose levels. Pts were enrolled with fusions of all 3 NTRK genes: *NTRK1* (n=6), *NTRK2* (n=1), and *NTRK3* (n=5) in heterogeneous tumor diagnoses: infantile fibrosarcoma (IFS) (n=6), other sarcoma (n=4), and papillary thyroid cancer (n=2). Most common AEs regardless of attribution were vomiting, diarrhea, and fatigue. While 8 (47%) pts experienced grade 3-4 AEs, none were attributed to larotrectinib. No DLTs were observed and an MTD was not established. Both formulations delivered dose-dependent PK comparable to the adult RP2D at dose level 3. 12 pts (10 with TRK fusions, 2 without TRK fusions) remain on treatment with median follow-up of 2.8 months (0.7 – 8.4). Among TRK fusion pts, the vast majority have achieved confirmed RECIST responses regardless of tumor diagnoses. No responses were seen in pts without TRK fusions (n=4). 5 pts discontinued therapy, including 2 with TRK fusions: 1 pt with IFS had sufficient response to allow tumor resection, and 1 pt with IFS progressed with a documented acquired resistance mutation. **Conclusions:** Larotrectinib has demonstrated a favorable tolerability profile and histology-independent efficacy in pediatric pts harboring TRK fusions. Updated safety and efficacy data will be presented, including the RP2D, response rate, duration of response, and use of larotrectinib in the pre-surgical setting. Clinical trial information: NCT02637687.

10511 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase II trial of dasatinib (DAS) in pediatric patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP). *First Author: Lia Gore, University of Colorado School of Medicine/Children's Hospital Colorado, Aurora, CO*

Background: Safe and effective treatment options for newly diagnosed (ND) or imatinib (IM) resistant/intolerant (R/I) pediatric CML pts are limited, and a large prospective study is needed. DAS has proven safety and efficacy in adults with ND or IM-R/I CML and is now being evaluated in a phase II trial of pediatric pts. **Methods:** CA180-226/NCT00777036 is an open-label nonrandomized prospective study of pts aged $<$18 y in 3 cohorts: (1) CML-CP R/I to IM treated with DAS tablets 60 mg/m^2 QD, (2) IM-R/I CML-AP/BP or Ph+ ALL (enrollment closed early due to poor response), and (3) ND CML-CP treated with DAS tablets 60 mg/m^2 or DAS 72 mg/m^2powder for oral suspension (PFOS) QD. Primary objectives were major cytogenetic response (MCyR) for CML-CP R/I to IM and complete cytogenetic response (CCyR) for ND CML-CP (MCyR $>$30% and CCyR $>$55% considered of clinical interest). **Results:** 113 pediatric CML-CP pts were treated. Cumulative rate of MCyR $>$30% was reached as early as 3 mo (55%; [95% CI 36, 74]) for IM-R/I CML-CP. Cumulative rate of CCyR $>$55% was reached as early as 6 mo (64% [95% CI 53, 74] for ND CML-CP; 61% [95% CI 46, 74] for pts on tablets and 70% [95% CI 51, 84] for pts on PFOS). Estimated PFS by 48 mo was $>$75% for CML-CP R/I to IM and $>$90% for ND CML-CP. One CML-CP pt R/I to IM died 1 y after stopping DAS from gastrointestinal bleeding. AEs were consistent with those observed in adults, except no DAS-related pleural/pericardial effusion or pulmonary arterial hypertension (PAH) were reported here. **Conclusions:** In the largest prospective trial of pediatric pts with CML-CP, target responses were met early and increased over time with DAS treatment. The efficacy and safety of DAS were consistent with previous reports in adults, except no cases of pleural/pericardial effusion or PAH were observed. These results suggest DAS is safe and highly effective in the first- or second-line treatment of pediatric CML-CP. Clinical trial information: NCT00777036.

10512 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Inotuzumab ozogamicin in pediatric patients with relapsed/refractory acute lymphoblastic leukemia (R/R ALL). *First Author: Deepa Bhojwani, Children's Hospital Los Angeles, Los Angeles, CA*

Background: Inotuzumab ozogamicin (InO), a CD22-targeting antibody linked to calicheamicin demonstrated exceptional activity in R/R ALL in adults. InO has been available to pediatric patients with R/R ALL via a compassionate access program. **Methods:** Participating international pediatric oncology centers received IRB approval to submit retrospective demographic, outcome and toxicity data on pediatric patients who received at least one dose of InO. **Results:** Thirty-four patients, age 2.3-21.4 yrs (median 11.7) received 1-4 cycles (3 weekly doses) of InO. Patients were heavily pretreated in 1^{st}-5^{th}relapse; 28 were refractory to their preceding regimen. Thirteen patients had prior hematopoietic stem cell transplant (HSCT), 27 received prior CD19 and 8 prior CD22-directed therapy. Pre-InO disease was M3 (> 25% blasts) in 26 patients, M2 (5-25%) in 3, and MRD only in 5 (1 with extramedullary disease). Of 29 patients with M2/M3 disease at baseline, 18 (62%) achieved a complete remission (CR), 13 of whom were MRD negative. Post-InO, 15 patients proceeded to HSCT and 5 to CAR T-cell therapy. Alterations in CD22 expression at subsequent relapse were noted in two patients with available blasts samples. No deaths were attributed to InO during therapy. The incidence of grade 3/4 infections was 38% and were of the expected types. Grade 1-4 hepatic toxicity was noted in 11/34 (32%) patients, primarily asymptomatic elevations in transaminases/bilirubin. There was no sinusoidal obstruction syndrome (SOS) during InO therapy but 8/15 patients who received HSCT post-InO developed SOS. One patient died from SOS, but the others recovered. The incidence of SOS was higher in patients who had undergone prior HSCT (6/8) versus no prior HSCT (2/7). SIRS (1), neurotoxicity (2) and hemorrhage (3) were infrequent. Three patients had musculoskeletal pain associated with edema. **Conclusions:** Single agent InO had a CR rate of 62% in heavily pretreated pediatric patients. Toxicities were similar to adults with hepatic and infectious toxicity being the most common. Overall InO was well tolerated, but the incidence of SOS was high in patients who underwent HSCT post-InO, particularly in those who had undergone a prior HSCT.

10513 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Efficacy and safety of defibrotide (DF) to treat hepatic veno-occlusive disease/ sinusoidal obstruction syndrome (VOD/SOS) after primary chemotherapy (CT): A post hoc analysis of final data. *First Author: Nancy A. Kernan, Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. DF is approved to treat hepatic VOD/ SOS with renal or pulmonary dysfunction post-HSCT in the US and to treat severe hepatic VOD/SOS post-HSCT in the EU. However, VOD/SOS can occur after CT without HSCT. **Methods:** In an expanded-access protocol for patients (pts) with VOD/SOS post-HSCT or CT, with/without MOD (renal/pulmonary), DF 25 mg/kg/d (6.25 mg/kg q6h) was given a recommended ≥21 days. Post-CT subgroup survival was analyzed post hoc from the day DF was started (days 0–30 after start of CT) for 70 days (ie, up to 100 days, as follow-up was collected for 100 days post-CT). **Results:** Of 1154 VOD/SOS pts receiving DF, 137 (12%) developed VOD/SOS post-CT without HSCT. Among 82 pts (38 with MOD) treated by day 30 after start of CT, median age was 7.5 yrs (range, 0–68 years) and 66 (81%) were ≤16 yrs. Most common primary diseases were acute leukemias (65%). Kaplan-Meier estimated survival at day +70 was 74% overall (95% CI, 63–82%); 66% (49–79%) and 81% (66–90%) in pts with/ without MOD, respectively. In the pediatric pts, estimated survival at day +70 was 80% (68–88%); in adult pts, 50% (25–71%). Adverse events (AEs) were reported in 54/82 pts (66%); 22 (27%) had AEs assessed as possibly related to DF, most commonly (≥2%) pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Hemorrhagic AEs of any relatedness (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). Related AEs led to discontinuation in 6 pts and were associated with 1 death (pulmonary hemorrhage, hypotension). **Conclusions:** The 74% survival rate at day +70 in pts with VOD/SOS receiving DF within 30 days of starting CT (80% in pts ≤16 yrs) is clinically encouraging. Of note is the 66% survival rate in pts with MOD. The safety profile was consistent with that previously reported in the overall population of this protocol. Support: Jazz Pharmaceuticals Clinical trial information: NCT00628498.

10514 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Measuring mercaptopurine (6MP) adherence using red cell 6MP metabolite levels in children with acute lymphoblastic leukemia (ALL): A COG AALL03N1 study. *First Author: Anna Lynn Hoppmann, University of Alabama at Birmingham, Birmingham, AL*

Background: Non-adherence to 6MP (monitored with medication event monitoring system [MEMs]) is associated with an increased risk of relapse in children with ALL.(JAMA Oncol, 2015) Self-report over-estimates true medication intake, particularly in non-adherent patients.(Blood, 2017) However, monitoring adherence using MEMs is logistically difficult. We investigated whether red cell 6MP metabolite levels (thioguanine nucleotide [TGN] and methylated mercaptopurine [MMP]) taken together, could identify non-adherent patients. **Methods:** The analysis included children with ALL in maintenance. To minimize variability in TGN and MMP levels due to pharmacogenetics, we excluded *TPMT* heterozygotes and homozygote mutants. We also excluded Asians to remove variability due to *NUDT15*. TGN and MMP levels were drawn at 6 consecutive monthly time points for each patient and averaged. TGN and MMP levels (pmol/8 x 10^8red cells) were standardized, adjusted for 6MP dose intensity, and then analyzed using cluster analysis (Spath, H. [1980]). **Results:** The 373 patients eligible for analysis yielded 5 clusters. Cluster #1 (n = 119; mean MMP: 15,656; mean TGN: 158); Cluster #2 (n = 211; MMP: 6,042; TGN: 135); and 3 very small outlying clusters (total N = 43). Adjusting for age, sex, race/ethnicity, cytogenetics and NCI risk, we found that patients in Cluster #2 were 2.6 times as likely to be non-adherent (MEMs-based adherence < 95%) compared to Cluster #1 (95% CI 1.5-4.4; *P*= 0.0007). Mean MEMs-based adherence was significantly higher for patients in Cluster #1 (94.3%) when compared to those in Cluster #2 (87.8%, p = 0.0002). Using Fine-Gray proportional subdistribution hazards models for competing risks and adjusting for clinical and sociodemographic factors, we found that patients in Cluster #2 were at a 2.3-fold higher risk of relapse compared with those in Cluster #1 (95%CI, 1.0-6.4, p = 0.058). **Conclusions:** These findings illustrate the potential for using a combination of red cell TGN and MMP levels in identifying non-adherent patients. We propose to use these and clinical and demographic factors associated with non-adherence in creating an adherence calculator.

10515 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Four versus five chemotherapy courses in patients with low risk acute myeloid leukemia: A Children's Oncology Group report. *First Author: Kelly D. Getz, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: For pediatric patients with low risk (LR) acute myeloid leukemia (AML), the Children's Oncology Group (COG) trial AAML1031 used a 4-course chemotherapy backbone consisting of two induction courses of cytarabine/ daunorubicin/etoposide, a third course of cytarabine/etoposide and a fourth course of cytarabine/mitoxantrone. The prior COG trial, AAML0531, included the same four courses plus a fifth course of high dose cytarabine. Removal of course 5 from AAML1031 was based in part on prior studies that suggested no benefit from a fifth course. **Methods:** We compared overall survival (OS), disease free survival (DFS), and relapse risk (RR) for LR patients receiving four versus five chemotherapy courses in a pooled analysis of comparable patients treated on AAML0531 and AAML1031. LR was defined as the presence of inv (16)/t(16;16) or t(8;21) cytogenetic features, NPM1 or CEBPA mutations, or MRD < 0.1% post-Induction I in those with no high risk features. AAML0531 patients assigned to gemotuzumab were excluded. Follow-up for outcomes began at the start of course 4. Cox (OS and EFS) and risk (RR) regressions were used to estimate unadjusted hazard ratios (HR) comparing outcomes for patients who received only four versus five chemotherapy courses. Start of a fifth chemotherapy course was assessed as a time-varying exposure in all analyses to avoid exposure misclassification. **Results:** A total of 921 LR patients (225 from AAML0531, 696 from AAML1031) were included; 191 (21%) received a fifth course. There were no significant differences in distributions of sex, age, race, or ethnicity between patients treated with four or five courses. Median times to absolute neutrophil count and platelet count recovery after course 4 were also comparable. Patients who received only four courses had significantly lower OS (HR = 1.83, 95% CI: 1.22-2.74, p = 0.003), DSF (HR = 1.49, 95% CI: 1.13-1.97, p = 0.005), and higher RR (HR = 1.42, 95% CI: 1.08-1.88, p = 0.013) compared to those who received five courses. **Conclusions:** Removal of a fifth cytarabine-containing course appears to result in worse OS, DFS, and RR in pediatric patients with LR AML. Multivariable analyses to further refine the estimates are ongoing.

10516 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Temporal trends in late-onset morbidity and mortality after medulloblastoma diagnosed across three decades: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Ralph Salloum, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Therapy for medulloblastoma and primitive neuroectodermal tumor has evolved from surgery and adjuvant radiotherapy to risk-adapted multimodal regimens. The impact of these changes in treatment on long-term outcomes remains unknown. **Methods:** Cumulative incidence of late mortality (> 5 years from diagnosis), subsequent malignant neoplasms (SMN), chronic health conditions and psychosocial functioning were evaluated among 5-year survivors in CCSS diagnosed between 1970 and 1999. Survivors were stratified according to treatment decade (1970s, 1980s, 1990s) and treatment exposure (surgery + craniospinal irradiation [CSI] ≥30 Gy, no chemotherapy; surgery + CSI ≥30 Gy + chemotherapy [high-risk therapy], surgery + CSI ˂30 Gy + chemotherapy [standard-risk therapy]). Rate ratios (RRs), odds ratios (ORs) and 95% confidence intervals (CIs) were estimated for long-term outcomes among treatment eras and exposure groups using multivariable piecewise-exponential models. **Results:** Among 1,380 eligible survivors (median [range] age 29 [6-20] years; 21.4 [5-44] years from diagnosis), the 15-year cumulative incidence of all-cause (21.9% 1970s vs. 12.8% 1990s; p = 0.003) and recurrence-related (16.2% vs 9.6%, p = 0.03) late mortality decreased with no reduction in mortality attributable to late effects of therapy including SMN. Among 959 participants, the incidence of SMN did not decrease by era or by treatment group. However, survivors treated in the 1990s had an increased cumulative incidence of severe, life-threatening and fatal health conditions (16.9% 1970s vs 25.4% 1990s; p = 0.03), and were more likely to develop multiple severe or life-threatening health conditions, RR = 2.98 (95% CI, 1.10-8.07). Survivors of standard-risk therapy were less likely to use special education services than high-risk therapy patients, OR = 0.51 (95% CI, 0.33-0.78). **Conclusions:** Historical changes in therapy have improved 5-year survival, reduced risk of late mortality due to disease recurrence, and reduced special education utilization, at the cost of increased risk for multiple, severe and life-threatening chronic health conditions.

10517 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Subcortical brain volumes and neurocognitive function in survivors of childhood acute lymphoblastic leukemia (ALL) treated with chemotherapy-only. *First Author: Nicholas Steve Phillips, St. Jude Children's Research Hospital, Memphis, TN*

Background: Brain deep grey nuclei and glucocorticoid receptor rich hippocampal subregions may be sensitive to neurotoxic effects of chemotherapy-only protocols for childhood ALL and associated with neurocognitive problems in long-term survivors. **Methods:** Brain MRIs and neurocognitive tests were obtained on 176 survivors (49% male, mean [range] age at diagnosis 6.8 [1-18] years, 14.5 [8-27] years at evaluation). MRI's were also obtained on 82 healthy community controls (57% male, 13.8 [8-26] years at evaluation). General linear models were used to compare subcortical brain volumes between survivors and controls. Among survivors, gender stratified multivariable linear models were used to test associations between subcortical volumes, and serum concentration of dexamethasone (DEX) and high-dose methotrexate (HDMTX), adjusting for age at diagnosis, and intracranial volume (ICV). Volumes were also compared to neurocognitive tests. **Results:** Survivors had smaller volumes in bilateral thalami (p's < 0.05) and hippocampal subregions (p's < 0.001) compared to controls. After controlling for ICV, HDMTX exposure and younger age at diagnosis were associated with smaller bilateral thalami in male survivors (p's < 0.05). DEX was associated with a smaller right thalamus in males (p = 0.04). Smaller hippocampi in both males and females were associated with younger age at diagnosis (p's < 0.01). Smaller left thalamus was associated with worse verbal fluency scores in all survivors (p's < 0.05). Smaller bilateral thalami and hippocampal subregions in girls were associated with worse processing speed, inhibition and cognitive flexibility; poor memory span correlated with smaller left CA1 and right thalamus volumes (all p's < 0.05). Smaller bilateral thalami and right hippocampal subregions, in girls, correlated with slower processing speed (p's < 0.05). In males, smaller left fimbria volume was correlated with poor attention (p = 0.03). **Conclusions:** ALL survivors have significantly smaller thalamic and hippocampal volumes compared to healthy community controls. In survivors, smaller volumes correlate with worse cognitive performance.

Family history of cardiovascular disease and cardiovascular comorbidities risk in a pediatric cancer population. *First Author: Thomas Patrick Curtin, University of Utah School of Medicine, Salt Lake City, UT*

Background: Survival rates for childhood cancer patients have improved dramatically, but the growing survivor population suffers from increased treatment-related toxicity including high risk for cardiovascular disease (CVD). While the link between chemotherapy and radiation to cardiotoxicity is well established, few studies seek to determine if an underlying familial risk for cardiovascular disease contributes or predicts this risk. The Utah Population Database (UPDB) is a genealogical resource linked to statewide cancer diagnoses and electronic medical data in which family history is objectively determined. **Methods:** We calculated the risk of subsequent CVD (ICD-9 401-449) in relatives of 5602 pediatric cancer patients diagnosed at ages 0-19 in Utah from 1966-2013 with no congenital CVD-related anomalies (ICD-9 745-747, 758-759). We identified 964 patients with subsequent CVD diagnoses. Cox models provided recurrence-risk estimates in first-degree relatives of patients compared to relatives of 5:1 matched controls. **Results:** Pediatric cancer patients were at 5-fold risk of CVD compared to controls ($P< 10^{-15}$). In pediatric patients with subsequent CVD, first-degree relatives were at 30% increased CVD risk compared to relatives of cancer-free controls (HR = 1.31, 95%CI 1.16-1.47; $P< 10^{-5}$). In pediatric patients without CVD, only parents exhibited slight CVD risk (HR = 1.08, 95%CI 1.03-1.14; $P= 0.002$). In 685,000 individuals with a non-congenital CVD history, pediatric cancers among their first-degree relatives were associated with a similar increased risk of subsequent CVD, compared to pediatric cancers among relatives of controls with no CVD events (HR = 1.39, 95%CI 1.18-1.64, $P< 10^{-4}$). **Conclusions:** The UPDB is powerful for investigating comorbidities in cancer patients and their families without recall bias from self-reported family medical history. A family history of CVD may increase risk of CVD-related comorbidities among pediatric cancer patients by 30-40% beyond that observed in patients without a CVD family history. This finding suggests that in addition to a cancer family history, a CVD-related family history should be assessed in children diagnosed with cancer.

Complete dexrazoxane cardioprotection for cardiac function but incomplete female cardioprotection for cardiac structure in doxorubicin-treated osteosarcoma survivors: Hearts too small for the body. *First Author: Lisa M. Kopp, University of Arizona, Tucson, AZ*

Background: Dexrazoxane is protective for lower-dose doxorubicin (< 300 mg/m^2) cardiotoxicity in childhood cancer, but the effect of dexrazoxane (DXRZ) administered with higher-dose (HD) doxorubicin (DOXO) is unknown. **Methods:** We evaluated patients from Children's Oncology Group trials for localized (P9754) and metastatic (AOST0121) osteosarcoma (OS) who received HD DOXO (375-600 mg/m^2) preceded by DXRZ (10:1 ratio), methotrexate, and cisplatin; some also received ifosfamide alone or ifosfamide/etoposide ± trastuzumab. Cardiotoxicity was identified by echocardiography and by serum N-terminal pro-brain natriuretic peptide (NT-proBNP) concentrations. **Results:** 81 DXRZ -treated OS patients (age at enrollment = 13.7 years; range 3.8 - 23.7 years) had normal left ventricular (LV) systolic function as measured by LV fractional shortening and no heart failure. Female sex and longer follow-up since DOXO were associated with a significantly smaller LV dimension z-score normalized to BSA (μ = -1.20, 95%CI [-1.70, -0.70]). Similarly, in the one-third of patients treated $>$ 81 days after minimal expected treatment (groups equally partitioned by time), significantly thinner LV posterior wall thickness for BSA (μ = -0.57, [-1.05, -0.09]) was found. Interventricular septal wall thickness (μ = -0.84, [-1.2, -0.48]) and LV mass (μ = -0.73, [-1.06, -0.40]) were significantly smaller for BSA than normal for both sexes. For females, these became significantly more abnormal with increasing length of follow-up. Females also showed progressive increases in NT-proBNP. **Conclusions:** DXRZ is cardioprotective for HD DOXO in terms of LV function and heart failure. Females had progressive abnormalities of LV structure, leading to smaller hearts for body size. This was associated with increasing cardiac stress, as measured by NT-proBNP. DXRZ protection was incomplete for HD DOXO effects on LV structure, resulting in higher LV stress and risk for late LV dysfunction. DXRZ should continue to be used in this population, including for females who exhibit more cardiotoxicity than males at specific cumulative DOXO doses.

Risk of subsequent breast cancer after radiotherapy according to hormone-receptor status: A nested case-control study in the Childhood Cancer Survivor Study (CCSS). *First Author: Lindsay M. Morton, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Survivors of childhood cancer have a high absolute risk of subsequent breast cancer after chest-directed radiotherapy; however, it is not known if this risk differs by hormone-receptor status and radiation to the ovaries. **Methods:** We conducted a nested case-control study within the CCSS of 282 five-year survivors of childhood cancer with subsequent breast cancer and 1202 matched controls. Radiation dose to the location of the breast tumor (or corresponding location for controls) and mean dose to the ovaries were estimated from treatment records for each patient. Risk of radiation-related breast cancer was measured with the Excess Odds Ratio per Gray (EOR/Gy) and corresponding 95% confidence interval (CI), derived from conditional logistic regression. **Results:** The median age at subsequent breast cancer diagnosis was 39 years (range 21-58). Although 87% of cases and 70% of controls received radiotherapy, breast doses were higher in cases than controls (61% vs 24% breast dose $>$ 10Gy), whereas ovarian doses were lower (7% vs 13% ovary dose $>$ 5Gy). In the subset of cases (n = 159) with currently available estrogen receptor (ER) status (76% cases ER+, 24% cases ER-), there was a linear dose-response relation with radiation dose to the breast that was similar for ER+ (EOR/Gy = 0.51; 95%CI: 0.19-1.34) and ER- breast tumors (EOR/Gy = 0.41; 95%CI: 0.05-2.88). If the patient received an ovarian dose $>$ 5Gy, this dose-response was significantly reduced for ER+ tumors but not for ER- tumors. **Conclusions:** Preliminary analyses demonstrate that radiation exposure to the breast to treat childhood cancer results in an increased risk of both ER+ and ER- breast cancers. The novel finding that only the risk of ER+ breast cancer is lowered if the ovaries are also exposed is consistent with known differences by hormone receptor status in the biological mechanisms of breast carcinogenesis.

Biomarkers of brain injury and neurologic outcomes in children treated with chemotherapy for acute lymphoblastic leukemia (ALL). *First Author: Yin Ting Cheung, St. Jude Children's Research Hospital, Memphis, TN*

Background: Little is known about neurotoxic mechanisms associated with chemotherapy in children with ALL. Cerebrospinal fluid (CSF) biomarkers of brain injury may provide insight into this process. **Methods:** 235 patients (51% male; mean [SD] age diagnosed 6.8 [4.7] years) treated on a chemotherapy only protocol provided CSF samples following diagnosis and through consolidation. CSF was assayed for biomarkers of myelin degradation (myelin basic protein [MBP]), neuronal damage (nerve growth factor [NGF], total-Tau [T-Tau]) and astrogliosis (glial fibrillary acidic protein [GFAP]). Leukoencephalopathy was evaluated by brain MRI's during therapy. At $\geq$5 years post-diagnosis, 138 (70%) of the 198 still eligible survivors (without relapse and unrelated neurologic injury) completed neurocognitive testing and brain diffusion tensor imaging of white matter integrity at age 13.6 [4.6] years. Log-binomial and general linear models were used to examine whether biomarker changes from baseline through consolidation were related to serum methotrexate exposure, acute leukoencephalopathy, and long-term brain outcomes. **Results:** NGF and T-Tau increased from baseline to consolidation (P's $<$ 0.001), while MBP and GFAP were elevated at baseline and remained so through consolidation. The number of intrathecal injections (methotrexate, hydrocortisone, cytarabine) was positively correlated with NGF increase at consolidation (P= 0.005). Increases in GFAP (RR 1.2; 95% CI [1.0 – 1.4]), MBP (RR 1.1 [1.0 – 1.1]) and T-Tau (RR 1.8 [1.1 – 2.8]) were related to higher risk for acute leukoencephalopathy, and higher diffusivity in frontal lobe white matter at $\geq$5 years post-diagnosis (P's $<$ 0.05). Increase in T-Tau at consolidation was associated with worse long-term sustained attention (P= 0.03), and visual- (P= 0.04) and visual-motor (P= 0.02) processing speed. **Conclusions:** Glial injury, which is evident at diagnosis, may be related to leukemia and methotrexate exposure. Neuronal injury is associated with intrathecal chemotherapy and long-term neurocognitive and brain imaging outcomes. Monitoring CSF biomarkers may be useful in identifying individuals at risk for poor neurological outcomes.

10522 Poster Discussion Session; Unassigned in Poster Discussion Session, Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Longitudinal analysis of quality of life outcomes in children during treatment for acute lymphoblastic leukemia: A report from the Children's Oncology Group (COG) AALL0932. *First Author: Daniel Zheng, Yale School of Medicine, New Haven, CT*

Background: 5-year event-free survival for average-risk acute lymphoblastic leukemia (AR-ALL) in children is ~95%. However, therapy involves multi-agent chemotherapy, frequent hospital visits (duration of therapy is 26 months for girls and 38 months for boys) and painful procedures that can adversely affect quality of life (QOL). **Methods:** AR-ALL patients enrolled on COG AALL0932 were offered participation if $\geq$4 years old at diagnosis with an English-speaking parent. At ~2, 8, 17, 26, and 38 (boys only) months after diagnosis, parents completed the PedsQL4.0 and the Family Assessment Device instruments for QOL (assessing physical and emotional functioning) and family functioning, respectively. The proportions of individuals scoring in the impaired range (i.e. 2 SD below population mean) were calculated at each timepoint. Patterns of impairment over time and potential predictors were examined. **Results:** 594 participants with AR-ALL (48% female, 68% white) were diagnosed at a median age of 5.6 (IQR: 4.6–7.1) years. At 2 months, a significant percentage of participants had impaired scores compared to population norms for physical (36.5 vs. 2.3; 95% CI 32.3-40.8) and emotional functioning (26.2 vs. 2.3; 95% CI 22.5-30.2). Although scores improved over time, elevations persisted at 26 months for physical (11.9 vs. 2.3; 95% CI 8.4-16.1) and emotional (9.8 vs. 2.3; 95% CI 2.0-6.7) functioning. In repeated measures analysis with multivariate modeling, emotional impairment at 2 months (OR 3.7; 95% CI 1.5-7.7) and abnormal family functioning (OR 1.5; 95% CI 1.1-2.1) significantly predicted emotional impairment. QOL outcomes were similar for girls at 26 months and boys at 38 months. **Conclusions:** Many children with AR-ALL experience severe impairment in both physical and emotional functioning that begins early in treatment and persists. Family functioning is a modifiable risk factor that may be targeted for early screening and intervention.

Patient-reported quality of life (QOL) following CTL019 in pediatric and young adult patients (pts) with relapsed/refractory (r/r) b-cell acute lymphoblastic leukemia (B-ALL). *First Author: Andrew Charles Dietz, Children's Center for Cancer and Blood Diseases, Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA*

Background: The global ELIANA trial (NCT02435849) evaluates the efficacy and safety of CTL019, a single infusion of genetically modified autologous chimeric antigen receptor–expressing T cells targeting CD19+ cells in pediatric and young adult r/r B-ALL pts. Analyses show a complete response rate of 82% with or without complete blood count recovery $\leq$ 3 months. A serious adverse event rate of 71% was observed in $\leq$ 8 weeks of infusion, decreasing to 17% at $>$ 8 weeks (Grupp S, et al. *Blood*. 2016;128(22) [abstract 221].). This analysis further evaluates the clinical benefit of CTL019. QOL was assessed before and after CTL019 infusion. **Methods:** Infused pts were 3-23 y/o with CD19+ B-ALL who were chemo refractory, relapsed after allogeneic stem cell transplant (SCT), or otherwise ineligible for SCT. Pts $\geq$ 8 y completed the Pediatric Quality of Life Inventory (PedsQL) and EuroQol EQ-5D at baseline and following CTL019 infusion. Minimal clinically important differences are estimated to be 4.4 and 7 to 10 for PedsQL and EQ-5D, respectively. **Results:** 62 of 81 enrolled pts were infused; 56% had relapsed after SCT with median of 3 prior therapies. At interim analysis, 50 pts were treated $\geq$ 3 months prior to data cutoff and eligible for primary efficacy analysis. A total of 39 pts were $\geq$ 8 y. Mean PedsQL total and EQ-5D VAS scores, respectively, were 58.4 and 69.4 at baseline. Mean changes from baseline for the PedsQL total and EQ VAS scores, respectively, were 13.9 and 13.7 at month 3 and 12.8 and 10.9 at month 6, supporting clinically meaningful improvements in QOL. Similar trends were observed with each PedsQL subscale. With EQ-5D, the proportions of pts reporting problems with mobility, self-care, usual activities, anxiety/depression, or pain/discomfort were notably decreased at months 3 and 6 compared with baseline. **Conclusions:** Clinically meaningful improvements in QOL were observed at 3 and 6 months after CTL019 therapy in pediatric and young adult r/r B-ALL pts, including fewer problems in each EQ-5D domain. These results suggest improved QOL after this one-time immunocellular therapy beyond the period of acute toxicities. Clinical trial information: NCT02435849.

A phase I/II study of atezolizumab in pediatric and young adult patients with refractory/relapsed solid tumors (iMATRIX-Atezolizumab). *First Author: Birgit Geoerger, Gustave Roussy, Villejuif, France*

Background: Atezolizumab targets programmed death-ligand 1 (PD-L1), leading to enhanced anticancer T-cell response. The iMATRIX-Atezolizumab study (phase I/II, multicenter, open-label; NCT02541604) assessed the safety, pharmacokinetics (PK) and preliminary activity of atezolizumab in pediatric/young adult patients with refractory/relapsed solid tumors. **Methods:** Patients aged < 30 years with refractory/relapsed non-central nervous system solid tumors received atezolizumab every 3 weeks until loss of clinical benefit (< 18 years old, 15mg/kg [maximum dose 1200mg]; ≥18 years old, 1200mg). Safety/PK were assessed across tumor types and initial response was assessed by tumor-type cohorts after approximately 10 patients in each cohort had been treated. **Results:** As of July 19 2016, 74 patients (median age 14 years; range 2–29) were enrolled: osteosarcoma, n = 12; Ewing sarcoma, n = 11; neuroblastoma, n = 11; rhabdomyosarcoma (RMS), n = 10; non-RMS soft tissue sarcoma, n = 10; Wilms tumor, n = 6; Hodgkin lymphoma (HL), n = 5; non-HL, n = 1; other tumor types, n = 8. PK data (n = 48) were similar to that in adults (geometric mean C_{min}, μg/mL [cycle 2, day 1, pre-dose]: 53.6 [2– < 6 years old]; 54.1 [6– < 12 years old]; 62.0 [12– < 18 years old]; 68.0 [adult]). Most tumors, except HL, had < 1% (score 0) tumor cell [TC]/tumor-infiltrating immune cell (IC) PD-L1 expression with overall TC/IC-positive expression rates (≥1%, score 1–3) of 7% and 10%, respectively. All available HL samples had ≥5% (score 2–3) TC/IC PD-L1 expression. 67/71 patients who received atezolizumab (median cycles 2; range 1–10) had ≥1 adverse event (AE; mainly immune-related grade 1–2); 17 patients (24%) had treatment-related grade 3–4 AEs. One AE (grade 3 transaminase increase) led to study drug discontinuation. Common AEs were pyrexia (37%), fatigue (34%) and constipation (32%). 2/5 patients with HL had a partial response (PR); the only patient with atypical rhabdoid tumor (RT) had an unconfirmed PR. **Conclusions:** The PK and safety profile of atezolizumab in pediatric and young adult patients is similar to that in adults. Preliminary antitumor activity was seen in HL and RT; new cohorts are planned in RT and atypical teratoid RT. Clinical trial information: NCT02541604.

Phase 1/2 KEYNOTE-051 study of pembrolizumab (pembro) in pediatric patients (pts) with advanced melanoma or a PD-L1$^+$ advanced, relapsed, or refractory solid tumor or lymphoma. *First Author: Birgit Geoerger, Gustave Roussy, Villejuif, France*

Background: In phase 1 of the KEYNOTE-051 study (NCT02332668), the 2 mg/kg Q3W approved adult dose of pembro was also determined to be the pediatric recommended phase 2 dose. In phase 2, presented herein, we further evaluated this dose in pediatric pts with advanced cancer. **Methods:** Children aged 6 mo to < 18 y with advanced melanoma or a PD-L1$^+$ advanced, relapsed or refractory solid tumor or lymphoma, measurable disease per RECIST v1.1, and performance score ≥50 using Lansky Play or Karnofsky scales received pembro 2 mg/kg Q3W for 35 cycles or until confirmed disease progression per immune-related RECIST by investigator review, intolerable toxicity, or pt/investigator decision to discontinue. Tumor imaging was performed every 8 wk for the first 6 mo, then every 12 wk thereafter. AEs were graded by NCI CTCAE v4.0. Key efficacy endpoints were ORR, disease control rate (DCR), and PFS per RECIST v1.1 by investigator and OS. **Results:** Of 369 pts prescreened, 364 were evaluable for PD-L1 expression; of these, 121 (33.2%) were PD-L1$^+$. 66 pts were enrolled; median follow-up was 2.5 mo (range, 0.2-18). As of the data cutoff (Nov 7, 2016), 23 (34.8%) pts were still on treatment. Median age was 13 y (range, 1-17), 77.3% had metastatic disease, and 34.8% had ≥3 prior lines of therapy for recurrent/metastatic disease. Primary diagnoses were non-CNS solid tumors (n = 45), CNS tumors (n = 16), and lymphoma (n = 5). 5 (7.6%) pts had grade 3-4 treatment-related AEs (TRAEs), most commonly neutropenia (n = 2). No treatment-related deaths occurred; 1 pt discontinued for a TRAE (grade 3 AST increased). 1 pt each with Hodgkin lymphoma, adrenocortical carcinoma, mesothelioma, and glioblastoma had partial response for an ORR of 6.1% (95% CI, 1.7-14.8); 7 (10.6%) pts had stable disease for a DCR of 16.7% (95% CI, 8.6-27.9). Median PFS and OS were 1.8 mo and 9.2 mo, respectively; 12-mo PFS was 10.2% and OS was 40.5%. Potential effects of pembro on the developing immune system (eg, T and B cells, vaccinated antibodies) will also be presented. **Conclusions:** Pembro showed low toxicity and warrants further study to determine activity in select pediatric tumors. Enrollment in KEYNOTE-051 is ongoing. Clinical trial information: NCT02332668.

10526 Poster Discussion Session; Unassigned in Poster Discussion Session, Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

ADVL1412: Initial results of a phase I/II study of nivolumab and ipilimumab in pediatric patients with relapsed/refractory solid tumors—A COG study. *First Author: Kara L. Davis, Lucile Packland Childrens Hosptal Stanford University, Stanford, CA*

Background: Checkpoint inhibitors have produced impressive responses in cancer. We report results of a Phase 1 study of nivolumab (nivo) alone and in combination with ipilumumab (ipi) in children with relapsed/refractory solid tumors and activity of nivo in patients with osteosarcoma (OS) and Ewing sarcoma (EWS) treated with the RP2D. **Methods:** Children with relapsed/refractory solid tumors (excluding CNS tumors or metastases) were eligible for Phase I Cohorts A and C. Using a rolling 6 design, Cohort A tested nivo at the adult RP2D, 3mg/kg Q14d (cycle = 28d). Cohort C tested nivo + ipi at 2 dose levels (DLs): DL1 nivo 1mg/kg + ipi 1mg/kg and DL2 nivo 3mg/kg + ipi 1mg/kg Q21d x 4 then nivo alone Q14d. At the RP2Ds, 6 additional patients were enrolled in each cohort for pharmacokinetics (PK). Phase II expansion cohorts enrolled patients with measurable OS (Cohort B2, n = 10) or EWS (Cohort B4, n = 10) respectively to assess activity of the RP2D of single agent nivo. **Results:** Twelve evaluable patients enrolled in Cohort A, none had DLTs. The pediatric RP2D of nivo alone was identified as 3 mg/kg Q14d. Five evaluable patients enrolled in Cohort C:DL1 without DLT, then 12 patients enrolled in Cohort C:DL2 with one DLT within the 21d reporting period (Gr 2 creatinine increase), defining the RP2D of nivo 3mg/kg + ipi 1mg/kg at the schedule above. In 39 patients treated in cohorts A, B2, B4 and C, pleural effusions occurred in 7 with variable attributions to drug, leading to a protocol amendment mandating supportive care and corticosteroids for pleural effusions on study. Common toxicities included anemia, elevated liver enzymes, rash, fatigue, and nausea, generally Grade 1. In Cohort A, nivo C_{max}, $t_{1/2}$ and Cl_pvalues were 63.2±15.7 mg/mL, 10.7±1.8 d and 0.196±0.075 ml/h/kg, respectively. In the Phase II expansion cohorts, no objective responses were observed in OS or EWS. **Conclusions:** Nivo alone or with ipi at the doses tested is safe in pediatric patients with relapsed/refractory solid tumors. The pediatric RP2D of nivo is 3mg/kg alone or in combination with ipi 1mg/kg. Single agent nivo did not have antitumor activity in OS or EWS. Enrollment to other expansion cohorts with nivo or nivo/ipi is ongoing. Clinical trial information: NCT02304458.

Type, intensity, and duration of chemotherapy (CHT) and their correlation with prognosis of localized soft tissue Ewing tumors (STET): Experience of the Cooperative Weichteilsarkomstudiengruppe (CWS). *First Author: Ewa Koscielniak, Klinikum Stuttgart Olgahospital, Stuttgart, Germany*

Background: The optimal type and intensity of CHT in the treatment of STET is still a matter of debate. The CWS group has treated STET similar to rhabdomyosarcoma. We have analyzed the prognosis of STET in relation to the CHT regimens used in three consecutive CWS studies CWS-91, -96 and CWS-2002P. **Methods:** 243 pts with localized STET were included. Their median age was 12 (range 0.1-29) yrs. In the CWS-91 pts with primary tumor resection (IRSG I and II) were treated with VACA (vincristine (VCR), actinomycin D (Act D), cyclophosphamide (CYC), doxorubicin (DOX), for 10 or 20 weeks. All other CWS-91 pts (high risk group, HRG) received EVAIA (ifosfamide (IFO) instead of CYC plus VP16) for 37 weeks. In the CWS-96 and CWS-2002P all STET pts were allocated to the HRG. In CWS-96 therapy was randomized: VAIA (IFO, DOX, Act D, VCR) vs. CEVAIE (Epi-DOX instead of DOX, plus carboplatin and VP16), for 25 weeks. In CWS-2002P VAIA (25 weeks) plus maintenance CHT with CYC and vinblastine (VBL) for 26 weeks were used. The cumulative doses varied: IFO 24-72 g/m^2, CYC 4.8-7.35 g/m^2, DOX 120-360 mg/m^2, Act D 3-9 mg/m^2, VP16 1.8-5.4 g/m^2. Irradiation was stratified depending on results of the primary or secondary resection and response. **Results:** 5 yr event free (EFS) and overall survival (OS) were 64% and 73%. The median observation time of survivors was 9 yrs. 5yr EFS and OS by study were: CWS-91 64 % and 72 %, CWS-96 57% and 70 %, CWS-2002P 78 % and 86 % respectively (n.s.). 5 yr EFS and OS for VACA arm were 79% and 90%. 5 yr EFS and OS by CHT for HRG were: EVAIA 57% and 65%, VAIA 64% and 80%, CEVAIE 45% and 54%, VAIA with CYC/VBL 84% and 87%, respectively (p = 0 .003). 5yr EFS and OS for irradiated (n = 181) vs. not irradiated (n = 48) patients were 63 % and 72% vs. 63% and 79%, respectively. **Conclusions:** The outcomes between CHT arms differed significantly: CEVAIA correlated with the worst outcome while VAIA with CYC/VBL showed the best results. A small group of low risk patients have an excellent prognosis with substantially reduced CHT. Ewing tumors are biologically heterogeneous and more diversification in therapy stratification is warranted to avoid overtreatment.

10528 Poster Discussion Session; Unassigned in Poster Discussion Session, Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Risk stratification including FOXO1 fusion status (FOXO1) in patients with rhabdomyosarcoma (RMS) treated on six recent frontline trials: A report from the Children's Oncology Group (COG). *First Author: Emily Hibbitts, Children's Oncology Group, Gainesville, FL*

Background: Clinical risk factors associated with outcome in children with either localized or metastatic RMS were identified by Meza et al. (2006) and Oberlin et al. (2008). We re-examined risk stratification by adding FOXO1 to traditional clinical prognostic factors in children with localized or metastatic RMS in a large cohort from COG frontline clinical trials. **Methods:** Data from six COG clinical trials (D9602, D9802, D9803, ARST0331, ARTS0431, ARST0531) accruing previously untreated patients with RMS from 1997 to 2013 yielded 1,853 eligible patients (two studies each for low, intermediate and high risk patients). Survival tree regression for event-free survival (EFS) and overall survival (OS) was conducted to determine prognostic impact of risk factors. Recursively, the factor most strongly associated with outcome was selected for branching and split using a goodness of fit measure. Factors included were age, FOXO1, group, histology, nodal status, number of metastatic sites, primary site, sex, tumor size, and presence of metastases in bone/bone marrow, soft tissue, effusions, lung, distant lymph nodes, and other sites. **Results:** 5-year overall EFS and OS was 0.67 (SE, 0.01) and 0.77 (SE, 0.01), respectively. Survival trees for EFS and OS found localized versus metastatic at the first split and included FOXO1 as a significant risk factor. **Conclusions:** FOXO1 improves risk stratification of patients with localized RMS, although histology and pattern of metastases are more predictive for patients with metastatic RMS. Our findings support incorporation of FOXO1 in risk stratified clinical trials.

Top prognostic factors identified based on EFS.

Branch 1		Branch 2		Branch 3	
	EFS ± SE		EFS ± SE		EFS ± SE
Localized (N=1624)	0.73 ± .01	Favorable site (N=746)	0.82 ± .02	FOXO1 – (N=706)	0.84 ± .02
				FOXO1 + (N=40)	0.57 ± .09
		Unfavorable site (N=878)	0.65 ± .02	FOXO1 – (N=605)	0.70 ± .02
				FOXO1 + (N=273)	0.52 ± .04
Metastatic (N=229)	0.26 ± .03	Embryonal (N=98)	0.47 ± .06	1 Metastatic site (N=60)	0.57 ± .07
				> 1 Metastatic site (N=38)	0.32 ± .09
		Alveolar (N=131)	0.11 ± .03	No bone metastases (N=46)	0.22 ± .06
				Bone metastases (N=85)	0.05 ± .02

Genomic index in pediatric synovial sarcoma (SYNOBIO study): The European Pediatric Soft Tissue Sarcoma Group (EpSSG) experience. *First Author: Daniel Orbach, Institut Curie, Paris, France*

Background: A genomic index (GI) tool using array comparative genomic hybridization (aCGH) on tumor cells has recently been developed, and shown a high prognostic value in adult soft tissue sarcomas. GI correlates with genomic instability, and has emerged as independent prognostic factor associated with the risk of metastases developing in synovial sarcoma (SS). The aim, therefore, was to assess GI in pediatric patients with SS, to assess its value as a prognostic factor and its role in risk stratification. **Methods:** All pediatric/adolescent/young adults' (<25 years) with localized SS prospectively included in the European EpSSG-NRSTS05 protocol with a contributive aCGH were selected. Tumors had a central pathological review or harbored the specific fusion transcript (SYT-SSX). Definition of GI was A^2/C, where A is the total number of alterations (segmental gains and losses) and C is the number of involved chromosomes on aCGH results. GI_1 group corresponds to cases with no or few alterations (flat profile, GI≤1) and GI_2 group cases with many alterations (complex CGH profile; GI>1). **Results:** A total of 48 patient's samples were available. The median age of the cohort was 13 years (range: 4-24). Patients received surgery only (19%), with adjuvant therapy (17%) or perioperative therapy (64%). GI_1 group corresponded to 54.2%, and GI_2 to 45.8%. After a median follow up of 58 months (range: 0.1-107), 10 tumor events occurred and 5 patients died. Patients with high GI have more axial (P<0.01), invasive (P=0.04) and higher therapeutic risk groups' tumors (unresectable/axial tumors; P<0.015). Respectively for GI_1 vs. GI_2 groups, 5-year event free survival (EFS) rates were 91.8±5.6% vs. 58.9±11.2% (P<0.0084) and 5Y-Metastatic Free Survival 91.8±5.5% vs. 68.6±10.6% (P=0.055). In multivariate analysis, GI adjusted for IRS groups, site and tumor size remains prognostic for EFS (P<0.025). **Conclusions:** Although tumor events were rare for SS in NRSTS 2005, high GI selected patients with high risk tumor features and predicted a poorer outcome. GI may explain aggressive behavior of some pediatric SS. Founding sources: "Enfant-et-santé/SFCE," "Info sarcome," and "La ligue contre le cancer."

10530 Poster Session (Board #287), Sun, 8:00 AM-11:30 AM

Blinatumomab use in pediatric patients (pts) with relapsed/refractory B-precursor acute lymphoblastic leukemia (r/r ALL) from an open-label, multicenter, expanded access study. *First Author: Franco Locatelli, Bambino Gesù Children's Hospital, Rome; University of Pavia, Pavia, Italy*

Background: Blinatumomab (blin), a bispecific T-cell engaging antibody construct, has shown antileukemia activity and tolerability in pts with r/r ALL. We further evaluated safety and efficacy of blin in the first 40 pediatric pts with r/r ALL enrolled in an expanded access study (NCT02187354). **Methods:** Eligible pts (28 d to < 18 yrs) had ≥ 5% blasts and r/r ALL (refractory, ≥ 2 relapses or relapse after transplant [HCT]). Blin was dosed by continuous infusion (4 wks on/2 wks off) for up to 5 cycles (≥ 5 to < 25% blasts: 15 $\mu g/m^2$/d; ≥ 25% blasts: 5 $\mu g/m^2$/d on d1−7 in cycle 1, then 15 $\mu g/m^2$/d). The primary endpoint was incidence of treatment-emergent (TE) and treatment-related (TR) adverse events (AEs); key efficacy endpoints were complete response (CR) and minimal residual disease (MRD, by PCR or flow cytometry) in the first 2 cycles, relapse-free survival, overall survival and HCT rate. **Results:** Of the first40 treated pts (median age, 9 [range, 1−17] yrs), 24 (60%) had ≥ 2 relapses, 20 (50%) relapsed after HCT and 5 (13%) were primary refractory; 18 (45%) had ≥ 50% blasts and 21 (53%) had prior HCT. Safety and key efficacy outcomes are shown in the table, including 63% CR in the first 2 cycles. There were 8 relapses and 20 deaths after treatment. Regardless of causality, the most frequent TEAEs were pyrexia (78%), cytokine release syndrome (CRS; 23%) vomiting (23%) and anemia (20%); all 9 CRS events were grade (gr) 1 or 2 and 1 tumor lysis syndrome was gr 3. 10 (25%) pts interrupted treatment and 2 (5%) discontinued due to TRAEs; 13 (33%) pts had gr ≥ 3 TRAEs, including 2 of 3 neurologic events (depressed level of consciousness and headache; both gr 3); 2 fatal AEs were considered unrelated to blin. **Conclusions:**Here single-agent blin showed antileukemia activity in pediatric pts with high-risk r/r ALL including t(17;19) and AEs consistent with those previously reported for r/r ALL. Clinical trial information: NCT02187354.

10531 Poster Session (Board #288), Sun, 8:00 AM-11:30 AM

Cardiac effects of chimeric antigen receptor (CAR) T-cell therapy in children. *First Author: Danielle S. Burstein, Pediatric Cardiology, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Treatment with CAR T-cells targeting CD19 for pediatric leukemia has demonstrated significant efficacy with the principal toxicity being cytokine release syndrome (CRS). However, the cardiac effects related to CAR T-cell therapy have not been systematically evaluated. **Methods:** A retrospective chart review was performed on a large cohort who received CAR T-cell therapy from April 2012 through September 2016. Baseline oncologic and cardiac characteristics were recorded. Cardiomyopathy was defined as an ejection fraction < 55%, shortening fraction < 28%, or diastolic dysfunction. Primary outcome was cardiac event, defined as need for inotropic support or echocardiographic decline in function. Descriptive and univariate analyses were performed. **Results:** 93 patients were included [55% male, mean age 11.8 yrs (range 1.7-27.1)]; 98% had B cell ALL. Prior to treatment, 15% had cardiomyopathy and 1 patient had single ventricle Fontan palliation. Cardiac events occurred in 34 (36%) with mean onset 4.8 days (range 1-9) after CAR T-cell infusion, of whom 12 (35%) had abnormal systolic or diastolic function on echocardiogram and 6 (18%) required milrinone for cardiac support. 21 (22%) patients had CRS requiring tocilizumab and vasoactive infusions; there were no cardiac-related deaths. Factors associated with cardiac events included higher pre-treatment blast % on bone marrow biopsy [OR 10.45 (95% CI 3.87-28.22) for blast > 10%; p < 0.001] but not cardiomyopathy (p = 0.356), total body irradiation (p = 0.717) or anthracycline dose (p = 0.711). At discharge, 7 (7.5%) patients had worse cardiac function than at baseline, but only 2 (2%) had persistent cardiac dysfunction by 6 months post-infusion. Pre-treatment factors were not associated with persistent dysfunction. **Conclusions:** This is the first study to describe the cardiac effects of CAR T-cell therapy in children. CAR T-cell therapy appears to be safe, even in patients with cardiomyopathy. Although one-third experienced a cardiac event, persistent cardiac dysfunction is rare. Children with a pre-treatment blast > 10% were most at risk for cardiac events, a finding that may help identify patients who warrant close observation and early intervention with pressor support.

10532 Poster Session (Board #289), Sun, 8:00 AM-11:30 AM

Risk-adapted therapy utilizing upfront brentuximab vedotin (Bv) and rituximab (R) with reduced toxicity chemotherapy in children, adolescents, and young adults with Hodgkin lymphoma. *First Author: Jessica Hochberg, New York Medical College, Valhalla, NY*

Background: Cure rates for CAYA patients with Hodgkin Lymphoma remain high, however are limited by significant toxicity of chemoradiotherapy. Brentuximab Vedotin and Rituximab have shown efficacy in relapsed HL. We hypothesize that the addition of both to combination chemotherapy will be safe in newly diagnosed HL preserving current EFS with elimination of more toxic chemoradiotherapy. Objective: To evaluate the safety and overall response and EFS of Brentuximab and Rituximab in combination with risk adapted chemotherapy in CAYA with newly diagnosed HL. **Methods:** Age 1-30 yrs with newly diagnosed classical HL given 3 to 6 cycles of chemoimmunotherapy: Brentuximab vedotin with Doxorubicin, Vincristine, Prednisone and Darcarbazine (Bv-AVPD) for Low risk patients or Doxorubicin, Vinblastine, Darcarbazine and Rituximab (Bv-AVD-R) for Intermediate/High risk. Early response measured by PET/CT scan following 2 cycles. Slow responders received an additional 2 cycles of Bv-AVD-R for Intermediate Risk or Ifosfamide/Vinorelbine for High Risk patients. Radiation therapy was given ONLY to those patients not in CR. **Results:** Total = 19 patients. Median age = 15yr (range 4-23yr). Risk = 2 low, 13 intermediate, 4 high. Toxcity = 1 episode of GrIII mucositis, 1 episode of GrIII infusion reaction to Brentuximab. 17 patients have completed therapy. All 17 patients achieved a complete response to therapy for a CR = 100%. Eleven (58%) have achieved a rapid early response. No patient has required radiation therapy. For 17 patients who have completed therapy, the EFS and OS is 100% with a median follow up time of 915 days (30 months). **Conclusions:** The addition of Brentuximab vedotin and Rituximab to combination chemotherapy for newly diagnosed Hodgkin Lymphoma appears to be safe. Our early results show significant promise with a CR rate of 100% and 58% rapid early response. We have successfully deleted toxic alkylator, topoisomerase inhibitor, bleomycin and radiation from this treatment regimen. The EFS/OS to date is 100% with a median follow up time of 2.5 years. Further follow up and a larger cohort is needed to determine long term outcomes of this approach. Clinical trial information: NCT02398240.

10533 Poster Session (Board #290), Sun, 8:00 AM-11:30 AM

Intensified induction therapy with reduced total anthracycline exposure in pediatric low-risk acute myeloid leukemia. *First Author: Katherine Ashley Minson, Department of Pediatrics, Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta and Emory University, Atlanta, GA*

Background: Despite advances in risk stratification and therapy, the post-induction disease free survival (DFS) and overall survival (OS) for children with low-risk acute myeloid leukemia (LR-AML) remain low with DFS and OS of 50% and 68%, respectively, on the standard arm of the recent Children's Oncology Group (COG) trial, AAML1031. Additionally, current therapy for pediatric LR-AML contains anthracycline doses exceeding thresholds known to increase the risk of adverse cardiac effects. In an effort to decrease exposure to cardiotoxic therapy, the Aflac Cancer and Blood Disorders Center adopted an institutional practice to treat LR-AML patients with a regimen of intensified induction therapy with decreased anthracycline exposure (Aflac-AML consisting of ADE10, Mitox/HiDAC, HiDAC/VP, Capizzi II). The aim of this study is to describe the associated toxicities and outcomes of this regimen in pediatric LR-AML. **Methods:** We retrospectively reviewed medical records of patients diagnosed with de novo LR-AML and treated per the Aflac-AML regimen from 2011-2014. Charts were reviewed for cardiac outcomes, ICU admissions, and the rate of infectious toxicities. DFS and OS were determined using Kaplan-Meier survival analysis. **Results:** We identified 11 LR-AML patients treated with Aflac-AML therapy. Patients received a planned 317 mg/m^2 cumulative anthracycline dose vs 442 mg/m^{2}for those treated on AAML1031. There was no decrease in LVEF with a mean change of +2.17% for Aflac-AML patients from the time of diagnosis to therapy completion (p = 0.23). The primary infectious toxicities observed were febrile neutropenia and bacterial infections with a median of 36.4±6% documented bacterial infections per cycle. Fungal and viral infections were rare as were ICU admissions – median 4.5±4% per cycle – and there were no toxic mortalities. The 3-year DFS and OS from end of induction I for Aflac-AML patients were 72.7% and 90.9%, respectively. **Conclusions:** The Aflac-AML regimen resulted in short-term toxicities and outcomes comparable to current chemotherapy regimens for pediatric LR-AML but with reduced anthracycline exposure. These data support use of this regimen for pediatric LR-AML patients.

10534 Poster Session (Board #291), Sun, 8:00 AM-11:30 AM

Early response rates and Curie scores at end of induction: An update from a phase II study of an anti-GD2 monoclonal antibody (mAb) with chemotherapy (CT) in newly diagnosed patients (pts) with high-risk (HR) neuroblastoma (NB). *First Author: Wayne Lee Furman, St. Jude Children's Research Hospital, Memphis, TN*

Background: We are conducting a Phase II trial of the anti-GD2 mAb hu14.18K322A given concomitantly *with* CT in newly diagnosed pts with HR NB. Our primary objective is to compare the response rate (RR; defined as ≥ PR) after two courses of CT with cyclophosphamide (CTX)/topotecan (TPT) and hu14.18K322A with GM-CSF and IL-2 to the RR reported by Park et al. (JCO 29:4351, 2011), using identical CT with GCSF only, in a two-stage group sequential design. Semiquantitative MIBG scoring (Curie; CS) has been shown to be a prognostic indicator of outcome in pts with HR NB (Yanik et al, J Nucl Med, 2013), particularly, those with CS > 2 at end of induction (EoI) CT have inferior outcomes. Here we update the RR and report the CS at EoI CT. **Methods:** Pts received induction CT (6 cycles) as described by Park et al, with the addition of hu14.18K332A (on d 2-5; 40mg/m^2/d x 4d), daily sc GM-CSF and sc IL-2 (1 x 10^6 IU/m^2/dose) qod x 6. ^{123}I-MIBG scans and scoring (CS) were obtained on all pts at diagnosis, after second course of CT and at EoI. **Results:** 42 evaluable pts completed the first two courses of CT (24 male, median age 2.9 yrs (range 6 m -15.2 yrs), 36 INSS 4, 19 *MYCN*amplified); 40/42 evaluable pts had measurable reductions in primary tumor volume after two courses of CT (median 79%, average 69%, range +5 – 100%). Responses (≥ PR) after two courses were seen in 32/42 (76.2%; 95% CI 61.3 – 87.9%); No mAb dose-reductions were made but 20/43 (47%) pts had infusion times extended. The development of human anti-human antibody reactivity (HAHA) to hu14.18K322A in the first 22 pts is minimal. Of the 36 INSS 4 pts, 1 withdrew prior to EoI and 2 are too early. The median CS at diagnosis for the 33 stage 4 pts who have completed induction CT was 18 (range 1 – 28). At EoI the median CS was 0 (range 0 -23); 29/33 INSS 4 pts had EoI CS ≤ 2. **Conclusions:** The addition of hu14.18K322A to two courses of CTX/TPT significantly improves the RR compared to two courses of CTX/TPT alone (32/42 vs 12/30 as reported by Park et al,; P = 0.000004). The improved median CS of the stage 4 patients from 18 at diagnosis to 0 at EoI suggest the improvement in early RR may translate into improved EFS as well. Clinical trial information: NCT01857934.

10535 Poster Session (Board #292), Sun, 8:00 AM-11:30 AM

Targeting the cell cycle for cancer therapy in rhabdomyosarcoma. *First Author: Elizabeth Stewart, St. Jude Children's Research Hospital, Memphis, TN*

Background: Rhabdomyosarcoma (RMS) is an aggressive malignancy of childhood with a poor prognosis in patients with metastatic or recurrent disease. Inhibitors of Wee1 kinase and heat shock protein 90 (HSP90) have in vitro activity in RMS and have emerged as potential novel treatment strategies. We performed a comprehensive preclinical phase III study to compare the Wee1 inhibitor AZD1775 and HSP90 inhibitor ganetespib (GANET) in combination with irinotecan (IRN) and vincristine (VCR). **Methods:** Orthotopic xenografts (O-PDXs) were created by injecting luciferase labeled RMS cells into the hind-leg muscle of CD-1 nude mice. Pharmacokinetic studies on RMS O-PDXs were performed to determine matched human AUC-guided dosing. A total of 540 O-PDXs derived from 4 high risk RMS patients, 2 alveolar and 2 embryonal, were randomly enrolled into 14 treatment groups. Six courses of blinded placebo-controlled therapy were given on a clinically relevant schedule. Mice were classified as having progressive disease if tumor approached 20% body weight at any time in the study. For mice completing all 6 courses, bioluminescence was used to determine complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD). **Results:** The addition of AZD1775 to IRN and VCR demonstrated the most significant response for all 4 O-PDX lines tested; 70% of mice achieved a CR or PR. GANET combined with IRN and VCR had a 54% response (CR + PR) which was not significantly better than IRN plus VCR for most O-PDXs tested. Overall response data for select treatment groups is shown in the table below. **Conclusions:** Comprehensive preclinical testing using multiple O-PDX models of RMS that represent the clinical spectrum of disease is feasible. Comparison of novel treatment regimens to standard of care at clinically relevant doses is warranted as justification for future clinical trials. Observation to assess durable response following completion of therapy is ongoing to determine if AZD1775 remains a promising treatment strategy.

Treatment Group	CR%	PR%	SD%	PD%	CR+PR%	CR+PR+SD%
Control	0	0	0	100	0	0
GANET	0	0	0	100	0	0
AZD1775	0	0	0	100	0	0
IRN + VCR	22	14	8	56	36	44
GANET + IRN	14	17	17	53	31	47
AZD1775 + IRN	19	22	11	47	42	53
GANET + IRN + VCR	29	26	3	43	54	57
AZD1775 + IRN + VCR	43	27	19	11	70	89

10536 Poster Session (Board #293), Sun, 8:00 AM-11:30 AM

Clinical outcomes of adolescents and young adults (AYA) with advanced solid tumors participating in phase I trials. *First Author: Raghav Sundar, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: AYA cancer patients are relatively under-represented in clinical trials, with no published data regarding their outcomes in phase I studies. Trials utilizing novel therapeutic agents are often considered in these patients, due to their tendency to have good organ reserve, and ability to tolerate additional lines of therapy. This study describes the experience of AYA patients with advanced solid tumors treated in a specialized drug development unit. **Methods:** Patient characteristics and clinical outcomes of AYA patients (defined as age 15 to 39 years at time of initial cancer diagnosis) treated at the Drug Development Unit, Royal Marsden Hospital, United Kingdom, between 2002 and 2016, were captured and analyzed from case and trial records. **Results:** From a database of 2631 patients treated on phase I trials, 219 AYA patients (8%) were identified. Major tumor types included gynaecological cancer (24%), sarcoma (18%), gastrointestinal (16%) and breast cancer (11%). Patients had a median of 3 previous lines of systemic chemotherapy (range 0 – 6), and 19% participated in 2 or more phase I studies. Twenty (9%) had a known hereditary cancer syndrome (most commonly BRCA), 27% had a family history (FH) of cancer, 15% no FH and 49% no FH documented. Molecular characterization of tumors (n = 45) identified mutations most commonly in *p53* (33%), *PI3KCA* (18%) and *KRAS* (9%). Major trial categories included DNA damage repair (16%), PI3K (16%) and anti-angiogenesis (15%) agents. Grade 3/4 toxicities were experienced in 25% of patients (10% hematological). Of the 214 evaluable patients, objective response rate was 12%, with clinical benefit rate at 6 months of 22%. Median progression free survival was 2.3 months (95% CI: 1.9 to 2.8), median OS was 7.6 months (95% CI: 6.3 to 9.5), and 2-year OS was 11%. Of patients with responses, 35% were matched to phase I trials based on germline or somatic genetic aberrations. **Conclusions:** A sub-group of AYA patients with advanced solid tumors derive considerable benefit from participating in trials involving novel therapeutics. Future research must focus on predictive biomarkers and molecular profiling to identify those that would benefit from novel therapies.

10537 Poster Session (Board #294), Sun, 8:00 AM-11:30 AM

ADVL1522: A phase 2 study of IMGN901 (lorvotuzumab mertansine; IND# 126953, NSC# 783609) in children with relapsed or refractory Wilms tumor, rhabdomyosarcoma, neuroblastoma, pleuropulmonary blastoma, malignant peripheral nerve sheath tumor (MPNST), and synovial sarcoma: A Children's Oncology Group study. *First Author: James I. Geller, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Lorvotuzumab mertansine (IMGN901; LM) is an antibody-drug conjugate, linking anti-mitotic agent (DM1) to an anti-CD56 antibody. Preclinical data show effects in Wilms tumor (WT), rhabdomyosarcoma (RMS), and neuroblastoma (NBL). Synovial sarcoma (SS), MPNST and pleuropulmonary blastoma (PPB) also express CD56. A phase 2 trial assessing the efficacy and tolerability of LM administered at the adult recommended phase 2 dose (RP2D) was conducted in children with relapsed tumors. **Methods:** LM (110 mg/m^2/dose) was administered IV on days (d) 1 and 8 of 21 d cycles, with dexamethasone pre-medication. The tolerability of LM was assessed in 6 patients prior to trial activation group-wide. Dose limiting toxicity (DLT) was assessed using CTCAE. Response was assessed by RECIST. Pharmacokinetics (PK) were obtained during cycle 1. Peripheral blood CD56-positive cells were measured d1 and d8 pre-dose. Tumor CD56 expression by immunohistochemistry in archival tissue was scored (0-3+). **Results:** Sixty-two patients were enrolled. The median (range) age was 14.3 y (2.8–29.9); 35 were male. Diagnoses included WT (17), RMS (17), NBL (12), SS (10), MPNST (5) and PPB (1). One patient was ineligible due to lack of measurable disease. Of 61 eligible patients, 47 were evaluable for toxicity, 50 for response, 50 for tumor CD56 expression; and 18 consented to optional PK. Five patients experienced 9 DLTs: hyperglycemia (1), colonic fistula (1) with perforation (1), nausea (1) with vomiting (1), increased ALT (2 in cycle 1; 1 in cycle 2 with increased AST (1)). Non-dose limiting toxicities (Grade $\geq$3) attributed to LM included lymphopenia, anemia, vomiting, dehydration, hypokalemia, hyperuricemia, hypophosphatemia. Mean DM1 C_{max}, $t_{1/2}$ and $AUC_{0-\infty}$values were 922 ng/ml, 33 h and 27400 ng/ml*h, respectively. Tumor CD56 expression was 0 (8%), 1+(4%), 2+(12%), 3+(76%). LM and CD56 antibody PK, and response, will be reported. **Conclusions:** LM (110 mg/m^2) is tolerated in children at the adult RP2D. Clinical trial information: NCT 02452554.

10538 Poster Session (Board #295), Sun, 8:00 AM-11:30 AM

Mortality in young adults with Ewing sarcoma treated at specialized cancer centers in California. *First Author: Elysia Marie Alvarez, Stanford University Medical Center, Palo Alto, CA*

Background: Ewing sarcoma is a rare malignancy of the soft tissue or bone that is most frequently seen in children and adolescents. One study suggested that care at specialized cancer centers (SCC) may mitigate survival disparities associated with public insurance in patients with sarcoma, but no large population-based studies have considered how location of care affects survival outcomes. **Methods:** We performed a retrospective, population-based cohort analysis of patients hospitalized within one year of diagnosis with primary Ewing sarcoma between 2000–2013 using the California Cancer Registry linked with state hospitalization data. Patients were divided into two groups based on whether they received inpatient treatment at a SCC [Children's Oncology Group (if age $\leq$25) and/or National Cancer Institute-designated center] or not. We excluded 12 patients whose location of cancer treatment could not be determined. Multivariable Cox proportional hazards regression identified factors associated with mortality. Results are presented as adjusted hazard ratios (HR) and 95% confidence intervals (CI). **Results:** Of the 470 patients with newly diagnosed Ewing sarcoma, 40% were female, 52% were non-Hispanic white, and 53% had private health insurance. Sixty-one percent received their inpatient care at a SCC. Multivariable analysis across all ages demonstrated that higher mortality was associated with increasing age, metastatic disease, and large tumors, but mortality was not impacted by treatment at an SCC (HR 0.77, CI: 0.55-1.08; p = 0.134). However, when analyses were stratified by age, treatment at a SCC was associated with lower mortality among patients ages 19–39 years, but not among younger or older patients, and this association was only apparent within 2 years of diagnosis (HR = 0.43, CI: 0.23-0.79; p = 0.007). **Conclusions:** Our results suggest that treatment for Ewing sarcoma at a SCC significantly improves survival in young adults adjusted for other factors known to be associated with poor prognosis (metastatic disease, larger tumor size and older age). The lower mortality in this age group may be due to access to clinical trials and other specialized services specific to young adults available at SCCs.

10539 Poster Session (Board #296), Sun, 8:00 AM-11:30 AM

Pilot study of a comprehensive precision medicine platform for children with high-risk cancer. *First Author: Loretta Lau, Sydney Children's Hospital, Sydney, Australia*

Background: Genomic analyses can identify actionable mutations in a subset of childhood cancers. However it has been challenging to translate actionable mutations into substantial benefits for adult cancers despite high mutation frequency. **Methods:** To test whether we could enhance identification of personalised therapies for high risk (HR) childhood cancers we conducted a pilot study (TARGET) evaluating a novel, comprehensive precision medicine platform incorporating molecular profiling, *in vitro* and *in vivo* drug testing. **Results:** We evaluated the first 29 patients with HR cancer (expected survival $<$ 30%) enrolled prospectively over 15 months. Samples were collected from 15 CNS tumors, 10 solid tumors and 4 leukemias. All samples underwent targeted DNA sequencing. Pathogenic or likely pathogenic mutations were found in 59% (17/29) of tumors. 41% (12/29) had potentially actionable mutations. RNA-sequencing was performed on 27 samples. Previously described fusions were identified in 19% (5/27; 1 targetable, 1 clinical relevant and 3 diagnostic fusions). 37% (10/27) of samples also had actionable aberrations related to copy number changes or RNA expression. *In vitro* culture and establishment of patient-derived xenograft (PDX) were attempted in 19 and 21 fresh samples, respectively. The success rate of establishing a primary culture was 42% (8/19) and PDX engraftment rate was 67% (14/21). At least 1 drug hit was identified in 5 (56%) of the 9 samples screened using a high throughput drug screen of up to 165 compounds. Drug testing has been completed in 4 PDXs and was informative in all 4 cases allowing prioritisation of treatment recommendations. Genomic analysis in combination with RNA-seq, *in vitro* drug screening and PDX drug testing enriched the analysis and increased the ability to make personalised treatment recommendations from 41% (targeted panel alone) to 66%. **Conclusions:** This pilot study demonstrates that this novel, comprehensive platform is feasible and has the potential to improve outcome for HR childhood cancers. A multicentre study testing the implementation of the platform on a national level (PRISM trial) will open for Australian children with HR cancer under the Zero Childhood Cancer Program in 2017.

10540 Poster Session (Board #297), Sun, 8:00 AM-11:30 AM

Outcomes of children with hereditary medullary thyroid carcinoma (MTC) treated with vandetanib. *First Author: Ira Lignugaris Kraft, Center for Cancer Research, Division of Cancer Treatment and Diagnosis, Bethesda, MD*

Background: Vandetanib is well tolerated and active in children with advanced or metastatic hereditary MTC (NCT00514046) [data cutoff 7/2011; Clin Cancer Res. 2013 Aug 1;19(15):4239-48]. We report outcomes as of 1/2017. **Methods:** We monitored toxicities, RECISTv1.0, carcinoembryonic antigen (CEA), and calcitonin (CT) response. Patients (pts) removed from the vandetanib trial were followed on a natural history study (NCT01660984). **Results:** Of 17 pts (8 male, age 13 years (9-17)*) enrolled, 1 was lost to follow-up. Of the 16 pts analyzed, 15 had a *RET* p.M918T germline mutation. The duration of vandetanib therapy was 5.6 years (0.1-9.2+) with treatment ongoing in 8 pts. Best response was partial response (PR) in 10, stable disease (SD) in 5, and progressive disease (PD) in 1 pt. Time to achieve PR (n = 10) was 0.6 years (0.4-2.4). Time to best response (n = 16) was 1.5 years (0.1-4.1). Duration of response was 5.1 years (1.3-8.6+) in pts with PR and 4.8 years (0.6-7.3+) in pts with SD. Seven of 8 pts with PD subsequently received sunitinib, sorafenib, and/or cabozantinib. Disease progression occurred as increase in target (n = 2), non-target/new lesions (n = 5), or CT/CEA (n = 1). Six pts died from disease 2.1 years (0.4-4.3) after stopping vandetanib. Progression free survival was 6.2 years (95% CI 3.0-na) and overall survival was 7.9 years (95% CI 5.9-na).Pts had no difference in enrollment age, baseline CT/CEA, or tumor size per response categories (n = 16). Rate of CEA/CT decrease during initial 4 months of treatment was not associated with PR/SD compared to PD (n = 16). While on vandetanib, 6 pts with PD had CEA or CT doubling time (DT) of $<$ 2 years within 1 year prior to PD. All pts with ongoing PR/SD had CEA and CT DT $>$ 2 years while on vandetanib. No pts came off treatment for toxicity. Dose reductions occurred in 8 pts for grade (gr) 2 weight loss (n = 2), palpitations (n = 1), arrhythmia (n = 1), elevated creatinine (n = 1), diarrhea (n = 2), and gr 3 constipation (n = 1). **Conclusions:** Many children with hereditary MTC sustained PR/SD on vandetanib. However, half ultimately developed PD and died from disease despite treatment with other targeted therapies. CEA/CT DT $<$ 2 years within 1 year of progression on vandetanib may be associated with PD. *Median (range)

10541 Poster Session (Board #298), Sun, 8:00 AM-11:30 AM

Role of radiotherapy to primary/metastatic sites in pediatric patients with metastatic rhabdomyosarcoma in the BERNIE study. *First Author: Alison Cameron, Bristol Haematology and Oncology Centre, Bristol, United Kingdom*

Background: Local control is a key part of treatment of local/locoregional rhabdomyosarcoma (RMS) and often involves radiotherapy (RT) with/without surgery. The role of RT in metastatic RMS is uncertain, with little published evidence to guide clinicians. We analyzed data from the BERNIE trial to assess the benefit of RT for patients (pts) with metastatic RMS. **Methods:** In the BERNIE study (NCT00643565) pts aged $\geq$6 months to $<$18yrs with metastatic RMS and non-RMS soft tissue sarcoma were randomized to receive chemotherapy (CT) with/without bevacizumab (BEV), surgery, and/or RT (at cycle 6–9) then maintenance CT. RT was recommended for all sites of metastases if feasible (investigator discretion allowed, resulting in variability in actual RT given). Pts were categorized into those receiving: RT all sites, partial RT, no RT. Event-free survival (EFS) and overall survival (OS) were calculated using Cox proportional hazards models and a landmark approach: only pts who were event free at day 221 (i.e. end of cycle 9 + 1 month) were included (EFS, n=85; OS, n=97). Variables adjusted were: treatment (as randomized), disease type (alveolar/embryonal/other), risk group, age $>$10yrs, metastatic lesion count (1, 2–3, 4+). The analysis was non-randomized, exploratory and post hoc. **Results:** Of 102 pts with RMS, 22 received no RT, 49 partial RT, and 31 RT to all sites. Baseline characteristics were mostly balanced, and comparable proportions of pts received BEV. Better OS was observed in the RT group (Table) (comparable with unadjusted results). A non-significant EFS improvement was observed for the RT groups. **Conclusions:** Partial RT and RT to all sites of disease in metastatic RMS was associated with significant OS benefits, albeit in small pt numbers. This should be confirmed in a prospective randomized trial. Clinical trial information: NCT00643565.

Effect of receiving RT for RMS on EFS and OS (adjusted data).

	Hazard ratio*	p*	% Pts event free/surviving at 3yrs (95% confidence interval)
No RT (n=22)			
EFS	-	-	9 (2–56)
OS	-	-	23 (10–56)
Any RT (n=80)			
EFS	0.52	0.0541	47 (35–63)
OS	0.25	0.0002	64 (53–77)
Partial RT (n=49)			
EFS	0.51	0.0621	42 (28–64)
OS	0.31	0.0020	53 (39–72)
RT all sites (n=31)			
EFS	0.54	0.1841	58 (41–82)
OS	0.11	0.0020	84 (71–100)

10542 Poster Session (Board #299), Sun, 8:00 AM-11:30 AM

Phase I study of talazoparib and irinotecan in children and young adults with recurrent/refractory solid tumors. *First Author: Sara Michele Federico, St. Jude Children's Research Hospital, Memphis, TN*

Background: Poly (ADP-ribose) Polymerase inhibitors (PARPi) target tumors with deficiencies in DNA repair mechanisms. Talazoparib (TAL), a potent PARP inhibitor, demonstrated significant efficacy in a Ewing sarcoma model when combined with DNA-damaging irinotecan (IRN). We performed a phase I trial to determine the maximum tolerated doses (MTDs) of TAL and IRN in pediatric patients with solid tumors. **Methods:** Cohorts of 3-6 eligible patients (pts) with recurrent/refractory solid tumors received escalating doses of oral (PO) TAL and intravenous (IV) IRN in a 3+3 design (Table 1). Each course was 21 days. Serum for TAL and IRN pharmacokinetics (PK) were obtained. Toxicities were assessed using CTCAE v.4 and responses were evaluated by RECIST v.1.1. **Results:** Twenty-four pts (9 male; median age, 11 years; 18 recurrent) received a median of 2 courses (range, 1-18). Fifteen pts had prior exposure to IRN. Table 1 summarizes the dose-limiting toxicities (DLTs) in course 1. The most common grade 3 or higher non-hematologic and hematologic toxicities in 82 evaluable courses were febrile neutropenia (5), elevated gamma-glutamyltransferase (GGT, 4), neutropenia (22) and lymphopenia (17). Two of 22 evaluable patients had a response (CR Ewing sarcoma, 18 courses; PR synovial sarcoma, 10 courses) and 9 had disease stabilization, median 4 courses (range, 4-10). Results of PK tests will be presented. **Conclusions:** The recommended phase II doses are TAL 600mcg/m^2 (max 1000mcg/dose) days 1-6 and IRN 40mg/m^2/day days 2-6. This regimen is feasible with evidence of anti-tumor activity and warrants further investigation. Clinical trial information: NCT02392793.

Dose level	TAL mcg/m^2/dose, PO	TAL Schedule Days (D)	Maximum TAL (mcg/dose)	IRN mg/m^2/dose, IV daily	# of pts	DLT course 1 (# of pts)
1	400	D 1-6: daily	800	20	6	Thrombocytopenia (1), GGT (1)
2	600	D 1: twice a day D 2-6: daily	D 1: 500mcg/dose D 2-6: 1000mcg/dose	20	3	0
3	600	D 1: twice a day D 2-6: daily	D 1: 500mcg/dose D 2-6: 1000mcg/dose	30	6	Neutropenia (1)

5	600	D 1: twice a day D 2-6: daily	D 1: 500mcg/dose D 2-6: 1000mcg/dose	50	3	Thrombocytopenia (2), neutropenia (2), GGT (1), colitis (1)

10543 Poster Session (Board #300), Sun, 8:00 AM-11:30 AM

A phase I trial of pomalidomide for children with recurrent, progressive/refractory central nervous system (CNS) tumors: A Pediatric Brain Tumor Consortium (PBTC) study. *First Author: Jason R. Fangusaro, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Background: CNS malignancies are the most common solid tumors among children. Novel therapies are needed to help improve the survival outcomes in children with recurrent disease. Pomalidomide is an immunomodulatory agent thought to also function through a combination of anti-angiogenic, anti-inflammatory and cytotoixic activity making it a good candidate to explore in pediatric CNS tumors. **Methods:** A Phase I trial of pomalidomide was conducted among children $\geq$ 3 to $<$ 21 years old with recurrent, progressive/refractory CNS tumors using the "rolling 6" dose escalation design. The primary objective was to determine the maximum tolerated dose (MTD) and/or recommended Phase II dose (RP2D) when given orally once daily for 21 consecutive days of a 28-day course. Once the MTD was established, 12 additional patients were enrolled on expansion cohorts based on age and steroid use. **Results:** 29 children were enrolled and 25 were evaluable for dose limiting toxicity (DLT) evaluation. The MTD was 2.6 mg/m^2 (Dose level 2). DLTs observed at dose level 3 (3.4 mg/m^2) included diarrhea (n = 1), thrombocytopenia (n = 1) and lung infection (n = 1), all grade 3. The most common toxicities were grade 1 lymphopenia (55%), leukopenia (62%) and thrombocytopenia (38%). There were no obvious differences in tolerability based on age or steroid use. Pharmacokinetics were similar to those observed in adults and increased in a dose-dependent manner. At the RP2D of 2.6 mg/m^2, the C_{max} was 97.4 ng/mL and the $t^1/_2$ was 4.1 hours. The median number of treatment cycles was 1.6 (0.2-12.3). Two patients, one with an oligodendroglioma and one with anaplastic pleomorphic xanthoastrocytoma, had long term stable disease for 9 and 18+ cycles. No objective responses were observed. Twelve month progression-free and overall-survivals were 5.2+/-3.6% and 12.8+/-8.5%, respectively. Immunologic correlate analyses are ongoing. **Conclusions:** The RP2D of pomalidomide is 2.6 mg/m^2 in children with recurrent brain tumors. Further prospective evaluation of this agent alone or in combination will be necessary to better understand its efficacy in specific pediatric CNS tumor populations. Clinical trial information: NCT02415153.

10544 Poster Session (Board #301), Sun, 8:00 AM-11:30 AM

Single-agent dose-finding cohort of a phase 1/2 study of lenvatinib (LEN) in children and adolescents with refractory or relapsed solid tumors. *First Author: Nathalie Gaspar, Institut Gustave Roussy, Villejuif, France*

Background: LEN is an inhibitor of vascular endothelial growth factor (VEGF) receptors 1–3, fibroblast growth factor receptors 1–4, platelet-derived growth factor receptor α, RET, and KIT. LEN is approved in adults for radioiodine-refractory differentiated thyroid cancer (DTC) and in combination with everolimus in patients (pts) with advanced renal cell carcinoma. We show results from the single-agent LEN dose-finding part of a phase 1/2 study in children and adolescents with solid tumors. **Methods:** Pts had any relapsed or refractory solid tumor, evaluable or measurable disease, were aged 2 to ≤18 years, had < 2 prior VEGF-targeted therapies, and adequate organ function. A starting dose of LEN 11 mg/m^{2}was escalated with a time-to-event continual reassessment method. The primary endpoint was to determine the LEN recommended dose (RD). Secondary objectives included best overall response (BOR), objective response rate, safety, and pharmacokinetics (PK). **Results:** 23 pts enrolled (11 mg/m^2: n = 5, 14 mg/m^2: n = 11, 17 mg/m^2: n = 7). The most common tumors were rhabdomyosarcoma (n = 5), Ewing sarcoma (n = 4), and neuroblastoma (n = 3). 3 Dose-limiting toxicities occurred in cycle 1 at 14 mg/m^2 (increased alanine aminotransferase: 1; hypertension: 2). All pts had any-grade treatment-emergent adverse events (TEAEs; grade 3/4: 65%). Most common any-grade TEAEs were vomiting (52%), abdominal pain (48%), decreased appetite (48%), diarrhea (44%), and hypothyroidism (44%). 1 Pt discontinued LEN due to a LEN-related TEAE (hypertension). BOR was stable disease (n = 10). Effect of age on oral clearance and central volume of distribution was not significant. Exposure was similar to that in adults. LEN 14 mg/m^2/day was therefore identified as the RD. Updated cohort 1 data will be shown. **Conclusions:** The LEN RD in children and adolescents was similar to the adult dose and showed a reasonable safety profile. PK in these pts did not differ significantly from that in adults. The phase 1b dose-finding study of LEN in combination with chemotherapy in osteosarcoma (OS) and phase 2 LEN monotherapy (RD 14 mg/m^2) parts in DTC and OS are ongoing. Clinical trial information: NCT02432274.

10545 Poster Session (Board #302), Sun, 8:00 AM-11:30 AM

A curative approach to central nervous system metastases of neuroblastoma. *First Author: Kim Kramer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neuroblastoma metastatic to the central nervous system (CNS NB) is associated with significant mortality (median survival < 6 months, < 10% survival at 36 months). Intraventricular compartmental radioimmunotherapy (cRIT) with radio-iodinated murine IgG1 monoclonal antibody ^{131}I-8H9 targeting tumor cell-surface glycoprotein B7-H3 offers a therapeutic strategy. We analyzed overall survival of patients with CNS NB treated with intraventricular ^{131}I-8H9 cRIT at Memorial Sloan Kettering Cancer Center (MSK) since 2003. **Methods:** After radiographic and/or pathologic confirmation of CNS NB, and assessment of adequate CSF flow, cRIT eligible patients underwent treatment on an IRB-approved protocol with either temozolomide/irinotecan-based CNS salvage regimen incorporating craniospinal radiation therapy, ^{131}I-8H9 cRIT plus systemic immunotherapy (group 1), or non-regimen therapies with ^{131}I-8H9 cRIT (group 2). cRIT administration involved a 2mCi tracer of ^{124}I- or ^{131}I-8H9 with nuclear imaging and CSF sampling for dosimetry followed by 1 or 2 therapeutic injections up to 70 mCi ^{131}I-8H9. Disease surveillance included serial MR brain/spine, MIBG, CT, and bone marrow evaluation. Data are presented as overall survival after detection of CNS metastasis. **Results:** 105 patients with CNS NB were evaluated;80 patients (76%) were treated (57 group 1, 23 group 2). Of the 25 patients who were not eligible for cRIT, survival averaged 8.6 months. Of 19 patients with radiographic evidence of disease at the time of cRIT, 7 (36%) demonstrated post cRIT radiographic improvement. At analysis, 45/80 (56%) patients were alive 4.8–152 months (median 58 months) after CNS metastasis, including 36 (45%) at 36 months and 23 (29%) > 60 months. Subgroup analyses of ^{131}I-8H9–treated patients identified age at NB diagnosis (≤18 months), relapse restricted to CNS and group 1 status as factors positively correlated with survival. **Conclusions:** 76% of patients with CNS NB treated at MSK received ^{131}I-8H9 cRIT, and approximately half completed multimodality CNS salvage regimen with ^{131}I-8H9 cRIT. Despite advanced CNS involvement, over 50% of patients treated with ^{131}I-8H9 cRIT are still alive and nearly 50% have survived at least 36 months. Clinical trial information: NCT00089245.

10546 Poster Session (Board #303), Sun, 8:00 AM-11:30 AM

Phase I study of pexidartinib (PLX3397) in children with refractory leukemias and solid tumors including neurofibromatosis type I (NF1) related plexiform neurofibromas (PN). *First Author: Lauren Hittson, Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Refractory tumors remain a significant treatment challenge, and novel approaches targeting the tumor microenvironment may hold promise. Pexidartinib, an oral inhibitor of tyrosine kinases including CSF1R, KIT and FLT3, has activity in adults with tenosynovial giant cell tumor. **Methods:** We are conducting a phase 1 trial (NCT02390752) to determine the maximum tolerated dose (MTD) and plasma pharmacokinetics (PK) of pexidartinib in patients (pts) 3-21 years old with refractory leukemias and solid tumors including NF1 PN. The MTD is based on cycle (C) 1 toxicities. Pexidartinib is given once daily continuously (1C = 28 days) at DL 1: 400 mg/m2/dose, 2: 600mg/m2/dose, or 3: 800 mg/ m^2/dose. Response is assessed after C1 and then every other C, and for NF1 PN with volumetric MRI analysis after every 4 C. **Results:** Fourteen pts (8 M:6 F, median age 16 years, (range 4-21) with CNS tumors (n = 2), sarcomas (n = 7), peritoneal mesothelioma (n = 1), leukemia (n = 1), NF1 PN (n = 3) have enrolled at DL1 (n = 4), DL2 (n = 4) and DL3 (n = 6). No dose-limiting toxicities have been observed and 11 pts are evaluable for MTD determination (received ≥ 85% of pexidartinib doses in C1). Common non-DLT toxicities are fatigue, decrease in WBC, increase in creatinine kinase and serum amylase, headache, anorexia, vomiting, diarrhea, and hair hypopigmentation. Mean (SD) pexidartinib C1 day 1 PK parameters at [DL1 (n = 4), DL2 (n = 4), and DL3 (n = 4)] were: C_{max} DL1 2,813 ng/mL (1,483), DL2 6,065 ng/mL (1,308), DL3 10,323 ng/mL (2,129); $AUC_{0\text{-}24h}$ DL1 44,492 ng·h/mL (12,904), DL2 76,569 ng·h/mL (25,790), DL3 132,903ng·h/mL (40,482). The mean (SD) accumulation ratio (C1 D15 $AUC_{0\text{-}24h}$: C1 D1 $AUC_{0\text{-}24h}$) was 3.9 (0.7) for DL1, 2.4 (0.3) for DL2, and 1.4 (0.6) for DL3. Pts received a median of 1 C (range (1-21+). Pts with NF1 PN received 1, 4, and 6 C of pexidartinib and had stable disease. One pt with peritoneal mesothelioma is receiving C 21. **Conclusions:** In children, pexidartinib was tolerated at all dose levels, and the recommended phase II dose (RP2D) is 800 mg/m^2/dose once daily. This dose exceeds the adult RP2D of 1000 mg/day. Enrollment on the expansion cohort is ongoing. Clinical trial information: NCT02390752.

10547 Poster Session (Board #304), Sun, 8:00 AM-11:30 AM

Pazopanib therapy for adolescent and young adult desmoid tumors. *First Author: Laura Agresta, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: There is a lack of reliably effective medical therapies for desmoid tumors (DT). Surgical resection may be morbid, and even a complete resection does not preclude recurrence. Radiotherapy is associated with potentially severe late-effects, a risk that may be particularly detrimental in young patients. In a previous review of our single institution DT experience, we found that objective treatment responses to medical therapies were rare.However,we have recently observed promising effect from therapy with the tyrosine kinase inhibitor pazopanib in adolescent and young adult (AYA) patients with DT. **Methods:** Retrospective single institution chart review evaluating all pazopanib treatment in AYA patients with DT. **Results:** Five AYA patients, ages 15-21 years, with previously treated DT received pazopanib. Four patients with sporadic DT were documented by next generation sequencing to have mutations of *CTNNB1*, and 1 patient with intra-abdominal tumors following colectomy was known to carry a large germline interstitial chromosomal deletion (5q21.2q23.1) including the *APC* locus. The median duration of pazopanib treatment was 6 months at the time of analysis (range: 5-21), with treatment ongoing for 4 patients. None of the patients demonstrated progressive disease while on treatment. Best responses by Response Evaluation Criteria in Solid Tumors 1.1 (RECIST) were partial response in 3 of 5 and stable disease in 2 of 5 cases. One response was nearly complete. In one case of stable disease, tumor necrosis was evident on magnetic resonance imaging after 2 months on pazopanib. Four patients reported pain relief while on pazopanib, including one patient with stable disease. Pazopanib was discontinued in 1 patient after 18 months due to recurrent facial edema. Other grade 1-2 adverse effects responded to dose reduction. The only grade 3 adverse effect was increasing weakness in a patient with pre-existing myopathy; this patient tolerated pazopanib at a reduced dose. **Conclusions:** This is the first report of objective responses to pazopanib by RECIST criteria in AYA patients with DT. Given these benefits and relatively mild toxicity, we conclude that pazopanib therapy should be considered in this patient population.

10548 Poster Session (Board #305), Sun, 8:00 AM-11:30 AM

Effect of PD1/PD-L1 checkpoint blockade on efficacy of anti-GD2 antibody ch14.18/CHO in neuroblastoma. *First Author: Holger N. Lode, University Medicine Greifswald, Greifswald, Germany*

Background: Immunotherapy (IT) with anti-GD_2 antibody (Ab) ch14.18/CHO is effective for treatment of high-risk neuroblastoma (NB) patients mainly due to induction of GD_2-specific Ab-dependent cellular cytotoxicity (ADCC). Methods to further enhance the effect are important and currently explored in prospective clinical trials randomizing ch14.18/CHO ± scIL-2. Programmed death-1 (PD-1) is an inhibitory receptor expressed by activated T- and NK-cells, and cancer cells express PD-1 ligand. Here, we report for the first time effect and mechanism of PD-1/PD-L1 blockade in the context of ch14.18/CHO-based IT in preclinical models. **Methods:** Expression of PD-L1 and PD-1 on NB cells and leukocytes was analyzed by RT-PCR and flow cytometry in the presence of ch14.18/CHO or IL-2. Mechanism of PD-L1 induction was analyzed with anti-CD11b Ab. The effect of PD-1/PD-L1 blockade on ch14.18/CHO-mediated anti-NB immune response was evaluated using anti-PD-1 Ab both in vitro (Nivolumab) and in the syngeneic GD_2^+ NB NXS2 mouse model (anti-mouse PD-1). Mice (n = 10) were treated with ch14.18/CHO (5x300 μg, i.p.) in combination with anti-PD-1 (8x250 μg, i.p.), and compared to controls. **Results:** Culture of LA-N-1 (low PD-L1 baseline expression) in the presence of leukocytes and subtherapeutic ch14.18/CHO concentrations for 24h induced strong upregulation of PD-L1 resulting in complete inhibition of ADCC mediated by ch14.18/CHO. Co-incubation with anti-CD11b Ab abrogated this PD-L1 upregulation. Importantly, blockade with Nivolumab reversed the PD-L1-dependent inhibition of ADCC. Mice treated with ch14.18/CHO in combination with PD-1 blockade showed a strong reduction of tumor growth and prolonged survival as well as the highest level of NB cell lysis mediated by serum and leukocytes compared to controls. **Conclusions:** Ch14.18/CHO-mediated effects upregulate the inhibitory checkpoint PD-1/PD-L1 and combination of ch14.18/CHO with PD-1/PD-L1 blockade results in synergistic treatment effects in mice. This concept will be evaluated in a clinical trial.

10549 Poster Session (Board #306), Sun, 8:00 AM-11:30 AM

Long-term outcomes after irradiation (RT) for pediatric low-grade glioma. *First Author: Derek S. Tsang, St. Jude Children's Research Hospital, Memphis, TN*

Background: Treatment for pediatric low-grade glioma (LGG) is variable, depending on age and tumor location. Systemic therapy (ST) is often used to delay RT, but ST does not result in durable local control. The goal of this study was to evaluate event-free survival (EFS) and toxicities for pediatric LGG treated with RT over a 30-year period. **Methods:** All patients age ≤21 with intracranial pediatric LGG (WHO grade I-II) treated with RT at a single institution since May 1986 were included in this retrospective review. Patients with metastatic disease (M+) received craniospinal irradiation (CSI); otherwise, RT was conformal. EFS and overall survival (OS) were measured from the first day of RT. Events included death, progression, or secondary high-grade glioma. **Results:** 221 patients were eligible. Median follow-up was 11.3 yrs (range, 0.1-30.5). Median RT dose was 54 Gy. 10-yr EFS and OS were 67.9% (95% CI 60.4-74.3) and 91.1% (95% CI 85.8-94.5) for non-metastatic patients, respectively. For 12 M+ patients treated with CSI, 10-yr EFS and OS were 58.9% (95% CI 23.4-82.5) and 70.0% (32.9-89.2), respectively. 28.6% developed pseudoprogression (PP) with median time to onset and resolution of 6.1 months (IQR 3.6-14.6) and 6.4 months (IQR 3.5-11.7), respectively. Patients with PP had improved 10-yr EFS (83.4% vs. 61.0%, HR 0.40, p = .006). Patients with grade II tumors and who received pre-RT ST had lower EFS (Table). Sex, NF-1, tumor location, extent of surgery and CSI were not independently associated with EFS. 10-yr cumulative incidence of grade ≥2 vasculopathy was 7.5% (95% CI 4.9-11.4). There were 12 cases of secondary high-grade glioma, with a 20-yr cumulative incidence of 5.5% (95% CI 2.6-11.4). **Conclusions:** Irradiation provides long-term control of pediatric LGG in a majority of patients. Receipt of pre-RT systemic therapy was associated with reduced EFS; this association requires further investigation.

10550 Poster Session (Board #307), Sun, 8:00 AM-11:30 AM

Anti-GD2 immunotherapy in adults with high-risk neuroblastoma (HR-NB): The Memorial Sloan Kettering Cancer Center (MSKCC) experience. *First Author: Maya Suzuki, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The diagnosis of NB in adulthood is rare and little is known about its biology and clinical course. There is no established therapy for adult NB. Anti-GD2 immunotherapy is now standard in children with HR-NB but its use has not been reported in adults. **Methods:** After obtaining IRB waiver, records of all patients with adult-onset (≥18 years) NB seen at MSKCC between 1983 and 2015 were reviewed. Overall survival (OS) was tested by log-rank test. Cox-regression was used for multivariate analysis. **Results:** The subjects were 42 adults (median: 25; range18-71 years); 23 male and 19 female. Five, 1, 1 and 35 patients had INSS stage 1, 2, 3 and 4 disease, respectively. Genetic abnormalities included somatic *ATRX* (59%) and *ALK* mutations (43%) but not *MYCN*-amplification. 16 patients remain alive at a median follow-up of 5.3 years. OS for non-stage 4 patients was superior to stage 4 (median survival 14.6 vs 5.3 years; $p < 0.05$). However 5/7 patients with < stage 4 NB progressed to stage 4. Among 35 stage 4 patients, 4 achieved complete remission (CR) after induction chemotherapy and surgery, 11 underwent autologous stem cell transplant (ASCT) and 15 received multiple cycles of anti-GD2 antibodies 3F8 or hu3F8 without complications. In univariate analysis, patients ≤ 29 years old (n = 24) at diagnosis, those achieving CR, and those receiving anti-GD2 antibodies had superior OS ($p < 0.05$ for each). ASCT was not beneficial (p = 0.3 for ASCT vs no ASCT). For stage 4 patients, anti-GD2 immunotherapy was associated with favorable OS in multivariate analysis (95% CI of anti-GD2 antibody: 1.270 to 7.990). **Conclusions:** Adult-onset stage 4 NB demonstrates a high incidence of somatic mutations and is only partially chemosensitive. However, 3F8/hu3F8-based anti-GD2 immunotherapy appears to improve long-term survival and is well tolerated.

10551 Poster Session (Board #308), Sun, 8:00 AM-11:30 AM

Management of uni- or bilateral retinoblastoma with radiologic optic nerve invasion at diagnosis. *First Author: Marie-Louise Choucair, Institut Curie, Paris, France*

Background: To evaluate treatment and outcome of patients with uni- or bilateral retinoblastoma (RB) with radiologic optic nerve invasion (RONI) at diagnosis. **Methods:** Retrospective clinical, radiological and histological review of patients with uni- or bilateral RB with RONI at diagnosis treated in the Institut Curie. **Results:** Between 1997 and 2014, 936 patients with RB were treated in the Institut Curie. Eleven patients had detectable RONI confirmed by Computed Tomography and/or Magnetic Resonance Imaging. RB was unilateral in 10/11 patients, bilateral in 1. Median age at diagnosis was 29 months (range 12-96). The patient with the bilateral RB had a unilateral RONI. Nine patients had ON enhancement and 3 had meningeal sheath enhancement. Nine received neoadjuvant chemotherapy (CT) and 2 had a primary enucleation. Partial response to neoadjuvant CT was obtained for all the patients. Enucleation was performed in 10/11 patients, by anterior approach in 3 patients, by anterior and subfrontal approach in 7 patients. Three patients had positive ON margin and among them, 2 were primary enucleated. All enucleated patients received adjuvant treatment (conventional CT: 10, High Dose CT: 7 and radiotherapy: 5). Three patients died of meningeal progression (2 during treatment and 1 during the first year after treatment). The patient with the bilateral RB was lost to follow up just after a meningeal progression during treatment. Seven are still alive (median follow up: 8 years, range : 1.5-17.5). **Conclusions:** Neoadjuvant CT has an important place in the management of unilateral RB with RONI at diagnosis. Pretreatment accurate staging by orbital and brain MRI is mandatory, as well as preoperative reassessment. Surgery should be performed by experienced ophthalmologists and if necessary neurosurgical team in order to obtain the best conditions for a tumor-free resection margin in patients with RONI.

10552 Poster Session (Board #309), Sun, 8:00 AM-11:30 AM

Noninvasive molecular profiling of high-risk relapsed neuroblastoma by plasma cell-free DNA analysis. *First Author: Prachi Kothari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neuroblastoma (NB) is the most common extracranial solid tumor in children. 5-year survival rates for high-risk NB are < 50% despite intense multimodality treatment. Recent studies revealed that as opposed to diagnostic samples, relapsed NB tumors have a significantly higher mutational burden as a result of clonal evolution. This poses a challenge for the development of personalized therapies and warrants molecular profiling at relapse. However, tumor samples are not always accessible at relapse. Our study evaluates the feasibility of using cell-free DNA (cfDNA) to noninvasively characterize tumor profiles at relapse to identify targetable genetic variants. **Methods:** Tumor specimens, plasma and matched control samples from 10 patients with high-risk stage 4 NB were collected during multimodality treatment. Samples were analyzed using the MSK-IMPACT platform, a targeted deep sequencing assay to interrogate the exons and selected introns of 410 actionable genes. Tumor samples were collected from surgeries performed either at diagnosis, disease progression, or relapse. Plasma samples were collected at a time of disease progression, at an average 395 days (range of 47-1597 days) from tumor collection. Matched control samples were used to filter germline variants. **Results:** We detected somatic mutations and copy number alterations in tumor tissues and cfDNA of 10/10 and 6/10 patients, respectively. These included recurrent NB drivers such as MYCN amplification and ATRX mutations. In 4 patients, cfDNA also revealed somatic variants that were not detected in the original tumor specimens, including potentially targetable mutations in NRAS, MLL2, CIC and IDH2 that were recently reported to be enriched in the relapse setting, as well as ARID1B mutation that is associated with poor prognosis. **Conclusions:** This study suggests that it is feasible to noninvasively profile the dynamic genetic heterogeneity of NB by plasma cfDNA analysis. Such analysis can potentially supplement tumor profiling especially in the relapse setting to guide treatment plans. Our findings call for incorporation of cfDNA analysis in clinical trials to further evaluate its utility for clinical management of NB patients.

10553 Poster Session (Board #310), Sun, 8:00 AM-11:30 AM

Effects of the multikinase inhibitor regorafenib in neuroblastoma. *First Author: Peter E. Zage, Texas Children's Hospital, Pearland, TX*

Background: Neuroblastoma (NB) is the most common extracranial solid pediatric tumor, and children with high-risk NB have poor survival rates and need novel treatment strategies. Regorafenib, a multi-receptor tyrosine kinase (RTK) inhibitor approved for treating adult solid tumors such as advanced metastatic colorectal cancer and gastrointestinal stromal tumors, inhibits many RTKs, including PDGFR-β, VEGFR1-3, RET, c-Kit and FGFR family members. Based on the potential roles for these targets in neuroblastoma pathogenesis, we explored the therapeutic potential of Regorafenib alone and in combination with 13-cis-retinoic acid against neuroblastoma cells. **Methods:** We treated NB cell lines with increasing concentrations of Regorafenib and measured cell viability using MTT assays. We further measured the occupied percent confluence over time using continuous live cell imaging. We performed Western blots for caspase cleavage to measure apoptosis and flow cytometry to determine cell cycle expression. We performed Reverse Phase Protein Array (RPPA) analysis of neuroblastoma cells before and after treatment with regorafenib combined with 13-*cis*-retinoic acid. **Results:** IC_{50}values for the tested cell lines ranged between 2.5mcM and 12.5mcM after 72 hours of exposure to Regorafenib, and decreased viability was due to a combination of apoptosis and cell cycle arrest. RPPA analysis identified alterations in multiple proteins and pathways after Regorafenib with retinoic acid treatment, including the PI3K/Akt/mTOR and Jak/Stat pathways. Phosphorylation of Erk1/2, S6, Akt, and c-Jun were decreased, while protein expression of GATA3 was increased in a dose-dependent manner. **Conclusions:** Regorafenib treatment results in reduced neuroblastoma cell viability and increased apoptosis via effects on several signaling pathways. Effects on intracellular signaling pathways associated with responses to the combination of regorafenib plus retinoic acid represent opportunities to develop novel combination therapies, representing potential new therapeutic strategies for children with neuroblastoma.

10554 Poster Session (Board #311), Sun, 8:00 AM-11:30 AM

Long-term growth and development in 268 bevacizumab (BEV)-treated and 135 control pediatric/adolescent patients (pts): An integrated analysis. *First Author: Hermann L. Müller, Klinikum Oldenburg AöR, Medical Campus University Oldenburg, Oldenburg, Germany*

Background: BEV has an established safety profile in adults, but long-term data in children are limited. This analysis examined the effects of BEV on growth/development in pediatric/adolescent pts. **Methods:** Data (height, weight, body mass index [BMI], bone age data) were pooled (5 trials): NCT00643565 (Ph2/soft tissue sarcoma); NCT01390948 (Ph2/high-grade glioma); NCT00085111 (Ph1/refractory solid tumors); NCT00667342 (Ph2/osteosarcoma); NCT00381797 (Ph2/glioma, medulloblastoma, ependymoma). Pts (<18 yrs old) received ≥1 dose of BEV + chemotherapy (CT) (n=268) or CT alone (n=135). Analyses were exploratory/descriptive. Reference growth data: WHO (<2 yrs); Centres for Disease Control (≥2 yrs). **Results:** Across the trials, mean number of BEV administrations per pt ranged 5.6–19.9 (dose 5–15mg/kg every 2/3 weeks). Median follow-up time, months (range): BEV+CT, 37.9 (2.4–64.2); CT, 22.9 (2.8–69.2). At baseline, median height, weight, and BMI were close to that of the reference population (mean standard deviation scores [SDS] close to 0). Over 60 months, a slight decline was observed in the mean SDS for height and weight in both arms in this cohort with different tumors/treatments (Table), but remained within normal range of healthy children. Trends were similar for BMI. No delay in growth velocity or bone age in BEV-treated pts vs CT only was observed up to 3 yrs, regardless of age/gender. A subgroup analysis of pts in the growth hormone-dependent development phase was consistent with the overall results. **Conclusions:** In this analysis, BEV inclusion in the treatment regimen did not have a negative impact on pediatric growth/development beyond that of CT alone.

Mean SDS vs time.

Neuroblastoma metastatic to the central nervous system: Survival analyses from the German Childhood Cancer Registry and the literature. *First Author: Frank Berthold, University of Cologne, Cologne, Germany*

Background: Therapeutic innovation has resulted in an overall decline in childhood neuroblastoma (NB) mortality; however, metastatic NB to the central nervous system (CNS NB), which has emerged as a sanctuary site for NB metastases, remains difficult to treat and is typically fatal. The objective of this study was to describe the natural course of CNS NB. **Methods:** Data were sourced from a custom query of the German Childhood Cancer Registry (GCCR) and from the literature. Survival statistics were prepared from a diverse, thus generalizable, pool of CNS NB patients. Data are presented as secondary event-free and overall survival (EFS and OS) after diagnosis of first CNS recurrence from initial high-risk NB. **Results:** The GCCR query identified 85 patients with CNS NB diagnosed from 1990–2010, including 57 with isolated CNS disease. The median (95% confidence) EFS and OS times were 2.6 (1.5–3.8) and 4.7 (2.1–7.2) months, respectively, for all CNS NB patients, and 2.8 (1.4–4.1) and 6.8 (2.1–11.5) months, respectively, for isolated CNS NB patients. Secondary OS at 12, 18, and 36 months was 29.4%, 18.8%, and 8.2%, respectively, for all CNS NB patients, and 35.1%, 22.8%, and 12.3%, respectively, for isolated CNS NB patients. Thirteen publications were selected with 83 patients treated from 1979–2013. In addition to an inclusive analysis, a restricted analysis was performed, excluding patients who did not receive therapy with curative intent, to assess survival after therapeutic intervention. Median OS (95% confidence) was 5.6 (3.0–8.0) and 8.7 (5.8–11.0) months in the inclusive and restricted analyses, respectively. The proportion of patients surviving 12, 18, and 36 months at reporting were 24%, 12%, and 3.6%, respectively, for the inclusive population, and 33%, 17%, and 5%, respectively, for the restricted population. **Conclusions:** An assessment of the natural course of CNS NB from two sources arrived at similar conclusions with respect to overall and long-term survival. In general, median secondary OS is < 6 months and < 10% of patients survive 36 months. The findings were consistent across geographic regions and have not changed appreciably in 4 decades.

10556 Poster Session (Board #313), Sun, 8:00 AM-11:30 AM

A biomarker-guided approach to combining PARP inhibitors with radiotherapy in pediatric solid tumors. *First Author: Anang Shelat, St. Jude Children's Research Hospital, Memphis, TN*

Background: Ewing sarcoma (EWS) expresses high levels of Schlafen-11 (SLFN11). SLFN11 disrupts checkpoint maintenance and may serve as a biomarker to assess sensitivity to Poly (ADP-ribose) polymerase 1 and 2 inhibitors (PARPi). The goal of this study is to evaluate SLFN11 protein expression in a panel of pediatric solid tumors and correlate levels of protein with sensitivity to PARP inhibition combined with ionizing radiation (IR), a component of therapy for many pediatric solid tumors and a potent inducer of DNA damage. **Methods:** SLFN11 mRNA and protein levels were assessed by quantitative RT-PCR, and immunohistochemistry, Western blot, and immunofluorescence microscopy, respectively. PARPi included: talazoparib (TAL), niraparib (NIR), veliparib (VEL), and olaparib (OLA). Approximately 30 minutes after addition of systemic therapy, graded doses of radiation were delivered and viability across a panel of pediatric solid tumor cell lines was measured using the ATP-based Cell TiterGlo assay and confirmed with the colony formation assay. **Results:** We found that SLFN11 mRNA and protein is expressed at high levels in EWS, and SLFN11 is also variably present in a subset of other pediatric solid tumor lines, including desmoplastic small round cell tumor, osteosarcoma, and rhabdomyosarcoma. In all tumor cells with detectable SLFN11 expression, viability was reduced by greater than 90% when exposed to 2Gy IR and 1-10nM TAL, whereas cells with undetectable levels of SLFN11 were 5-10 times less sensitive. Intriguingly, variation in the potentiation between specific PARPi and IR correlated with the ability to form drug-induced PARP-DNA adducts, with the strong PARP trapper TAL showing ~10-fold higher potency compared to the moderate trapper NIR, and ~300-fold more potency relative to the weak trapper VEL. Consistent with our PARPi findings, the toposiomerase 1 inhibitor irinotecan, which also forms DNA adducts, potentiated with IR similarly to TAL at concentrations $<$ 10nM in tumor cells expressing detectable levels of SLFN11. **Conclusions:** SLFN11 is present in select pediatric solid tumors and may induce a DNA repair defect that is best exploited by combining low-doses of TAL and irinotecan with IR.

10557 Poster Session (Board #314), Sun, 8:00 AM-11:30 AM

Risk factors associated with metastatic site failure in patients with high-risk neuroblastoma. *First Author: John Thomas Lucas, St. Jude Children's Research Hospital, Memphis, TN*

Background: This retrospective study sought to identify predictors of metastatic site failure (MSF) in patients with high-risk (HR) neuroblastoma (NB). **Methods:** Seventy-six patients with HR NB treated on prospective trials at from 1997 to 2014 were eligible for inclusion. All patients were treated with induction chemotherapy (chemo) with surgery followed by myeloablative chemo & stem cell rescue. Primary & metastatic site (MS) RT were applied according to institutional protocol. CT & I-123 MIBG scans were used to assess Curie scores at diagnosis, post-induction, post-transplant & failure. Overall (OS), & progression-free survival (PFS) were described using the Kaplan-Meier estimator. Cox proportional hazards frailty (cphfR) & CPH regression (CPHr) were used to identify covariates predictive of MSF & new site MSF. **Results:** Forty-two (55%) patients had documented MSFs. Consolidative MS RT was applied to 30 MSs in 10 patients. Original site MSF occurred in 146 of 383 (38%) & 18 of 30 (60%) non-irradiated & radiated MSs respectively. Original site MSF occurred in post-induction MIBG avid lesions in 68 of 81 (84%) & 12 of 14 (85%) non-irradiated & radiated MSs respectively. The median OS & PFS were 61 mo (95% CI 42.6-NR) & 24.1 mo (95% CI 16.5-38.7). Univariate cphfR identified an increased hazard for original MSF when MIBG avid following induction chemo (HR 4.9, 95%CI 1.1-20.9, p = 0.03) & transplant (HR 7.3 95%CI 1.8-30.2, p = 0.006) relative to lesions that cleared after induction. Notably, MS RT nor site location did not modify the hazard for MSF. Multivariate CPHr identified inability to undergo transplant (HR 32.4 95%CI 9.3-96.8, p $<$ 0.001) &/or maintenance chemo (HR 5.2, 95%CI 1.7-16.2, p = 0.005) & the presence of lung metastases (HR 4.4 95%CI 1.7-11.1, p = 0.002) at diagnosis as predictors of new site MSF. The new MSF free survival at 3 years was 25% vs. 87% in patients with high-risk factors relative to those without the risk factors suggesting limited benefit of consolidative MS RT in this population. **Conclusions:** Metastatic lesions that remained MIBG avid following induction chemo & post-transplant had an increased hazard for MSF. Consolidative site RT likely has limited benefit in patients with HR features.

10558 Poster Session (Board #315), Sun, 8:00 AM-11:30 AM

Diabetes risk in childhood cancer survivors: A population-based study. *First Author: Iliana Carolina Lega, Women's College Research Institute, University of Toronto, Toronto, ON, Canada*

Background: Cure rates for childhood cancer have improved significantly over the last three decades. Diabetes has emerged as a delayed side-effect of treatment for childhood cancer. Methodologic limitations may have led to underestimation of the risk for diabetes in previous studies. Understanding the extent of diabetes risk and identifying risk factors for diabetes is imperative for improving screening and prevention strategies in this population. **Methods:** We used the Ontario population-based cancer registry and administrative health databases to evaluate the risk of diabetes in adult survivors of childhood cancer. Diabetes was measured using a validated algorithm. Survivors were compared to age and sex-matched controls from the general population using a multivariable, cause-specific hazard regression model where death and development of another cancer was treated as a competing risk. **Results:** We identified 10,438 1-year survivors of childhood cancer diagnosed prior to age 21 years between January 1st, 1990 and December 31st, 2010. Mean age at cancer diagnosis was 10.7 years (standard deviation [SD] 6.8) and the mean follow up was 11.2 years (SD 6.9). In multivariable models adjusted for rurality and income status, cancer survivors had a 55% increased rate of developing diabetes compared to matched controls (HR 1.55, 95% CI 1.31-1.83). Individuals treated for cancer between age 6-10 years (HR 4.01, 2.33-6.91) had the highest increased rate for diabetes among age categories. Leukemia (HR 2.39, 1.74-3.27) and lymphoma (HR 1.61, 1.12-2.31) was also associated with an increased risk for diabetes compared to the general population. **Conclusions:** Our study provides evidence of an increased risk for diabetes in adult survivors of childhood cancer. The increased risk is highest among those treated at younger ages, and after treatment for leukemia and lymphoma. Future research is warranted to identify optimal ways for diabetes screening and prevention in this population. Given the burden of cardiovascular disease in survivors, identifying and treating diabetes early may help improve overall morbidity and mortality.

10559 Poster Session (Board #316), Sun, 8:00 AM-11:30 AM

Solid organ transplant after treatment for childhood cancer: A report from the Childhood Cancer Survivor Study. *First Author: Andrew Charles Dietz, Children's Hospital Los Angeles, Los Angeles, CA*

Background: Childhood cancer therapy is associated with late onset, organ-specific impairment. However, the prevalence of and outcomes after solid organ transplant (SOT) in childhood cancer survivors (CCS) are unknown. **Methods:** Data on U.S-based participants in the Childhood Cancer Survivor Study were linked with the Organ Procurement and Transplantation Network. Cumulative incidence of transplant (CIT) 35 years after cancer diagnosis, multivariable Cox regression models for hazard ratios (HR), Kaplan-Meier (KM) survival and corresponding 95% confidence intervals (CI) were estimated. **Results:** Among 13,318 survivors, median follow-up age 39 years (interquartile range, IQR 33-46), and median time since cancer diagnosis 31 years (IQR 28-36 years), 100 CCS had SOT after study entry with characteristics and outcomes provided (table). **Conclusions:** Organ-specific radiation and chemotherapy exposure increase the risk for SOT after childhood cancer. Five-year survival rates after renal and cardiac SOT are favorable.

Relationship between the cumulative burden (CB) of chronic health conditions (CHC) and health-related quality of life (HRQoL) among childhood cancer survivors (CCS): The St. Jude Lifetime (SJLIFE) cohort. *First Author: Nickhill Bhakta, St. Jude Children's Research Hospital, Memphis, TN*

Background: Adult CCS experience an excess burden of CHC. The association between disease burden (estimated using CB) and HRQoL has not been extensively assessed. **Methods:** 2878 CCS (mean [range] age 32.1 [18.3-66.2] years; time from diagnosis 25.0 [10.2-51.0] years) were enrolled in SJLIFE (eligibility: survived >10 years and >18 years of age) and clinically evaluated for 168 graded CHC using the St. Jude modified Common Terminology Criteria for Adverse Events. HRQoL was assessed using the Short Form 36 survey and categorized into Low (< -0.5 SDs), Average (-0.5 to 0.5 SDs), and High (> 0.5 SDs) subgroups from the Physical and Mental Component Summary (PCS, MCS) and Vitality Scale using cohort age- and sex-specific values. CB (average number of grade 3-4 [severe/life-threatening] CHC/survivor) for each CHC was calculated and summed for each HRQoL subgroup. **Results:** Survivors with low PCS had, on average, more CHC CB compared to those with High and Average PCS. Higher CHC CB was also associated with poorer Vitality and MCS, but the differences in effect size were smaller than PCS. When CB for each of the 3 HRQoL scores were compared by subgroups across 12 organ systems and subsequent neoplasms, CB at age 50 differed significantly ($p<0.05$) across PCS, MCS, and Vitality in 9, 3 and 7 of the 13 systems, respectively. **Conclusions:** Survivors with lower HRQoL scores have more CHC, but the patterns of this association vary in PCS, MCS and Vitality by CHC organ systems, suggesting adult CCS adjust better to certain types of CHC than others. Future research will focus on CHC with greatest impact on functioning.

CB (average number of grade 3-4 CHC/Survivor) and HRQoL by subgroups and age.

Late complications among adult survivors of neuroblastoma in the St. Jude Lifetime Cohort Study (SJLIFE). *First Author: Carmen Louise Wilson, St. Jude Children's Research Hospital, Memphis, TN*

Background: Assessment of late outcomes in neuroblastoma survivors has generally consisted of self-reported health events within retrospective cohorts. We aimed to characterize the health outcomes of a clinically-assessed cohort of long-term survivors of neuroblastoma diagnosed between 1963-2003. **Methods:** In a cohort of 239 ten-year survivors of neuroblastoma, of whom 137 (57%) underwent comprehensive clinical assessments, chronic conditions were graded using a modified version of the Common Terminology Criteria of Adverse Events, version 4.03. Comparisons were made using 272 clinically assessed community controls. Log-binomial regression was used to compare the prevalence of chronic conditions (grade 1-5) between survivors and controls and to calculate prevalence ratio (PR) and 95% confidence intervals (CI). Mean cumulative count (treating death as a competing risk) of chronic conditions by age was used to estimate cumulative burden with imputation of outcomes for non-clinically assessed survivors. **Results:** The median age at diagnosis was 0.9 (range: 0.0-14.4) and the median age at follow-up was 31.9 (range: 20.2-54.6) years for clinically assessed survivors. Median age of controls was 34.7 (range: 18.3-70.2). Treatment consisted of chemotherapy (75%), radiation (23%) and surgery (91%). Survivors were more likely than controls to have hearing loss (31.4% vs. 2.9%, PR = 10.7, 95% CI = 5.2-22.0), cardiomyopathy (8.8% vs. 0.7%, PR = 11.9, 95% CI = 2.7-52.5), hypothyroidism (10.9% vs. 5.2%, PR = 2.1, 95% CI = 1.1-4.3) or neurological disorders (56.9% vs. 32.4%, PR = 1.8, 95% CI = 1.4-2.2). At 35 years of age, the cumulative incidence of survivors experiencing at least one grade 3-5 condition was 67.3% (95% CI = 58.3-76.0%). By age 35 survivors experienced, on average, 8.5 (95% CI = 7.6-9.3) grade 1-5 and 2.4 (95% CI = 2.0-2.8) grade 3-5 conditions per 100 survivors, which was higher than the burden of grade 1-5 (3.3 [95%CI = 2.9-3.7]) and grade 3-5 (0.9 [95%CI = 0.7-1.0]) conditions identified among controls. **Conclusions:** Two-thirds of survivors are affected by severe or life-threatening health conditions. Continued follow-up, screening and intervention provide opportunities to optimize health.

10562 Poster Session (Board #319), Sun, 8:00 AM-11:30 AM

Long-term incidence of venous thromboembolism (VTE) among survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Arin L Madenci, Boston Children's Hospital, Boston, MA*

Background: This study aimed to estimate the incidence of late-occurring VTE among survivors of childhood cancer, and to identify associated demographic and clinical factors that define high-risk subgroups for potential screening and prevention. **Methods:** Using data from CCSS, a multi-institutional, longitudinal cohort of 5-year survivors of childhood cancer (diagnosed 1970-1999) and their siblings, the primary endpoint of self-reported late VTE (occurring ≥5 years after diagnosis) was estimated using multivariable piecewise exponential models adjusted for age, sex, and race. Generalized estimating equations accounted for potential within-family correlation where applicable. **Results:** Among 23,601 survivors and 5051 siblings, the incidence of VTE was 1.15 and 0.48 events per 1000 person-years, respectively. For survivors, median age at last follow-up was 28.6 years (range 5.6-58.3) and median follow-up time from diagnosis was 21.2 years (range 5.0-39.3). The adjusted rate ratio (RR) for survivors compared to siblings was 2.2 (95% confidence interval [CI] = 1.7-2.8, $P< 0.01$). Among survivors, risk factors for VTE included BMI≥30kg/m^2 (ref. BMI 18.5-24.5; RR = 1.5, CI = 1.2-2.0, $P< 0.01$), increasing number of severe or life-threatening (i.e. CTCAE grades 3 or 4) non-VTE chronic conditions (ref. 0 conditions; 1-2 conditions: RR = 2.5, CI = 2.0-3.1, $P< 0.01$; ≥3 conditions: RR = 3.5, CI = 2.5-4.9, $P< 0.01$), and cancer recurrence or second malignant neoplasm (RR = 3.5, CI = 2.7-4.6, $P< 0.01$). Incidence of late VTE was associated with increased subsequent mortality, independent of non-VTE chronic conditions (RR 2.2, 95% CI = 1.7-2.8, $P< 0.01$). **Conclusions:** Survivors of childhood cancer remain at increased risk for VTE across their lifespan. While typically not causal, late VTE was associated with subsequent mortality. Care providers should be aware of this increased risk and consider interventions that target modifiable co-morbidities such as obesity. Surveillance and education should be directed toward high-risk survivors.

10563 Poster Session (Board #320), Sun, 8:00 AM-11:30 AM

Infection related late mortality in survivors of childhood cancer with asplenia or radiation-induced hyposplenism: A report from the Childhood Cancer Survivor Study. *First Author: Brent Weil, Boston Children's Hospital, Boston, MA*

Background: Asplenia or hyposplenism can develop in survivors of childhood cancer following splenectomy or radiotherapy exposure to the left upper quadrant of the abdomen (LUQ). Knowledge regarding long-term infection related outcomes for these survivors is limited. **Methods:** Infection related late mortality (sepsis, meningitis or pneumonia) was evaluated in 20,805 5-year survivors (diagnosed <21 years of age from 1970-1999, median follow-up 26 years, range 5-44) using cumulative incidence and Poisson regression models to calculate adjusted relative risk (RR) and 95% confidence intervals (CI). Average LUQ radiation was calculated as a surrogate for splenic radiation. **Results:** Treatment included splenectomy for 1328 survivors (6%). An additional 10,295 (49%) were exposed to LUQ radiotherapy without splenectomy. The cumulative incidence of infection related late mortality was 1.4% (95%CI: 0.7%-2.2%) at 35 years after splenectomy and 0.6% (95%CI: 0.4%-0.8%) after LUQ radiotherapy, with a total of 78 deaths attributable to infectious causes (25 sepsis, 1 meningitis, 52 pneumonia). Splenectomy (RR=8.4, $p<0.001$) and increasing LUQ radiotherapy dose ($p<0.001$) were independently associated with infection related late mortality (Table). **Conclusions:** Splenectomy and LUQ radiotherapy increased risk for infection related late mortality. While infectious mortality increased with increasing LUQ radiation dose, even lower dose exposure (<10Gy) increased risk substantially. Accordingly, cancer survivors exposed to LUQ radiotherapy should be considered at risk for functional asplenia and managed similarly to asplenic individuals with respect to vaccinations and febrile illnesses.

Multivariate analysis of factors associated with infection related late mortality.*

Treatment	RR (95% CI)	P
No splenectomy; no RT (Ref.)	1.0	
Splenectomy	8.4 (3.5 - 20.1)	<0.001
No splenectomy, 0.1-10 Gy LUQ RT	2.4 (1.1 - 5.2)	0.028
No splenectomy, 10-19 Gy LUQ RT	6.1 (2.5 – 14.9)	<0.001
No splenectomy, 20+ Gy LUQ RT	9.3 (3.2 – 27.0)	<0.001

*Adjusted for age at diagnosis, attained age, sex, race and chronic health conditions. *RT*, radiotherapy.

10564 Poster Session (Board #321), Sun, 8:00 AM-11:30 AM

Endothelial dysfunction in adult survivors of childhood cancer: A report from the St. Jude Lifetime Cohort study. *First Author: Daniel A. Mulrooney, St. Jude Children's Research Hospital, Memphis, TN*

Background: Endothelial dysfunction, as an indicator of vascular disease in childhood cancer survivors (CCS) has not been widely studied. **Methods:** Markers of vascular inflammation (high sensitivity C-reactive protein [hsCRP]), hemostasis (fibrinogen), activation (endothelial cell expression of vascular cell adhesion molecule [VCAM-1]) and functional testing (large/small artery elasticity [L/SAE], pulse wave velocity [PWV]) were assessed in 200 CCS, ≥10 years from diagnosis, and 192 age/gender matched healthy controls. Exclusion criteria included: inflammatory processes, use of anti-inflammatory or cardiovascular medications, or pregnancy. Differences were assessed by adjusted multivariable linear regression. **Results:** CCS (53% male) of leukemia/lymphoma (59%), central nervous system tumors (6%), sarcomas (11.5%), embryonal tumors (22.5%), and other (1%) had a mean age at diagnosis 7.3 years (SD ±5.7). CCS and controls did not differ in current age (mean 34.1 ±9.2 vs. 33.5 years ±9.8), body mass index, smoking, mean systolic (124 mm Hg ±11.7 vs. 123 ±11.9) or diastolic blood pressure (73 ±9.5 vs. 71 ±9.5). Fasting low- (110 mg/dl ±31 vs. 102 ±30) and high-density (52 ±16 vs. 56 ±18) cholesterol levels differed between survivors and controls ($p<0.01$). Endothelial expression of VCAM-1 and PWV were statistically significantly increased in CCS; arterial elasticity was significantly reduced (table). Therapeutic exposures (anthracyclines and radiation) were not significantly associated with endothelial dysfunction. **Conclusions:** Childhood cancer survivors have greater endothelial dysfunction, a sign of atherosclerosis, and preventive measures should be investigated.

Vascular biomarkers and functional testing.

10565 Poster Session (Board #322), Sun, 8:00 AM-11:30 AM

Mental healthcare use and severe psychiatric diagnoses in adult survivors of childhood cancer: A population-based study using health services data. *First Author: Sumit Gupta, Hospital for Sick Children, Toronto, ON, Canada*

Background: Though physical late effects in childhood cancer survivors are well documented, their risk for adverse mental health outcomes is less clear; existing evidence is contradictory. Health services data offer an objective method for measuring population-based mental health outcomes. **Methods:** Using a provincial registry with detailed patient, disease, treatment, and outcome data, we assembled a cohort of all five-year survivors of childhood cancer diagnosed before age 18 years and treated in an Ontario pediatric cancer centre between 1987-2008. Patients were linked to population-based healthcare data capturing inpatient, outpatient, and emergency department (ED) visits. The primary outcome was the rate of mental healthcare visits (primary care, psychiatrist, ED or hospital). Secondary outcomes included the time to a severe mental health event (ED visit, hospitalization, or suicide) both overall and by psychiatric diagnostic categories. Outcomes were compared between survivors and matched controls using recurrent event and survival analyses, and predictors of adverse outcomes modeled. **Results:** When compared to 20,269 controls, 4,117 survivors had a significantly higher rate of mental health visits [47.1 vs. 36.1 visits/100 person years; adjusted relative rate (RR) 1.3, 95% confidence interval (CI) 1.2-1.5]. Higher rates of visits were associated with female gender (RR 1.4, CI 1.1-1.7; $p = 0.008$) and adolescent age at diagnosis (RR 2.0, CI 1.3-3.0; $p = 0.004$). Cancer type, treatment intensity or treatments targeting the central nervous system were not significant predictors. The hazard of a severe mental health event did not differ between survivors and controls. Though rare in both groups, survivors were at increased risk of a severe event due to a psychotic disorder (HR 1.8, CI 1.1-2.8; $p < 0.05$). **Conclusions:** Childhood cancer survivors experience higher rates of mental health visits than the general population, but are no more likely to experience a severe mental health event. Their risk is not attributable to a specific diagnosis or aspect of treatment. An increased risk of severe psychotic disorders requires confirmation in other cohorts.

10566 Poster Session (Board #323), Sun, 8:00 AM-11:30 AM

Human papillomavirus (HPV)-associated malignancies as subsequent malignant neoplasms (SMN) in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Tara O. Henderson, The University of Chicago, Chicago, IL*

Background: It is not known whether childhood cancer survivors (CCS) develop human papillomavirus (HPV)-associated malignancies more frequently than the general population. **Methods:** We assessed the cumulative incidence of SMN in sites typically associated with HPV (HPV-SMN) and evaluated standardized incidence ratios (SIR) and absolute excess risks (AER) using age-, sex- and calendar-year specific rates from the Surveillance, Epidemiology and End Results (SEER) program. Multivariate Cox regression models identified associations between key risk factors and HPV-SMN development. **Results:** Among 27,620 CCS, 36 developed an HPV-SMN at a median age of 27 years (range: 8-42) and a median of 15 years (range: 5-29) after their primary cancer. The 30-year cumulative incidence of an HPV-SMN was 0.20% (95% confidence interval [CI]: 0.13%-0.28%). HPV-SMN locations included oral cavity/pharynx (N = 26, 72%), rectum (N = 4, 11%), cervix/uteri (N = 3, 8%), and vulva (N = 3, 8%). The incidence of HPV-SMN was almost 3-fold higher among CCS than the general population (SIR = 2.8, 95% CI 2.0-4.1) with an AER of 6.0/100,000 person-years. Rates were elevated in those exposed (SIR = 3.3, CI 2.1-5.2) and not exposed to radiotherapy (RT; SIR = 2.6, CI 1.4-4.8). Risk of oral cavity/pharynx SMN was elevated in both those exposed (SIR = 7.3, CI 3.9-13.6) and not exposed (SIR = 4.2, CI 2.2-8.1) to head or neck RT, whereas, risk in GU locations was elevated in those exposed (SIR = 4.1, CI 1.9-9.2) but not in those not exposed to pelvic RT (SIR = 0.8, CI 0.3-2.1). Male sex (HR = 2.9, CI 1.3-6.1), exposure to head/neck/pelvic RT (HR = 2.6, CI 1.2-6.1), and platinum chemotherapy (HR = 6.1, CI: 2.6-13.9) increased the risk. Among 15 deceased HPV-SMN cases, 10 (67%) died of their HPV-SMN. **Conclusions:** While the overall incidence is low, CCS are at increased risk of developing malignancies in locations commonly associated with HPV infection in the general population. Further research examining the role of HPV in the etiology of these SMNs is warranted. As HPV-SMNs are potentially preventable, promotion of HPV vaccination efforts should be considered in this population.

10567 Poster Session (Board #324), Sun, 8:00 AM-11:30 AM

Hepatic injury after treatment for childhood cancer: A report from the St. Jude Lifetime Cohort study. *First Author: Daniel M. Green, St. Jude Children's Research Hospital, Memphis, TN*

Background: We assessed hepatic injury (HI) in a large cohort of childhood cancer survivors (CCS). **Methods:** We measured aspartate aminotransferase (AST) and alanine aminotransferase (ALT) in 2751 SJLIFE CCS (> 10 years (yrs) post-diagnosis, age ≥18 yrs), and graded using the Common Terminology Criteria for Adverse Events (CTCAE) v 4.03. Multivariable log binomial regression was used to estimate associations between demographic and clinical factors and grades 1–4 ALT and AST. Variables with a $p < 0.1$ were examined in multivariable models. **Results:** 1339 (48.7%) CCS were female. 2271 (82.6%) were non-Hispanic white (NHW). Median age at diagnosis - 7.4 yrs, median age at evaluation - 31.4 yrs, and median time from diagnosis to evaluation - 23.2 yrs. 177 (6.4%) had grades 1-4 AST (grade 1 = 164, grade 2 = 9, grade 3 = 4), and 421 (15.3%) had grades 1-4 ALT (grade 1 = 394, grade 2 = 18, grade 3 = 8). The multivariable results are shown in the table below. **Conclusions:** Male gender, obesity, hepatitis C virus infection, and treatment with busulfan are risk factors for increased AST and ALT. V10 is an additional risk factor for increased ALT. These results may guide future treatment designs and lifestyle interventions.

	Grades 1-4 ALT		Grades 1-4 AST	
	Odds ratio (95%CI)	p-value	Odds ratio (95% CI)	p-value
Male vs female	2.93 (2.33 to 3.68)	< 0.001	2.18 (1.52 to 3.14)	< 0.001
Non-Hispanic black vs NHW	0.66 (0.46 to 0.94)	0.021	*	*
Other vs NHW	1.09 (0.67 to 1.78)	0.737	*	*
BMI ≥ 25 to < 30 vs ≥ 13 to < 25	1.98 (1.47 to 2.68)	< 0.001	1.16 (0.73 to 1.83)	0.536
BMI ≥ 30 vs ≥ 13 to < 25	3.07 (2.24 to 4.23)	< 0.001	1.58 (1.04 to 2.40)	0.033
Hepatitis C (Yes vs No)	2.70 (2.01 to 3.63)	< 0.001	7.66 (4.70 to 12.49)	< 0.001
Busulfan (Yes vs No)	2.52 (1.38 to 4.59)	0.003	4.83 (1.45 to 16.07)	0.01
V10 (per 10%)	1.09 (1.06 to 1.12)	< 0.001	1.04 (1.00 to 1.08)	0.058

* - univariable $p > 0.1$; V10 – percentage of the lung that received ≥ 10 Gy

10568 Poster Session (Board #325), Sun, 8:00 AM-11:30 AM

Impact of a formal human papilloma virus (HPV) education program in a childhood cancer survivor center. *First Author: Karen Cristly Burns, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: The HPV vaccine has proven efficacy in preventing secondary cancers. It was approved for females age 11-26 in 2006 and for males age 11-21 in 2011. Despite this, vaccination rates in the US have been poor. The Cancer Survivorship Center (CSC) at Cincinnati Children's Hospital Medical Center (CCHMC) instituted an education program in July, 2016 to improve education and vaccination rates in a childhood cancer survivor population. The following is a summary of program effectiveness. **Methods:** Providers in the CSC identified females age 11-26, and males age 11-21, presenting for annual visit from 7/1/16 thru 12/31/16. Patients received HPV education materials published by the CDC at registration. Materials were also displayed in exam and waiting rooms. During the visit, providers reviewed and documented vaccination history and discussed the importance of the HPV vaccine in preventing cancer. Patients interested in starting the vaccine series received the first vaccine in clinic and a follow-up schedule for further vaccination. Education and immunization status was documented in the electronic medical record using smart phrase trackable format. All patients were asked to sign a release to obtain vaccine records from the primary physician. A comparison group consisted of HPV eligible patients seen in the CSC during the six months prior to program initiation. Groups were compared for education completed and vaccination rate. **Results:** A total of 156 eligible patients were seen in the comparison group. None received HPV-directed education during their visit. Only 37 (23.7%) had any HPV vaccine, with 5 given during the clinic visit (13.5%). By comparison, 176 eligible patients were seen after initiation of the education program. All patients received materials at registration and 89% had documented education completed by a health care provider. Ninety one (55%) had any HPV vaccine, with 30 given during the clinic visit (33%). **Conclusions:** Through the implementation of a standardized education program in the CSC, we saw more than a 200% increase in rate of HPV vaccination. This demonstrates the importance of knowledgeable providers and the value of a dedicated HPV education program.

10569 Poster Session (Board #326), Sun, 8:00 AM-11:30 AM

Second malignant neoplasms in a nationwide population-based cohort of childhood cancer survivors in Taiwan. *First Author: Chu-Ling Yu, Taipei Cancer Center, Taipei Medical University, Taipei, Taiwan*

Background: Childhood cancer survivors have excess risk of second malignant neoplasms, but data are limited in Asian populations. We established a nationwide retrospective cohort of childhood cancer survivors in Taiwan to study the risk of second malignant neoplasms in the population. **Methods:** Children and adolescents diagnosed with cancer before age 21 years between 1990 and 2011 were identified from the Taiwan Cancer Registry, the national cancer registry in Taiwan. One-year survivors of childhood cancer were ascertained through data linkage with the national death registry. Survivors were followed up through December 2012. Standardized incidence ratios (SIRs), absolute excess risks (AERs), and cumulative incidence of second malignant neoplasms were calculated. **Results:** A total of 186 second malignant neoplasms occurred among 15,263 1-year survivors of childhood cancer after a mean follow-up time of 8.0 years (SIR = 5.4, 95% confidence interval [CI] = 4.6-6.2; AER = 12.4 per 10,000 person-years). The most common types of second malignant neoplasms were gastrointestinal cancers (n = 37), leukemia (n = 28), endocrine cancers (n = 18), and brain cancer (n = 17). Cancers in the liver (n = 11, including 9 hepatocellular carcinoma) and colorectum (n = 16) accounted for 73% of second gastrointestinal malignant neoplasms in this population. The cumulative incidence of second malignant neoplasms at 10 and 20 years from follow-up was 1.0% (95% CI = 0.8-1.2%) and 3.0% (95% CI = 2.3-3.6%), respectively. **Conclusions:** Childhood cancer survivors in Taiwan experience excess risk of second malignant neoplasms, in particular gastrointestinal cancers, compared with the general population.

10570 Poster Session (Board #327), Sun, 8:00 AM-11:30 AM

Accuracy of self-reported smoking status in adult survivors of childhood cancer: A report from St. Jude Lifetime Cohort study. *First Author: I-Chan Huang, St. Jude Children's Research Hospital, Memphis, TN*

Background: Although clinicians often evaluate smoking behavior in cancer survivors via self-report, the validity of this approach is unknown. We validated self-reported smoking status by serum cotinine data in clinically assessed adult survivors of childhood cancer and identified factors contributing to misclassification. **Methods:** The study sample consists of 287 randomly selected adult survivors of childhood cancers participating in the St. Jude Lifetime Cohort Study and undergoing a risk-based clinical assessment in a survivorship clinic. Self-reported smoking status was classified as never (N = 105), past (N = 111), and current (N = 71) smokers. Age, sex, and race/ethnicity were balanced among the three groups (p's $>$ 0.05). Blood samples were obtained and serum cotinine levels were quantified by liquid chromatography tandem mass spectrometry. Misclassification was determined by the discrepancies between self-reported smoking status and race/ethnicity-specific serum cotinine thresholds (Benowitz et al. Am J Epidemiol 2009). Multiple logistic regression model was used to identify factors related to misclassification. **Results:** Of the 287 survivors (mean age = 34 years [range = 19-61]; mean time from diagnosis = 24 years [range = 11-46]), 55.4% were male and 84.0% non-Hispanic white. Cotinine levels consistent with recent active smoking were present in 39.4% compared to 24.7% who self-reported as being a current smoker (X^2 = 14.1; p = 0.0002). Rates of misclassification were 36.9%, 8.4%, and 6.7% in survivors who reported themselves as past, current, and never smokers, respectively. Among self-reported past smokers, 18-30 years of age at survey, male, and current marijuana use increased the risk of misclassification: RR = 3.0 (95%CI = 1.2-7.6), 2.5 (95%CI = 1.1-5.4) and 3.2 (95%CI = 1.1-9.3), respectively. **Conclusions:** Within a clinical setting, reliance on self-report of smoking status by survivors results in a high misclassification rate. For research, serum cotinine levels should be utilized to assign smoking status. For clinical care and health promotion, clinicians need to be aware of the high rate of misclassification when relying upon self-reported smoking status.

10571 Poster Session (Board #328), Sun, 8:00 AM-11:30 AM

Genome-wide discovery of novel susceptibility loci for treatment-associated hypothyroidism among survivors of pediatric medulloblastoma. *First Author: Austin L Brown, Baylor College of Medicine, Houston, TX*

Background: Pediatric medulloblastoma patients exposed to craniospinal radiation (CSI) are at high risk of developing endocrinopathies, including hypothyroidism. We sought to evaluate the role of genetic variation on hypothyroidism susceptibility among survivors of pediatric medullobastoma. **Methods:** Records from 61 medulloblastoma survivors treated at Texas Children's Hospital between 1997 and 2013 were reviewed. All patients completed baseline and yearly follow-up thyroid assessments. Genome-wide genotyping was performed on Illumina HumanOmni1 and HumanOmni2.5 BeadChip single nucleotide polymorphism (SNP) arrays. Following standard quality control measures and exclusion of rare variants (minor allele frequency [MAF] $<$ 5%), 572,562 autosomal SNPs were included in our analyses. The association between each SNP and hypothyroidism was tested using Fisher's exact test and logistic regression, assuming additive allelic effects. **Results:** A total of 25 patients (41%) developed hypothyroidism with median follow-up of 8.3 years from diagnosis (range: 1.8-17.2 years). Primary hypothyroidism was identified in 9 (36%) cases, while the remaining 16 (64%) developed central hypothyroidism. Hypothyroidism was detected in 13 of 40 (33%) individuals exposed to $<$ 30 Gy CSI and 12 of 21 (57%) individuals exposed to $\geq$30 Gy CSI (p = 0.06). Genome-wide association analysis identified several risk loci, including 3 variants associated with hypothyroidism (p-value $< 1x10^{-5}$) at chromosome 2q11.2 (*NPAS2* gene). The top overall SNP (MAF = 27.5%, p-value = $6.5x10^{-7}$) remained strongly associated with hypothyroidism after accounting for possible confounders, including CSI dose, CSI type (proton/photon), age, sex, and genetic ancestry. **Conclusions:** Our findings suggest susceptibility to treatment-related hypothyroidism is strongly influenced by common genetic variation in *NPAS2*. The *NPAS2* gene, a central component of the circadian rhythm network, is a transcriptional activator and regulator of DNA damage response and DNA repair genes.

10572 Poster Session (Board #329), Sun, 8:00 AM-11:30 AM

Prevalence of attention-deficit/hyperactivity disorder in pediatric brain tumor survivors. *First Author: Emily Kauvar Shabason, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Pediatric brain tumor survivors (PBTS) often have neurodevelopmental late effects, including attention and concentration deficits, which may impact cognitive and academic functioning. Such symptoms are also seen in attention-deficit/hyperactivity disorder (ADHD), which affects ~5-8% of children and adolescents. This study examined the prevalence of ADHD diagnosis and ADHD medication use in PBTS and identified higher risk subsets of patients. **Methods:** A retrospective chart review was completed of PBTS (n = 106), diagnosed from 1999-2013, who were at least 2 years from the end of tumor-directed therapy (surgery, chemotherapy and/or radiation therapy) and without a multi-system genetic disorder or severe developmental delay prior to brain tumor diagnosis. Subjects were already screened for or enrolled in 3 other studies of PBTS late effects. Statistical analysis involved chi-squared analysis. **Results:** Among the 106 patients, 55.7% were male, with an average age at time of brain tumor diagnosis of 5.9 years (0-12.2 years). The most common tumor types were glioma (51.9% with 47.2% low grade, 4.7% high grade), medulloblastoma (13.2%) and ependymoma (11.3%), with 50% of tumors supratentorial, 46.2% infratentorial and 3.8% either extending or multifocal across the tentorium. Of the patients, 42.5% received radiation therapy, 38.7% chemotherapy and 86.8% surgery. Nineteen patients (17.9%) had ADHD diagnoses, and 20 (18.9%) had been on ADHD medications. Clinical factors associated with an ADHD diagnosis were supratentorial vs. infratentorial tumors (28.3% vs. 6.1%, p = 0.013), no radiation therapy vs. radiation therapy (27.9% vs. 4.4%, p = 0.002) and no chemotherapy vs. chemotherapy (24.6% vs. 7.3%, p = 0.024). ADHD diagnosis was not associated with age of brain tumor diagnosis or surgical treatment. **Conclusions:** Our study suggests that PBTS have over twice the ADHD prevalence as the general population, most notably in patients with supratentorial tumors or without a history of radiation therapy or chemotherapy. The results suggest that a closer look at this population is warranted and that select patients may benefit from behavioral or pharmacologic ADHD treatments to optimize functioning.

10573 Poster Session (Board #330), Sun, 8:00 AM-11:30 AM

Predictors of specialized pediatric palliative care involvement and impact on patterns of end-of-life care in children with cancer: A population-based study. *First Author: Sumit Gupta, Hospital for Sick Children, Toronto, ON, Canada*

Background: Children with cancer are at risk of receiving high-intensity (HI) care at the end-of-life (EOL) and associated high symptom burden. The impact of palliative care (PC) delivered by generalists or of specialized pediatric palliative care (SPPC) on patterns of EOL care is unknown, with previous studies limited by small sample sizes or low response rates. **Methods:** Using a provincial registry, we assembled a retrospective cohort of Ontario children with cancer who died between 2000-2012 and who received care through a pediatric institution with a SPPC team and a clinical PC database. Patients were linked to population-based healthcare data capturing inpatient, outpatient, and emergency visits. Clinical PC databases were used to identify patients receiving SPPC. Remaining patients were categorized as having received either general PC (GPC) or no PC depending on the presence of PC associated physician billing or inpatient codes. We determined predictors of SPPC involvement, and whether either SPPC or GPC was associated with HI-EOL outcomes: ICU admission $<$ 30 days from death, mechanical ventilation $<$ 14 days from death, or in hospital death. Sensitivity analyses excluded treatment-related mortality (TRM) cases. **Results:** 572 patients met inclusion criteria. Children less likely to receive SPPC services included those with hematologic cancers [odds ratio (OR) 0.33, 95th confidence interval (CI) 0.30-0.37; $p < 0.001$)], in the lowest income quintile (OR 0.44, 95CI 0.23-0.81; p = 0.009), and living at increased distance from the treatment center (OR 0.46, 95CI 0.40-0.52; $p <$ 0.0001). In multivariate analysis, SPPC was associated with a 3-fold decrease in the odds of an EOL ICU admission (OR 0.32, 95CI 0.18-0.57), while GPC had no impact. Similar associations were seen with all other HI-EOL indicators. Excluding TRM had little impact. **Conclusions:** SPPC, but not GPC, is associated with lower intensity care at EOL. Access to such care however remains uneven. In the absence of randomized trials, these results provide the strongest evidence to date supporting the creation of SPPC teams. These results can be used to support PC advocacy and policy efforts.

10574 Poster Session (Board #331), Sun, 8:00 AM-11:30 AM

Intensity of end-of life-care in children with cancer: A population-based study. *First Author: Emily E. Johnston, Stanford University Medical Center, Palo Alto, CA*

Background: There is growing evidence that adult oncology patients who know they are dying choose less intense care. Further, high intensity care is associated with worse caregiver outcomes. Little is known about pediatric oncology end-of-life care intensity. **Methods:** Using the California Office of Statewide Health Planning and Development administrative database linked to death certificates, we performed a retrospective population based analysis of cancer patients aged 0-21 who died between 2000 and 2011. The frequency of previously defined end-of-life intensity markers (hospital death, intense medical interventions, IV chemotherapy, and gastrostomy and tracheostomy tube placement) were calculated and multivariable logistic regression was used to determine clinical and sociodemographic factors associated with $>$ 2 intensity markers (as above), intense medical intervention (cardiopulmonary resuscitation, intubation, ICU admission, or hemodialysis), and hospital death. **Results:** The 3,732 pediatric cancer decedents were 34% non-Hispanic whites and 45% Hispanic; 41% had hematologic malignancies and 59% solid tumors. The most prevalent intensity markers included: hospital death (63%) and ICU admission (20%). 65% had $>$ 1 intensity marker, 23% $>$ 2, and 22% $>$ 1 intense medical intervention. There was a bimodal association between age and intensity: the youngest patients (age $<$ 5) and adolescent patients (age 15-21) were more likely to receive intense care: $<$ 5y (intense medical intervention: OR = 1.42; 95% CI, 1.1-1.9; hospital death: OR = 1.72; 95% CI, 1.4-2.2; $>$ 2 markers: OR = 1.37, 95% CI 1.1-1.8); 15-21y (intense medical: OR = 1.48; 95% CI, 1.2-1.9; hospital death: OR = 1.39; 95% CI, 1.1-1.7; $>$ 2 markers: OR = 1.35, 1.1-1.7) (references: 5-9y). Other factors associated with intensity included, hematologic malignancies, minority status, and death between 2008 and 2011 vs. $<$ 2008. **Conclusions:** Nearly two-thirds of the pediatric cancer decedents had $\geq$1 marker of intense care and disparities exist. Patients $<$ 5 and adolescents were more likely to receive intense end-of-life care. Further research needs to determine if these rates and variation are consistent with patient goals and factors associated with goal concurrent care.

10575 Poster Session (Board #332), Sun, 8:00 AM-11:30 AM

Fosaprepitant use in children and adolescents at Memorial Sloan Kettering Cancer Center. *First Author: Dazhi Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recent NCCN guidelines recommend the addition of a neurokinin-1(NK1) receptor antagonist (e.g. fosaprepitant) to the serotonin 5-hydroxytryptamine type 3 (5-HT3) receptor antagonist-corticosteroid combination for controlling both acute and delayed chemotherapy induced nausea and vomiting(CINV) associated with high emetogenic chemotherapy (HEC) in adults. Fosaprepitant is bioequivalent to aprepitant and could offer benefits to patients who are unable to tolerate oral antiemetics. However, little is known about the efficacy and safety of fosaprepitant in children. **Methods:** This retrospective chart review included all pediatric patients less than 18 years of age who received fosaprepitant at Memorial Sloan Kettering Cancer Center from July 2011 to November 2016. **Results:** Thirty-one patient charts representing a total of 105 doses of fosaprepitant were reviewed. Median age was 15 (range 2-17) years. Fifty-one doses (49%) were administered for primary prophylaxis for 11 patients; 40 doses (38%) for 12 patients who had a history of severe CINV and 14 doses (13%) as rescue for CINV in 10 patients after chemotherapy. Seventy-eight of the 101 chemotherapy cycles were highly emetogenic including 39 containing cisplatin. In the first two groups, patients did not have any episodes of vomiting in 97% and 88% of chemotherapy cycles respectively after fosaprepitant therapy. Seven of 12 patients receiving fosaprepitant for $>$ 3 episodes of breakthrough vomiting within 24 hours had no vomiting episodes during the first 24 hours post fosaprepitant administration. No fosaprepitant-related side effects were reported. **Conclusions:** Fosaprepitant appears to be safe and tolerable in children with cancer in whom it may provide benefit as prophylaxis and treatment of CINV. However a phase III study is warranted to formally study its role in pediatrics.

TPS10576 Poster Session (Board #333a), Sun, 8:00 AM-11:30 AM

Phase 1 multicenter trial of CUDC-907 in children and young adults with relapsed or refractory solid tumors, CNS tumors, and lymphoma. *First Author: David Stephen Shulman, Dana-Farber Cancer Institute/Boston Children's Hospital, Boston, MA*

Background: CUDC-907 is an oral first-in-class small molecule inhibitor of histone deacetylases (HDACs) and phosphatidylinositol-3-kinases (PI3Ks), two enzyme classes commonly implicated in pediatric malignancies. Preclinical data demonstrate that inhibition of these enzymes decreases tumor growth across a range of histologies. Data from preclinical and clinical studies suggest that down-regulation of Myc or Mycn signaling may be important in the antineoplastic effects of CUDC-907. Myc or Mycn signaling appears to drive a number of pediatric cancers, heralds a poor prognosis in many of these diseases and has proven difficult to target. CUDC-907 has completed adult phase I testing in patients with hematologic malignancies. The drug was tolerable using a 5 days on/2 days off (5/2) dosing strategy, with a recommended phase II dose of 60 mg. Diarrhea, fatigue, nausea and thrombocytopenia were the most commonly reported side effects. Partial and complete responses were observed in patients with Myc-altered diffuse large B cell lymphoma. **Methods:** This study is a phase I, open-label, multicenter trial of CUDC-907 in patients 1-21 years of age with relapsed/refractory solid tumors, brain tumors and lymphomas (NCT02909777). The primary objectives are to determine the recommended phase II dose, describe toxicities, and describe pharmacokinetic parameters of CUDC-907 in this population. Other objectives include evaluation of disease response and exploration of the pharmacodynamic effects of CUDC-907. Patients receive CUDC-907 orally on a 5/2 schedule in 28-day cycles, with a pediatric mini-tab formulation available for younger children. Part A consists of a standard 3+3 design evaluating up to three dose levels. Following dose escalation, Part B consists of two expansion cohorts for patients with Mycn/Myc-driven neuroblastoma or mature B-cell lymphoma. Up to 44 patients may be enrolled across Parts A and B. Detailed pharmacokinetic testing is required in the first two cycles. Optional pharmacodynamic testing will quantify histone acetylation, Myc protein, and phospho-S6 in serial blood samples. Enrollment began in October 2016 and is ongoing. Clinical trial information: NCT02909777.

TPS10577 Poster Session (Board #333b), Sun, 8:00 AM-11:30 AM

Phase 1/2 study of the selective TRK inhibitor larotrectinib in pediatric patients with cancer. *First Author: Noah Federman, University of California, Los Angeles, Los Angeles, CA*

Background: Neurotrophin ligands and their receptors TRKA, TRKB, and TRKC (encoded by *NTRK1, NTRK2, and NTRK3)* are important for growth regulation, differentiation and survival of neurons. Translocations involving the *NTRK1/2/3* kinase domain, mutations involving the TRK ligand-binding site, and amplifications of *NTRK*, have been described in diverse tumor types and may contribute to tumorigenesis. A broad range of pediatric malignancies have been found to harbor *NTRK* fusions, including infantile fibrosarcoma (IFS), spindle-cell sarcoma, congenital mesoblastic nephroma, pediatric papillary thyroid cancer, pediatric gliomas and Ph-like acute lymphoblastic leukemia. Larotrectinib is the first small-molecule selective inhibitor of TRKA, -B, and -C in clinical development and preliminary data from the adult phase 1 trial demonstrate prolonged responses in patients with TRK fusions and a favorable safety profile. **Methods:** We have initiated an open-label, multi-center, international Phase 1/2 study with larotrectinib in pediatric patients with solid tumors and primary CNS tumors (NCT02637687). Patients with advanced cancer between the ages of 1 year and 21 years are eligible, as well as patients as young as 1-month of age with a documented *NTRK* fusion. Patients with IFS who have not had definitive surgery are also eligible. Larotrectinib is administered orally twice daily on a continuous 28-day schedule. Dosing is based on body surface area. Larotrectinib is available in an oral liquid formulation and capsules. Following identification of the maximum tolerated dose of larotrectinib in the phase 1 portion, the phase 2 portion will commence. The phase 2 portion will enroll patients with *NTRK*-translocated tumors and measurable disease into three cohorts: 1) infantile fibrosarcoma; 2) extracranial solid tumors; and 3) primary CNS tumors. The primary endpoint for the phase 2 portion is objective response rate, with duration of response and progression free survival as secondary efficacy endpoints. Each phase 2 cohort will enroll in a single stage of up to 10 patients per cohort. Molecular abnormalities will be characterized through the analysis of archival tissue. Enrollment began in December 2015 and is ongoing. Clinical trial information: NCT02637687.

TPS10578 Poster Session (Board #334a), Sun, 8:00 AM-11:30 AM

Comparative genomic analysis for pediatric cancer patients evaluated in a California Initiative to Advance Precision Medicine Demonstration Project. *First Author: Olena Morozova, University of California, Santa Cruz, Santa Cruz, CA*

Background: California Kids Cancer Comparison (CKCC), a demonstration project for the California Initiative to Advance Precision Medicine, evaluates the utility of incorporating gene expression information into the genomic analysis of difficult-to-treat pediatric cancers. CKCC is a partnership between UC Santa Cruz and clinical genomic trials conducted by Children's Hospital of Orange County, UC San Francisco (Pacific Pediatric Neuro Oncology Consortium), and Stanford University. **Methods:** CKCC compares each prospective tumor's RNA sequencing profile to over 11,000 uniformly analyzed tumor profiles from pediatric and adult cancer patients. These comparisons are used to identify genes and pathways that are significantly over expressed in each patient's tumor. The pathways are reviewed by data analysis for the potential for clinical impact and presented to the treating oncologist in a molecular tumor board setting.

TPS10579 Poster Session (Board #334b), Sun, 8:00 AM-11:30 AM

Phase 1 trial of lyso-thermosensitive liposomal doxorubicin (LTLD) and magnetic resonance guided high intensity focused ultrasound (MR-HIFU) for pediatric refractory solid tumors. *First Author: AeRang Kim, Children's National Health System, Washington, DC*

Background: Prognosis for children and young adults with refractory solid tumors remains unacceptably poor. Current approaches have reached the limits of maximal dose intensification, and the acute and late side effects of therapy are substantial. MR-HIFU is an innovative therapy that uses an external applicator to focus ultrasound energy inside a tumor non-invasively and without radiation. The resulting heating is precisely controlled and accurately targeted with the aid of MR thermometry and anatomic imaging. The flexibility and control over local heating by MR-HIFU provide an ideal system to be used with LTLD, a novel formulation of liposomal doxorubicin with the unique property of rapid heat-activated release of doxorubicin, an active agent in most pediatric solid tumors. The potential synergistic effects include enhanced permeability of the tumor vasculature, enhanced extravasation of the drug and subsequent high local concentrations of doxorubicin in the targeted tumor, inhibition of DNA repair, and stimulation of immune responses. **Methods:** This is the first pediatric trial of LTLD with MR-HIFU in refractory solid tumors (NCT02536183). Part A is a phase 1 dose escalation study to determine the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D) of LTLD combined with MR-HIFU ablation in children. Part B combines LTLD at the MTD/RP2D with MR-HIFU induced mild hyperthermia (MHT) in an expanded cohort. Patients $\leq$21 (Part A) and $\leq$30 (Part B) years of age with refractory solid tumors at sites accessible to MR-HIFU, adequate organ function including cardiac function, and prior anthracycline dose of $\leq$ 450 mg/m^2 are eligible. LTLD is administered intravenously over 30 min followed immediately by MR-HIFU on day 1 of a 21-day cycle. Patients can receive a maximum of 6 cycles (or lifetime of 600 mg/m^2 of cumulative anthracycline) provided treatment is tolerated and have at least stable disease. Secondary objectives evaluate changes in quality of life and pharmacodynamic immune markers in children treated with LTLD and MR-HIFU. Clinical trial information: NCT02536183.

11000 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Phase III study of aldoxorubicin vs investigators' choice as treatment for relapsed/refractory soft tissue sarcomas. *First Author: Sant P. Chawla, Director, Sarcoma Oncology Center, Santa Monica, CA*

Background: Aldoxorubicin (A) is a novel drug that binds covalently to albumin in the circulation, accumulates in tumors and releases doxorubicin in the acidic tumor environment. It has demonstrated enhanced antitumor activity in several murine models and in a phase IIb STS study when compared with doxorubicin. *Trial Design*: Phase III open-label study evaluating efficacy and safety of A compared to investigators' choice (IC) of treatment in subjects with soft tissue sarcomas (STS) who have relapsed or were refractory to prior chemotherapy. *Objectives*: (1) Primary: Efficacy of A vs IC: progression-free survival (PFS); (2) Secondary: Efficacy of A vs IC: tumor response (ORR), disease control rate (DCR; CR+PR+SD > 4 months), overall survival (OS) and safety. **Methods:** A: 350 mg/m^2 (260 mg/m^{2}dox. equiv.) iv q3 wks. IC drugs: dacarbazine, doxorubicin, pazopanib, ifosfamide, gemcitabine/docetaxel administered per package insert or study site's standard practice; provided, with G-CSF, by the sponsor. AEs, serum chemistries, CBCs, EKG and ECHOs obtained frequently. CT scans every 6 weeks for 30 weeks, then every 12 weeks; analyzed using RECIST 1.1 by Blinded Independent Central Review. **Results:** Randomized 433 subjects; 79 countries; 313 (72%) in North America (NA) and 121 (28%) in Rest of World (ROW). Leiomyosarcoma 42.5%, liposarcoma 15%, synovial sarcoma 9%, others 33.5%, L-sarcomas (lipo+leiomyo) 57.5%. Median PFS Total Pop. (months): A= 4.06; IC= 2.96; p = 0.12; HR = 0.82 (0.64-1.06). Median PFS NA (months): A= 4.21; IC= 2.96; p = 0.027; HR = 0.71 (0.53-0.97). Median PFS L-sarcomas (months): A= 5.32; IC= 2.96; p = 0.007; HR = 0.62 (0.44-0.88). DCR Total Pop.(%): A= 30.3; IC= 20.9; p = 0.028; DCR NA (%): A= 32.9; IC= 19.2; p = 0.007; DCR L-Sarcomas (%): A= 37.5; IC= 23.0; p = 0.018. ORR and OS will be reported. TEAEs gr 3 or 4 (%): A= 61.0; IC= 46.4. Trtmt Rel. SAEs (%): A= 27.0; IC= 14.0. TEAEs leading to Drug Discontinue (%): A= 4.2; IC= 6.3. Trtmt Related Deaths (#); A= 3; IC= 0; LVEF < 50% expected (%): A= 2.8%; Dox = 12.8%. **Conclusions:** Aldox is an active, well-tolerated drug for treating relapsed or refractory STS and is significantly better than standard treatments for patients with L-sarcomas. Clinical trial information: NCT02049905.

11001 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Impact of next-generation sequencing (NGS) on diagnostic and therapeutic options in soft-tissue and bone sarcoma. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: The utility of NGS in management of sarcoma pts remains undefined. **Methods:** We retrospectively analyzed the NGS profile of patients who were sequenced using a panel of 405 cancer-related genes in DNA and 265 genes rearranged in RNA. Diagnostic and therapeutic implications of mutations (mut) were evaluated through published literature (OncoKb.org, Pubmed). An algorithm was applied to determine germline mut. Following IRB approval, we evaluated the clinical outcomes of pts who underwent NGS at MSKCC. **Results:** From 2012–2016, 5635 pts worldwide with 56 histologies were tested. Median age of 52 yrs (< 1-88), 52% females and sarcoma NOS (n = 858) was most frequent. Tumors were sequenced to a mean coverage of 634X; 1165 fusions and > 60,000 mut were found. Mut suspicious for germline defects were seen in 542 pts (9.6%) in known and novel genes (*BRCA*, *ARID1*, *FANC*). Tumor mutational burden was 2.5/Mb (0–329) and glomus tumors and EHE had the highest and lowest mut, respectively. 16% and 7% of pts had treatment-linked alterations (TLA) known to respond to an FDA approved or study drug, respectively. 42% of pts had TLA eligible for NCI-MATCH, ASCO-TAPUR or other studies. Novel TLA include *AKT*, *ESR1*, *BRCA*, *NTRK*, *PTCH1, SMARCB1 and others.* Of the 107 MSKCC pts with clinical data, 60/107 (57%) had at least one TLA, of which 31 (30%) enrolled on a matched trial and 26 pts were ineligible or lacked access to trials. Partial/complete responses were seen with inhibitors to NTRK, IDH1, BRAF, PI3K/mTOR, MDM2, SMARCB1 and others. NGS changed the initial pathology diagnosis and treatments in 5% pts (e.g. LMS to liposarcoma, clear cell to melanoma). Resistance mutations averted futile therapies in 5% pts (e.g. Rb loss and palbociclib in liposarcoma). **Conclusions:** Our data suggests that NGS has a significant impact in aiding diagnosis and selecting matched therapies in sarcoma. Suspected germline aberrations, while intriguing, needs further validation.

11002 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Genetic landscape of soft-tissue sarcomas: Moving toward personalized medicine. *First Author: Antoine Italiano, Institut Bergonié, Bordeaux, France*

Background: Patients with advanced soft-tissue sarcomas have a very poor outcome with a median overall survival of less than 18 months. Identification of molecular abnormalities for which targeted therapies are available or can be developed is critical for improving their outcomes. **Methods:** We have analyzed the mutational and copy number profiles of patients with sarcoma sequenced through the AACR Project GENIE Consortium in order to identify the proportion of cases bearing actionable mutation. **Results:** 587 patients (pts) were included in the study (295 males). 331 pts (56%) had complex genomics sarcomas, 144 (25%) translocation-related sarcomas and 112 (19%) others sarcomas (inactivating mutation, simple amplicon). The five most frequent histology were: Leiomyosarcoma (n = 112; 19.1%); Undifferentiated Pleomorphic Sarcomas (n = 74, 12.6%), dedifferentiated liposarcoma (n = 55, 9.4 %), angiosarcoma (n = 43, 7.3%), synovial sarcoma (n = 38, 6.5%). 430 pts (73%) had at least one mutation. The ten most frequently mutated genes were: *TP53* (34.7%); *ATRX* (9.1%), *RB1* (8.4%), *KMT2D* (5.8%), *NF1* (5.3%), *ATM* (5.1%), *PI3KCA* (4.9%), *ERBB4* (4.2%), *PTEN* (4%), and *ARID1A* (3.7%). 504 patients (85.9%) presented at least one copy number alteration. The 5 five most frequently amplified genes were: *MDM2* (20%), *CDK4* (16.7%), *GLI1*, *MAP2KA*, and *TERT* (3.2% for each gene), and the most frequently deleted were *RB1* (12.7%), *CDKN2A* (10.3%), *CDKN2B* (9.7%), *TP53*(9.5%), *PTEN* (8.5). 92.5% of pts had at least one targetable mutation, copy number alteration and/or fusion gene (Leiomyosarcoma n = 100/17%, UPS n = 74/12%, dedifferentiated diposarcoma n = 54/9%, angiosarcoma n = 41/7%, synovial Sarcoma n = 36/6%), with incidences reported that will be reported in details at the meeting. **Conclusions:** This is the first large report of genomic landscape including mutation and copy number profiling through NGS of soft-tissue sarcomas. Our results indicate a significant proportion of actionable mutations and represent a rationale for the MULTISARC study: the first study implementing Exome Seq and RNA Seq for clinical decision making in patients with advanced STS. The design of this study supported by the French government and launched in 09/2017 will be presented at the meeting.

11003 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Multi-institutional European single-arm phase II trial of pazopanib in advanced malignant/dedifferentiated solitary fibrous tumors (SFT): A collaborative Spanish (GEIS), Italian (ISG), and French (FSG) sarcoma groups study. *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS), Seville, Spain*

Background: SFT is a rare soft tissue tumor. In advanced SFT chemotherapy has only limited activity. With the rationale of a rich vascular network & VEGF (tumor cells and endothelium) and VEGFR1/2 (endothelial cells) expression in SFT, we designed an international, single-arm phase II trial to test pazopanib (P) in advanced SFT. Clinical and preclinical evidence suggesting that anti-angiogenics was less effective in more aggressive compared with less aggressive SFT (Stacchiotti et al), led us to conduct the trial on two different cohorts: typical and malignant (M)/dedifferentiated (DD) SFT. Here we present the outcome of the latter cohort. **Methods:** Most relevant inclusion criteria were: unresectable or metastatic, M/DD SFT confirmed by central pathologic review with evidence of STAT6 (IHC and /or FISH or RT-PCR), ≥ 18 years, ECOG 0-2, progressive and measurable disease. Main endpoint was response rate (RR) according Choi criteria. Central radiological assessment was mandatory. P was administered at 800 mg/d continuously until progression or toxicity. **Results:** From June 2014 to November 2016, 34 patients (pts) were enrolled with a median age of 61 y (23-87). Median tumor size and mitosis at diagnosis were 77 mm and 8x10 HPF. Most relevant grade 3-4 toxicity were neutropenia (9%) and hypertension (12%). At the time of the present analysis, 31 pts are evaluable for response. RR according to Choi and RECIST were: PR 16 (52%), SD 7 (22%), PD 8 (26%) and PR 1 (3%), SD 19 (61%), PD 11 (35%) respectively. With a median follow-up of 15 months, the median PFS was 5.53 months (4.24-6.82), while 72% survived at 18 months. Size > 5 cm, mitosis > 8 and DD subtype showed significantly worse PFS. The 18-month OS was 90% for those with SD and PR and 25% for PD according to Choi ($p < 0.001$), while 94% for SD and PR and 45% for PD according RECIST ($p = 0.002$). In multivariate analysis, only Choi was an independent prognostic factor for OS with PD showing a HR of 11.9 (2.3-63.1), $p = 0.003$ for the risk of death. **Conclusions:** Pazopanib showed activity in malignant SFT. Choi criteria exhibited a more accurate assessment of response than RECIST. Clinical trial information: NCT02066285.

11004 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Activity of cediranib in alveolar soft part sarcoma (ASPS) confirmed by CASPS (cediranib in ASPS), an international, randomised phase II trial (C2130/A12118). *First Author: Ian Robert Judson, Cancer Research UK Centre for Cancer Therapeutics, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: ASPS is a rare disease (0.5-1% of soft tissue sarcomas) mainly affecting young people. It is unresponsive to conventional chemotherapy. Cediranib (C), an inhibitor of vascular endothelial growth factor receptors and other receptor tyrosine kinases, has shown significant activity in ASPS in single arm phase II trials. CASPS (NCT01337401) was designed to permit discrimination between the impact of cediranib and the often intrinsically indolent nature of the disease. **Methods:** CASPS compared C (30mg od) with placebo (P) in a 2:1 double blind randomisation in patients (pts) age ≥16 years with metastatic ASPS progressive in the previous 6 months. Pts were unblinded at week 24, or at progression if sooner, when those on P started C. The primary endpoint of percentage change in the sum of target marker lesions (TML_{sum}) between baseline and week 24 (or progression if sooner) was compared between groups by Mann-Whitney test. Secondary endpoints were progression-free survival (PFS), week 24 response rate and best response (RECIST v1.1), safety/tolerability and overall survival (OS). One-sided p-values and two-sided 90% confidence intervals are reported. **Results:** 48 pts were recruited between 07/2011 and 07/2016 from 12 centres (UK, Australia & Spain). 52% of pts were female, median age was 31. Most common grade ≥3 adverse events on C were hypertension (23%), diarrhoea (14%) and fatigue (9%). In the evaluable population (N = 44) median change in TML_{sum} on C was minus 8.3% (IQR minus 26.2% to +5.9%); versus P: +13.4% (IQR minus 0.6% to +21.3%), p = 0.0013. Best response by week 24 was partial response for 6/28 (21%) C pts compared with 0/16 on P (p = 0.053) and stable disease for an additional 19/28 (68%) on C and 12/16 (75%) on P. The PFS HR (C versus P) was 0.54 (90% CI 0.30-0.97, p = 0.041), median PFS: 10.8 mths on C versus 3.7 mths on P, OS at 12 mths was C: 96%; P: 64.3%. **Conclusions:** CASPS, the largest randomised trial to date in this disease, confirms the activity of C in ASPS, showing a significant reduction in tumour burden and improvement in PFS. Tumour tissue and serial blood samples will subsequently be investigated to identify potential predictive and prognostic biomarkers. Clinical trial information: NCT01337401.

11005 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

A phase II trial of regorafenib (REGO) in patients (pts) with advanced Ewing sarcoma and related tumors (EWS) of soft tissue and bone: SARC024 trial results. *First Author: Steven Attia, Mayo Clinic, Jacksonville, FL*

Background: Pazopanib is approved for soft tissue sarcoma pts after failure of other therapy, but there are few subtype-specific data regarding kinase inhibitor activity. We report on a single arm, phase II trial of REGO in advanced EWS. **Methods:** EWS pts (age > 18, ECOG 0-2, good organ function) who had at least 1 line of therapy and had PD within 6 mo were eligible. Prior oral kinase inhibitors were not allowed. Initial REGO dose was 160 mg PO QD x21 q28d. Dose reductions were employed for toxicity and AEs. The primary endpoint was PFS at 8 weeks (PFS8w) employing RECIST 1.1. Sample size of 30 allowed determination of the difference between PFS8w of 50% vs 25% with alpha = 0.05 and power of 91%. **Results:** 30 pts (median age 32, range 19-65; M/F = 20/10; ECOG 0/1/2 = 16/13/1; bone, 12; soft tissue, 18; median prior treatments 5, range 1-10) enrolled at 14 US sites (09/2014-03/2016). Most common grade (G3) toxicities were hypophosphatemia (6), hypertension (2), high ALT (2) and 1 each: fatigue, abd pain, diarrhea, hypokalemia, oral mucositis, neutropenia and rash; no G4 toxicities were noted. 13 pts required ≥1 dose reduction, most commonly hypophosphatemia (n = 7); 2 stopped REGO for toxicity. There was 1 death in the 30 day post study period, not REGO related. Median dose at study end: 140 mg (3.5 tabs, range 80-160 mg) 3 wks on/1wk off. 18/30 pts were without PD at 8 wks. Median PFS: 3.6 mo (95%CI 2.8-3.8 mo). PFS8w by KM was 73% (95%CI 57-89%). Best responses: PR/SD/PD/not evaluable of 3/18/7/2, for RECIST RR 10%. Two pts with PR had *EWSR1* translocation by FISH; a third had *CIC-DUX4*. Median duration of response: 5.5 mo (95%CI 2.9-8.0). Median OS is not reached. **Conclusions:** The substudy met its primary endpoint. REGO toxicity was similar to that seen previously. Enrollment continues in LPS and OGS cohorts, and is being expanded to further study variant EWS without *EWSR1-FLI1* fusion. Study of the existing tissue may elucidate which EWS patients may benefit from REGO. Clinical trial information: NCT02048371.

11006 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Immune response, safety, and survival impact from CMB305 in NY-ESO-1+ recurrent soft tissue sarcomas (STS). *First Author: Neeta Somaiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CMB305 is an active immunotherapy regimen designed to generate and expand anti-NY-ESO-1 T cells. It consists of LV305, a dendritic cell targeting lentiviral vector encoding NY-ESO-1, and a boost with G305, an NY-ESO-1 recombinant protein plus GLA-SE, a TLR-4 agonist. An LV305 phase 1 study demonstrated a 1-yr survival of 81% and induction of anti-NY-ESO-1 T cells in sarcoma patients (pts). This first-in-human study of CMB305 examined safety, immunogenicity, and efficacy in pts with NY-ESO-1 positive (+) solid tumors. **Methods:** Adults with previously treated NY-ESO-1^+ sarcomas, NSCLC, ovarian cancer were enrolled in a 3+3 dose-escalation with an expansion phase 1 study. The CMB305 regimen included 4 intradermal injections of LV305 at 10^9 or 10^{10} vector genomes, alternating with 3 intramuscular G305 injections at 250 μg for 3 months, then bimonthly G305 injections up to 1 yr. **Results:** As of 31Dec2016, 25 pts with STS (15 synovial (SS), 8 myxoid/round cell liposarcoma (MRCL), 2 other) were evaluable for safety; 23 SS/MRCL pts were evaluable for immune response (IR) and efficacy. All SS and MRCL pts received prior therapy for locally advanced/metastatic disease, 67% > = 2 prior chemo regimens. No DLTs were observed; treatment related AEs were grade 1 and 2, except 1 pt with grade 3 SAE (prostatic pain). Of 11 SS/MRCL pts tested, 64% pts developed NY-ESO-1 specific T cells and 72% pts anti-NY-ESO-1 antibodies. T cell receptor sequencing indicated increased clonality, and antigen spreading after CMB305. Best response by immune related response criteria was stable disease in 8/15 (53%) SS pts and 6/8 (75%) MRCL pts. The 3 month PFS rate was 74% and 75% for SS and MRCL pts. Median survival has not been reached with 1-yr survival rate of 86% and 100% for SS and MRCL pts. **Conclusions:** CMB305 is safe, well tolerated, and demonstrates a survival rate that is favorable when compared with approved agents for recurrent STS. CMB305 resulted in a stronger and broader integrated IR than LV305, including antigen spreading. These data warrant further investigation of CMB305 as a monotherapy in a randomized clinical study in STS. A randomized study of CMB305 in combination with atezolizumab in SS/MRCL pts is ongoing. Clinical trial information: NCT02387125.

11007 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

A multi-center phase II study of nivolumab +/- ipilimumab for patients with metastatic sarcoma (Alliance A091401). *First Author: Sandra P. D'Angelo, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with metastatic sarcoma (SAR) have limited options. Nivolumab(N), a fully human anti-PD-1 mAb and ipilimumab (I), a humanized anti-CTLA-4 mAb, have favorable safety & efficacy in other tumors. Pembrolizumab demonstrated a response rate (RR) of 12% in SAR pts. We evaluated N, independently from N+I, in SAR pts. **Methods:** This open-label multi-center phase II study enrolled pts failing prior regimens. Randomized (non-comparative) pts received either N3 [N (3 mg/kg q2W)] or N3+I1 [N(3 mg/kg Q3W x4, then Q2W) & [I(1 mg/kg q3W x4)]. Treatment continued beyond progressive disease (PD) in 1^{st}12 weeks. 5 confirmed responses in 38 evaluable pts yielded 90% power (0.05 1-sided alpha) to detect a 20% (vs 5%) confirmed RR. Other endpoints: adverse events (AEs), progression-free, overall survival (PFS, OS), and correlative studies including PD-L1 expression by IHC, mutational burden/neoantigen analysis, TCR clonality and TIL characterization. **Results:** 85 pts (43 - N3; 42 - N3+I1) were enrolled [mean age 54 yrs (21–81), 52% female). No significant differences in histological subtypes across cohorts: 36% LMS, 4% LPS, 10% UPS/MFH, 6% synovial, 5% bone, 5% Ewing's, and 34% other. Pts were refractory to 1(20%), 2(22%), and ≥3 (58%) regimens. Grade 3-4 treatment related adverse events (TRAE) occurred in 7% (N3) and 14% (N3+I1) and 0 Gr 5 TRAEs. 8% of pts stopped due to AEs (2% N3, 14% N3+I1). 2/3 confirmed responses on N3, with 2 ongoing (range 1.1-3.2 months). 6/7 confirmed responses (2 complete) on N3+N1, with 5 ongoing (range 6-13 months). Responses occurred in 7 histologies. See Table for pt outcomes. **Conclusions:** N + I showed acceptable safety and encouraging antitumor activity with most responses ongoing across multiple SAR histologies, passing efficacy criteria. There was minimal activity observed with N alone. Increased TRAEs were observed in N3+I1. Correlative analyses ongoing. NCT02500797. Support: U10CA180821, U10CA180882, Conquer Cancer Foundation, BMS. Clinical trial information: NCT02500797.

	N3 (n = 38)	N3+I1 (n = 38)

11008 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Multicenter phase II study of pembrolizumab (P) in advanced soft tissue (STS) and bone sarcomas (BS): Final results of SARC028 and biomarker analyses. *First Author: Melissa Amber Burgess, University of Pittsburgh Physicians, Pittsburgh, PA*

Background: SARC028 is the first multicenter Phase II study of P monotherapy in patients (pts) with STS and BS. Designed to detect clinical efficacy signals in multiple histologies, the study collected blood & tissue samples on all pts. We report extended clinical follow-up and in-depth biomarker correlates of response. **Methods:** The primary endpoint was objective response rate (ORR) by RECIST 1.1. Secondary endpoints were safety, 12 wk progression-free survival (PFS), and overall survival (OS). The STS arm had 10 pts in each of 4 cohorts: undifferentiated pleomorphic sarcoma (UPS), dedifferentiated liposarcoma (DDLPS), synovial sarcoma (SS) and leiomyosarcoma (LMS). The BS arm included 40 pts with osteosarcoma (OS), Ewing sarcoma (ES) or dedifferentiated chondrosarcoma (CS). Pre- and on-P biopsies were required as well as blood at multiple time points. Tumor was assessed for PD-L1 expression (clone 22C3) and immune infiltrates by multi-color IHC (Vectra). Ongoing analyses include circulating cytokine and checkpoint levels and exome (DNA), transcriptome (RNA), and T-cell receptor (TCR) sequencing. **Results:** 86 pts were enrolled, 80 were evaluable for response. For STS, median follow-up was 14.5 months. The ORR in the overall STS cohort was 18% and the 12-wk PFS 55% [95% CI, 42-71]). Clinical activity was variable by histologic subtype with 40% ORR in UPS (1 CR and 3PR out of 10 evaluable pts), 2 PR/10 were seen in DDLPS, 1PR/10 in SS and 0/10 in LMS. For BS, median follow-up was 12.3 months (ORR 5%; 12-wk PFS 28% [95% CI, 14-41]), with 1PR/22 OS, 1PR/5 CS and 0/13 ES. 70 pre-P tissues were analyzed (11 excluded for insufficiency), with PD-L1+ in 3/70 (4%); all 3 were UPS. Of the 2 evaluable pts, 1 had CR and 1 PR. 2 OS were PD-L1+ on multi-color IHC, 1 had PR. All PD-L1+ samples had CD8+ T-cell infiltration. There were no post-P PD-L1+ samples. **Conclusions:** P has clinical activity in UPS and LPS, and expansion cohorts in those subtypes are planned. Pre-treatment PD-L1 expression was infrequent, but correlated with T-cell infiltration and response in UPS & OS. Ongoing biomarker analyses that may guide combination strategies are ongoing and will be presented at the meeting. Clinical trial information: NCT02301039.

11009 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Extended treatment with adjuvant imatinib (IM) for patients (pts) with high-risk primary gastrointestinal stromal tumor (GIST): The PERSIST-5 study. *First Author: Chandrajit P. Raut, Brigham and Women's Hospital and Harvard Medical School, Boston, MA*

Background: Adjuvant IM reduces risk of recurrence and improves survival in pts with high-risk primary GIST. Joensuu et al 2016 demonstrated higher 5-yr overall survival (OS) rates of 91.9% vs 85.3% in pts treated with adjuvant IM for 3 vs 1 yr, respectively. It is unknown if further extension of treatment duration can improve outcome. **Methods:** PERSIST-5 is a single-arm, phase II trial that enrolled pts ≥18 yrs of age, who underwent macroscopically complete resection of primary KIT (+) GIST with high risk of recurrence within 12 wks prior to IM treatment. High risk was defined as primary GIST (any site) ≥2 cm with a mitotic count ≥ 5/50 HPF or non-gastric primary GIST ≥5 cm. Pts were treated with IM 400 mg/d for 5 yrs or until progression, relapse, or intolerance. Primary endpoint was recurrence-free survival (RFS, defined as time of treatment start to first recurrence or death). **Results:** IM was administered to 91 pts with a median age of 60 yrs (range 30-90). Median tumor size was 6.5 cm (range 2.3-30 cm; 55% gastric origin). Median treatment duration was 55.7 mos (range, 0.5-75). Forty-six (50.5%) pts completed study treatment. The 5- and 8-yr estimated RFS rates were 90% (95% CI, 80-95) and 81% (95% CI, 62-91), respectively. The 5- and 8 year OS rate was 95% (95% CI, 86-99). There were 7 recurrences; 1 pt recurred and died while on IM (*PDGFRA* D842V mutation) and 6 pts recurred after IM discontinuation. Two pts died after IM discontinuation, unrelated to study treatment and without recurrence. Forty-five pts discontinued study treatment; common reasons included patient choice (20%), adverse events (AEs, 17%), protocol deviation (4%), and loss of follow-up (4%). The most common AEs of all grades (regardless of relationship to IM) were nausea (71%), diarrhea (63%), fatigue (50%), muscle spasm (41%), vomiting (39%), and periorbital edema (34%). **Conclusions:** Five yrs of IM treatment was effective in preventing recurrence in pts with sensitive mutations who underwent resection of primary GIST. Nearly half of the patients discontinued treatment early, and most recurrences occurred after IM discontinuation. Clinical trial information: NCT00867113.

11010 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

The clinical impact of performing routine next generation sequencing (NGS) in gastrointestinal stromal tumors (GIST). *First Author: Ciara Marie Kelly, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The majority of GISTs harbor activating mutations in KIT or PDGFRα but the clinical relevance of other genomic alterations is unknown. We sought to determine the clinical impact of performing routine NGS and to describe the molecular landscape in GIST. **Methods:** From April 2014 to August 2016, 177 patients (pts) consented to an IRB-approved protocol. Tumor and matched normal samples were prospectively analyzed in a CLIA-compliant laboratory, with MSK-IMPACT, a NGS assay of up to 468 cancer-associated genes. **Results:** 191 samples were analyzed. NGS was most often performed in the setting of advanced disease (n = 108 (57%)). The primary tumor was most commonly tested (n = 120 (63%)). NGS guided clinical management in 79% (n = 150) of cases [matched therapy (MT) offered, n = 120/150 (80%); MT not offered, n = 24/150 (16%)]. In 25/41 cases (61%) where NGS did not influence management, treatment was not indicated because the GISTs were low risk. Most samples had ≤ 3 mutations (muts) (range: 0-17). Actionable muts were identified in 155/191 samples (81%). These included muts in KIT, PDGFRα and BRAF [oncoKB stratification: level 1 (84%), 2A (13%), 2B (2%), 3A(1%)]. 33/177 pts did not have a KIT/PDGFRα mut [SDH deficiency, n = 15 (45%), NF1, n = 10 (30%), BRAF, n = 1(3%), NF1&BRAF, n = 1 (3%)]. 5pts had quadruple wild type GIST. Most GISTs had at least one genetic alteration in a non-driver allele (74%, n = 141/191)[frequently mutated genes in KIT exon 11 driven i) primary tumors include TP53, MAX, MLL2, SETD2, PIK3CA, TSC1; and ii) metastatic tumors include RB1, SETD2, PTEN, ANKRD11, TP53, TSC1]. CDKN2A deletion was the most common copy number alteration identified in KIT driven GIST and occurred most often in metastatic samples (with and without co-occurring, secondary KIT muts) and those with high mitotic rate. **Conclusions:** NGS of GIST informs clinical management in the majority of pts through the identification of muts in canonical driver genes. NGS also identifies a high prevalence of tumor-specific genetic alterations in non-canonical driver genes. These genes function in multiple pathways including intracellular signaling, chromatin remodeling, proteasomal degradation and cell cycle regulation.

11011 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Clinical activity of BLU-285 in advanced gastrointestinal stromal tumor (GIST). *First Author: Michael C. Heinrich, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: Oncogenic mutations in KIT or PDGFRα drive > 85% of GIST. However, primary and acquired mutations in the activation loop of PDGFRα and KIT are not effectively treated by approved therapies. A phase 1 study (NCT02508532) was initiated in advanced GIST to assess the safety, PK and clinical activity of BLU-285, a potent, highly-selective oral inhibitor that targets KIT Exon 17 and PDGFRα D842 activation loop mutants. **Methods:** Adult patients (pts) with unresectable GIST, who had received ≥2 kinase inhibitors including imatinib or who had a primary PDGFRα D842 mutation regardless of prior therapy, were given BLU-285 once daily on a 4-week cycle following a 3+3 escalation design, which allowed additional accrual to dose levels demonstrated to be safe. Adverse events (AEs) per CTCAE v4.03, PK and plasma/tumor mutant DNA levels were assessed. Response was determined by RECIST 1.1 every 8 weeks. **Results:** At a 01JAN17 cutoff, 40 pts (21 PDGFRa/19 KIT) have been treated with BLU-285 at doses of 30-600 mg. Median number of prior kinase inhibitor regimens was 4.5 (2-12) KIT/2.5 (0-4) PDGFRα. RECIST 1.1 responses were seen across all dose levels for PDGFRα GIST and at higher dose levels for KIT GIST. Of 17 PDGFRα D842V pts with ≥1 radiographic assessment, 7 had confirmed PR (ORR 41%) and 10 had SD. Of 11 evaluable KIT pts treated at doses ≥ 135 mg, 2 had PR (1 confirmed; ORR 18%) and 5 SD. BLU-285 is rapidly absorbed (T_{max} 2-8 h), exposure increases linearly with dose, and half-life is > 24 h supporting QD dosing. Most AEs were grade 1 or 2, most commonly nausea (48%), fatigue (45%), peripheral edema, periorbital edema, vomiting (30% each), diarrhea (25%), anemia, dizziness, and lacrimation (23% each). There were no grade 4 or 5 BLU-285-related AEs, dose limiting toxicities, or discontinuations. 29 pts (all 21 PDGFRα pts) remain on treatment (duration 1-14 mo). Updated results including MTD, ct-DNA and central radiographic assessments will be presented. **Conclusions:** Precision targeted therapy with BLU-285 demonstrates important clinical activity in pts with both PDGFRα- and KIT-mutant GIST that is resistant to available therapies. Clinical trial information: NCT02508532.

Pathologic complete response and survival outcomes in patients with localized soft tissue sarcoma treated with neoadjuvant chemoradiotherapy or radiotherapy: Long-term update of NRG Oncology RTOG 9514 and 0630. *First Author: Dian Wang, Rush University Medical Center, Chicago, IL*

Background: We sought to determine the prognostic significance of pathologic complete response (pCR) in soft tissue sarcoma (STS) in patients (pts) receiving neoadjuvant chemoradiotherapy (RTOG 9514) or radiotherapy (RTOG 0630) with long-term outcomes. **Methods:** RTOG has completed two phase II trials (RTOG 9514 and RTOG 0630) for pts with localized STS. Pts with high-grade STS ≥8 cm of extremities or body wall were enrolled to 9514 from 1997-2000 and received 3 cycles neoadjuvant chemotherapy (CT), interdigitated with RT, and 3 cycles postop CT. Pts with STS of extremities were enrolled to 0630 from 2008-2010 and received preoperative RT without CT. One pathology expert (DL) assessed pts for pCR at time of surgery without knowledge of disease outcomes. Overall and disease-free survival (OS and DFS) were calculated from the date of surgery. Pts that did not have surgery or had an amputation were excluded. Hazard ratios (HR) and p-values were estimated by multivariate Cox model stratified by study, where possible (i.e., > 0 events in both groups); otherwise p-values were calculated by stratified log-rank test. **Results:** Of 135 who had surgery, 123 were evaluable for pCR: 14/51 (27.5%) on 9514 and 14/72 (19.4%) on 0630 had pCR. With median follow-up of > 5 years for surviving pts, OS is 100% for pts with pCR vs. 5-year 76.5% (95% confidence interval 62.3-90.8) and 56.4% (43.3-69.5) for pts with < pCR in 9514 and 0630, respectively. pCR is associated with improved OS (p = 0.01) and DFS [HR 4.91 (1.51-15.93); p = 0.008] relative to < pCR. Local failure rate was 0% in pts with pCR vs. 5-year 11.7% (3.6-25.1) and 9.1% (3.3-18.5) for pts with < pCR in 9514 and 0630, respectively. Leiomyosarcoma/liposarcoma/myxofibrosarcoma are associated with better OS [hazard ratio 2.24 (1.12 and 4.45)] while liposarcoma/myxofibrosarcoma are associated with better DFS [hazard ratio 2.42 (1.23-4.76)]. **Conclusions:** Results from this analysis have demonstrated that pCR is associated with improved survival outcomes in pts with STS treated with either neoadjuvant RT or CT-RT. pCR should be considered as a survival surrogate for future STS studies. Clinical trial information: RTOG 9514 and RTOG 0630.

Clinical, radiological and genetic features, associated with the histopathologic response to neoadjuvant chemotherapy (NAC) and outcomes in locally advanced soft tissue sarcoma (STS) patients (pts). *First Author: Sophie Cousin, Institut Bergonié, Bordeaux, France*

Background: Two large phase III studies have shown an improved overall survival in soft-tissue sarcoma (STS) pts treated with neoadjuvant chemotherapy. The prognostic impact of pathologic response is not known neither the clinical, radiological and genetic features associated with response. **Methods:** Data from pts with localized STS of the extremities or trunk wall and treated with anthracyline-based NAC at Institut Bergonie (Bordeaux, France) were reviewed. Central pathology (diagnosis, histological response) and radiology (MRI, DCE-MRI) reviews were performed for all the cases. A good histological response (GR) was defined as <10% residual viable tumor. Exome and RNA sequencing of pre-treatment tumor samples was performed in order to identify genetic aberrations predictive of response. **Results:** 150 patients (88 male) were included in the study. Median age was 60 years (17-84). 40 pts (26.7%) were good responders. GR was associated with undifferentiated pleomorphic sarcomas and very large tumors (> 20 cm). Median OSwas 10.3 year [IC95 : 5.8 ; 14.9]. On multivariate analysis, only GR (HR= 0.36, 95%CI 0.184-0.703, p=0.0028) and performance status (PS) (HR= 3.799, 95%CI 1.72-8.387, p=0.001 for PS=2-3) were prognostic factors for OS. Early *DCE-MRI* parameters (after 2 cycles of treatment) such as, area under the contrast concentration vs. time curve for 90 seconds after contrast injection (*IAUC90*) were strongly associated with histological response (p=0.027) whereas RECIST 1.1 was not. **Conclusions:** As for bone sarcomas, histological response to NAC is a crucial prognostic factor in STS. Multiparametric MRI parameters obtained post-2nd cycle of NAC are predictive of histological response and should be considered to adjust the therapeutic strategy. Genetic features (including the CINSARC signature) associated with response to NAC will be presented at the meeting.

The sarculator stratified prognosis of patients with high-risk soft tissue sarcomas (STS) of extremities and trunk wall treated with perioperative chemotherapy in a randomised controlled trial (RCT). *First Author: Sandro Pasquali, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Patients with extremity and trunk wall STS with high malignancy grade and size larger than 5cm are considered at high risk of death, but in fact this risk varies broadly depending on histologic subtype and size. The Sarculator, a nomogram for STS, can improve prognostic assessment of these patients. This tool was evaluated for stratifying risk of distant metastasis (DM) and overall survival (OS) in a RCT investigating perioperative chemotherapy. **Methods:** High-risk STS patients were randomly assigned to receive either three cycles of preoperative chemotherapy with epirubicin (120 mg/m2) and ifosfamide (9 g/m2) or the same three preoperative cycles followed by two further postoperative cycles. The Sarculator was used to stratify patient risk according to predicted 10-year cumulative incidence of DM and OS rates. **Results:** The Sarculator identified three different prognostic groups of patients at low (N = 101), intermediate (N = 102), and high (N = 107) risk. Cumulative incidence of DM was 0.26 (SE: 0.04), 0.31 (SE: 0.05), and 0.48 (SE: 0.05) for low, intermediate, and high risk patients, respectively. Similarly, OS rates were 0.78 (95%CI 0.68-0.85), 0.63 (95%CI 0.53-0.72), and 0.42 (95%CI 0.32-0.52), respectively. Patients in the low risk group were at significantly lower risk of death compared to those in the intermediate (HR 0.51, 95%CI 0.34-0.78, P = 0.002) and high (HR 0.28, 95%CI 0.17-0.46, P < 0.001) risk groups. Subgroup analysis performed by jointly considering these three groups and the two study arms did not identify statistically significant survival differences between the treatment arms within each risk category. **Conclusions:** Patients with high-risk STS included in this RCT were not a homogeneous population. The Sarculator identified different risk groups for DM and OS even in patients included in a RCT investigating perioperative treatments. This tool should be considered for redefining high-risk STS and stratifying patient risk in future RCT investigating perioperative chemotherapy. Clinical trial information: 2004-003979-36.

Factors impacting contemporary management of high-grade extremity sarcoma: An analysis of 12,020 patients. *First Author: Stephen Ramey, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Previous studies noted racial/ethnic disparities in high-grade extremity soft tissue sarcoma (ESS) treatment and overall survival (OS). Retrospective series have noted worse OS for Amputation (Amp) vs limb salvage surgery (LSS) and for LSS alone vs LSS plus radiation (RT). Given superior functional outcomes, LSS is now favored over Amp when possible. This study examines racial/ethnic disparities in receipt of Amp vs LSS and impact on OS using modern data from a national registry. **Methods:** The National Cancer Database was used to identify patients (pts) with stage II-III, high-grade ESS diagnosed between 2004-2014 and treated definitively with 1) Amp alone, 2) LSS alone, 3) Preoperative RT [pre RT] + LSS or 4) LSS + Post-operative RT [post RT]. Multivariate analyses (MVA) utilized logistic regressions for patterns of local treatment and Cox proportional hazards regression for OS. The Kaplan-Meier method was used to estimate 5-year OS. **Results:** Among 12,020 pts, receipt of LSS vs Amp did not differ significantly by race, ethnicity, age, insurance status, income, or educational attainment on MVA. The rate of Amp was higher in academic centers (OR 2.42; p = .006) or integrated network programs (OR 2.30; p = .014) vs community programs and rural vs. Metro settings (OR 1.88; p = .035). Actuarial 5-year OS by treatment was Amp 43%, LSS 59%, pre RT + LSS 61%, and LSS + post RT 66% ($p < .001$). On MVA, OS was worse with Amp vs. LSS alone (HR 1.37; $p < .001$) while pre RT + LSS (HR 0.70; $p < .001$) and LSS + post RT (HR 0.72; $p < .001$) had improved OS vs LSS alone. Treatment at a comprehensive community, academic, or integrated network programs vs community program; private insurance vs none; Hispanic vs. non-Hispanic (HR 0.85, p = .048); and higher educational attainment were associated with improved OS. More comorbidities, other primary cancers, older age, and no transitions in care were associated with worse OS. **Conclusions:** The only racial/ethnic disparity identified when evaluating rates of Amp and OS for ESS was a small OS benefit for Hispanic pts. OS was inferior with Amp and best with LSS with either pre RT or post RT. OS was improved at non-community programs, potentially indicating a need for referral to experienced centers.

Radiation-associated versus sporadic osteosarcoma: A single-institution experience. *First Author: Brittany Siontis, University of Michigan, Ann Arbor, MI*

Background: Osteosarcoma (osarc) can be a rare complication from radiation (rt) therapy. Radiation-associated osarc (RAO) is reported to have a worse prognosis than non rt-associated osarc with limited objective data comparing the two. We conducted a retrospective study comparing demographics, therapy and outcomes of sporadic osarc (SO) to RAO. This study was confined to adults. **Methods:** We identified patients (pts) > age 18 years (yr) with osarc treated at our institution between 1990 and 2016 using an institutional database. We categorized tumors as SO or RAO based on history of prior rt within field of osarc. We extracted data on demographics, treatment, and primary malignancy characteristics. **Results:** We identified 159 pts with osarc, 28 were RAO tumors. Results are in Table 1. Median follow-up was 2.8 yr (0.1-19.6 yr). For RAO, median time from rt to diagnosis was 11.5 yr (1.5-28 yr) with a median cumulative dose of 60 Gy (44-75.8 Gy). Median progression free survival (PFS) and overall survival (OS) were not significantly different in pts presenting with metastatic osarc; PFS 10.3 mo vs 4.8 mo (p=0.45) and OS 15.6 mo vs 6.1 mo (p=0.96) in SO vs RAO pts, respectively. For pts with localized osarc, median relapse-free survival (RFS) and OS were significantly different, not reached vs 12.2 mo ($p<0.001$) and not reached vs 27.6 mo (p=0.001) in SO vs RAO, respectively. **Conclusions:** In our series, there was a significant difference in age, size and location of RAO vs non rt-associated osarc. Overall, all osarc pts with metastatic disease at diagnosis fared poorly. Pts presenting with localized RAO had worse outcomes than patients with localized SO. This was not associated with a detectable difference in therapy rendered or treatment effect in resection specimens.

Variable	SO	RAO	p value
Age, median (range)	38 (18-79)	61 (18-77)	<0.001
Tumor size cm, median (range)	8.7 (1.8-20)	5.6 (2-12)	0.003
Primary location, n (%)			
Axial	41 (31.3)	22 (78.6)	< 0.001
Appendicular	90 (68.7)	6 (21.4)	< 0.001
Neoadjuvant Chemotherapy, n (%)	77 (58.8)	17 (60.1)	0.899
Resection, n (%)	115 (87.8)	21 (77.8)	0.216
< 10% viable tumor, n (%)	16/54 (29.6)	3/12 (25)	0.752
Adjuvant Chemotherapy, n (%)	22 (16.8)	5 (17.9)	0.889
Mets at diagnosis, n (%)	20 (15.3)	6 (21.4)	0.409

Analysis of osteosarcoma subtypes by clinical genomic testing to identify clinically actionable alterations. *First Author: John Andrew Livingston, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Genomic testing is being utilized with increasing frequency to identify matched therapies for patients (pts) with advanced disease; however, the utility of such testing has not been defined in osteosarcoma (OS). We report our experience with 36 pts with recurrent/metastatic OS who underwent testing on a genomic testing protocol, including actionable alterations across multiple histologic subtypes of OS. **Methods:** Standardized hotspot mutation analysis was performed in 36 pts with recurrent/metastatic OS, using either a 46-, 50-gene, or 128-gene CLIA certified multiplex platform. 12 pts had a 200-gene analysis on a companion research protocol. We used the Catalogue Of Somatic Mutations In Cancer (COSMIC) database to identify alterations that are in mutation hotspots in OS or in other cancers. Clinical outcomes were retrospectively collected. Histologic subtype classifications were made by an experienced sarcoma pathologist based upon the pre-treatment and resection specimens. Cases with only metastatic samples available were classified as "other high-grade osteosarcoma." Additional clinical correlations are ongoing. **Results:** A total of 36 pediatric and adult pts were analyzed. All osteosarcomas were high grade; the most common osteosarcoma histologic subtypes were chondroblastic, osteoblastic, and other. Samples analyzed were from primary tumor in 15/36 (42%), with the remaining from metastatic specimens (58%). Mutations were identified in 26 pts (72%). The most common mutations were in *TP53*. An activating *PIK3CA* E545K mutation was found in chondroblastic OS. Other notable hotspot mutations include a *GNAS* R201 mutation in osteoblastic osteosarcoma and a *KRAS*G12V mutation in a fibroblastic osteosarcoma. **Conclusions:** Clinical gene panel sequencing can identify a limited number of potentially actionable mutations in patients with osteosarcoma. Given the heterogeneity of osteosarcoma at the molecular level, clinical genomic testing may be warranted to identify patients for participation on matched clinical trials.

Osteosarcoma prognostic nomograms for predicting the 10-year probability of mortality and recurrence. *First Author: Haotong Wang, Massachusetts General Hospital, Boston, MA*

Background: The multidisciplinary approach in treatment of osteosarcoma has been well established and well adopted nationwide. This study combined the clinical prognostic factors at initial presentation into a nomogram to predict local control (LC), metastasis free survival (MFS), and overall survival (OS) for patients with non-metastatic bone osteosarcoma. **Methods:** We reviewed 397 osteosarcoma patients treated from 1995 to 2014. Patients with metastatic disease at diagnosis or limited follow up were excluded, resulting in 283 cases for analysis. Clinical and pathologic variables were recorded. Predictive variables included age at diagnosis, gender, previous radiation history, site, tumor size, histologic subtype, histologic grade, extra-osseous extension (EOE), lymphovascular invasion (LVI), necrosis rate and margin. The multivariate Cox proportional hazards regression was used to analyze survival outcomes and risk variables. **Results:** At 10 years, LC was 70.4% (95% confidence interval, CI: 64.0%-76.7%), MFS was 64.7% (95% CI: 58.1%-71.3%), and OS was 61.5% (95% CI: 54.9%-68.1%). Multivariate Cox model identified age (p = 0.033), site (p = 0.020), EOE (p = 0.017), LVI (p = 0.011), and margin (p = 0.039) were correlated with LC; age (p = 0.028), tumor size ($p < 0.001$), histologic grade (p = 0.039), and LVI (p = 0.014) were correlated with MFS; whereas age ($p < 0.001$), prior radiation history (p = 0.010), tumor size (p = 0.002), histologic subtype (p = 0.012), EOE (p = 0.002), and LVI (p = 0.001) were associated with OS. The nomograms were drawn on the basis of the Cox regression model and were internally validated using bootstrapping, with predictive accuracy of ±7.2% for 10-year LC, ±7.4% for 10-year MFS, and ±7.5% for 10-year OS. **Conclusions:** Nomograms have been developed to predict the 10-year local-control failure, recurrence and death. We suggest that this tool at presentation may be useful for individualized risk evaluation, patient counseling, and making clinical decisions.

Cost effectiveness of surveillance for distant recurrence in extremity soft tissue sarcoma. *First Author: Trevor Joseph Royce, Brigham and Women's Hospital and Dana-Farber Cancer Institute, Boston, MA*

Background: Optimal surveillance strategies for extremity soft tissue sarcoma (STS) are unknown. We performed a cost-effectiveness analysis of competing imaging modalities performed at National Cancer Comprehensive Network guideline-specified intervals. **Methods:** We developed a Markov model simulating lifetime outcomes for 54-year-old patients after definitive treatment for Stage II-III extremity STS using four surveillance strategies: watchful waiting (WW), chest x-ray (CXR), chest computed tomography (CCT) and positron emission tomography-computed tomography (PET/CT) performed every 3-6 months for the first 3 years, every 6 months until year 5, and then annually. We used probabilities, utilities and costs extracted from the literature and Medicare claims to determine incremental cost-effectiveness ratios (ICER). **Results:** While the model showed that CCT is the most effective strategy, CXR is the most cost-effective strategy at a societal willing-to-pay (WTP) of $100,000/quality-adjusted life year (QALY). The ICER is $14,306/QALY for CXR versus $117,683/QALY for CCT while PET/CT is never cost effective (Table). Sensitivity analyses demonstrated CCT becomes the preferred imaging modality as the lifetime risk of DR increases beyond 38% or as the societal WTP increases beyond $130,000/QALY. **Conclusions:** Optimal DR surveillance imaging for Stage II-III extremity STS should be individualized based on patients' risks for DR. CXR, or CCT at more protracted intervals, may be preferred for lower risk patients (i.e. DR risk less than 38%), whereas CCT may be preferred for higher risk patients (i.e. DR risk greater than 38%). These findings can help refine guidelines to reduce resource overutilization during surveillance of sarcoma patients.

Strategy	Cost ($)	Incremental Cost ($)	Effectiveness (QALY)	Incremental Effectiveness (QALY)	ICER ($/QALY)
WW	1,290		7.29		
CXR	4,006	2,715	7.48	0.19	14,306
CCT	7,952	3,947	7.51	0.03	117,683
PET/CT	24,304	16,351	7.47	-0.04	-382,006

Abbreviations: ICER, incremental cost-effectiveness ratio; QALY, quality-adjusted life-year; WW, watchful waiting; CXR, chest x-ray; CCT, chest computer tomography; PET/CT, positron emission tomography-computed tomography.

Prospective development of a patient reported outcomes (PRO) tool in desmoid tumors: A novel clinical trial endpoint. *First Author: Jean Paty, QuintilesIMS, New York, NY*

Background: Desmoid tumors (DT) are locally aggressive and cause significant morbidity. Clinical trials in DT typically utilize response rates and progression free survival as primary endpoints. However, these endpoints do not capture improvements in clinical symptoms. To date, there are no validated PRO tools in DT to capture the patient experience and efficacy of a drug. **Methods:** A review of the published literature and interviews with sarcoma clinicians were used to formulate a list of signs and symptoms and impact on patients (pts). These were collected to build a conceptual model. DT pts (n = 31) with a range of anatomical locations and presentations were interviewed, initially in an open-ended fashion, followed by interrogating the conceptual model. For the concepts that pts reported, they were asked to rate how disturbing each was on a 0-10 scale (0 being not at all, and 10 being as bad as they can imagine). The pts interview data was then used to refine the conceptual model and generate two new PRO instruments **Results:** Pt interviews demonstrated that across tumor locations, the most frequent and disturbing symptoms were: 'muscle' pain (65% pts, median disturbance (MD) of 6.8), 'nerve' pain (73%, MD 6.0), and fatigue (65%, MD 5.0). Some symptoms were specific to tumor locations, especially abdominal tumors. Restricted range of motion (68%, MD 4.0), fear (84%, MD 6.5), sleep disturbance (77%, MD 7.5) , disfigurement (81%, MD 6.8), and impact on daily activities (65%, MD 6.8) were the most frequent and disturbing impact on pts lives. These concepts were then used to develop two new PRO instruments: the sign and symptom PRO includes 11 items; the impact on pts lives instrument includes 17 items. The instruments vary in asking pts about the last 24 hours, or the last week. **Conclusions:** This is the first validated PRO tool in DT. This tool adequately captures symptoms central to the DT pts experience and its impacts on their lives. The instruments are ready for implementation in a DT clinical trial for further evaluation of their measurement properties.

11023 Poster Discussion Session; Displayed in Poster Session (Board #346), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

Toxicity and efficacy of bolus (BOL) versus continuous intravenous (CIV) dosing of doxorubicin (DOX) in soft tissue sarcoma (STS): Post hoc analysis of a prospective randomized trial. *First Author: Lee D. Cranmer, University of Washington Seattle Cancer Care Alliance, Seattle, WA*

Background: DOX remains critical in STS treatment. Controversy exists regarding its optimal administration route (BOL vs CIV). BOL vs CIV could affect toxicity and/or efficacy. A randomized trial to assess this is unlikely. We conducted a *post hoc* analysis to explore differences in these routes of DOX administration. **Methods:** Data from a prospective randomized phase III study of doxorubicin with or without evofosfamide (TH-302) were used. At the discretion of treating physician, BOL or CIV DOX could be used. Grade 3-5 hematologic, non-hematologic and cardiac toxicities and treatment response were explored using multivariable logistic regression. OS and PFS were analyzed using Kaplan-Meier and Cox proportional hazards. **Results:** 640 subjects were enrolled (556 BOL, 84 CIV). Baseline differences in age, extent of disease and prior radiotherapy were controlled for in regression models. Hematologic toxicity was associated with age, performance status (PS) and cumulative (CUM) DOX dose. Non-hematologic toxicity was associated with age, PS, receipt of prior radiotherapy and CUM TH-302 dose. Cardiac toxicity was only associated with CUM DOX dose. Odds of response were strongly associated with CUM DOX dose (mg/m^2, OR = 1.011, $p < 0.0001$), and, to a lesser extent, with CUM TH-302 dose (g/m^2, OR = 1.081, p = 0.0008), STS subtype and prior radiotherapy. Comparing CIV to BOL DOX, neither OS (median 21.7m vs 18.3m, HR = 0.85, p = 0.29) nor PFS (median 6.1m vs. 6.1m, HR = 0.89, p = 0.43) was affected by manner of DOX administration (CIV vs BOL). Cox analyses indicated that factors reflecting tumoral biology and host status, rather than treatment received, were associated with OS (PS, histologic STS subtype, histologic grade, receipt of prior radiotherapy) and PFS (PS, treatment-related toxicity). **Conclusions:** Our analyses provide no evidence for superiority of either BOL or CIV administration of DOX as regards toxicity or efficacy in STS treatment. Thus, the logistically simpler BOL administration of DOX should be favored over CIV administration.

11024 Poster Session (Board #347), Sun, 8:00 AM-11:30 AM

Weekly paclitaxel (WP) +/- bevacizumab (B) in angiosarcoma (AS) patients (pts): Analysis of prognostic/predictive factors from a randomized phase 2 trial. *First Author: Loic Lebellec, Centre Oscar Lambret, Lille, France*

Background: WP is an active regimen for treatment of AS pts (Ray-Coquard JCO 2015). We report here the correlative analysis conducted during a phase 2 trial assessing WP +/- B. **Methods:** Circulating pro/anti-angiogenic factors (FGF, PlGF, SCF, Selectin, thrombospondin, VEGF, VEGF-C) were collected at D1 and D8. Prognostic value for PFS was assessed using Cox model (biomarkers as continuous variables). We attempt to identify subgroups of pts benefiting from adding B using interaction tests (predictive factors). **Results:** Among the 51 pts enrolled in this trial, 45 were analyzable: 20 in Arm A (WP without B) and 25 in Arm B (with B). Median PFS was 5.5 and 6.1 months, respectively (p = 0.84). Samples were collected in 45 pts at D1 and 42 pts at D1 and 8. Baseline biomarkers were similar in both arms (excluding Selectin, significantly lower in arm A: median of 25 *vs.* 35 ng/mL, p = 0.03). In arm A, there was no significant difference between values at D1 and D8. In arm B, there were a significant decrease in VEGF (from a median of 0.49 to 0.08 ng/mL; $p < 0.01$) and selectin (from a median of 35.3 to 31.7 ng/mL; $p < 0.01$), and a significant increase in PlGF (from a median of 16.1 to 30.0 pg/mL; $p < 0.01$). In univariate analysis, factors associated with PFS were: de novo *vs.* radiation-induced AS (HR = 2.39 ($p < 0.01$), visceral *vs.* superficial AS (HR = 2.04; $p < 0.03$), VEGF-C at D1 (HR = 0.77; $p < 0.03$), FGF at D8 (HR = 1.17; $p < 0.01$), difference in FGF D8-D1 (HR = 1.24; $p < 0.01$), and PlGF value at D1 (HR = 1.02; $p < 0.05$). In multivariate analysis, factors associated with PFS were: de novo AS (HR = 2.39; p = 0.03), VEGF-C at D1 (HR = 0.73; $p < 0.02$) and FGF difference between D8 and D1 (HR = 1.16; $p < 0.02$). None of these factors were associated with benefit of adding B. **Conclusions:** Baseline VEGF-C levels and change in FGF were independent prognostic factors in pts with or without B. Addition of B significantly decreased the level of circulating VEGF and selectin and increased the level of circulating PlGF in AS patients. We did not identify subgroup of pts benefiting from adding of B to WP. Clinical trial information: NCT01303497.

11025 Poster Session (Board #348), Sun, 8:00 AM-11:30 AM

Immune-infiltrate characterization in localized osteosarcoma patients treated within protocol ISG-OS1. *First Author: Emanuela Palmerini, Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: We hypothesized that immune-infiltrates were associated with survival, and examined a primary osteosarcoma tissue microarrays (TMAs) to test this hypothesis. **Methods:** Biopsies of patients (pts) treated from 04/2001 to 11/2006 were analyzed. TMAs from representative areas were assembled. Clinical and pathological characteristics at diagnosis, expression of CD8, CD4, CD3, FOXP3, CD20, CD68/CD163 (tumor associated macrophage), Tia-1 (cytotoxic T cell), CD303 (plamacytoid dendritic cells: pDC), Arginase-1 (myeloid derived suppressor cells: MDSC), PD-1 on immuno-cells (IC), and PD-L1 both on tumor cells (TC) and IC were correlated with patients outcome. A TMA of surgical specimens of the same cases also was assembled, and chemotherapy-induced changes analysis is ongoing. **Results:** 86 pts identified. Median age: 16 (range 4-39); high LDH: 36/86; high serum alkaline phosphatase (SAP): 18/86. All pts underwent neoadjuvant chemotherapy and surgery. A good pathologic response (≥90% necrosis) was achieved by 45/86 pts. IHC results are displayed in the Table. With a median follow-up of 8 years (range 1-13), the 5-year overall survival (5-yr OS) was 74% (95% CI 64-85). Univariate analysis showed better 5-yr OS for: a) good responders (good 89% vs poor 57%, p=0.0001); b) pts with CD8/Tia1 tumoral infiltrates (+/+ 81% vs +/- 60% vs -/- 45% p=0.002); c) pts with normal SAP (normal 85% vs high 44%, p=0.04). A numerically lower 5-yr OS was found in PD-L1 (IC) positive (+ 58% vs - 77%, p=0.14) and CD163 negative (+ 81% vs - 56%, p=0.17) cases. After multivariate analysis, poor histologic response (p=0.007) and lack of CD8/Tia1 infiltration (p=0.02) were independently correlated with poorer survival. In the subset of CD8+ patients, poorer (p= 0.02) OS was observed for PD-L1 (IC) + cases. **Conclusions:** Our findings support the hypothesis that CD8/Tia1 (cytotoxic T cells) infiltrate in tumor microenvironment at diagnosis is associated with superior survival for patients with localized osteosarcoma, while PD-L1 expression is associated with poorer survival.

11026 Poster Session (Board #349), Sun, 8:00 AM-11:30 AM

Neoadjuvant denosumab treatment of locally advanced giant cell tumor of bone (GCTB). *First Author: Piotr Rutkowski, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

Background: Retrospective study on locally advanced GCTB patients (pts) treated with neoadjuvant Denosumab (Db) outside clinical trials in 6 European reference centers. **Methods:** From 138 pts (median age 30yrs) with histologically confirmed advanced GCTB treated with Db(2011-2016), we included into analysis 87pts who underwent surgery after preoperative Db. All 87 patients had locally advanced tumors with extensive soft tissue involvement(54) or penetration to joint, not amenable to limb-sparing surgery/ primary curettage or with high risk of recurrence. In 39/42(93%) cases diagnosis was confirmed by *H3F3A*gene mutation. Median follow-up time -22 months. **Results:** Primary tumor was located in lower limb(54%; n = 47) -mostly in tibia(25%) and femur(23%), upper limb(33%; n = 29), and pelvis/axial skeleton/ribs(13%; n = 11). 68(78%) patients had primary tumors, 19(22%) recurrent tumors after surgery (+/-radiotherapy). Median Db duration was 7months (range 1.5-35months), 17pts received also Db postoperatively. 39(45%) had wide en-bloc resection -WE (+17 implantation of prosthesis), 48(55%) cases had intralesional curettage -C, no extremity amputation. Pts who underwent prosthetic replacement had longer median preoperative Db therapy as compared to pts without prosthesis. All pts demonstrated a response to Db Progression after surgical treatment was observed in 15 pts -13 of them after intralesional curettage (13/48, 27%); 9 patients underwent D re-challenge -all responded. Two-year progression-free survival (PFS; from Db start) rate was 80%, 91% in WE group vs 73% in C group (p = 0.04), one-year PFS (from operation date) rate was 84%: 92% in WE and 79% in C group(p = 0.01). Treatment was well tolerated with only 1 grade 3 toxicity. **Conclusions:** Our study confirms that Db is active in a neoadjuvant setting with excellent efficacy and short-term tolerability. It implies that neoadjuvant therapy with Db is the option for treatment of initially locally advanced tumors to facilitate complete surgical resection or avoid mutilating surgery. The risk of recurrences after curettage of GCTB following Db raises questions about the optimal duration of preoperative treatment and if Db is indicated postoperatively.

11027 Poster Session (Board #350), Sun, 8:00 AM-11:30 AM

Characterizing the end-of-life period in young patients with sarcomas. *First Author: Sujana Movva, Fox Chase Cancer Center, Philadelphia, PA*

Background: There is a paucity of data surrounding the end-of life transition (EOLT) in young adult (YA) patients with sarcoma. Discussions surrounding prognosis, goals of care (GOC), hospice and death can be challenging in these patients as they may be at a particularly hopeful stage of their life. The purpose of this study is to better understand the EOLT in YA patients with sarcoma by determining the survival and number of lines of treatment at different periods in the disease course. In addition, the study aims to determine what impacts the decision to discontinue anti-cancer therapy. **Methods:** Fox Chase Cancer Center (FCCC) patients, 18-39 years old who died from sarcoma between January 2013 and December 2016 were included in this study. Patient demographics, tumor specific data, treatment and treatment decisions were collected from electronic medical records and retrospectively analyzed. **Results:** 38 FCCC patients who were diagnosed between the ages of 18-39 died between January 2013 and December 2016. Of these 21 patients were between the ages of 18-39 at the time of their death. Median age at death was 30 (range: 22-40). The most common histologies were Ewing Sarcoma, GIST (n = 3) and osteosarcoma, synovial sarcoma (n = 2). Median time from diagnosis of metastatic disease to death was 21.4 months. Median time from metastatic disease to discussion of GOC and hospice by any provider was 9.6 and 16.7 months respectively. The hospice discussion was held by the treating oncologist 87.5% (n = 16) of the time (outpatient 35.7% and inpatient 64.3%). 60% (n = 15) of patients/family selected hospice when it was originally presented to them (multi-organ failure, unarousable, paralysis). The hospice discussion was held at a median of 21 days prior to death and median time on hospice was 13 days (range: 1-63). Patients were treated a median of 54 days prior to their death (range: 6-1823). Median times on first, 2ndto last and last treatments were 273, 67 and 22.5 days respectively (P = 0.002). **Conclusions:** Focusing on this particular group of patients will generate benchmark data that can help counsel them about their specific expected survival and changes in clinical status as their disease progresses. We plan to compare this data with that of older patients.

11028 Poster Session (Board #351), Sun, 8:00 AM-11:30 AM

Failure rate of standard rescue with leucovorin for high-dose methotrexate (HDMTX) in osteosarcoma. *First Author: Mikael Eriksson, Skane University Hospital and Lund University, Lund, Sweden*

Background: HDMTX followed by leucovorin rescue is well established as part of MAP chemotherapy for osteosarcoma. However, leucovorin rescue is not always effective as rescue, resulting in delays to subsequent courses of chemotherapy. **Methods:** This retrospective observational study involved patients ≥2 years of age with osteosarcoma treated with MAP during 2009 - 2014. Data was extracted from medical records from five clinics in Poland, Hungary, Norway and Sweden. The study objective was to determine to what extent patients treated with MAP encountered treatment delays due to MTX-related toxicity or delayed MTX elimination. **Results:** All patients fulfilling the inclusion criteria were included. Of 116 patients (ages 5-39 with a mean of 14 years; 59% males), 97% completed their first MAP cycle while only 48% completed six treatment cycles. The analysis of the primary endpoint included 114 evaluable patients. At least one treatment delay due to MTX toxicity or delayed MTX elimination was reported for 89 patients (78%) and only six patients (5%) completed the entire MAP treatment according to plan. Delay in subsequent treatment was observed following 183 of 369 evaluated MAP cycles (50%). About three quarters of the delays were found to be due to MTX-related toxicity while only a small number were related to delayed MTX elimination. The treatment related issues most commonly registered were increased liver enzymes, hematological disturbances, increased bilirubin and mucositis. **Conclusions:** We found at least one treatment delay due to MTX toxicity or delayed MTX elimination in 78% of all MAP-treated patients and that 50% of the administered MAP cycles resulted in a delay in subsequent treatment, mostly due to MTX toxicity. Only six patients (5%) completed the entire MAP treatment according to plan. The retrospective methodology with broad inclusion criteria implies that the results can be extrapolated to the entire target population. Thus, there appears to be an unmet need for a more effective HDMTX rescue that could reduce MTX toxicity and be expected to enable more patients to maintain planned MAP treatment intensity and duration, thereby improving the overall efficacy of the MAP regimen.

11029 Poster Session (Board #352), Sun, 8:00 AM-11:30 AM

The genomic and evolutionary landscape of osteosarcoma progression and lung metastasis. *First Author: Jin Wang, Department of Musculoskeletal Oncology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Osteosarcoma (OS) is a primary malignant bone tumor that has a high potential to metastasize to lungs. Recent studies have characterized somatic mutations of primary OS tumors. Nevertheless, lung metastases of OS are poorly studied, and whether they harbor distinct genetic alterations beyond those observed in primary tumors is largely unknown. **Methods:** We performed whole-exome sequencing (WES) of matched primary tumors and lung metastases in a cohort of 15 OS patients. Somatic single nucleotide variations (SNV) and copy number alterations (CNA) were analyzed to characterize the genomic and evolutionary landscape of metastatic OS. **Results:** Compared to matched primary tumors, lung metastases exhibited higher transversion rate for base substitution, and poor overlap ($< 10\%$) of genetic alterations was observed between primary and metastasis tumors. Multiple novel significantly mutated genes were identified, including *ZNF717* in lung metastases, *SPDYE1* in primary tumors, and *CRIPAK* in both. Copy number analysis indicated recurrent CNAs, including *NEURL1B* deletion and *FLG* amplifications in lung metastases, *GSTT1* deletion in primary tumors, and *CEACAM* gene family deletion in both. Furthermore, phylogenetic analyses revealed that paired primary tumors and metastases underwent parallel evolution with few ubiquitous clonal mutations, suggesting that OS metastases are likely to be derived from primary tumors at a very early stage of their evolution. **Conclusions:** This study for the first time provides important evidence that OS metastases harbor distinct genetic alterations compared with primary tumors. Our findings strongly support a parallel evolution model of primary and metastatic tumors. Moreover, several novel CNAs and significantly mutated genes that are specifically associated with lung metastases may provide future therapeutic insight for OS.

11030 Poster Session (Board #353), Sun, 8:00 AM-11:30 AM

Does *MGMT* (O6-methylguanine–DNA methyltransferase) have a role in metastatic Ewing sarcoma (ES) patients (pts) undergoing temozolomide (TMZ) and irinotecan (IRI)? *First Author: Emanuela Palmerini, Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: TMZ+IRI has significant activity in metastatic ES. Epigenetic silencing of the *MGMT* DNA gene by promoter methylation has been associated with response to TMZ in glioblastoma. Our aim was to assess if *MGMT* methylation 1) has a role in ES progression and 2) is predictive of response to TMZ. **Methods:** 1) In 10 ES cell lines presence of *MGMT* gene (Real-time PCR), methylation of its promoter (methylation-specific PCR) and protein expression (western blot) were assessed. MGMT protein (IHC) and methylation of its promoter was searched in 97 ES pts samples (74 localized; 23 metastatic). 2) In metastatic ES pts treated with TMZ+IRI, with pre-treatment FFPE tissue and measurable disease, the relation between RECIST response, PFS and MGMT expression (IHC) was assessed. **Results:** 1) The expression of *MGMT* gene and its protein was detected and concordant ($p = 0.02$) in all ES cell lines evaluated; methylation was a rare event. In ES tissue samples the methylation of the *MGMT* gene was found at a low intensity as compared with the unmethylated gene, but the protein expression was relatively low: 36% in localized, 65% in metastatic pts (p 0.03). 2) 24 pts (median age 19 years, range 3-50 years; F/M: 7/17) treated with TMZ + IRI from 2010 to 2015 were identified. Line of treatment: 8 patients were in 1st line; 16 ≥ 2nd line. Median n of cycles was 6 (range: 2-31). Pattern of metastases: 16 multiple sites, 4 lungs, 3 multiple sites + bone marrow, 1 bone. MGMT was positive in 63% of cases. ORR: 16.5% (1 CR , 3 PR); SD: 50% (13 pts); PD: 33.5% (7 pts). According to MGMT expression the ORR was 11% in negative and 20% in MGMT positive patients ($p = 0.8$). 6-mos PFS rate was 59% (38-80 %IC), no differece according to MGMT expression (pos 61% vs neg 56%, p 0.7). **Conclusions:** Whereas in cell lines the *MGMT* gene and its protein expression is a generalized event, in tissue samples MGMT protein is present in a minority of localized pts, and might be associate with tumor progression. Methylation of *MGMT* gene does not seem responsible for its regulation in ES, and post-transcriptional mechanisms are more likely to be involved. The presence of MGMT protein does not predict the response to TMZ + IRI in this small series.

11031 Poster Session (Board #354), Sun, 8:00 AM-11:30 AM

Apatinib for patients with unresectable high-grade osteosarcoma progressing after standard chemotherapy: A multi-center retrospective study. *First Author: Wenxi Yu, Affiliated Sixth People's Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: Prognosis for patients with relapsed/metastatic osteosarcoma is dismal and the optimal treatment strategy remains to be refined. Sorafenib and sorafenib plus everolimus are the only two second-line targeted therapies recommend by FDA. The median progression-free survival (PFS) was 4–5 months. In this study, the efficacy and safety of apatinib, another oral tyrosine kinase inhibitor targeting VEGFR-2, were evaluated in patients (pts) with inoperable high-grade osteosarcoma progressing after standard multidisciplinary treatment. **Methods:** This retrospective study reviewed the medical records of 26 pts with metastatic osteosarcoma who received apatinib at a dose of 500 mg qd or 250 mg bid after failure of standard treatment including doxorubicin, cisplatin, ifosfamide and high-dose methotrexate from Jul 2015 to Nov 2016. **Results:** Among all pts, 25 (96.2%) had pulmonary metastases and 4 (15.4%) had metastases in the bone (Table). Eleven pts achieved partial response, 10 stable disease and 5 progressive disease, yielding an objective response rate of 42.3% and a clinical benefit rate of 80.8%. Followed up to Dec 31 2016, the median PFS was 8 months (95%CI, 3.2–12.8 months), and the median overall survival (OS) was not reached. The 12-month PFS and OS rates were 22.5% (95%CI, 1.6%–58.1%) and 68.7% (95%CI, 37.5%–86.5%), respectively. Noteworthy, the 12-month PFS rate for patients treated with apatinib in the second-line setting was 51.3% (95%CI, 9.1%–83.1%). The most frequent treatment-related adverse events (AEs) were hand-foot skin reaction (HFSR) (84.6%), hypertension (46.2%), and diarrhea (23.1%). Severe AEs included grade 3 HFSR (7.7%) and hypertension (3.8%). No unexpected AE was found. **Conclusions:** Apatinib was well tolerated and demonstrated activity as a second- or later-line treatment in patients with metastatic osteosarcoma, which deserves further investigations.

Baseline characteristics.

Characteristics		N	%
Age	Median (range), years	18.5 (8–63)	
	<18	11	42.3

11032 Poster Session (Board #355), Sun, 8:00 AM-11:30 AM

Clone evolution and genomic alteration analysis of osteosarcoma and matched lung metastasis. *First Author: Di Wang, Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China*

Background: Lung metastasis (LM), as the most common metastatic site, is the main reason resulting in treatment failure and death of osteosarcoma (OS). But there was no report about the clone evolution and genomic alteration in the process of LM of OS. **Methods:** Multiregion whole-genome sequencing and whole-exome sequencing were performed on ten patients with primary OS and matched lung metastatic tumors. A set of high confident somatic nucleotide variants (SNV), small insertion and deletion (indel) and copy number variation (CNV) in each sample were identified, then the *n*-dimensional Bayesian Dirichlet process was applied to define the constituent mutation clusters as clone or subclone. Neoantigen prediction and HLA typing were performed using NetMHC3.0 and POLYSOLVER algorithm, respectively. **Results:** There were diversified metastatic progression during lung metastasis of OS including linear evolution (7/10) and parallel evolution (3/10), and metastasis-to-metastasis spread was also found in a patient with multiple metastasis; Mutation accumulative effect during the metastasis of OS was evident, LM had much higher mutation load (fold change = 4.1, P-value < 0.01) and neoantigen burden (fold change = 4.5, P-value < 0.001) than the primary tumor; DNA mismatch repair (MMR) genes relevant deleterious mutation events were found in germline in 8/10 metastatic OS cases and MMR genes mutation were much more in LM than primary cancer; The genome instability of LM was prevalently much more significant than primary tumor, with higher copy number variation frequency (fold change = 7.01, P-value < 0.01). **Conclusions:** The evolution of OS during LM was very complex with diversified metastatic progression. For the LM of OS, the novel therapy should be considering the much higher mutation load, especially those causing tumor neoantigens, higher genomic instability which were associated with tumor immune therapy. Furthermore, the findings of germline MMR genes mutation in primary OS which had occurred LM and more MMR genes mutation in LM of OS indicated potential clinical benefit on immune checkpoint inhibitor therapy and other small molecular drugs for MMR genes.

11033 Poster Session (Board #356), Sun, 8:00 AM-11:30 AM

Multicentric randomized phase II trial of gamma knife surgery (GKS) versus image-guided, intensity-modulated radiation therapy (IG-IMRT) in patients with sacrococcygeal chordoma. *First Author: Shun Lu, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China*

Background: Chordoma is a rare slow-growing neoplasm arisen from cellular remnants of the notochord. About 30% occur in the sacrococcygeal region. Surgical resection is recommended treatment. Due to the high recurrence rate, adjuvant radiation therapy was suggested to receive as an effective method to improve local control rates. **Methods:** Thirty eight patients were pathologically diagnosed as non-metastatic sacrococcygeal chordoma from Aug. 2003 to May. 2015 were recruited retrospectively to analysis. All patients received surgical resection after diagnosed. Initial surgery included subtotal resection (24% of patients), and gross total resection (76% of patients). Among these patients, 25 patients treated with adjuvant IG-IMRT, while 13 patients treated GKS after surgical resection. The median follow-up was 40 months (range, 6–151 month) for all patients, The PTV of IG-IMRT group received total doses were 60 Gy (range, 56-74Gy), delivered with 2-2.2 Gy/fraction, while GKS group underwent a total of 6-8 sessions treatment. **Results:** For the IG-IMRT group and the GKS group, the 5-year overall survival and local control rates were 87.5% and 67.7%, respectively. And 5-year local control rates were 35% and 22.2%, respectively. In total, 18 patients progressed locally: 11 were in the IG-IMRT group and 7 in the GKS group. In comparison with GKS group, the IG-IMRT group has a better overall recurrence-free survival ($p = 0.03$), the significance remained after adjusted for surgery results, age and gender. Moreover, there is no significant difference of overall survival was found between these two groups. **Conclusions:** We report favorable local control and adverse event rates following IG-IMRT, and suggested IG-IMRT is the first choice of adjuvant radiation therapy for sacrococcygeal chordoma treatment.

11034 Poster Session (Board #357), Sun, 8:00 AM-11:30 AM

A DNA methylation-based classifier for accurate molecular diagnosis of bone sarcomas. *First Author: Shengyang Wu, NYU School of Medicine, New York, NY*

Background: Bone sarcomas present a unique diagnostic challenge because of the considerable morphologic overlap between different entities. The choice of optimal treatment, however, is dependent upon accurate diagnosis. Genome-wide DNA methylation profiling has emerged as a new approach to aid in the diagnosis of brain tumors, with diagnostic accuracy exceeding standard histopathology. In this work we developed and validated a methylation based classifier to differentiate between osteosarcoma, Ewing's sarcoma, and synovial sarcoma. **Methods:** DNA methylation status of 482,421 CpG sites in 15 osteosarcoma, 10 Ewing's sarcoma, and 11 synovial sarcoma samples were measured using the Illumina HumanMethylation450 array. From this training set of 36 samples we developed a random forest classifier using the 400 most differentially methylated CpG sites (FDR q value < 0.001). This classifier was then validated on 10 synovial sarcoma samples from TCGA, 86 osteosarcoma samples from TARGET-OS, and 15 Ewing's sarcoma from a recently published series (Huertas-Martinez et al., Cancer Letters 2016). **Results:** Methylation profiling revealed three distinct molecular clusters, each enriched with a single sarcoma subtype. Within the validation cohorts, all samples from TCGA were correctly classified as synovial sarcoma (10/10, sensitivity and specificity 100%). All but one sample from TARGET-OS were classified as osteosarcoma (85/86, sensitivity 98%, specificity 100%) and all but one sample from the Ewing's sarcoma series was classified as Ewing's sarcoma (14/15, sensitivity 93%, specificity 100%). The single misclassified osteosarcoma sample was classified as Ewing's sarcoma, and was later determined to be a misdiagnosed Ewing's sarcoma based on RNA-Seq demonstrating high EWRS1 and ETV1 expression. An additional clinical sample that was misdiagnosed as a synovial sarcoma by initial histolopathology, was accurately recognized as osteosarcoma by the methylation classifier. **Conclusions:** Osteosarcoma, Ewing's sarcoma and synovial sarcoma have distinct epigenetic profiles. Our validated methylation-based classifier can be used to provide an accurate diagnosis when histological and standard techniques are inconclusive.

11035 Poster Session (Board #358), Sun, 8:00 AM-11:30 AM

Association of genomically unstable Ewing sarcoma tumors with HOTAIR overexpression and clinical outcome. *First Author: Jamie D. Gardiner, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Ewing sarcoma (ES) is the second most common bone cancer in children, characterized by the EWS-FLI1 fusion protein. Like most translocation-driven pediatric cancers, ES is a genomically "quiet" cancer with a low mutational burden and strong epigenetic regulation. However, recurring copy number alterations (CNAs) still arise in some ES tumors (e.g., chromosome 1q gain, 8 gain, 12 gain, and 16q loss) while other ES tumors completely lack genomic CNAs. We hypothesized that clinical, molecular, and epigenetic differences exist between these two unstable vs. stable genomic subtypes of ES. **Methods:** We performed CNA analysis on over 200 ES FFPE tumors. 30% of ES tumors had stable genomes while 60% had one or more CNAs across the genome. We performed gene expression and methylation microarray analyses on 24 ES FFPE tumors (11 stable, 13 unstable). Expression and methylation signatures were compared between stable vs. unstable ES and combined with clinical outcome. **Results:** Patients with unstable vs. stable ES tumors revealed worse 5-year overall (OS) and event-free survival (EFS) (38% vs. 67% EFS, $p = 0.005$; 58% vs. 84% OS, $p = 0.0016$). The subtypes had distinct expression and methylation signatures and clustered by methylation patterns. We identified differentially expressed and methylated genes, including upregulation ($p = 0.0005$) and unmethylation ($p = 0.0009$) of the long non-coding RNA *HOTAIR* in unstable vs. stable ES tumors. *HOTAIR* expression is higher in metastatic ES tumors compared to primary ES tumors ($p = 0.02$). Per the Cancer Cell Line Encyclopedia (Broad), ES cell lines have increased HOTAIR expression compared to 36 other cancers. **Conclusions:** ES genomic profiling through copy number, gene expression, and methylation identified at least two subtypes of ES (stable and unstable) that differ in outcome, gene expression and methylation. This data suggests *HOTAIR's* involvement in ES pathogenesis, particularly in unstable tumors that have worse prognosis. Investigation is ongoing for *HOTAIR* expression as a prognostic and therapeutic target for ES, including a marker for LSD-inhibitor response.

11036 Poster Session (Board #359), Sun, 8:00 AM-11:30 AM

Inhibition of autophagy sensitizes gastrointestinal stromal tumor cells to TKI/Bcl-2 inhibitors-induced apoptosis. *First Author: Shuchao Zhang, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumor of the GI tract. Most GISTs are driven by mutations in KIT or platelet-derived growth factor receptor-α (PDGFRA), which responds well to imatinib, a tyrosine kinase inhibitor (TKI) that blocks KIT and PDGFR-α signaling. Bcl-2 family plays a critical role in the regulation of cell apoptosis in GISTs. ABT-737 as an inhibitor of Bcl-2/Bcl-xL can result in a time and dose-dependent activation of apoptosis. Autophagy is a key mechanism to promote tumor cells survival, inhibition of which can induce the cell death in GISTs. Chloroquine, an antimalarial drug, has been also identified as an autophagy inhibitor. In this study, we assessed the combinational effects of imatinib, ABT-737 and chloroquine in GIST cells. **Methods:** Human GIST cell lines, GIST-T1 and GIST-882, were employed in our study. Cells were treated with imatinib, ABT-737 and chloroquine either separately or in different combinations. Cell viability was tested by means of MTS and synergistic effects were analyzed by isobologram software. The levels of related proteins of apoptosis (PARP, Caspase-3) and autophagy (LC3-II, beclin-1) were measured by western blot. Cell apoptosis and cell cycle were tested by flow cytometry. **Results:** Cell viability assay indicated cell survival percentage of double or triple drug combinations ($< 5\%$) dramatically decreased compared to single drug treatments (42%, 36% or 12%) ($P < 0.05$). Isobologram analysis revealed triple drugs combination had stronger synergistic effects than double drugs combinations (CI = 0.204 vs 0.309 or 0.356, $P < 0.05$). Cell apoptosis percentage of double (32.9% or 36.6%) or triple drugs combinations (66.5%) significantly increased compared to single treatments (6.1%, 6.1% or 13.1%) ($P < 0.05$). Western blot showed drugs combinations increased cleavage of PARP and Caspase-3 levels, but inhibited autophagy. **Conclusions:** The combination of imatinib, ABT-737 and chloroquine has collaborative effects on the treatment of GISTs *in vitro*. The combined strategy may enhance the clinical efficacy, which provides a rationale for the clinical evaluation of these drug combinations in GISTs treatment.

11037 Poster Session (Board #360), Sun, 8:00 AM-11:30 AM

The role of neoadjuvant imatinib therapy of patients with primary locally advanced GIST. *First Author: Peter Arkhiri, N. N. Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russia*

Background: percutaneous biopsy of gastrointestinal tumors is contraindicated, that is why prospective randomized trials of efficiency of preoperative imatinib therapy weren't conducted. According to the results of theRTOG S-0132/ACRIN 6665, CST1571-BDE43 and other studies, neoadjuvant imatinib therapy increase tumor resectability and improve progression-free and disease-specific survival. The optimal timing of surgical intervention is likely during the maximal response on treatment (6 to 12 months as a rule). **Methods:** We have analyzed the treatment results of 86 patients with locally advanced GIST which were treated since January 1st 2002 till 20 January 2016 at N.N. Blokhin Russian Cancer Centre. The primary tumor was located in the stomach - 32 pts (37,2%), duodenum and small bowel - 37 (43,1%), other (colon, rectum and extraorgan) – 17 pts (19,7%). The median follow-up time was 4.9 years. There are 4 groups in the trail: group 1 - 29 patients received only surgical treatment, group 2 - 12 pts– surgical resection with adjuvant imatinib therapy for 1 year; group 3 - 25 pts – adjuvant imatinib therapy for 3 years and group 4 - 17 pts– surgical resection with neoadjuvant and adjuvant imatinib therapy (1 - 3 years). The remained 3 patients received surgical resection with adjuvant imatinib therapy for 5 years. **Results:** Survival analyses showed a significant improvement of RFS and OS in patients who received combined treatment with neoadjuvant and adjuvant imatinib therapy. The five-year RFS in first group of patients was 10,8%, in 2 group - 16,7%, in 3 group - 68,4%, and 4 group - 79,8% (p = 0.0001). The 5-year overall survival in these groups was 42,6%, 66,7%, 76,1% and 91.6% (p = 0,0072) respectively. In the patients with 5-years adjuvant therapy, diseases progression was not noted. During neoadjuvant therapy disease progression has been registered in two patients. The median time of preoperative imatinib therapy was 11 month (from 3 to 24 month). Neoadjuvant imatinib therapy increased the rate of R0 (14 pts – 82,4%) and organ-sparing (12 pts – 70,6%) resections. **Conclusions:** The optimal approach in patients with locally advanced GIST is combined surgical treatment with neoadjuvant and adjuvant (at least for 3 years) imatinib therapy.

11038 Poster Session (Board #361), Sun, 8:00 AM-11:30 AM

Rechallenge in advanced GIST progressing to imatinib, sunitinib and regorafenib: An Italian survey. *First Author: Bruno Vincenzi, Medical Oncology Department, University Campus Bio-Medico, Rome, Italy*

Background: We retrospectively collected data from metastatic Italian GIST patients treated with imatinib or sunitinib reintroduction after progression to conventional three or four lines of therapy. **Methods:** 82 eligible advanced GIST patients, previously treated with imatinib, sunitinib and regorafenib, were collected in the present analysis from 6 cancer centres. All patients received all three standard kinase inhibitors. Imatinib dose increase as active second line or 800 mg upfront in exon 9 mutant GIST were allowed. Specific mutations were recorded if available (deletion versus others) and correlated with survival and response according to RECIST 1.1 or CHOI criteria. **Results:** Seventy-four of 82 patients received Imatinib 400 mg as rechallenge, while 8 patients were treated with sunitinib at personalised dose and schedule according to the physician's choice. Mutational status was available in all patients and in 68 patients details about type of mutation were achievable. The median follow-up was 13 months (range 1-42 months). The median time to progression (TTP) in patients receiving a rechallenge therapy was 5.4 months (95% CI 1.9-13.5) and Overall Survival (OS) was 10.6 months (95% CI 2.8-26.9). Apparently, in this setting a correlation between mutational status and response rate, TTP or OS was not found. On the contrary, considering only exon 11 mutated patients and comparing patients with deletion vs non deleted ones a significant difference was identified both in terms of TTP and OS (respectively, P = 0.04 and P = 0.02). **Conclusions:** Our retrospective data confirm that the rechallenge of imatinib or sunitinib is a reasonable option in advanced GIST patients after failure of previous treatments. As expected, imatinib is the most frequently prescribed option in the Italian real-life setting, demonstrating a TTP and OS longer than those observed in previous studies. Also the prognostic value of the specific type of exon 11 KIT mutations has been confirmed in our series.

11039 Poster Session (Board #362), Sun, 8:00 AM-11:30 AM

A phase Ib study of BGJ398 in combination with imatinib in patients with advanced gastrointestinal stromal tumor (GIST). *First Author: Ciara Marie Kelly, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Preclinical studies suggest that imatinib resistance (IR) in GIST can be mediated by MAP-kinase activation via FGF signaling. In FGF stimulated GIST cell lines, BGJ398, a pan-FGFR inhibitor in combination with imatinib, is cytotoxic and superior to imatinib alone, or imatinib in combination with MEK-inhibition. In GIST with FGF signaling, the combination of BGJ398 and imatinib may provide a mechanism to overcome IR. **Methods:** This phase Ib study of BGJ398 in combination with imatinib was performed in patients (pts) with imatinib resistant advanced GIST. A standard 3+3 dosing schema was utilized to determine the recommended phase II dose. Two treatment schedules were evaluated incorporating imatinib 400mg daily continuously in combination with (A) BGJ daily 3 wks on, 1 wk off or (B) BGJ daily 1 wk on, 3 wks off. Response was evaluated by RECIST and CHOI every 8 wks x4 and then every 12 wks. **Results:** 16 pts enrolled. Median age 54 (range: 44-77), 81% male, median prior therapy 4 [range: 2-6, 13/16 pts had $\geq$ 3 prior therapies (81%)]. 12 pts received treatment on schedule A [dose level (DL)1 (BGJ 75mg), n = 6; DL-1 (BGJ 50mg), n = 3; DL-2 (BGJ 25mg), n = 3]: 3 DLTs (myocardial infarction, grade (G)4 CPK elevation, G3 ALT elevation) were observed on schedule A at DL1, hyperphosphatemia (on target effect) was not observed raising concern for therapeutic efficacy at the maximum tolerated dose. Following protocol amendment that allowed an alternative dosing schedule, 4 pts enrolled on schedule B [DL1 (BGJ 75mg), n = 3; DL2 (BGJ 100mg), n = 1]: one DLT occurred (G3 intra-abdominal hemorrhage) at DL2. The most common non-DLT G3/4 toxicity was HTN (2/16pts) and G2 toxicity was prolonged QTc interval (3/16pts). Of the 12 pts with evaluable CT scans, stable disease (SD) was the best response observed in 7 pts by RECIST and 9 pts by CHOI. 3pts achieved SD for $>$ 6 months. 2 pts remain on study at data cut-off (range: 1 – 67 wks). Median progression free survival is 8 weeks. Pharmacokinetic analysis of imatinib and BGJ is forthcoming. **Conclusions:** In heavily pre-treated pts, durable disease control was observed in 3/16 pts. This signal of efficacy suggests that further evaluation of FGF signaling in the development of IR is warranted. Clinical trial information: NCT02257541.

11040 Poster Session (Board #363), Sun, 8:00 AM-11:30 AM

Numerical, dimensional or mixed progression disease to imatinib as prognostic factor in patients with metastatic GIST. *First Author: Giuseppe Badalamenti, Department of Surgical, Oncological, and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy*

Background: The majority of GIST patients with advanced disease initially achieves disease control from imatinib treatment. Approximately 10% of patients progresses within 6 months of starting therapy (primary resistance) and also 50-60% of the responding patients develops progression disease within two years (secondary resistance). Progression disease (PD) can be numerical, dimensional or mixed. The known prognostic factors of risk stratification in local disease are tumor size, mitotic activity and anatomic site. In this retrospective analysis we explore several clinical factors affecting survival in metastatic setting. **Methods:** The population included in this large database of 128 patients with metastatic GIST was obtained examining data collected from four Oncologic Centres with expertise for the GIST management. The clinical factors analyzed were sex, tumor size, mitotic activity, anatomic site, *KIT* and *PDGFRa* mutational status, site of metastasis, FDG-PET status at progressing disease and pattern of tumor progression to I line imatinib 400, II line Imatinib 800 or Sunitinib, evaluated with CT scan or MRI: PD with dimensional growth (dimensional, dPD), with new lesions appearance (numerical, nPD) and with both numerical and dimensional growth (Mixed, mPD). Every factor has been correlated with Overall Survival (OS) measured in months. Survival analyses were performed by using the Kaplan-Meier method. Univariate and multivariate Cox proportional hazard regression models were executed to search for association with the outcome. **Results:** Univariate analysis showed significant value for primary tumor site ($p < 0.0001$), mitotic activity (p = 0.02), tumor size (p = 0.05) and PD pattern (p = 0.008): OS nPD group was 102.7 months, in dPD group 87 and in mPD group 70. The multivariate analysis confirm significant prognostic factors for OS tumor site (p = 0.0004) and PD pattern (p = 0.02). **Conclusions:** with the limitations of a retrospective analisys, this study shows for the first time the impact of pattern of progression on OS: patients with dPD have a worse prognosis than those with nPD or mPD, suggesting type of PD as an independent prognostic factor for OS in advanced GISTs.

11041 Poster Session (Board #364), Sun, 8:00 AM-11:30 AM

Long-term survival (over 10 years) of inoperable/metastatic GISTs: A retrospective series of 141 patients (pts) of the french sarcoma group (FSG). *First Author: Florence Duffaud, Hopital de la Timone, Marseille, France*

Background: A subset of metastatic GIST exhibit very long-term survival after imatinib (IM) introduction. The aim of this study was to analyse the clinico-biological characteristics of GIST pts alive > 10 years (yrs) after diagnosis (dx) of metastases (mets) and identify possible factors associated with long-term survival. **Methods:** Pts were identified from 2 sarcoma databases; NetSarc and ConticaGIST. Clinical data prospectively registered in the databases were supplemented with retrospective review of medical records. **Results:** We identified 141 pts (75 men, 66 women) with median age 54 (17-84) yrs and median ECOG 0 (0-2). Primary tumors (T) were all CD117+, and mainly gastric or intestinal (64 & 45 pts), with median size 10 (2-40) cm, CD34+ (82 pts), mitoses/50 HPF ≤ 5 (n = 36), or > 5 (n = 81). Genotype was documented in 82 (58%) pts with 73 (89%) *KIT* mutations (in exons 11,9 and 12 of 69, 3, and 1 pts respectively) and 9 WT *KIT*. 129 (91%) T were resected, 124 upfront, 5 post IM, with R0/R1/R2 resections in 61, 11, and 10 pts. Mets were mainly hepatic or peritoneal (78 & 51 respectively). 1st line TKI was given to 139 pts: 130 received IM; 88 (63%) within a clinical trial (CT), 41 (29%) had mets resection. Second, 3d and 4th line TKI were given to 81, 51 and 37 pts respectively, comprising 27, 7 and 10 from CT. Median number of TKIs was 2 (0-7), but 60 (44%) pts received only 1st line with no GIST progression within or after 10 yrs. 2 pts never received TKI but had mets resection. After median FU of 14.3 yrs (10-34.5), 104 remain alive, 37 died. Mean and Median OS from initial dx are 24 yrs (CI95% 21.6-27) and 20,8 yrs. Median PFS on TKIs are 127, 29, 21 and 22 mos on 1st, 2d, 3d and 4th line of TKI. In univariate analysis no factor is significantly associated with OS, but T size (≤ 10 vs > 10 cm) and oligometastatic disease (≤5 vs > 5 mets) are borderline significant (p = 0.056 and 0.07), and good PS (ECOG ≤ 1) at 2dline TKI initiation is associated with better PFS (p = 0.03). **Conclusions:** This large series of long-term (> 10 yrs) survivors of metastatic GIST shows a high proportion of mets resection and a longer duration of PFS for TKI at any line. In this selected population, no prognostic factor is associated with long OS.

11042 Poster Session (Board #365), Sun, 8:00 AM-11:30 AM

Analysis of tumor-infiltrating immune cells in gastrointestinal stromal tumors (GIST) after tyrosine kinase inhibitor therapy. *First Author: Peter Hohenberger, Division of Surgical Oncology and Thoracic Surgery, Mannheim University Medical Centre, University of Heidelberg, Mannheim, Germany*

Background: There is initial evidence that immune-infiltrates of tumor may correlate with the clinical course of patients with GIST beyond the response to tyrosine kinase inhibitors (TKI) according to the mutational status. We were interested to analyze the composition of tumor-infiltrating immune cells in GIST tumor tissues after different TKI regimens vs untreated controls. **Methods:** From 40 GIST patients who were treated with imatinib alone (neoadjuvant group) and other TKIs (M1 HEP group, progressing on more than ≥2 TKI inhibitors) prior to tumor removal, surgical specimens were available at ten 10 cases each,. They were compared with 20 untreated primary tumors graded for malignant behaviour (low vs high risk) acc. to Miettinen&Lasota 2006. 2-μm sections of formalin-fixed, paraffin-embedded tissue samples were used for IHC-staining anti-CD68 (Dako); anti-CD11c, anti-CD11b, anti-FOXP3 (all Abcam); anti-CD163, anti-CD4 , anti-CD8 (all Leica). Evaluation was performed with Dako REAL EnVision Detection System (K5007). The phenotypes of immune cells were compared in the defined GIST groups. In the neoadjuvant group we used recurrence-free survival (RFS) for correlation, and overall survival (OS) after TKI failure in the M1 HEP group. **Results:** Foxp3+ Tregs, CD163+ M2 macrophages and CD11b+ myeloid cells are significantly higher in TKI resistance or neoadjuvant (viable cells > 30%) tissues compared with neoadjuvant (viable cells < 10%) cases. The rate of CD11c+ M1 macrophages is higher in low-risk GISTs compared to high risk GISTs, but CD11b+ myeloid cells are exactly the opposite. Kaplan-Meier curves show high CD163+ M2 macrophages or CD11b+ myeloid cells to correlate significantly with worse RFS in after neoadjuvant IM (p 0.01). In the TKI resistant condition, patients with high CD11c+ M1 macrophages show better median OS (p = 0.07, ns). **Conclusions:** Our study reveals dynamic changes of tumor-infiltrating immune cell protagonists in GISTs after different TKI therapeutic regimen and after neoadjuvant treatment. We could not detect a different immune infiltrate in untreated primary tumors of different risk categories.

11043 Poster Session (Board #366), Sun, 8:00 AM-11:30 AM

Impact of pharmacogenomics on imatinib toxicity in gastrointestinal stromal tumors. *First Author: Wei Zhuang, Sun Yat-Sen University, Guangzhou, China*

Background: Imatinib-induced side effects are common, although most of these side effects are mild, some will be severe and lead to disruption of Imatinib treatment in gastrointestinal stromal tumor (GIST). It is necessary to explore a biological predictors to predict and optimal therapeutic strategy. But there were few studied conducted to explore the mechanisms of Imatinib-induced side effects. The present study comprehensively investigated the effects of genetic polymorphisms of cytokines involved in cell proliferation and metabolic enzymes and transporters involved in Imatinib metabolism on these side effects. **Methods:** A total of 154 GSIT patients treated with Imatinib were enrolled. 22 SNPs (single nucleotide polymorphisms) in *KIT/ PDGFRA/ PDGFRB/ SHC1/ FLT1/ MAPK1/ EGFR/ CCL5/ CXCL14*were detected using Agena Massarray matrix-assisted laser desorption / ionization-time of flight (MALDI-TOF) platform. Logistic regression analyses were performed to evaluate their effects on Imatinib-induced toxicities. This study was approved by the ethical committee of Sun Yat-Sen University Cancer Center. **Results:** Imatinibdose, *FLT1* rs9951465, *MAPK1* rs13515, *PDGFRB* rs55712339 and *SHC1* rs3766920 were found to be correlated with the incidence of myelosuppression (*P*= 0.027, 0.009, 0.002, 0.008, < 0.001, respectively), moreover, *FLT1* rs9554314 was correlated with severe myelosuppression (Grade 0,1 vs. 2+, *P*= 0.009, OR (95%CI) = 3.042 (1.314-7,042)). Meanwhile, *EGFR* rs10228436 was found to be correlated with the incidence of skin rash (*P*= 0.027), moreover, *CCL5* rs4796120 and *CXCL14* rs7716492 were correlated with severe skin rash (Grade 0,1 vs. 2+), with OR (95%CI) and p value were 8.542 (0.934-78.107), 13.504 (2.308-79.004) and 0.057, 0.020, respectively. **Conclusions:** This is the first comprehensive report on the biomarkers for Imatinib toxicities. These biomarkers might be able to distinguish patients with mild or more severe forms of Imatinib toxicities, thus enabling the optimization of Imatinib therapy and lead patients benefit from Imatinib treatment in a long-term.

11044 Poster Session (Board #367), Sun, 8:00 AM-11:30 AM

LMTK3 as a novel regulator of oncogenic KIT in KIT-mutant cancers. *First Author: Lillian Rose Klug, Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR*

Background: Multiple cancers, such as gastrointestinal stromal tumors (GIST) and melanoma, have been shown to be caused by somatic activating mutations in the receptor tyrosine kinase KIT. The major cause of death in patients with advanced KIT-mutant cancers is due to the development of KIT tyrosine kinase inhibitor-resistant (TKI-resistant) metastatic disease. Drug resistance arises almost exclusively from secondary mutations within KIT, highlighting the importance of KIT in the proliferation and survival of these tumors. **Methods:** We performed a human kinase siRNA screen in multiple KIT-mutant cancer cell lines using viability as a read out. We defined candidate targets as those whose knockdown decreased viability in all cell lines. Validation and mechanistic studies were done using a library of KIT-mutant GIST and melanoma cells. **Results:** We identified lemur tyrosine kinase 3 (LMTK3) as candidate target in three KIT-mutant cell lines. LMTK3 silencing reduced the viability of all KIT-mutant GIST and melanoma cells tested to date, including cell lines with KIT TKI-resistance mutations. Importantly, LMTK3 silencing decreased the viability of KIT-mutant cells specifically, but not that of KIT-independent GIST and melanoma cells. Further, we found that decreased cell viability was due to induction of apoptosis, as assessed by measuring caspase 3 and 7 activity within 96 hours of LMTK3 silencing. LMTK3 knockdown also reduced tumor growth *in vivo* in a GIST xenograft model. Because these cells depend so heavily on KIT and the loss of KIT signaling results in cell death, we hypothesized that LMTK3 silencing may affect this pathway. Indeed, LMTK3 silencing decreased levels of autophosphorylated KIT. We also observed a significant decrease in total KIT protein expression. This phenotype and corresponding viability was rescued with exogenous expression of full length LMTK3. **Conclusions:** LMTK3 is an important regulator of oncogenic KIT expression and activity in KIT-mutant GIST and melanoma and represents a novel, tractable target.

11045 Poster Session (Board #368), Sun, 8:00 AM-11:30 AM

Prognostic factors of recurrence and survival of gastrointestinal stromal tumors: First multicentric study of Mexico. *First Author: Rafael Medrano Guzman, Hospital De Oncologia Centro Medico Nacional Siglo XXI, Mexico, Mexico*

Background: Gastrointestinal stromal tumors are mesenchymal lesions arising from the interstitial cells of Cajal. In GIST the location, size, number of mitosis and risk group are accepted as prognostic factors; some factors in which there are still controversies about their value as prognostic factors include male gender, tumor cellularity, the margins of resection, the presence or absence of p16 or intraperitoneal tumor breakdown. **Methods:** Observational, retrospective and longitudinal study. Patients admitted to the Oncology Hospital, CMN Siglo XXI of January 1, 1991 to April 30, 2012. **Results:** We identified 384 patients, the mean follow-up time was 55.86 months, the mean age was 58 years, 80.3% had symptoms and only 4.54% the finding was incidental. The most common site was the stomach (66.6%), followed by small intestine (28.7%) and colon (1.54%). The 7.57% had metastases at diagnosis, 4.54% in liver and 3.03% in the peritoneum. Were expressed by abdominal pain (39.39%) and gastrointestinal bleeding (30.30%), intestinal obstruction in 1.5%. The most common site was the stomach (66.6%), followed by small intestine (28.7%) and colon (1.54%). The 7.57% had metastases at diagnosis. The average tumor size was 10.84 cm (2.2 to 38 cm). Immunohistochemical markers were studied: 94.28% positive for CD117, CD34 74.28%, 11.42% S100 protein, desmin 5.71% and 51.72% for smooth muscle actin (AML). Overall rate at 5 years and 82% rate of recurrence-free survival at 5 years and 61% survival. The location of the tumor ($p = 0.0002$), size ($p = 0.03145$), the number of mitosis ($p = 0.008$), risk group ($p = 0.020$) and adjuvant treatment with Imatinib showed a statistically significant difference for Survival Recurrence-free. For overall survival, lesion location was the only factor that showed statistical significance with $p = 0.0054$. **Conclusions:** The tumor location, size, number of mitosis, the risk group and adjuvant treatment with Imatinib were statistically significant prognostic factors for disease recurrence. The location of the lesion was the only factor that showed statistical significance as a predictor of overall survival.

11046 Poster Session (Board #369), Sun, 8:00 AM-11:30 AM

Influence of chemotherapy combined with radiotherapy on the time-to-development of radiation-induced sarcomas: A multicenter, retrospective analysis. *First Author: Alison Yan Zhang, Northern Beaches Cancer Service, Manly, Australia*

Background: An increasing number and proportion of cancer patients with apparently localised disease are treated with chemotherapy and radiation therapy in contemporary oncology practice. In a pilot study of radiation-induced sarcoma (RIS) patients, we demonstrated that chemotherapy was associated with a reduced time to development of RIS. We now present an international multi-centre collaborative study to validate this association. **Methods:** This was a retrospective cohort study of RIS cases across five large international sarcoma centres between the 1st January, 2000 to 31st December, 2014. The primary endpoint was time to development of RIS, defined as the date of diagnosis of the first malignancy to date of the RIS diagnosis. We also assessed the relationship between chemotherapy, patient and cancer characteristics, and time to RIS. **Results:** We identified 419 patients with RIS, who were predominantly diagnosed with their first malignancy at adulthood. The median interval from the index cancer to development of RIS for the entire cohort was 11 years (range 1-64). Chemotherapy for the first malignancy was associated with a shorter time to RIS development (HR 1·37; 95% CI: 1·08-1·72; $P = 0·009$). In the multi-variable model, older age (HR 2·11; CI 1·83-2·43; $P < 0·001$) and chemotherapy for the first malignancy (HR 1·61; CI 1·26-2·05; $P < 0·001$) were independently associated with a shorter time to RIS. Anthracyclines and alkylating agents significantly contribute to the effect. **Conclusions:** This study confirms an association between chemotherapy given for the first malignancy and a shorter time to development of a RIS. Our data highlights the importance of vigilance in surveillance for RIS after chemotherapy and radiation therapy, particularly in younger patients who also have a longer potential time to develop a second malignancy.

11047 Poster Session (Board #370), Sun, 8:00 AM-11:30 AM

Prognosis of desmoid tumors (DT): A prospective nationwide survey of 771 patients (pts). *First Author: Thomas Ryckewaert, Centre Oscar Lambret, Lille, France*

Background: Prognostic factors and optimal management of DT are not yet established. **Methods:** We analyzed the outcome of 771 consecutive DT pts treated between 01/2010 and 12/2016 in France. We have calculated event-free survival (EFS) defined as local relapse after surgery, progressive disease during non surgical approach or change in treatment strategy (e.g. from wait and see to systemic treatment or local treatment). **Results:** The sex ratio M/F was 219/552, the median age was 39 (2-90), and the median size 57 mm (4-700). 596 DT are found *CTNNB1*-mutated (71%). The 1st treatment was wait and see (369, 48%), surgery (343, 44%), systemic treatment (25, 3%), or radiotherapy (3, 0%). The median follow-up was 32 mo. 230 events occurred (including 1 death). The median EFS was 27 mo. After initial wait and see, pts required systemic treatment in 61 cases (15%), radiotherapy (4; 1%), cryotherapy (3; 1%), surgery (2; 0%) and radiofrequency (1, 0%). After initial surgery, DT pts required wait and see for relapse in 88 cases (25%), systemic treatment in 17 cases (5%), radiotherapy (6; 2%), cryotherapy (2; 0%) and surgery (1, 0%). Univariate analysis identified 3 factors associated with EFS: favorable locations (median not reached (NR) vs. 21 mo; $p = 0.0001$), nature of sampling (core needle biopsy: 31 mo; resection 26 mo and open biopsy 15 mo, $p = 0.046$) and superficial DT (NR vs. 28 mo, $p = 0.00001$). Favorable locations included: abdominal wall (236 pts), intra-abdominal (78 pts), breast (27 pts) and digestive viscera (42 pts). Chest wall (209 pts), head and neck (28 pts), lower limb (90 pts), upper limb (25 pts) and pelvis (18 pts) were all associated with poor EFS. Multivariate analysis identified only 1 prognostic factor for EFS: favorable location HR = 0.52 [0.39-0.69]. Compared to surgery, wait and see as 1st treatment was associated with better EFS in unfavorable DT locations (HR = 0.74 [0.74-0.56]; $p = 0.001$) but not associated with EFS in favorable locations (HR = 0.89 [0.69-1.13]; $p = 0.420$). **Conclusions:** Since primary location of DT is the major determinant of DT outcome, stratified approach according to location has to be prospectively assessed. Correlative biology analyses are warranted to better understand these findings.

11048 Poster Session (Board #371), Sun, 8:00 AM-11:30 AM

Tumor volume score (TVS), modified recist, and tissue damage score (TDS) as novel methods for assessing response in tenosynovial giant cell tumors (TGCT) treated with pexidartinib: Relationship with patient-reported outcomes (PROs). *First Author: Charles Peterfy, Spire Sciences, Inc., Boca Raton, FL*

Background: TGCT is a locally aggressive neoplasm of joint and tendon sheath synovia that may cause pain, limit joint function and destroy bone and local tissues. Measuring TGCT with RECIST is a challenge due to irregular shape and asymmetrical growth, and local tissue damage is not assessed. We reported earlier results of a longitudinal trial of pexidartinib, a selective CSF1R kinase inhibitor, using RECIST as well as novel TVS, modified RECIST and TDS. Here we examine concordance of these MRI measures with PROs. **Methods:** Patients (pts) with progressive TGCT in a single-arm, multi-center trial of pexidartinib (1000 mg po daily) were assessed by MRI every 2 months by 2 central radiologists (blind to visit order). For RECIST, longest measurable dimensions of up to 2 tumors per joint or tendon sheath were summed (SLD). Modified RECIST summed short axis dimensions (SSD). TVS was based on 10% increments of the estimated maximally distended normal synovial cavity or tendon sheath. TDS scored bone erosion (ERO), cartilage loss (CAR) and bone marrow edema (BME) in multiple regions of each joint. The relationship with PROs (Worst Pain numerical rating scale [NRS] and Worst Stiffness NRS) was assessed. **Results:** 15 pts (7 knees, 3 hips, 2 ankles, 1 elbow, 1 wrist, 1 thigh) with PRO data and evaluable MRI scans at baseline and Month 7 were assessed. All SLD, SSD and TVS scores improved with respective median changes of -25%, -39% and -50%. Baseline ERO, CAR, and BME ranged 0-19, 0-34, and 0-15, respectively. Median change for each was 0%: ERO worsened in 1 pt, CAR did not change, and BME improved in 4 and worsened in 2. Worst Pain NRS and Worst Stiffness NRS improved in 11 and 9 pts, respectively. **Conclusions:** TVS demonstrated the greatest pexidartinib effect size, followed by SSD and then conventional RECIST. All had good concordance with PROs. Clinical trial information: NCT01004861.

Concordance of MRI measures with PROs.

	Pain improved (Yes)	Pain improved (No)	Stiffness improved (Yes)	Stiffness improved (No)
SLD improved (Yes)	11	1	9	3
SLD improved (No)	0	0	0	0
SSD improved (Yes)	11	2	9	4
SSD improved (No)	0	0	0	0
TVS improved (Yes)	10	2	8	4
TVS improved (No)	1	0	1	0

11049 Poster Session (Board #372), Sun, 8:00 AM-11:30 AM

Elevated preoperative peripheral blood neutrophil-to-lymphocyte ratio to predict clinical outcome in patients with localized soft tissue sarcoma. *First Author: Jason Yongsheng Chan, National Cancer Centre Singapore, Singapore, Singapore*

Background: Recent studies suggest that markers of systemic inflammation such as blood neutrophil-to-lymphocyte ratio (NLR) may be prognostic for various cancers, though its clinical utility has not been widely accepted. This study aims to investigate its clinical relevance in patients (pts) with soft tissue sarcoma (STS). **Methods:** Five hundred and twenty-nine pts with localized STS who had available pre-operative blood counts at the time of diagnosis were retrospectively examined. An optimal cutoff for high NLR (>2.5) in predicting overall survival (OS) and relapse-free survival (RFS) in pts who underwent curative surgery (n = 473) was determined using receiver operating curve analyses. Cutoffs for platelet-lymphocyte ratios (PLR, >180) and lymphocyte-monocyte ratios (LMR, <3.6) were similarly obtained. Survival analysis was performed using the Kaplan-Meier method and multivariate Cox proportional models. Median follow-up was 40 months. **Results:** A high NLR was present in 311 (58.8%) pts, which was significantly associated with tumor grade ($p<0.0001$), depth ($p=0.003$) and size >5 cm ($p=0.0242$), but not with age at diagnosis, sex or ethnicity. High NLR was associated with both worse OS (HR 1.78; 95%CI 1.28-2.47; $p=0.0005$) and RFS (HR 1.54; 95%CI 1.17-2.03; $p=0.0019$), as were age at diagnosis, tumor grade, size, PLR and LMR. In multivariate models adjusted for clinicopathological predictors of survival, only NLR, in addition to tumor grade and size, were independently associated with worse OS (HR 1.52; 95%CI 1.09-2.11; $p=0.0131$) and RFS (HR 1.42; 95% CI 1.08-1.85; $p=0.0114$). Analysis of survival according to American Joint Committee on Cancer (AJCC) stages subdivided as NLR-high and NLR-low revealed a significant worse prognosis for NLR-high subgroups ($p<0.0001$), with a 2.2-fold and 1.5-fold higher risk of death within stages II (HR 2.20; 95%CI 1.20-4.01; $p=0.0103$) and III (HR 1.55; 95%CI 1.01-2.37; $p=0.0459$), respectively. **Conclusions:** High NLR is an independent marker of poor prognosis among pts with localized STS. Inclusion of NLR as a classifier into the AJCC staging of STS may improve estimation of survival.

11050 Poster Session (Board #373), Sun, 8:00 AM-11:30 AM

A pilot trial of irinotecan, temozolomide and bevacizumab (ITB) for treatment of newly diagnosed patients with desmoplastic small round cell tumor (DSRCT). *First Author: Heather D. Magnan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: DSRCT is a rare tumor with a dismal prognosis in the setting of current treatment options. Preclinical data suggested that VEGF-dependent angiogenesis is important for DSRCT tumor biology and that targeting angiogenesis with bevacizumab in combination with irinotecan was more effective than treatment with irinotecan alone. This pilot study was designed to explore the safety and feasibility of adding ITB to the existing "P6- like" regimen used to treat DSRCT. **Methods:** Fifteen patients with newly diagnosed DSRCT were enrolled onto this single-institution study. They began treatment with 2 cycles of irinotecan (20 mg/m2/dose x 10 days) and temozolomide (100 mg/m2/dose x 5 days). Bevacizumab 10 mg/kg q2 weeks was added after sufficient time had passed from initial biopsy or surgery. Patients were then treated with cycles of alkylator based chemotherapy (3 cycles of cyclophosphamide, doxorubicin, vincristine and 3 cycles of ifosfamide, etoposide). An initial surgical resection was performed after cycle 5 and a second resection or second look surgery after cycle 8. Toxicity was graded according to CTCAE v.4.0. Secondary efficacy objectives were assessed using RECIST 1.1 criteria and the Kaplan Meir method. **Results:** 14 of 15 patients completed planned protocol therapy. One patient was taken off study due to complications associated with surgery after cycle 5 of chemotherapy. Stopping rules for unacceptable toxicity were not met. No patients experienced toxicity attributed to bevacizumab, and surgical morbidity was no greater than expected. Grade 3 diarrhea associated with irinotecan was experienced by 2 patients. Expected toxicities with "P6-like" cycles included grade 3/4 hematologic toxicity and admissions for febrile neutropenia in all patients. Response rate to the ITB cycles was 27% (95% CI 8-55%) and to the 5 pre-resection cycles was 73% (95% CI 45-92%). Median time to progression was 18.1 months. Overall survival at 1 year was 100% and 3 years 61% (95% CI 25-84%). **Conclusions:** The combination of ITB is active in patients with DSRCT, and it is feasible to combine these agents with standard chemotherapy without greater than expected toxicity. Clinical trial information: NCT01189643.

11051 Poster Session (Board #374), Sun, 8:00 AM-11:30 AM

Administration of aldoxorubicin and 14 days continuous infusion of ifosfamide/mesna in metastatic or locally advanced sarcomas. *First Author: Frederick C. Eilber, University of California, Los Angeles, Los Angeles, CA*

Background: Aldoxorubicin (A) has demonstrated superior anti-tumor efficacy and lack of cumulative cardiac toxicity in multiple studies. A is doxorubicin (D) with a linker which rapidly binds in vivo to albumin after iv. We studied the combination of A administered on Day 1 with continuous infusion (CI) of ifosfamide/Mesna (I-M) days 1-14, as first line therapy or second line therapy in patients with soft tissue sarcomas (STS) to evaluate efficacy and toxicity. **Methods:** 27 patients have entered the study at 250 mg/m2 (185 mg/m2 D equiv) administered on Day 1. I-M (1 g/m2 of each per day) was given up to 14 days as a CI via an out-patient portable pump. Chemotherapy cycles were repeated at 28 day interval. I-M was limited to a maximum of 6 cycles to avoid cumulative marrow toxicity, but A was continued per investigator decision in responding or SD patients for clinical benefit. Subjects were followed for tumor response (RECIST 1.1) by CT scans and echocardiogram/ECG for cardiac toxicity every 8 weeks along with standard labs. Enrollment continues up to 50 patients. **Results:** Demographics: Leiomyosarc. = 20%, liposarc. = 20%, synovial sarc. = 20%, rhabdosarc. = 8%, others = 32%. Caucasian, 11% Asian, 4% Black; 67% no prior tx, 26% 1 prior tx, 7% >1 prior tx; Median cum. A = 1000 mg/m^2 (740 mg/m^2 D eq.; 185-4070 mg/m^2 D eq.); I = 6.9 g/m^2 (2.1-12.6 g/m^2). Best response: 42% PR, 58% SD. Median PFS not reached. 10 subjects with either PR or SD had surgery to remove accesible tumors. Range of tumor necrosis = 70 to >95%. Grade 3/4 AEs: neutropenia = 78%, febrile neutropenia = 9%, thrombocytopenia = 22%, anemia = 65%, nausea = 4%. Related SAEs = 4 (febrile neutropenia (2), pyrexia, stomatitis). No tx related deaths. No clinically significant cardiac AEs, no decrease in LVEF >20% **Conclusions:** A can be administered for prolonged periods and safely with CI ifosfamide/mesna and achieves high ORR and SD with substantial tumor necrosis. Clinical trial information: NCT02235701.

11052 Poster Session (Board #375), Sun, 8:00 AM-11:30 AM

Post-cross-over activity of regorafenib (RE) in soft tissue sarcoma: Analysis from the REGOSARC trial. *First Author: Nuria Kotecki, Oscar Lambret Center, Lille, France*

Background: Based on the placebo (PBO) controlled phase 2 trial (Mir, Lancet Oncol 2016), RE has shown to be an active drug in patients (pts) with leiomyosarcoma (LMS), synovial sarcoma (SS) and other non-adipocytic sarcoma (OTH), but not in liposarcoma. Pts initially allocated to PBO were allowed to cross-over to RE after progression. We here report the activity of RE after cross-over. **Methods:** From July 2013 to Dec 2014, 138 pts were enrolled in the non-adipocytic sarcoma cohorts (LMS, SS & OTH). After update in Dec 2016, median follow-up was 32 mo (vs 17 mo in the initial publication). Benefit of RE vs PBO in terms of progression-free survival (PFS) and overall survival (OS) from randomization was estimated by hazard ratio (HR) in Cox models. In the PBO arm, intra-patient benefit of RE after cross-over was evaluated by the growth modulation index (GMI), where PFS1=PFS with PBO before cross-over, and PFS2=PFS with RE after cross-over. The impact of timing of RE allocation (delayed after cross-over, vs early at study entry) was evaluated by comparing PFS after cross-over in PBO arm to PFS after randomization in RE arm. **Results:** As detailed in the table, major PFS benefit of RE vs PBO allocated by randomization was confirmed with long follow-up (HR=0.50 [95%CI 0.35-0.71] p<.0001). However, this translates into a smaller and non-significant OS benefit (HR=0.78 [0.54-1.12] p=.18). This finding may partially be explained by the fact that 55 of the 68 pts who progressed in the PBO arm (81%) could receive RE after progression and benefit from RE: 56% of them had a GMI greater than 1.3. Delayed start of RE was associated with a non-significantly shorter PFS compared to earlier treatment (HR=1.21, [0.84-1.73] p=.30). **Conclusions:** Efficacy of RE vs PBO is confirmed with longer follow-up in non-adipocytic sarcoma. PFS of pts receiving RE after cross-over is not significantly shorter than that of pts initially randomized to receive RE. Clinical trial information: NCT01900743.

	RE at randomization		PBO at randomization		RE post cross-over (PBO arm)		RE vs PBO post-randomization		Delayed vs early RE

11053 Poster Session (Board #376), Sun, 8:00 AM-11:30 AM

Combination of pembrolizumab and metronomic cyclophosphamide in patients with advanced sarcomas and GIST: A French Sarcoma Group phase II trial. *First Author: Maud Toulmonde, Institut Bergonié, Department of Medical Oncology, Bordeaux, France*

Background: There is a good rationale for immunotherapy in sarcoma. We report results of the first open-label multicentre phase 2 study assessing the anti-PD-1 antibody pembrolizumab in combination with metronomic cyclophosphamide (CP) in patients (pts) with advanced soft tissue sarcomas (STS) and gastro-intestinal stromal tumor (GIST). **Methods:** This trial included 4 cohorts of pts with advanced STS: leiomyosarcoma (LMS), undifferentiated pleomorphic sarcoma (UPS), other sarcomas (Others), and GIST. All pts received CP 50 mg BID one week on, one week off, and pembrolizumab 200mg IV q21 days. The primary endpoint encompassed non-progression and objective response at 6 months per RECIST evaluation criteria v1.1 for LMS, UPS, and Others, and 6-month non-progression for GIST. Correlative studies of immune biomarkers were planned on pt's tumor and plasma samples. **Results:** Between June 2015 and July 2016, 57 pts were included, and 50 were assessable for efficacy. Three pts experienced tumor shrinkage resulting in a partial response (PR) in one of them. The 6-month non-progression rate was 0%, 0%, 14.3% (95%CI 1.8-42.8), and 11.1% (95%CI 2.8-48.3) in LMS, UPS, Others, and GIST respectively. The most frequent adverse events were grade 1 or 2 fatigue, diarrhea, anemia. The only pt who experienced PR was the only one with a PD-L1-positive staining in more than 10% of immune cells on archived tumor sample. A strong macrophage infiltration was observed in tumor samples, and these macrophages largely expressed the inhibitory enzyme Indoleamine-2,3-dioxygenase-1 (IDO1). Moreover, a significant increase of the kynurenine/tryptophane ratio was observed in pts plasma samples during study treatment (p =0.0007). **Conclusions:** PD-1 inhibition has limited activity in advanced STS and GIST. This primary resistance may be explained by the low percent of PD-L1 positivity in these tumors, and an immune-suppressive tumor microenvironment resulting from macrophage infiltration and IDO1 pathway activation. Further strategies assessing drugs such as CSF1-R inhibitors and/or IDO inhibitors combined with anti-PD-1/PD-L1 in selected sarcoma subtypes are warranted. Clinical trial information: NCT02406781.

11054 Poster Session (Board #377), Sun, 8:00 AM-11:30 AM

SYNFRIZZ: A first-in-human (FIH) study of a radiolabeled monoclonal antibody (Mab) targeting frizzled homolog 10 (FZD10) in patients (pts) with advanced synovial sarcomas (SyS). *First Author: Philippe Alexandre Cassier, Centre Léon-Bérard, Lyon, France*

Background: Advanced SyS are rare tumors with limited curative options. FZD10 is highly expressed in SyS but not in normal adult tissue. OTSA101 is a MAb targeting FZD10, labelled with a radioisotope. **Methods:** We conducted a phase I, FIH study including adult pts with advanced, refractory SyS. In part 1, pts received OTSA101 labelled with In^{111} used as radiotracer to assess biodistribution and tumor uptake. In part 2, pts with significant tumor uptake were randomized to receive OTSA101 labelled with 370MBq of Y^{90} (Arm A) or 1110MBq Y^{90} (Arm B). Primary endpoints were occurrence of unacceptable biodistribution /lack of tumor uptake in part 1 and occurrence of related adverse events (AEs) Grade ≥ 3 during the first 8 weeks following injection of Y^{90}OTSA101 in part 2. Responses were assessed per RECIST 1.1. **Results:** From January 2012 to June 2015, 20 pts (10 females, median age 43, range 21-67) with advanced SyS were enrolled. Ten pts (50%) had sufficient tumor uptake to proceed to part 2 and 8 were randomized (Arm A: 3 and Arm B: 5). Two pts were not randomized due to worsening PS. During part 2, the most common Grade ≥ 3 AEs were haematological, including reversible lymphopenia, thrombocytopenia and neutropenia, and were more common in Arm B. One pt with SD after 12 weeks received a 2nd injection of ^{90}Y-OTSA101, but experienced fatal hemoptysis. No objective response was observed. Best response was SD in 5/8 pts lasting up to 21 weeks for 1 pt. **Conclusions:** This FIH shows that radioimmunotherapy targeting FZD10 is feasible and safe in SyS pts. Tumor uptake was heterogeneous but sufficient to select 50% of pts for ^{90}Y-OTSA101 treatment. Due to limited sample size, further clinical investigations are needed to assess the therapeutic activity of ^{90}Y-OTSA101 with a recommended dose of 1110MBq of ^{90}Y. Clinical trial information: NCT01469975.

11055 Poster Session (Board #378), Sun, 8:00 AM-11:30 AM

Outcome of 212 malignant phyllod tumor patients: A retrospective study from the French Sarcoma Group (GSF-GETO). *First Author: Mathias Neron, Institut du Cancer de Montpellier, Montpellier, France*

Background: The optimal management of malignant phyllod tumors (MPT) is poorly documented. Objective:To study the characteristics and outcome of MPT patients (pts). **Methods:** Retrospective study from the nation-wide French sarcoma network (NetSarc) from 2000 to 2016. Inclusion criteria was central pathological review of MPT. End-points were local recurrence-free survival (LRFS), metastasis-free survival (MFS), and overall survival (OS). **Results:** 212 pts, from 13 centers, were included. Median age was 52.8 years (range: 16.8 - 90.5). All localized MPT pts (96.7%) underwent surgery with 41.4% of mastectomy. The median size was 5.8 cm (range: 1.5 - 30). R1/R2 resection was achieved in 40.1% pts (26.9% 1-2 mm margin, 12.2% 3-7 mm, 20.3% ≥8 mm), with 44.8% of second surgery (SS) for a final mastectomy rate of 72.6%. Presurgical biopsy was performed in 86.3% and associated with R0 resection (p=0.044) and better LRFS (p=0.012). Median follow-up was 4.1 years (range 0-14.8) and revealed 34 (16.6%), 48 (22.9%), 44 (20.8%) events for LRFS, MFS and OS, respectively. The 2-year OS rate was 89%. Prognostic factors found in multivariate analysis are presented in Table 1. Wider margins (≥8mm) were not associated with better outcomes. Adjuvant radiotherapy and chemotherapy were performed in 43.6% and 13.3% respectively and associated with longer LRFS, not significant in multivariate analysis. **Conclusions:** Mastectomy is associated with better local control, but not with MFS and OS. Age, tumor necrosis and metastatic disease are associated with poor prognosis in MPT pts. Our study suggests that margins of 3 mm are necessary and sufficient for the surgical management of MPT and emphasizes the importance of SS to obtain clear margins.

Prognostic factors for each end-point (multivariate analysis).

End Point	Variable		Hazard Ratio	p
LRFS	Mastectomy at first or SS	Yes	1	<0.001
		No	4,85	
	Margins (mm)	0-2 without SS	1	
		0-2 with SS	0,82	0,62
		≥ 3	0,68	0,42
MFS	Age (y)	<50	1	0.038
		≥50	2.14	
	Tumor necrosis	Yes	1.96	0.047
		No	1	
	Margins (mm)	0-2 without SS	1	
		0-2 with SS	0,3	0,005
		≥ 3	0,75	0,43
OS	Metastatic disease at diagnosis	Yes	5.27	0.002
		No	1	
	Metastatic recurrence	Yes	7.29	<0.001
		No	1	
	Margins (mm)	0-2 without SS	1	
		0-2 with SS	0,32	0,005
		≥ 3	0,55	0,099

11056 Poster Session (Board #379), Sun, 8:00 AM-11:30 AM

Effects of temozolomide and bevacizumab in relapsed patients with heavily pretreated uterine leiomyosarcoma. *First Author: Hiroko Matsuura, National Defense Medical College, Tokorozawa, Japan*

Background: Uterine leiomyosarcomas (ULMs) tend to recur regardless of their stage, and there is no satisfactory report for relapsed ULMs. Temozolomide (T) is derivatives of dacarbazin and these agents have been used for treatment of ULMs. ULMs has a plenty of vessels compared to uterine myoma so that bevacizumab (B) was used in ULMs. In the present study, we evaluated the effect of TB in heavily pretreated relapsed ULMs. **Methods:** From 2009 to 2016, total 19 patients (pts) with heavily pretreated ULMs were enrolled. Patients were treated with T (80mg/body/day) and B (2mg/kg; days 1, 8 and 15, q4 weeks). Treatment was continued until disease progression and/or unmanageable toxicities. Response was evaluated with the response evaluation criteria in solid tumors (RECIST) v1.1, and adverse effect (AE) was assessed by common terminology criteria for adverse events (CTCAE) v4.0. **Results:** Seventeen of 19 pts were subjected to response evaluation. Median age of pts was 56.3 years (range: 31-69). Three pts (18%) had complete response (CR), 2 (12%) had partial response, and 7 (41%) had stable disease (SD). The response rate (RR: CR+PR) and clinical benefit rate (CBR: CR+PR+SD) were 29% and 71%. The median progression-free survival was 14.2 months (range: 0-89). Median administration cycle was 9.5 (range: 2-48). AE with grade 3 and more over were observed in 6 pts. There was one dead case from perforation, but toxicity was almost manageable. **Conclusions:** We experienced 3 cases of CR, and two of them had CR for more than two years. Intriguingly, TB could be substantially effective even in relapsed patients with heavily pretreated ULMs. These results warrant further prospective and randomized studies.

11057 Poster Session (Board #380), Sun, 8:00 AM-11:30 AM

Phase 2 multicenter study of the EZH2 inhibitor tazemetostat in adults with synovial sarcoma (NCT02601950). *First Author: Patrick Schoffski, University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Synovial sarcoma (SS) accounts for 5-10% of all soft tissue sarcomas (STS). Metastatic and/or locally advanced disease occurs in up to 70% of patients (pts), with reported median overall survival (OS) as short as 22 months. SS18-SSX translocations, a defining molecular feature of SS, generate a fusion protein that competes with native SS18 during SWI/SNF complex assembly disrupting complex function. SWI/SNF complexes containing the fusion protein lack INI1 and cellular INI1 expression levels are reduced to varying degrees in SS. This mechanism of INI1 reduction is distinct to that observed in malignant rhabdoid tumors, epithelioid sarcoma or other INI1 negative tumors. Tazemetostat, a potent and selective EZH2 inhibitor, has demonstrated activity in preclinical SS models with the proposed mechanism of sensitivity being via INI1 reduction inducing compromised SWI/SNF activity and tumor dependence on EZH2. **Methods:** This is a phase 2 multicenter open-label non-randomized study with 5 cohorts of different tumor types with INI1 loss/reduction or evidence of SS18 rearrangement. Adult pts in the SS cohort were treated with tazemetostat (800 mg po BID). Up to 30 pts were enrolled using a 2-stage Green-Dahlberg design. The primary endpoint is complete response, partial response or stable disease (SD) at 16 wks. Success at the end of stage 2 requires $\geq$9 of 30 treated pts meet this criterion. Key secondary endpoints include overall response rate, PFS, OS, safety/tolerability, PK and biomarkers of response. **Results:** In 33 treated SS pts with a median of 2 prior systemic treatments, best response of SD was observed in 11 pts (33%) with 5 pts (15%) having SD lasting $\geq$16 wks. No objective responses were observed. The protocol-defined success criterion at the end of study was not met. Tazemetostat was well-tolerated with grade 1/2 cough (36%), dyspnea (33%) and fatigue (33%) as the most frequently reported adverse events regardless of attribution. **Conclusions:** Tazemetostat was well tolerated with a favorable safety profile. Although there were no objective responses in heavily pretreated pts, the observation of SD in a subset of pts suggests further studies with tazemetostat in combination may be warranted in SS. Clinical trial information: NCT02601950.

11058 Poster Session (Board #381), Sun, 8:00 AM-11:30 AM

Phase 2 multicenter study of the EZH2 inhibitor tazemetostat in adults with INI1 negative epithelioid sarcoma (NCT02601950). *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Epithelioid sarcoma (ES) is a rare soft tissue sarcoma (STS) typically seen in young adults accounting for $<$ 1% of all STS. While local disease may be indolent, ES can rapidly spread and patients (pts) with distant metastasis are often resistant to systemic treatment with 1 year survival of $<$ 50%. The defining molecular feature of ES is the absence of tumor expression of INI1, a SWI/SNF subunit member involved in chromatin remodeling. Tazemetostat, a potent and selective EZH2 inhibitor, has demonstrated tumor regressions in INI1 negative preclinical malignant rhabdoid tumors (MRT) models and phase 1 clinical activity in MRT and ES pts. The proposed mechanism of tazemetostat sensitivity is INI1 loss inducing compromised SWI/SNF activity and tumor dependence on PRC2 activity (of which EZH2 is the catalytic subunit). Preliminary phase 2 safety and efficacy of tazemetostat in ES pts is reported here. **Methods:** This is a phase 2 multicenter open-label single arm study of tazemetostat (800 mg po BID) in adult pts with ES whose tumors harbor evidence of INI1 loss. Pts enroll into 1 of 5 cohorts of different tumor types with INI1 loss/reduction, up to 30 pts each, using a 2-stage Green-Dahlberg design. For the ES cohort, primary endpoint is disease control rate (DCR) defined as objective response of any duration or stable disease (SD) lasting $\geq$32 wks. Success at stage 2 required DCR in $\geq$5/30 treated pts. Key secondary endpoints include safety/tolerability, ORR, PFS, OS, PK and response biomarkers e.g. H3K27me3. **Results:** In 31 ES pts with a median of 1 prior systemic therapy, stage 2 DCR criteria was surpassed with a RECIST confirmed PR (4 pts) and SD $\geq$32 wks (2 pts) observed to date. 13 pts are still on treatment therefore DCR and ORR will be updated. Tazemetostat was well tolerated with grade 1/2 fatigue (39%), nausea (26%) and vomiting (19%) as the most frequently reported AEs regardless of attribution. **Conclusions:** In the largest prospective clinical trial of ES to date, tazemetostat monotherapy shows promising antitumor activity, including confirmed responses and long-term SD, with favorable safety/tolerability in ES. Enrollment has been expanded to 60 ES pts given the clinical activity described here. Clinical trial information: NCT02601950.

11059 Poster Session (Board #382), Sun, 8:00 AM-11:30 AM

Immunoprofiling in alveolar soft part sarcoma. *First Author: Samer Salah, Department of Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Alveolar Soft Part Sarcoma (ASPS) is a distinctive tumor characterized by a canonical *ASPL-TFE3* fusion. Treatment options are limited. We assessed tumor immune cell infiltrates, and correlated this with patients receiving PD-1 blockade. **Methods:** A retrospective institutional review was performed for 18 cases of ASPS. Immunohistochemistry was performed on paraffin-embedded tissue (PET) for T-lymphocyte markers (CD3/CD4/CD8), and PD-1/PD-L1 (Ventana). Expression was quantified by standard methods: (total cells per high power field: score; 0:0; 1-10:1; 11-50:2; 50-99:3; 100:4). Select cases underwent DNA sequencing analysis using whole exome (WES, $>$ 80X, n = 4) and genome (WGS, $>$ 30X, n = 1) sequencing. Indel analysis was conducted via mutect2 ($>$ 5% variant allele frequency) and mutational signature was performed using deconstructSigs. **Results:** The median age was 27 (15-54). Disease status at diagnosis was: 44% localized; 56% metastatic. The median overall survival was 17 yrs (2.9-31). Four patients (pts) received immunotherapy with PD-1 blockade with 1 complete response (CR), 2 durable partial responses (PR) and 1 stable disease (SD). PET was available in 12 cases. PD-1/PD-L1 expression ($\geq$1) was seen in 50% and 17%, respectively. Composite CD3, CD4 and CD8 infiltration were 2, 1, and 1, respectively. Patients with CR/PR to PD-1 blockade (n = 3) had no clear correlation with PD-1, PD-L1 or lymphocyte markers. Exomic characterization (n = 4) demonstrated no clear excess mutation burden compared to Ewing sarcoma (5.7 vs 6.4 mut/MB). Mutational signatures via COSMIC were identified in the mismatch repair (MMR) pathway in 2 of 4 cases (Pt A: Signature (S) 26; pt B: S6 and S15). Pt B also underwent WGS which confirmed a COSMIC signature in the MMR pathway. Indel analysis did not confirm aberrations in standard MMR or polymerase genes. **Conclusions:** Preliminary findings suggest activity with PD-1 blockade in ASPS; however, this does not appear to correlate with tumour-infiltrating T lymphocytes. Genomic analysis suggests an MMR signature may account for these responses, but standard MMR aberrations were not identified. Further validation is underway.

11060 Poster Session (Board #383), Sun, 8:00 AM-11:30 AM

Trabectedin for advanced soft tissue sarcoma: Ten-year real-life perspective. *First Author: Sivan Shamai, Tel Aviv Medical Center and Sackler School of Medicine, Tel Aviv, Israel*

Background: Trabectedin is a marine - derived chemotherapy, which lately received FDA approval for use in anthracycline resistant advanced soft tissue sarcoma (STS), especially liposarcoma and leiomyosarcoma (L-sarcomas). **Methods:** We report our ten-year real-life experience with trabectedin, 1.5mg/m2/d c.i.v. q3w till progression, regarding safety and efficacy in a cohort of 86 patients (24-83y). Liposarcoma was the diagnosis in 46% , leiomyosarcoma in 43%. **Results:** A total of 703 cycles of Trabectedin were given, with a median of five cycles per patient (range 1-59). Median overall survival (mOS) was 11 months for liposarcoma patients (range 1-63), and 15 months for leiomyosarcoma patients (range 1-35). There was no statistically significant difference in progression free survival (PFS), when stratified according to previous treatment lines given. Trabectedin exhibited a favorable safety profile, with only 22% requiring dose reductions. Grade 3 and more toxicity were noted in 25% of the patients, mostly myelosuppression. There was no treatment related death. **Conclusions:** In contrast to former trials, our retrospective data represents real life experience with Trabectedin, and includes patients with diverse age, histology, performane status, prior treatments and tumor burden. The group includes 10 patients (11.6%) who received Trabectedin as first line (Either due to congestive heart failure or to rapid progression following adjuvant Doxorubicin and Ifosfamide), 10 patients (11.6%) were above age 70, nine (10.5%) had histologies other than liposarcoma or leiomyosarcoma, and 23 (26.7%) had ECOG PS of 2 or higher. Trabectedin is a safe and effective drug in advanced high grade STS. Further research is needed to identify which patients will benefit most.

11061 Poster Session (Board #384), Sun, 8:00 AM-11:30 AM

Trabectedin and radiotherapy in soft-tissue sarcoma (TRASTS) study: An international, prospective, phase I/II trial—A collaborative Spanish (GEIS), Italian (ISG), and French (FSG) groups study. *First Author: Alessandro Gronchi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Myxoid liposarcoma/round cell liposarcoma (ML) exhibits especial sensitivity to trabectedin (T). In prospective series, long-lasting T treatment showed responses in 44% of patients (pts) with ML. ML is also sensitive to radiation therapy (RT) and preclinical data suggested radiosensitizing properties of T. Preoperative short-course of T with concurrent low-dose RT was conducted in a multicenter, European, phase I/II trial. We present here data from the phase I part in pts with centralized diagnosis of locally advanced, resectable ML. **Methods:** Pts received 3 cycles (C) of T in combination with RT (45 Gy) in 25 fractions (1.8Gy/fraction). The phase I had the classic 3+3 design. Dose Levels for T were: -1 (1.1 mg/m^2), 1 (1.3 mg/m^2) and 2 (1.5 mg/m^2). Dose-limiting toxicity (DLT) were defined as grade $\geq$3 events excluding G3/4 neutropenia lasting $<$ 5 days and G3-4 nausea/vomiting due to inadequate prophylaxis. RECIST responses were evaluated preoperatively at week 10. Surgical specimens were processed for histologic changes and residual tumor. **Results:** From February 2015 to May 2016,14 pts (M/F 7/7) with median age 36y (24-71) and median tumor size 12.5 cm were enrolled. 7 pts received T at dose Level 1 and 7 pts at Level 2. One DLT (G3 transaminitis) occurred at Level 1 and another (sepsis due to catheter infection) at Level 2. Overall, grade G 3/4 AEs were: ALT elevation (n = 6, 43%), and GGT elevation, neutropenia, anemia, epithelitis and sepsis (n = 1, 7% each). There were no deaths. One pt developed metastasis after C3 and did not undergo surgery; another one had a sepsis after C1 and received definitive RT. All pts completed RT. 13 pts were evaluable for response: 5 achieved PR (38%), 7 SD (53%), 1 distant PD (8%). 12 pts underwent surgery (7 R0/5 R1). Median viable residual tumor was 5% (0-60) with 9/12 pts (75%) with $\leq$ 10% viable remaining tumor, 3/12 (25%) complete responses. **Conclusions:** T in combination with RT was feasible and well tolerated in the preoperative setting. T dose of 1.5 mg/m^2 is the recommended phase II dose. A high proportion of patients achieved a good pathological response, with 3/12 (25%) complete responses. Clinical trial information: 2014-001549-26.

11062 Poster Session (Board #385), Sun, 8:00 AM-11:30 AM

International single-arm phase II trial of pazopanib in advanced extraskeletal myxoid chondrosarcoma: A Collaborative Spanish (GEIS), Italian (ISG) and French (FSG) Sarcoma Groups study. *First Author: Silvia Stacchiotti, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Extraskeletal myxoid chondrosarcoma (EMC) is an exceedingly rare sarcoma, marked by a specific translocation involving the gene *NR4A3* that can be rearranged with different partners. Preliminary retrospective data suggest that sunitinib is active, but no formal prospective studies are available. We report on a multicentric European prospective, investigator-driven, Phase 2 study on pazopanib (P) in NR4A3+ advanced EMC patients (pts), carried out by the Spanish, Italian and French Sarcoma groups. **Methods:** From June 2014 to November 2016, 24 advanced EMC pts entered this study (median age: 64 yrs - disease extent: metastatic 77%, locally advanced 23% - prior medical treatment: 18 (86%) naive; 2 (9%) 1 line, 1 (5%) $>$ 1 line). Path diagnosis and NR4A3 rearrangement (FISH and/or real-time PCR analysis) were centrally confirmed. Pts received P 800 mg/day (relative dose intensity = 0,82%, 658 mg/day), until progression or toxicity. The primary study end-point was response rate as per RECIST 1.1. Secondary end-points were overall survival, progression-free survival (PFS), clinical benefit rate (CBR) (RECIST CR+PR+SD$\geq$6mos). An exploratory evaluation of the correlation between the rearrangement subtype and the outcome is ongoing. **Results:** 20/24 pts were evaluable for response (1 early death; 3 too early). One patient (5%) had a partial response, 17 (75%) stable disease, 2 (10%) progression as their best RECIST responses. At the time of this analysis, 12 pts were still under treatment, while 12 interrupted P (10 progression, 1 toxicity, 1 other). At a 13-month median follow-up, the median PFS was 13 months (range 1.6-25.1), with 29% pts progression-free at 18 months and a 65% CBR. Median OS was not reached. **Conclusions:** This Phase 2 study is formally negative since the target of at least 3/21 RECIST responses was not reached. However, looking at PFS, P was associated with a prolonged disease stabilization in a significant proportion of pts. This suggests to further explore the use of P in EMC. Clinical trial information: NCT02066285.

11063 Poster Session (Board #386), Sun, 8:00 AM-11:30 AM

Circulating cell free tumor DNA detection as novel biomarkers to monitor desmoid tumors evolution. *First Author: S Bastien Salas, Hopital de la Timone, Marseille, France*

Background: Since desmoid tumors (DT) exhibit an unpredictable clinical course, with stabilization and/or spontaneous regression, an initial "wait-and-see" policy is the new standard of care to select best indications of active treatments in case of significant evolution. Therefore, translational research is crucial to identify predictive factors of progression. Most DT are characterized by *CTNNB1* mutation (CM) in exon 3 (T41A, S45F, S45P). Circulating cell-free tumoral DNA (ctDNA), named "liquid biopsy", has emerged as a new promising non-invasive tool to detect biomarker in several cancers. **Methods:** We present a method of detection of DT-specific CM using a targeted strategy digital droplet PCR (ddPCR) on cell-free DNA (cfDNA) extracted from blood samples of 31 DT patients (pts). T41A, S45P, S45F and their respective CTNNB1 wild-type probe were designed for ddPCR. Furthermore, we analyzed the correlation of cfDNA levels (CTNNB1 wt/ml plasma) and evolution of the tumor. **Results:** Initial DT CM statuswas known for 28 pts and unknown for 3 pts. 24 pts presented a CM (17 pts T41A, 6 pts S45F and 1 pt S45P), 2 pts a mutation of *APC*, 2 pts were wild-type, and 3 pts were undetermined. Among pts with a CM, *CTNNB1* mutants were detected in the cfDNA of 6 patients (19.4%). CM detection was not correlated with the quantity of cfDNA analyzed (p = 0,7263–Mann-Whitney (MW)). Absolute quantification of cfDNA (CTNNB1 wt) normalized by mL of plasma displayed higher levels for patients with progressive DT (p = 0,0009 - MW), this difference of cfDNA quantity was also present between progressive, stable and self-regressive DT (p = 0,0012 - MW). A threshold of 875 *CTNNB1* copies/mL predicted DT progression with a sensibility of 100% ($CI_{95\%}$: 59-100) and a specificity of 76.5% ($CI_{95\%}$: 50.1-93.2). Absolute cfDNA quantity was also higher in patients harboring multiple desmoids (p = 0.0292 - MW). **Conclusions:** The absolute quantification of normalized cfDNA is correlated with evolution of the disease, independently of the initial tumor type of CM. This study opens the perspective of using cfDNA as a genomic biomarker to assess the tumor dynamics at initial diagnosis, and to monitor treatment strategy in case of tumor evolution.

11064 Poster Session (Board #387), Sun, 8:00 AM-11:30 AM

Discordance of histo-pathological diagnosis of patients with soft tissue sarcoma referred to tertiary care center. *First Author: Sameer Rastogi, All India Institute of Medical Sciences, Ghaziabad, India*

Background: Reaching to the correct histo-pathological diagnosis of soft tissue sarcomas (STS) is a great challenge and is cornerstone for treatment planning. Need of expertise for diagnosis is limited by lack of expert pathologists and dedicated sarcoma oncologists in India. Through this study we highlight the pattern of pathological diagnosis and accuracy outside specialist centre. **Methods:** We did retrospective analysis of all patients referred to us with diagnosis of STS in the last 12 months (January 2016 to 2017). According to protocol, all patients had pathology review from our institute. If blocks were available then they were reviewed and if necessary, fresh biopsy was performed. Besides, pathological diagnosis was reviewed in joint clinic, giving clinico-radiological inputs to sarcoma pathologists. For patients diagnosed outside and had discordant report, we divided them into major discrepancy (including change of diagnosis of sarcoma to benign or other histological entity that could potentially change the treatment plan) or minor discrepancy (like mild change in grade or histopathological diagnosis not affecting the treatment plan). **Results:** There were 149 patients registered with median age of 36 years (14-77 years) and 93 patients (62.4%) were males. 85(57%) patients had localized disease. Most common subtypes were synovial sarcoma 16%, liposarcoma 9%, soft tissue ewings sarcoma 9%, MPNST 9%, leiomyosarcoma 8%, pleomorphic undifferentiated sarcoma 8% etc. Of 149 patients, 42 had not been worked up outside and thus comparison was not possible while 4 patients couldn't retrieve blocks and repeat biopsy could not be performed. Of 97 patients (biopsy = 84, FNAC = 13) who had diagnosis from outside, 37% had major discrepancy and 24% had minor discrepancy compared with our biopsy review. Major discrepancy was more in non extremity than extremity STS (p = 0.003). **Conclusions:** Pathological diagnosis of more than half of patients referred from outside was discordant with respect to diagnosis of our centre with major implications on 37%. We believe this is due to lack of sarcoma pathology experts and virtually non-existent multidisciplinary clinics in set up outside tertiary care centres.

11065 Poster Session (Board #388), Sun, 8:00 AM-11:30 AM

Anthracycline, gemcitabine, and pazopanib in epithelioid sarcoma: Results of a retrospective multi-institutional case series. *First Author: Anna Maria Frezza, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: To report on a multi-institution retrospective study on the activity of anthracycline-based (Ab) and gemcitabine-based (Gb) regimens as well as pazopanib (P) in patients with advanced epithelioid sarcoma (ES) treated within 16 sarcoma reference centres in Europe, US and Japan. **Methods:** Patients with a histologically confirmed diagnosis of locally advanced/metastatic ES were selected. Classic and distal subtypes were defined based on morphology (WHO 2014). INI1 expression is under evaluation.Response was evaluated by RECIST.Progression-free survival (PFS) and overall survival (OS) were computed by Kaplan-Meier method. **Results:** Ninety ES patients were identified (Table 1). They were treated with Ab (72), Gb (30) and P (20); 25 pts received more than one treatment. The median follow-up for Ab, Gb and P groups was 32, 24 and 22 months, respectively. The response rate (RR) for Ab was 25% (95% CI 16%-37%), with a median PFS and OS of 6 and 17 months. The RR for Gb was 23% (95% CI 10% - 42%), with 1 complete response and a median PFS and OS of 5 and 20 months. In the P group, no objective responses were reported, and median PFS and OS were 3 and 9 months. A non-statistically significant trend towards a greater RR in proximal than classic subtype was seen in both Ab (27% vs 22%) and Gb (30% vs 13%) groups. **Conclusions:** This retrospective series, the largest currently available, confirms the activity of Ab and Gb in ES, with a similar RR and PFS in both groups. In this population, the value of P seems limited. These data may serve as a benchmark for trials of novel agents in ES.

Population characteristics.

	Ab (N=72)	Gb (N=30)	P (N=20)
Median age (range)	32 (15-67)	37 (18-76)	34 (15-67)
Gender (%)			
M	51 (70.8)	17 (56.7)	13 (65)
F	21 (29.2)	13 (43.3)	7 (25)
Primary site (%)			
Distal	36 (50)	16 (53.3)	11 (55)
Proximal	36 (50)	14 (46.7)	9 (45)
Histological type (%)			
Classic	39 (54.2)	10 (33.3)	8 (40)
Proximal	33 (45.8)	20 (66.7)	12 (60)

11066 Poster Session (Board #389), Sun, 8:00 AM-11:30 AM

Potential therapeutic genomic alterations in desmoplastic small round blue cell tumor. *First Author: Joanne Xiu, Caris Life Sciences, Phoenix, AZ*

Background: Desmoplastic Small Round Blue Cell Tumor (DSRCT) originates from a cell with multilineage potential. A molecular hallmark of DSCRT is the EWS-WT1 reciprocal translocation. Ewing's and DSRCT are treated similarly due to similar oncogene activation pathways and DSRCT has been represented in very limited numbers in sarcoma studies. **Methods:** Thirty-five DSRCT tumors were tested with a multiplatform profiling service (Caris Life Sciences, Phoenix, AZ). Specific tests performed included sequencing (NextGen), protein expression (IHC) and gene amplification (CISH or FISH). Tumor mutational load (TML) was calculated as somatic nonsynonymous missense mutations sequenced with a 592-gene panel. Molecular alterations were compared to 88 Ewing sarcomas (ES). Chi-square tests were used for comparison and statistical significance was determined as $p < 0.05$. **Results:** In the 35 DSRCT tumors, high expression of TOP2A were seen in 63%, TOPO1 in 63%, PTEN in 62%, androgen receptor (AR) in 59%, EGFR in 42% of tumors; low expression of TUBB3 was seen in 44%, MGMT in 45%, TS in 48%, RRM1 in 57% and ERCC1 in 76% of tumors. When compared to ES, no significant difference was seen in protein expressions with the exception of a significantly higher overexpressson of AR in DSRCT (59% vs. 3%, p = 1.7E-10) and TUBB3 (56% vs. 29%, p = 0.03). Tumor expression of PD-L1 (Ab: SP142) was not seen in the 4 DSRCT and 10 ES tested. NextGen revealed a TP53 mutation (7%) and a FOXO3 mutation (L382fs) in DSCRT, while 6 TP53 mutations (13%), 2 APC mutations (L1129S and I1307K), 1 BRCA1(c.301+1G > A) and 1 CTNNB1 (T41A) mutation were identified in ES. Tumor mutational load evaluated in the 3 DSRCT and 11 ES tumors averaged 6 and 5 mutations per megabase, respectively. **Conclusions:** Molecular profiling on 35 DSRCT tumors and comparison with Ewing's sarcoma revealed low immunogenicity (< 10 Mutations/MB) and low frequency of actionable mutations including PD-L1 in both tumor types. High AR expression could present as a potential therapeutic target for DSRCT while taxanes may be more effective in Ewing's sarcoma compared to DSCRT based on TUBB3 expression. Genomic and Molecular assessment may help determine the ideal regimen that will help achieve maximal tumor debulking.

11067 Poster Session (Board #390), Sun, 8:00 AM-11:30 AM

Expression and prognostic significance of PDGF ligands (A, B, C, and D) and PDGFR (A, B, and L) in soft-tissue sarcomas and GIST. *First Author: Tom Lesluyes, Institut Bergonié, Bordeaux, France*

Background: Sarcomas are a variety of rare connective tissue cancers. Doxorubicin and olaratumab (Ab against PDGFRA) improved survival in a recent Phase 1/2 study. Besides PDGFRA mutated gastrointestinal stroma tumor (GIST) and dermatofibrosarcoma protuberans, the role of PDGFR and the according ligands in the biology of sarcoma remain unclear. **Methods:** The expression levels of PDGF (A,B,C,D) and PDGFRs (A,B,L) were studied in a series of 255 sarcoma pts in localized phase using the Agilent 014850 platform. Data are available online (http://atg-sarc.sarcomabcb.org). Histologies were GIST (n = 60), myxoid liposarcoma (MLPS, n = 50), synovial sarcoma (SyS, n = 58), and sarcoma with complex genomics (SCG, n = 87). Expression levels were analyzed and tested for prognostic values for metastasis free survival (MFS) in uni- and multivariate analysis using SPSS 19.0. **Results:** Expression levels (ELs) of *PDGFs* and *PDGFRs* varied across histotypes: *PDGFA* levels were highest in SyS and lowest in MLPS ($p < 0.0001$). *PDGFB* and *C* levels were lower in GIST ($p < 0.0001$), while *PDGFD* ELs were similar across histological subtypes. *PDGFRA* ELs were highest in MLPS, while *PDGFRB* & L ELs were lowest in GIST and SyS ($p < 0.0001$ all). Complex patterns of correlation of expression between ligands and receptors were observed in each individual subtypes. *PDGFA* ELs above median were associated with a marginally higher risk of metastasis . Conversely, *PDGFD* ELs above median was associated with a reduced risk of metastasis in the whole cohort (p = 0.02). The ELs of the 3 receptors were not correlated to MFS. In multivariate analysis using Cox model on the non-GIST sarcoma cohort (histology, grade, depth, with size, *PDGFA*, *PDGFD* as continuous variables): histology, size, grade and PDGFA ELs were independent adverse prognostic factors (PF), while PDGFD ELs was a favorable PF for MFS. In the GIST cohort, testing AFIP score, PDGFA & D ELs as continuous variable, PDGFD ELs was also an independent favorable PF for MFS, in addition to AFIP score. **Conclusions:** The expression of PDGFs and the according receptors varies across sarcoma histological subtypes. PDGFA and D expression levels correlate independently to the risk of metastatic relapse.

11068 Poster Session (Board #391), Sun, 8:00 AM-11:30 AM

Rates of survival throughout the years in soft tissue sarcoma with synchronous metastases: Results of a population-based study. *First Author: Melissa Vos, Erasmus MC Cancer Institute, Department of Medical Oncology and Surgical Oncology, Rotterdam, Netherlands*

Background: Roughly 10% of patients with soft tissue sarcoma (STS) present with synchronous metastases and generally cannot be cured anymore. With the registration of trabectedin, pazopanib and the identification of other agents exerting activity against STS, the treatment of these patients in the Netherlands has changed considerably in the last decade. The aim of this population-based study is to examine whether the overall survival (OS) of patients with STS and synchronous metastases has improved over the years. **Methods:** All patients diagnosed with adult-type STS and synchronous metastases between 1989 and 2014 were queried from the Netherlands Cancer Registry. Trends in OS were assessed by the Kaplan Meier method and log rank test in different timeframes based on year of registration of trabectedin (< 2007 vs. ≥2007) and pazopanib (< 2012 vs. ≥2012). A multivariable Cox regression analysis was performed to identify relevant characteristics prognostic for OS. **Results:** In total, 1,393 patients with adult-type STS and synchronous metastases were identified. Over the whole time period, median OS did not improve significantly (5.8 months in 1989-1994 to 8.1 months in 2010-2014, p = 0.095), but median OS < 2007 compared to ≥2007 did improve significantly (5.8 months to 7.3 months, p = 0.035). This was particularly apparent in the liposarcoma subgroup, where median OS doubled (5.2 months to 11.5 months, p = 0.020). Median OS < 2012 compared to ≥2012 did not increase significantly (6.1 months to 7.6 months, p = 0.062), though there was a relatively short follow-up of 2 years while the survival curve seems to reach a plateau phase. Aside from not receiving (any type of) treatment, elderly age, STS subtype other than lipo- or leiomyosarcoma, high or unknown grade and nodal involvement were significant negative predictors for OS, whereas primary tumor site in the extremity and surgery in an academic center had a favorable effect on OS. **Conclusions:** OS of STS patients with synchronous metastases has not improved significantly over the years, except for the subgroup of liposarcomas after 2007. A longer follow-up period is needed to clarify the impact of pazopanib on OS in patients with metastatic STS.

11069 Poster Session (Board #392), Sun, 8:00 AM-11:30 AM

Clinical utility of routine surveillance CT/MRI imaging in patients with localized soft tissue sarcoma (STS) following curative resection. *First Author: Chiew Woon Lim, National Cancer Centre Singapore, Singapore, Singapore*

Background: Guidelines recommend routine surveillance imaging in patients (pts) following curative resection of STS. However the benefit of such an approach is unclear. We sought to evaluate the utility of a surveillance imaging strategy in pts with localized STS treated with curative intent. **Methods:** Pts with localized non-indolent STS, seen between 2010 – 2016, who had undergone surgery with R0/R1 surgical margins were included. Epidemiology, treatment and relapse data were collected as was the mode of detection. We defined optimal surveillance as CT/ MRI performed at least 6-mthly following surgery; suboptimal surveillance was defined as CT/ MRI imaging performed less frequently than 6mthly. **Results:** Of 294 pts included, 31% (n = 92) vs 34% (n = 100) vs 35% (n = 102) had optimal, suboptimal and no routine CT/ MRI surveillance imaging respectively. At a median follow-up of 27mths (range 0-79), 36% (n = 105) experienced a relapse; 43% (n = 45) local and 57% (n = 60) had metastatic relapse. More relapses were noted in the optimal surveillance group, 57% (n = 52) vs 28% (n = 28) and 25% (n = 25) in the suboptimal and no surveillance groups respectively ($p < 0.001$). Within each cohort, relapses detected directly by routine surveillance imaging vs outside of surveillance imaging were as follows: 35% (n = 32) / 22% (n = 20) in the optimal, 17% (n = 17) / 11% (n = 11) in the suboptimal and 0 / 25% (n = 25) in the no surveillance arms respectively. Comparing the 3 strategies, the proportion of pts who then went on to receive curative resection/ metastacectomy was not significantly different, 38% (n = 20), 57% (n = 16) and 32% (n = 8) of relapses, in the optimal vs suboptimal vs no surveillance cohorts respectively ($p = 0.1$). Notably, routine surveillance imaging directly leading to curative resection occurred only in 15% (n = 14) of pts in the optimal and 9% (n = 9) in the suboptimal surveillance groups. **Conclusions:** While an intensive routine CT/MRI surveillance imaging strategy detected more recurrences, the impact it has on subsequent resection is less certain. Optimal frequency of surveillance imaging remains unclear.

11070 Poster Session (Board #393), Sun, 8:00 AM-11:30 AM

Correlation between a new growth modulation index (GMI)-based Geistra score and efficacy outcomes in patients (PTS) with advanced soft tissue sarcomas (ASTS) treated with trabectedin (T): A Spanish group for research on sarcomas (GEIS-38 study). *First Author: Javier Martinez-Trufero, Hospital Miguel Servet, Zaragoza, Spain*

Background: The GMI is a marker of drug activity and represents an intra-patient comparison of successive time to progression (TTP), defined as the TTP ratio between the second (or later) line (TTPn) of therapy divided by the prior line (TTPn−1). Defining a clinical profile of pts with GMI >1.33 could help to identify pts who can gain greater benefit from T. **Methods:** We retrospectively evaluated the concordance between the GMI and the efficacy outcomes and clinical profiles of 198 pts with ASTS treated with trabectedin 1.5 mg/m² (24-h infusion q3w) as a 2nd or further-line treatment from Jan 2007 to Jun 2016. **Results:** After a median follow-up of 58 months (m; range: 18-172) median overall survival from ASTS diagnosis (MOS) and from T (MT-OS) were 27.5 m (23-32.1) and 10.8 m (8.9-12.7), respectively, while median TTP from T (MT-TTP) and T-1 were 3.4 m (2.8-4) and 3.5 m (2.8-4.2). Overall, 106 pts (53%) had a GMI <1; 22 (11%) a GMI=1-1.33 and 70 pts (35%) a GMI >1.33. A high GMI (<1.33 *vs* >1.33) correlated with favorable efficacy outcomes: MT-OS: 23 *vs* 36 m ($p<0.001$), MT-TTP 2.3 *vs* 8.2 m ($p<0.001$) and clinical benefit (objective response + stable disease) 23% vs 68% ($p=0.001$). The multivariate analysis identified L-type sarcoma (Odds ratio: 1.99, 95% CI 1.06-3.71), metastatic free interval (MFI) from initial diagnosis >8.1 m (2.24, 95%CI 1.19-4.18) and Karnofsky >80 (2.3, 95%CI 1.00-5.28) as factors independently associated to GMI> 1.33. Based on these 3 variables we defined a new GEISTRA score assigning 1 point for each adversely affected variable: non L-Sarcoma, MFI<8.1m or Karnofsky <80. This score showed a strong correlation with MT-TTP ($p<0.001$) and MT-OS ($p<0.001$). **Conclusions:** Based on the high GMI we defined a new GEISTRA score, which is strongly associated with favorable efficacy outcomes in pts with ASTS treated with T. Thus, GEISTRA score could be a potentially useful predictable clinical tool for T benefit.

GEISTRA Score	MT-TTP m (range)	p	MT-OS M (range)	p
0	7.4 (5.8-9)	<0.001	25.7 (11.4-40)	<0.001
1	4.2 (2.7-5.8)		11.3 (8.6-14)	
2	2.5 (1.9-3.1)		6.4 (4.3-8.6)	
3	1.9 (0.7-3.2)		2.5 (0.2-4.8)	

11071 Poster Session (Board #394), Sun, 8:00 AM-11:30 AM

Predictive role of FAS for trabectedin in second lines of advanced soft tissue sarcoma (ASTS): A Spanish group for research on sarcoma (GEIS) study. *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS), Seville, Spain*

Background: There are currently several second-line options for the treatment of ASTS as gemcitabine combinations, trabectedin, pazopanib, eribulin or olaratumab plus doxorubicin in cases where anthracyclins are still possible. There is an unmet need for predictive biomarkers which hinders the rational selection of the best sequence in second line. We already published the prognostic value of FAS in first line of ASTS while this study analyzes its predictive role in different second line schemes. **Methods:** Most relevant selection criteria for this study were having received trabectedin in 2nd line or beyond for ASTS, progressive disease after at least one previous line for ASTS and signed CI. A TMA was set up for FAS staining (Cell Signaling) with blocks from diagnostic time. Two expert blinded pathologists reviewed and classified the cases as negative, weak or strong. Kaplan–Meier estimations were used for time-to-event variables and the log-rank test was used to compare groups. **Results:** A series of 198 patients accomplished selection criteria. Metastases at diagnosis occurred in 46 (24%) and median time to metastases was 18.8 months (CI 16,3; 21.3). Previous line to trabectedin consisted of gemcitabine combination 83 (42%), Doxorubicin-based 65 (33%) and others 50 (25%). Median PFS for previous and trabectedin lines were 3.5 (2.8-4.2) and 3.4 (2.8-4) months respectively. FAS positive entailed significantly better PFS for the previous trabectedin line: 4.1 (1.5-6.7) vs 3.0 (2.5-3.5) months, $p = 0.01$ whereas FAS positive was related with worse PFS for the trabectedin line 2.5 (2.2-2.8) vs 3.7 (2.7-4.8) months, $p = 0.028$. These results were more notorious for L-sarcoma cases: 7.0 (3.6-10.5) vs 4.3 (1.9-6.6) months, $p = 0.017$ in previous line and 2.4 (2.2-2.6) vs 6.5 (3.8-9.3) months, $p < 0.001$ in trabectedin. From trabectedin administration, FAS+ had significantly worse OS especially in L-sarcomas: 11.9 (5.2-18.7) vs 21.7 (12.7-30.8) months, $p = 0.002$. **Conclusions:** FAS showed predictive value in PFS and OS for trabectedin administration in ASTS. The different prognostic role of FAS across distinct lines and its relevance in L-sarcomas deserve further attention.

11072 Poster Session (Board #395), Sun, 8:00 AM-11:30 AM

Sensitivity to chemotherapy of low-grade endometrial stromal sarcoma (LGESS) versus high-grade endometrial stromal sarcoma (HGESS). *First Author: Roberta Sanfilippo, Instituto Tumori Milano, Milan, Italy*

Background: LGESS and HGESS are rare uterine neoplasms of endometrial stromal origin. The activity of hormonal therapy in LGESS is reported, whilst no data are available in HGESS. The activity of chemotherapy is unknown in both. We focused on LGESS and HGESS to explore their sensibility to chemotherapy **Methods:** Cases diagnosed with LGHSS and HGESS from 1997 at Istituto Nazionale Tumori, Milan, or within the Italian Rare Cancer Network (RTR), were reviewed. **Results:** We identified 39 patients (pts), 28 with LGESS (median age:43) and 11 (median age: 54) with HGESS. Seventeen LGESS pts received systemic therapy for advanced disease (1-5 lines). Eight received an aromatase inhibitor, with 2 PR, 5 SD and 2 PD; 8 received oral progestins, with 4 PR, 5 SD and 2 PD. Nine patients (6/9 in first line, 1/9 in second line and 1/9 in third line) received antracyclines +/- ifosfamide and were evaluable for response: 2 had a CR, 4 a PR and 3 a SD. Median PFS was 7,6 months. Five patients received high-dose ifosfamide (HDIFX), obtaining 2 PR and 3 SD. Five pts received trabectedin, with 1 PR, 3 SD and 1 PD. All eleven pts with HGESS received systemic therapy for advanced disease (1-5 lines). Three patients received oral progestins, with PD. Ten pts received an antracycline-based combination chemotherapy and were evaluable for response: 5 had SD and 5 had PD. Median PFS was 3 months. Four pts received HDIFX and all progressed. Four pts received gemcitabine-based chemotherapy, obtaining 1 SD and 3 PD. Five pts received trabectedin, obtaining 1 SD and 4 PD. One pt received Pazopanib, with a PR lasting 5 months. **Conclusions:** In this series of endometrial stromal tumor pts treated with medical therapy, chemotherapy with antracycline-based combinations resulted in some objective responses in LGESS, while it was essentially inactive in HGESS. An observational clinical study is ongoing to expand this series.

11073 Poster Session (Board #396), Sun, 8:00 AM-11:30 AM

Rhabdomyosarcoma (RMS) in adults: Histologic subtypes and overall survival with actinomycin-based chemotherapy vs doxorubicin-based chemotherapy. *First Author: Alia Vang, St. Olaf College, Northfield, MN*

Background: RMS typically occurs in children. Vincristine, Actinomycin and Cyclophosphamide (VAC) based chemotherapy is the current standard. Limited data exist on the frequency of the histologic subtypes and optimal chemotherapy regimen for the treatment of adult patients with RMS. **Methods:** We retrospectively identified patients ≥18 years with RMS seen at our institution from 2000-2015. The analysis was performed with JMP statistical software. **Results:** We identified 73 patients, with a median age of 51 (range 18-85 years). The majority of patients were male (40 of 73) and presented with localized disease (59 of 73). Histologic subtypes were as follows: 32% embryonal (E), 27% alveolar (A), 36% pleomorphic (P), and 6% variants (V) (botryoid and spindle cell/sclerosing). The median overall survival (OS) for patients with localized disease was 16.2 months and metastatic disease 9 months. The median OS for patients with localized disease treated with VAC was 20.3 months (4A, 7E, 3P) and VDC (vincristine doxorubicin cyclophosphamide) was 14.1 months (3A, 3E, 2P). For those with localized disease treated with a VAC/actinomycin-based chemotherapy had a median OS of 19.5 months (4A, 9E, 3P) and with a VDC/doxorubicin-based chemotherapy had a median OS of 15.9 months (8A, 5E, 13P, 2V). **Conclusions:** Adult patients with RMS have an even distribution among the histologic subtypes. Given the small, unbalanced number of patients in each histologic subtype treated with VAC/actinomycin-based or VDC/Doxorubicin-based regimens, the overall survival benefit favoring the use of VAC/actinomycin-based is hypothesis generating and confirmatory studies are needed to truly determine the optional regimen for adult patients with RMS.

11074 Poster Session (Board #397), Sun, 8:00 AM-11:30 AM

Prognostic value of microscopic evaluation of organ infiltration and visceral resection margins (VRM) in patients with retroperitoneal sarcomas (RPS). *First Author: Salvatore Lorenzo Renne, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Surgery with gross margin clearance (R0 and R1) is the standard treatment for RPS and visceral resection has been proposed even in the absence of macroscopic visceral infiltration. Formal definition and margin sampling procedures for pathological evaluation are lacking for RPS. This study investigated VRM as well as viscera infiltration and their association with patient survival. **Methods:** Consecutive patients operated on for primary RPS (2009-2014) were extracted from a prospectively maintained database. VRM were sampled for each resected organ and classified as negative and positive. Also, tumor infiltration of resected organs was classified as follow: absence of infiltration, infiltration of perivisceral fat, early infiltration (i.e., renal/adrenal capsule, muscular fascia, contact with muscular tunica of hollow viscera), and infiltration of the viscera. **Results:** In 207 patients VRM were negative in 182 (88%) and positive 25 (12%). Organ infiltration was absent, perivisceral, early, and visceral in 37 (18%), 13 (6%), 17 (8%), and 140 (68%), respectively. Overall survival analysis showed that patients with negative VRM plus organ infiltration (HR = 3.56; 95%CI 1.15-11.00, P = 0.028) and those with positive VRM irrespective of organ infiltration (HR = 7.76; 95%CI 2.18-27.65, P = 0.002) did worse that patients with negative VRM plus no organ infiltration, after adjustment from known prognostic features. **Conclusions:** After liberal multivisceral resection for primary RPS, up to 80% of patients have infiltrated organs at some extent, while VRM are positive in up to 10% of cases. Visceral resection is justified even in the absence of macroscopic infiltration. Systematic evaluation of microscopic involvement of adjacent viscera may stratify prognosis.

11075 Poster Session (Board #398), Sun, 8:00 AM-11:30 AM

NY-ESO-1 antigen expression as a prognostic factor for soft tissue sarcomas. *First Author: Yuriy Komarov, N. N. Petrov Research Institute of Oncology, St. Petersburg, Russia*

Background: While a number of antigens are known to be expressed in soft tissue sarcomas, little is known about the prognosis of patients with such tumors. Recent data have demonstrated immunologic activity in sarcoma patients expressing the NY-ESO antigen, found positive in 20-80% cases. MAGE A3 has also recently attracted attention with regard to soft tissue sarcomas. In our study we aimed to assess any association between antigen expression and prognosis. **Methods:** In a case-control study we retrospectively collected data from a prospective database of all 137 patients with sarcomas receiving first line therapy in the Petrov Research Institute of Oncology in Saint-Petersburg. All cases were morphologically verified, with mRNA expression of NY-ESO-1, MAGE A3, PDGFR A, PDGFR B, beta-tubullin and top2alpha additionally being tested by quantitative real-time PCR in a subset of patients. The log-rank test was applied to compare Kaplan-Mayer estimates of progression-free (PFS) and overall survival (OS) by univariate analysis. Hazard ratios were derived after adjustment for age, gender, several covariates for type of chemotherapy and disease stage with two-sided probability at a significance level of 0.05. **Results:** The positive rate for expression of NY-ESO was 20% (11/43).Only NY-ESO was significantly associated with PFS ($p < 0,001$), with a median durations of 10, 4 and 7 months for positive, negative and not tested for NY-ESO expression, respectively. The adjusted hazard ratio (HR) for NY-ESO positive patients was 2.2 (95%CI, 1.2;4.2) compared with their negative counterparts, The HR for patients not tested for NY-ESO was 2.0 (95%CI, 1.3;3.0). Among other covariates, only a combination of drugs was associated with a lower risk of progression (HR, 0.7 95%CI, 0.4;0.98) , as compared to those receiving a single chemotherapy agent. **Conclusions:** This first report showing prognostic significance of NY-ESO expression in soft tissue sarcoma patients, suggests that research should be focused on targeting this antigen. Participation in clinical trials for patients with positive NY-ESO expression is highly recommended, because of poor survival regardless of the type of standard treatment.

11076 Poster Session (Board #399), Sun, 8:00 AM-11:30 AM

The incidence of other malignancies before and after sarcoma diagnosis: A population-based study. *First Author: Winette T.A. Van Der Graaf, Institute of Cancer Research and The Royal Marsden NHS Trust Foundation, London, United Kingdom*

Background: Sarcomas encompass a group of rare and heterogeneous mesenchymal malignancies with mostly unknown origin. Both exogenous risk factors, in particular radiotherapy, as well as genetic risk factors have been described. Second tumors next to sarcomas suggest associated risk factors. In the current study, we investigate the incidence of sarcomas and other malignancies by using population-based data from the Netherlands Cancer Registry. **Methods:** In 29,638 patients diagnosed with sarcoma between 1989 and 2015, with a median age of 59 years, we quantified the risk of other malignancies *after* sarcoma diagnosis using standardized incidence ratios (SIRs). In assessing associations with malignancies *before* sarcoma diagnosis, we focussed on previous radiotherapy. Skin carcinomas, with the exception of melanomas, were excluded. **Results:** In total, 3,381 (11.4%) sarcoma patients, median age 71years, had a *previous* malignancy (at a median age of 66 years). The most frequent sarcomas associated with prior tumors were angiosarcoma (34.5%) and gastrointestinal stromal tumours (20.6%). In the angiosarcoma group, 78.6% of patients had received prior radiotherapy for their previous tumors. Subsequent tumors (diagnosed in patients with median age of 69.5 years) *after* sarcoma diagnoses were detected in 2,523 patients with median age of 63 years (SIR 1.13; 95%CI: 1.09–1.18). Risks appear notably elevated for breast cancer (SIR 1.19; 95%CI: 1.06–1.34), lung cancer (SIR 1.15; 95%CI: 1.04–1.27), cancers of the urinary tract system (SIR 1.33; 95%CI: 1.14–1.53) and hematological cancers (SIR 1.31; 95%CI: 1.13–1.51). Median time until diagnosis of subsequent cancer was 52.7 months. **Conclusions:** Sarcoma patients have a markedly increased risk on another malignancy, either before or after the sarcoma diagnosis. Further research into genetic and exogenous risk factors may help to explain the associations.

11077 Poster Session (Board #400), Sun, 8:00 AM-11:30 AM

When to treat Kaposi's Sarcoma? Paclitaxel survival benefit on classic versus AIDS/HIV-related subtypes. *First Author: Eduardo Eyzaguirre, Universidad Científica del Sur, Lima, Peru*

Background: Kaposi's Sarcoma (KS) is a angioproliferative disease related to AIDS/HIV (AIDS-KS) or not (Classic, CKS). Treatment options are limited in low-income countries where taxanes represent a cost-effective alternative. Our aim was to compare overall response (ORR) of paclitaxel and progression free survival (PFS) and overall survival (OS) between KS subtypes. **Methods:** We reviewed 203 medical records from pts diagnosed between 2002-2014 at the Instituto Nacional de Enfermedades Neoplasicas (Peru). Survival differences were calculated by log-rank test in the univariate analysis and Cox regression analysis for prognostic factors. **Results:** From 203 pts, 85 had CKS and 118 AIDS-CK. Mean age was 67 and 36years in CKS and AIDS-KS, respectively. Most pts were males (84.7%), coinfections as tuberculosis (11.9%) were more frequent in AIDS-CK. In CKS pts, 80% debuted with localized elevated lesions at lower limbs, 16% were resected, 48% received RT and 29% paclitaxel. Among AIDS-KS, 37% had poor risk, 22% were diagnosed concurrently to HIV infection. 76.9% had generalized lesions with origin at lower limbs, 50.5% had +ve nodes and 19% visceral disease. 25.8% had Zubrod $>$ 2 and mean neutrophil to lymphocyte ratio (NLR) was 3.5, CD4 count was lower in pts with recently diagnosis of AIDS/HIV (166 vs 268, p = 0.039) and no differences were noted on viral load (mean 233 411). 77.1% of AIDS-KS pts received ART and 56.8% paclitaxel. In AIDS-KS ORR was 77%(CR:52%, PR:22%) versus 86% in CKS (CR:43%, PR:43%). At 4.3year median follow-up, 3-year PFS and OS was 71% and 75% in AIDS-CK, while CKS had 78% and 79%, respectively. Paclitaxel was associated with better survival among AIDS-KS patients (PFS HR:0.41, 95%CI:0.2-0.7, p = 0.004 and OS HR: 0.37, 95%CI:0.1-0.7, p = 0.007), patients with Zubrod$\leq$2 had more survival benefit. There was not survival benefit in CKS pts. At multivariate analysis, ART and paclitaxel were associated with favorable PFS and OS, while higher NLR and poorer status performance to worse outcomes in AIDS-KS pts. **Conclusions:** Paclitaxel is an effective alternative treatment for AIDS-KS, there was not survival benefit in CKS patients. Poorer status performance and higher NLR were associated to worse prognosis.

11078 Poster Session (Board #401), Sun, 8:00 AM-11:30 AM

A phase I/II dose escalation and expansion study of cabiralizumab (cabira; FPA-008), an anti-CSF1R antibody, in tenosynovial giant cell tumor (TGCT, diffuse pigmented villonodular synovitis D-PVNS). *First Author: Kamalesh Kumar Sankhala, Sarcoma Oncology Center, Santa Monica, CA*

Background: TGCTis a proliferative, neoplastic joint disease that presents as single nodule (local) or multiple nodules (diffuse D-TGCT). Localized overexpression of colony stimulating factor 1 (CSF1) leads to recruitment of cells expressing the CSF1 receptor (CSF1R), formation of a tumor and inflammation of joints and tendons. Cabira is a monoclonal antibody that inhibits the interaction of the CSF1 and IL-34 ligands with their shared receptor CSF1R. **Methods:** This Ph 1/2 study is evaluating the safety and efficacy of cabira monotherapy administered IV Q 2wk for 6 mo in patients (pts) with D-TGCT. Eligible pts have inoperable D-TGCT or tumor for which resection would cause unacceptable morbidity. Response is evaluated by MRI, pt reported outcomes, and Ogilvie-Harris (O-H) score (which combines pain, synovitis, range of motion and functional capacity on a scale of 0-12). **Results:** As of 15 Dec 2016, 22 pts received $\geq$ 1 dose of cabira at 1, 2 or 4mg/kg. Dose-related exposure increase and significant reduction in target peripheral monocytes were observed. No dose limiting toxicity was identified. 4 mg/kg was chosen for Ph2 based on efficacy, tolerability, and PK. AEs $\geq$ Gr 2 ($>$ 10%) were CK elevation 46%, rash and other skin disorders 36%, fatigue 23%, and periorbital/peripheral/face edema 18% each. Gr 3 AEs in $\geq$ 2 pt were CK elevation (n = 8) and periorbital edema (n = 2). Four drug-related SAEs were reported in 3 pts; hypertension, fever, CRP elevation, and myocarditis. AEs of CK elevation were asymptomatic, improved to $<$ 2X ULN after protocol mandated drug discontinuation and are a known on-target effect of CSF1R inhibition. An amendment was made during Phase 2 to allow dosing with higher CK levels Activity at 4 mg/kg was: 1PR and 1 CK discontinuation in 3 pts in Ph1; 4 PRs in 7 evaluable pts with 6 additional ongoing in Ph2. Positive functional status improvements by O-H score were noted in objective responders (from 2 to 7). **Conclusions:** The initial demonstration of objective and functional activity supports further development of cabiralizumab in pts with D-TGCT. Updated data from the ongoing Ph2 will be presented. NCT02471716. Clinical trial information: NCT02471716.

TPS11079 Poster Session (Board #402a), Sun, 8:00 AM-11:30 AM

A bi-shRNA^{furin} and GMCSF engineered autologous tumor cell immunotherapy vs. gemcitabine + docetaxel for Ewing sarcoma and with cryoablation in Ewing family tumors. *First Author: Peter Meade Anderson, Cleveland Clinic, Cleveland, OH*

Background: Vigil, an immuno-stimulatory autologous cellular therapy, uses patient tumor cells transfected with a plasmid encoding genes for GM-CSF and furin (to down regulate TGFβ 1&2). A Phase I study in relapsed Ewing's sarcoma. (N = 16) had one 9 month partial response and a two-year survival rate of 44% [1]. Rapid, durable systemic immune activation was seen in the majority of patients using an IFNɣ ELISPOT assay [2]. We seek to extend these early findings in a randomized Phase 2 study (NCT02511132). **Methods:** Following surgery (for Vigil manufacture), patients are randomized 1:1 to Vigil (1 x 10^7cells/ml by monthly intradermal injection), or to chemotherapy with gemcitabine 675mg/m2 IV D1 and D8 and docetaxel 75 mg/m2 IV D8 every 21 days. Key eligibility criteria include: Age $>$ 2, histologically documented metastatic Ewing's, refractory or intolerant to $\geq$2 prior lines of chemotherapy, and availability of at least 4 doses of manufactured Vigil. Patients with bone only disease are ineligible. The primary objective is to compare the overall survival of patients treated with Vigil vs. chemotherapy. The sample size of 62 patients assumes a one-year survival rate of 25% in the chemotherapy group vs. 60% in the Vigil group, corresponding to a hazard ratio of 0.383 favoring Vigil. **Results:** As of January 2017, thirteen patients have been randomized at 10 centers in the U.S. The design allows for reduction in disease burden prior to surgery using modalities like SBRT and interventional radiology. Toxicity of Vigil has been low compared to chemotherapy. Time to disease progression is being assessed in patients who crossover to Vigil after progressing on chemotherapy. Systemic control of metastatic lesions using cryoablation is also being assessed in other patients (e.g. DSRCT liver metastases) using a separate IND. **Conclusions:** Although associated with systemic immune activation, additional means to reduce disease burden such as SBRT and cryoablation can possibly improve patient health and augment Vigil efficacy. References: 1.Ghisoli M, Barve M, et al. Mol Ther. 2016 Apr 25 2. Oh J, Barve M, et al. Gynecologic Oncology 2016; 143: 504–510. Clinical trial information: NCT02511132.

TPS11080 Poster Session (Board #402b), Sun, 8:00 AM-11:30 AM

A randomized, double-blind, placebo-controlled, phase III study of crenolanib in advanced or metastatic GIST patients bearing a D842V mutation in *PDGFRA*: The CrenoGIST study. *First Author: Jean-Yves Blay, Centre Léon-Bérard, Lyon, France*

Background: Activating mutations in the kinase domain of PDGFRA account for 10-15% of GIST. The most common PDGFRA mutation reported is D842V, which is known to confer resistance to imatinib and sunitinib. Currently, there is no approved treatment for GIST patients carrying such mutation. Cassier PA et al. showed that patients with D842V mutated GIST had a short median progression free survival (PFS) of 2.8 months with first line imatinib and 2.1 months with second line (2012 Clin Cancer Res). Crenolanib is a highly selective PDGFRA and FLT3 inhibitor with nanomolar activity against PDGFRα D842V mutation. In a previous dose-finding study, crenolanib showed a 31% clinical benefit rate with 2 pts achieving PR and 3 pts maintaining SD (total evaluable: 16 pts) in heavily pretreated GIST patients harboring the *PDGFRA D842V* mutation. In this study, 35% patients stayed on study for at least 7 months despite 80% patients having progressed after prior imatinib (15 pts), sunitinib (7 pts), dasatinib (5 pts), sorafenib (4 pts), nilotinib (2 pts), and regorafenib (2 pts). Therefore, a phase III trial has been initiated to further confirm the clinical activity of crenolanib in patients with *PDGFRA D842V*mutation. **Methods:** This randomized phase III study will enroll adult subjects with histologically or cytologically confirmed advanced or metastatic GIST with a *PDGFRA D842V* mutation. Prior treatment with TKI is allowed. Approximately 120 subjects will be randomized in a 2:1 ratio to receive either crenolanib 100 mg or matching placebo orally 3 times daily in combination with best supportive care. Randomization will be stratified by prior tyrosine kinase inhibitor exposure and ECOG performance status. The primary objective is PFS; key secondary objectives include OS. A formal interim analysis is planned after approximately 50 subjects have met the primary outcome. This study is already opened in the US, France, Norway, and Poland, and will soon be opened in Germany, Italy, Spain, UK and Asia. NCT02847429; EudraCT: 2015-000287-34 Clinical trial information: NCT02847429.

TPS11081 Poster Session (Board #403a), Sun, 8:00 AM-11:30 AM

Tappas: An adaptive enrichment phase 3 trial of TRC105 and pazopanib versus pazopanib alone in patients with advanced angiosarcoma (AAS). *First Author: Robin Lewis Jones, Royal Marsden Hospital, The Institute of Cancer Research, London, United Kingdom*

Background: AAS is an aggressive soft tissue sarcoma (STS) of endothelial cell origin with an expected median overall survival of 8-12 months. Pazopanib (P) is approved for treatment of advanced STS following progression on chemotherapy. In a retrospective study of 40 AAS patients treated with single agent P the median PFS was 3.1 months and median OS 9.9 months with no complete responses. Endoglin is an essential angiogenic receptor expressed on AAS that is upregulated following VEGF inhibition, and TRC105, an endoglin antibody, given with P produced durable complete responses in AAS patients with median PFS of 5.6 months in refractory patients including those receiving prior P. The TAPPAS trial is the first randomized Phase 3 trial performed in AAS, and was initiated following protocol assistance from the EMA and Special Protocol Assessment from the FDA. **Methods:** TAPPAS is a randomized multicenter study of TRC105/P vs P alone in the United States and Europe that is actively enrolling cutaneous and non-cutaneous AAS patients and incorporates an adaptive enrichment design. Key inclusion criteria: 0, 1 or 2 prior lines of therapy, ECOG ≤ 1. Primary endpoint is PFS and secondary endpoints include ORR and OS. The initial sample size of 124 patients, followed until 95 PFS events, provides more than 80% power to detect a hazard ratio of 0.55. At the time of interim analysis, projected to occur upon the occurrence of 40 events in approximately 70 patients, the result will be classified as belonging to either the favorable, promising, enrichment or unfavorable zones, based on conditional power. The sample size and PFS events will be unchanged in the favorable and unfavorable zones, and will be increased to a total of 200 patients followed for 170 PFS events in the promising zone. The trial will enroll 100 additional patients, with cutaneous disease only, in the enrichment zone and will follow them until 110 events are observed in the total cutaneous population. An independent DMC will follow the trial for safety and futility. The adaptive design requires the enrollment of fewer patients, preserves type-1 error, and protects power to detect a clinically meaningful survival benefit. (NCT 02979899). Clinical trial information: NCT02979899.

TPS11082 Poster Session (Board #403b), Sun, 8:00 AM-11:30 AM

Phase 2 trial of the novel multi-receptor tyrosine kinase inhibitor sitravatinib in well-differentiated/dedifferentiated liposarcoma. *First Author: Matthew Ingham, New York-Presbyterian Hospital, Columbia University School of Medicine, New York, NY*

Background: Well-differentiated/dedifferentiated liposarcoma (WD/DD LPS) is a sarcoma subtype of adipocytic origin characterized by amplification of cyclin dependent kinase 4 (CDK4) and MDM2. WD/DD LPS is resistant to chemotherapy and success with CDK4 inhibitors is limited. We recently characterized the landscape of activated receptor tyrosine kinases (RTKs) and intracellular signaling pathways finding marked heterogeneity by sarcoma subtype [Patwardhan et al. Oncotarget 2016;7(4)]. In WD/DD LPS cell lines, phosphorylated (p) IGF1-R, MET and PDGFRb are strongly expressed. Selective siRNA knockdown of expression of 1 or more of these RTKs inhibited growth of WD/DD LPS cell lines. Sitravatinib (S) is a novel inhibitor of a broad panel of related RTKs. We showed that S abrogates expression of p-RTKs, including IGF1-R, MET and PDGFRb, at low nanomolar concentrations and potently inhibits proliferation of WD/DD LPS cell lines, where anti-proliferative effects of S were superior to other RTK inhibitors including imatinib, crizotinib and pazopanib. S suppressed tumor growth *in vivo* in WD/DD LPS. A phase 1 trial of S in solid tumors showed clinical activity in WD/DD LPS. Recommended phase 2 dose was 150 mg/day. As there are no approved RTK inhibitors for adipocytic sarcomas, and based on these findings, we initiated a phase 2 trial of S in WD/DD LPS. **Methods:** This is a single-arm open-label multi-center Simon 2 stage phase II trial of S in 29 patients (pts) with advanced WD/DD LPS who failed 1 prior therapy and show disease progression before enrollment. Pts receive S 150 mg orally daily continuously. Primary endpoint is the progression free rate at 12 weeks (PFR_{12}) versus historical controls. The design has power of 85% to show improvement in PFR_{12} from 20% (inactive) to 40% (active) with $\alpha = 0.10$. Secondary endpoints are ORR, PFS and safety. A subset of pts undergo baseline and on-treatment biopsies and reverse phase protein array used to measure changes in expression of p-RTKs and signaling pathway proteins with confirmation by immunoblot. Genomic landscape of these tumors will be analyzed by next generation sequencing. The study opened in 1/2017. Clinical trial information: NCT02978859.

11500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

TCR repertoire sequencing of 254 resected non-small cell lung cancers to reveal TCR clonality in normal tissues compared to tumor tissues. *First Author: Alexandre Reuben, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The mechanisms underlying resistance to immune checkpoint blockade are poorly understood. Major efforts have been made to understand how mutations, through generation of neoantigens, may alter tumor immunogenicity and anti-tumor responses, particularly through T cell responses. However, the T cell repertoire and its interaction with cancers bearing specific molecular alterations have not been systemically studied. **Methods:** We delineated the landscapes in the T cell receptor (TCR) repertoire, immune infiltration (immunohistochemistry using multiple immune markers), genome (exome sequencing), epigenome (methylation array) and transcriptome (mRNA gene expression array) of 254 resected non-small cell lung cancers (NSCLC), matched normal lung tissues and peripheral blood mononuclear cells (PBMC). We report herein the preliminary analyses of TCR sequencing of NSCLC tumors and matched normal lung tissues. **Results:** We observed that: 1) Smaller tumors (smaller than median) had a higher T cell infiltrate ($p = 0.0016$) and higher entropy than larger tumors ($p = 0.0098$); 2) Tumors from ever/current smokers had higher T cell clonality than former/never-smokers ($p = 0.005$); 3) TCR clonality was positively correlated with mutational burden ($p = 0.0026$); 4) Compared to tumors, normal lung tissues demonstrated significantly less T cell infiltration ($p = 2.1x10^{-11}$), but a significantly higher clonality ($p = 3.9x10^{-7}$). Finally, many T cell clones, including major clones were shared between normal lung tissues and matched NSCLC tumors. **Conclusions:** Our preliminary data demonstrate the distinct immune microenvironment in different NSCLC tumors may be associated with particular clinicopathological features. The higher TCR clonality in normal lung tissues and overlap of T cell clones between normal lung and NSCLC tumors implies a significant proportion of tumor infiltrating T cells may be a function of constant exposure to mutagens rather than an anti-tumor response. Analysis of the peripheral TCR repertoire, the molecular landscape of these tumors and the association with immune profiling is underway.

11501 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Immune and molecular determinants of response to neoadjuvant chemotherapy in inflammatory breast cancer. *First Author: Sangeetha Meda Reddy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Inflammatory breast cancer (IBC) is the most aggressive form of primary breast cancer and has poor responses to standard of care neoadjuvant chemotherapy (NAC). Given there is a limited understanding of the immune microenvironment of IBC, this study aims to characterize the immune and molecular profiles of stage III and IV IBC and to identify biomarkers of response to treatment and targets for future therapies. **Methods:** IBC patients with available pre-treatment tumor samples and with intent to take to mastectomy were identified in the IBC tumor registry and tissue bank. Tumor infiltrating lymphocyte (TIL) infiltration in the tumor stroma was quantified on H&E slides per consensus guidelines ($n = 91$). On a subset of patients with available samples, deeper immune profiling was performed, including quantification of CD8 T cells by immunohistochemistry (IHC) ($n = 33$), PD-L1 tumor expression by IHC ($n = 14$), myeloid cells by multiplex IHC ($n = 15$), T cell clonality by T cell receptor sequencing ($n = 22$), and total mutational load (TML) by whole exome sequencing ($n = 20$). **Results:** Mean TIL were higher in tumors from patients that achieved a pathological complete response (pCR) to NAC than from those that did not (13.79 vs 7.24%, $p = 0.019$) and in patients with stage III compared to stage IV disease (11.90 vs 4.79%, $p < 0.001$). Though no statistically significant differences in CD8 infiltrate by response, stage, or receptor status were seen, the presence of a more clonal T cell population was predictive of pCR (13.27 vs 5.70% top 5 clone frequency, $p = 0.042$ among stage III patients). Myeloid cell staining revealed that tryptase staining, indicative of mast cells, was inversely associated with pCR (28.26 vs 108.0 counts/mm2, $p = 0.011$). Three of fourteen patient tumors displayed low PD-L1 tumor positivity (range 1-2%, 1+-2+) with the others being negative. Genomic profiling showed no statistically significant differences in TML by stage, receptor status, response, or immune infiltrate. **Conclusions:** Higher TIL, more clonal T cells, and lower mast cell infiltration are predictive of response to NAC in IBC. Comprehensive immune characterization of a larger cohort of pre- and post-treatment samples is currently underway.

11503 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Cancer-associated macrophage-like cells as prognostic indicators of overall survival in a variety of solid malignancies. *First Author: Daniel Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Cancer Associated Macrophage-Like cells (CAMLs) are a recently described circulating stromal cell subtype commonly found in the peripheral blood of patients in all stages of solid malignancies and in a variety of cancer subtypes. However, while their biological association to cancer is being studied, their clinical utilization as it relates to cancer prognosis has not been evaluated. **Methods:** A two year prospective study was undertaken to evaluate the relationship of CAMLs and overall survival (OS) in 6 solid tumor types. The single blind multi-institutional study consisted of 269 stage I-IV patients; breast ($n = 57$), esophageal ($n = 21$), prostate ($n = 43$), pancreatic ($n = 59$), lung ($n = 54$), and renal cell ($n = 35$), in treatment ($n = 134$) and untreated baseline ($n = 135$). 7.5mL of whole blood was filtered by CellSieve microfiltration assay and CAMLs enumerated, as previously described. Patients were grouped by CAML number (< 6 or ≥ 6) and by size (< 49 or ≥ 50 μm) to evaluate hazard ratios (HR) by censored univariate & multivariate analysis. **Results:** CAMLs were identified in 93% of samples, averaging 8.2 CAMLs/7.5mL blood sample, and found in all 6 cancers at baseline and during treatment. Average CAML number was associated with disease stage and CAML positivity was 4.4 & 80% (Stage I), 4.7 & 93% (Stage II), 9.3 & 98% (Stage 3), 12.1 & 97% (Stage IV). Univariate analysis of patients ($n = 269$) stratified by ≥ 6 CAMLs had reduced OS (HR = 1.8, 95%CI 1.1-2.9, $p = 0.03$). Further, CAML size also had reduced OS in patients with ≥ 50 μm CAMLs (HR = 2.7, 95%CI 1.8-4.0, $p < 0.0001$). **Conclusions:** Our data suggests that in solid malignancies, CAML number and size appear to clinically correlate with OS in early and late stage disease. Given these results relating CAMLs with OS, further analysis is warranted to determine if CAMLs can serve as a clinically-relevant blood-based marker.

11504 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Interferon-gamma (INFG), an important marker of response to immune checkpoint blockade (ICB) in non-small cell lung cancer (NSCLC) and melanoma patients. *First Author: Niki Karachaliou, Hospital Universitari Sagrat Cor - Grupo Quirónsalud- Oncology Department, Barcelona, Spain*

Background: PD-L1 can be induced by oncogenic signals or up-regulated via INFG in a STAT1- and NFκB-dependent manner. STAT3 opposes STAT1-mediated anti-tumor immune responses. I kappa B kinase epsilon (IKBKE) is an interferon signaling inducer. We explored whether INFG expression in pre-treatment tumors is associated with to the efficacy of ICB in NSCLC and melanoma patients. The role of inflammation-associated transcription factors STAT3, IKBKE and STAT1 was also examined. **Methods:** Total RNA from 17 NSCLC and 21 melanoma patients, was analyzed by qRT-PCR. INFG, STAT3, IKBKE, STAT1 and PD-L1 mRNA were examined. PD-L1 protein expression in tumor and immune cells was evaluated (Ventana SP142 assay). Progression free survival (PFS) and overall survival (OS) were estimated. **Results:** 17 previously treated NSCLC patients received nivolumab; 71% lung adenocarcinoma, 71% male, 53% smokers, 35% KRAS mutant, 88% EGFR wild-type (wt). 21 previously treated melanoma patients received pembrolizumab; 67% male, 67% BRAF wt. PFS to nivolumab was significantly longer in NSCLC patients with high vs. low INFG expression (5.12 vs. 2mo, $p = 0.0124$). PFS to pembrolizumab was significantly longer in melanoma patients with high vs. low INFG expression (4.99 vs. 1.86mo, $p = 0.0099$). Significantly longer OS was observed for melanoma patients with high vs. low INFG expression (not reached vs. 3.10mo $p = 0.0183$). There was a trend for longer OS for NSCLC patients with high vs. low INFG expression (10.15 vs. 4.86mo, $p = 0.0687$). The other gene levels and PD-L1 protein levels in tumor and immune cells did not affect the outcome to ICB. IKBKE was positively correlated with INFG and PD-L1 expression (NSCLC Spearman's $\rho = 0.58$ and 0.65; melanoma Spearman's $\rho = 0.61$ and 0.59), and STAT3 expression was loosely anticorrelated with PD-L1 expression (NSCLC Spearman's $\rho = -0.21$; melanoma Pearson's $\rho = -0.01$). **Conclusions:** INFG is an important marker for qRT-PCR mediated prediction of response to ICB in NSCLC and melanoma patients. Further research is warranted in order to validate that INFG is more accurate than PD-L1.

11505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Increased CD73 and reduced IFNG signature expression in relation to response rates to anti-PD-1(L1) therapies in EGFR-mutant NSCLC. *First Author: Katie Streicher, MedImmune, Translational Medicine (currently with EMD Serono), Gaithersburg, MD*

Background: Anti-PD-1(L1) therapies appear to be less efficacious in NSCLC patients whose tumors have EGFR activating mutations, but the underlying mechanism is poorly understood. We investigated the relationship between **Methods:** Flow cytometry and/or quantitative PCR were used to evaluate genes and proteins in five NSCLC EGFR mt cell lines and 6 wt lines. Anti-EGFR TKIs gefitinib and osimertinib were used at concentrations ranging from 0.001-100uM; EGF was used at 50 ng/mL. CP1108/NCT01693562 was a non-randomized phase 1/2 trial evaluating durvalumab (10 mg/kg Q2W) in advanced NSCLC. As of 24OCT16, 304 previously treated patients in CP1108 were enrolled. RNA sequencing was conducted on available tumor specimens from 97 patients in CP1108. CP1108 and TCGA were separated by EGFR status for genomic comparisons. **Results:** Median CD73 expression was increased 10-fold in EGFR mt NSCLC cell lines (n = 5) compared to wt cell lines (n = 6). EGF induced CD73 protein levels 5-40-fold in 3/6 EGFR wt lines. There was dose-dependent inhibition of CD73 expression (45-70 fold maximum) following treatment with gefitinib or osimertinib in 3/5 mt cell lines and 4/6 wt lines, suggesting a causal relationship between the EGFR pathway and CD73 expression. Consistent with these observations, EGFR mutant tumors had $\geq$2 fold increased expression of CD73 compared to wt ($p < 0.05$) in TCGA and CP1108 NSCLC adenocarcinoma patients. These EGFR mutants had significantly lower levels of IFNg signature, previously reported to be associated with enhanced benefit from durvalumab. **Conclusions:** Our findings identify a novel relationship in NSCLC between EGFR pathway activation, expression of the immunosuppressive molecule CD73 and reduced expression of IFNg mRNA signature. These results prompt the hypothesis that overexpression of CD73 in EGFR-mt NSCLC may explain, at least in part, the reduced benefit from anti-PD-1(L1) in this subset of NSCLC, and suggest evaluating anti-CD73 in combination with EGFR TKIs or anti-PD-L1 in EGFR-mt NSCLC.

11506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Genomic profiling of resistant tumor samples following progression on EGF816, a third generation, mutant-selective EGFR tyrosine kinase inhibitor (TKI), in advanced non-small cell lung cancer (NSCLC). *First Author: Daniel Shao-Weng Tan, National Cancer Centre Singapore, Singapore, Singapore*

Background: Up to 60% of patients (pts) with NSCLC harboring an activating EGFR mutation (mut) and treated with a 1st generation EGFR TKI develop a secondary gatekeeper T790M mut. EGF816 is an irreversible EGFR TKI that is highly potent against activating mut (L858R, ex19del) and T790M mut, while sparing wild-type EGFR. As previously reported, in a Phase I dose escalation study, the overall response rate to EGF816 in pts with advanced EGFR T790M mut NSCLC was 47% and the disease control rate was 87%. However, pts ultimately develop disease progression. Tumor biopsies were obtained from pts who had progressed on EGF816 to identify mechanisms of resistance. **Methods:** Pts with NSCLC with locally or centrally confirmed T790M status were enrolled in this multicenter, dose escalation study to determine the safety, tolerability and antitumor activity of EGF816 (NCT02108964). EGF816 was administered at 7 dose levels ranging from of 75-350 mg QD. Following disease progression, a tumor sample was obtained and was analyzed by the Foundation Medicine next-generation sequencing (NGS) T7 panel, which interrogates 395 cancer-related genes for base substitutions, insertion-deletions, and copy number changes, as well as introns of 31 genes involved in rearrangements. **Results:** Tumor samples taken following disease progression on EGF816 were analyzed from 9 pts. Of the 8 pts whose tumors were T790M+ at baseline, this was detected in only 3 pts' post-EGF816 progression samples. One patient developed an EGFR C797S mut and concurrent deletion in mTOR. Other identified alterations include BRAF fusions (n = 2) and c-MET amplification (n = 1). Only one patient was found to have concurrent TP53 mutation and RB1 truncating mutation. Individual patient response data, including duration of response, will be presented along with detailed genomic parameters. **Conclusions:** NGS analysis of tumors that developed resistance to EGF816 revealed multiple potential mechanisms of resistance. These data are hypothesis-generating and could lead to rational combination studies with EGF816 to improve the depth and/or duration of response to EGF816. Clinical trial information: NCT02108964.

11507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Genetic variations within the vitamin C transporter genes to predict outcome in metastatic colorectal cancer patients treated with first-line FOLFIRI and bevacizumab: Data from FIRE-3 trial. *First Author: Martin D. Berger, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Vitamin C is involved in many critical metabolic processes. Beside its major role as an antioxidant and free radical scavenger vitamin C exerts a regulatory influence on angiogenesis. Additionally, epidemiologic studies show an association between vitamin C levels and incidence of cancer.We therefore hypothesize that variations in genes encoding for vitamin C transporter proteins may predict outcome in patients (pts) with metastatic colorectal cancer (mCRC) treated with FOLFIRI and bevacizumab (bev). **Methods:** Theimpact of 3 functional SNPs within the SVCT1, SVCT2 and Glut1 genes on outcome was evaluated in 292 pts with mCRC treated with first-line FOLFIRI/bev in the randomized phase III FIRE-3 trial. 294 pts receiving FOLFIRI and cetuximab (cet) (FIRE-3) served as a negative control. Genomic DNA was extracted from formalin fixed paraffin embedded tissue and SNPs were analyzed by PCR-based direct sequencing. **Results:** Baseline characteristics in the FOLFIRI/bev arm were as follows: female/male 99/193; median age = 65y andmedian PFS/OS = 10.1/24.2 months (mts). The SVCT1 rs11242462 SNP showed significant association with PFS. T allele carriers had a longer median PFS compared to those with a C/C genotype (10.7 vs 9.7 mts) in both univariate (HR 0.77, p = 0.046) and multivariate analysis (HR 0.73, p = 0.028). The effect on outcome was most significant among KRAS mutant pts. Here, T allele carriers showed a markedly prolonged PFS and OS compared to pts with a C/C genotype (12.5 vs 7.0 mts, HR 0.50, p = 0.018 and 32.8 vs 14.7 mts, HR 0.45, p = 0.009). These associations remained significant in multivariate analyses (p = 0.009 and p = 0.021, respectively). However, the favorable impact on outcome was not observed among T allele carriers treated with FOLFIRI/cet. **Conclusions:** Our results provide the first evidence that the SVCT1 polymorphism rs11242462 might serve as a predictive marker in pts with mCRC treated with FOLFIRI/bev in the first-line setting. Targeting vitamin C transporter proteins might be a promising approach to further improve treatment options against mCRC and to overcome resistance to anti-angiogenic therapy.

11508 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Dissecting primary resistance to anti-EGFRs in *RAS* and *BRAF* wt metastatic colorectal cancer (mCRC): A case-control study. *First Author: Chiara Cremolini, Unit of Medical Oncology 2, Azienda Ospedaliera-Universitaria Pisana, the Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy*

Background: Almost half of *RAS* and *BRAF*wt mCRC patients do not respond to anti-EGFRs. Different molecular alterations suggested as predictors of resistance have not been validated. **Methods:** We conducted a case-control study to prospectively demonstrate the negative predictive impact of *HER-2* amplification or mutations (mut), *MET* amplification, *NTRK/ROS1/ALK/RET* rearrangements, and mut activating MAPKs or PI3K/Akt axis. Patients with *RAS* and *BRAF*wt mCRC clearly resistant (cases) or clearly sensitive (controls) to anti-EGFRs were selected. Hypothesizing a prevalence of candidate alterations of 0% and 15% among controls and cases, 47 cases and 47 controls were needed to be able to reject the null hypothesis of equally prevalent alterations, with a- and b- error 0.05 and 0.20. Since hypermutated tumors may hardly rely on a single pathway for their growth, we also evaluated the impact of microsatellite instability. **Results:** 47 cases and 47 controls were included. Primary endpoint was met: mentioned alterations were reported in 20 (42.6%) cases and 1 (2.1%) control ($p<0.001$). MSI-high was significantly more frequent among resistant than sensitive tumos (15% vs 0%, $p<0.001$). **Conclusions:** This is the first prospective demonstration that the combined assessment of these rare alterations allows to better select patients for anti-EGFRs, while opening the way to other tailored therapies.

Molecular alteration	Cases (Resistant patients) N=47	Controls (Sensitive patients) N=47
***HER-2* amplification**	7*	0
***HER-2* mut**	1 (G776V, exon 20)	0

***RAS* mutations concordance in circulating tumor DNA (ctDNA) and tissue in metastatic colorectal cancer (mCRC): RASANC, an AGEO prospective multicenter study.** *First Author: Jean-Baptiste Bachet, Hopital Universitaire Pitie-Salpetriere, Paris, France*

Background: *RAS* mutational status is required to prescribe anti-EGFR antibodies in mCRC. In comparison to molecular testing from tumor tissue, the characterization of *RAS* mutations in ctDNA is a promising and credible way to shorten the workflow. This study reports for the first time the performance of plasma testing in a large prospective series. **Methods:** Blood samples were prospectively collected before 1st line chemotherapy in mCRC patients. ctDNA was centrally assessed by NGS using the colon lung cancer V2 Ampliseq panel and by methylation digital PCR assay (WIF or NPY). Tumor tissue testing was done according to routine practice in each center. We expect a minimal kappa coefficient of 0.7 to reflect concordance. In order to have a precision of $\pm$ 0.07 with an estimated 5% of non-exploitable data 425 pts had to be included. Results were analyzed separately in the whole study population and in the subgroup of pts with ctDNA evidenced either by the presence of at least 1 mutation or by the presence of 1 methylated biomarker. **Results:** From 07/2015 to 12/2016, 425 patients were included, and 406 plasma samples were available for analysis. A *RAS* mutation was detected in 183 plasma samples (45.1%) As compared to tumor mutational status the kappa coefficient was 0.68 (95%CI: 0.61-0.75) with a concordance of 83.7%. Primary tumor removal, metachronous status, absence of liver metastases and peritoneal carcinomatosis were significantly associated with mutant *RAS* tumor and negative plasma status. In the subgroup of 324 samples for which ctDNA was evidenced, kappa coefficient was 0.85 (95%CI: 0.80-0.91) with a concordance of 92.9%. 23 pts had discordant results: *RAS* mutation in tumor tissue and not in ctDNA (15 pts, 4.6%), *RAS* mutation detected in ctDNA but not in tumor tissue (8 pts, 2.5%). Rectal tumor, absence of liver metastases, peritoneal carcinomatosis and tumor tissue cellularity $<$ 10% were associated with discordant cases. **Conclusions:** We confirm, in this large prospective multicenter study, the high concordance rate for RAS status assessment between blood and tumor samples. This result argues for the use of blood testing in daily practice for pts with detectable ctDNA. Clinical trial information: NCT02502656.

11510 Poster Discussion Session; Displayed in Poster Session (Board #210), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Evaluation of clinical outcomes by analysis of mutations in tumor tissue and circulating plasma DNA using next-generation sequencing (NGS) from STEAM, a prospective, randomized, multicenter study in metastatic colorectal cancer (mCRC). *First Author: John J. Lee, Roche Sequencing Solutions, Pleasanton, CA*

Background: STEAM (NCT01765582) assessed the efficacy and safety of concurrent (c) and sequential (s) FOLFOXIRI-bevacizumab (BEV) vs FOLFOX-BEV for first-line treatment of mCRC. **Methods:** The AVENIO ctDNA Expanded Kit (Research Use Only) was used to assess somatic mutations in 77 cancer-related genes by NGS in tissue, and both pre- and post-induction plasma samples (n = 182, 150 and 118 respectively) from STEAM. Four mutation classes including single-nucleotide variants (SNVs), indels, copy number amplifications (CNAs) and fusions were identified. SNVs and indels were called in tissue and plasma at allele frequencies of 5% and 0.25% respectively. **Results:** Overall concordance of mutations in pre-induction plasma with tissue was 83%. Concordance for the seven most mutated genes ranged from 91.5%-100%. In pts with matched samples (n = 118), RAS WT pts showed significantly longer progression-free survival (PFS) in both cFOLFOXIRI-BEV (A) and sFOLFOXIRI-BEV (B) arms versus FOLFOX-BEV (C), using genotyping of either tissue or plasma. This was not seen in RAS MUT pts. In contrast, TP53 WT showed no significant treatment differences while TP53 MUT showed longer PFS for cFOLFOXIRI-BEV versus FOLFOX-BEV. A list of mutation frequencies for all samples, as well as hierarchical clustering analysis of tissue mutations will be presented. **Conclusions:** The AVENIO ctDNA Expanded Kit identified mutations in 77 cancer-related genes, in both plasma and tissue, with high overall concordance. Compared to FOLFOX-BEV, longer PFS was observed for c- or s- FOLFOXIRI-BEV in RAS WT pts and for cFOLFOXIRI-BEV in TP53 MUT pts, irrespective of sample type. These results are hypothesis generating and require further clinical validation. Clinical trial information: NCT01765582.

Genomic analysis of circulating tumor DNA in 442 patients with carcinoma of unknown primary: Implications for targeted therapeutics. *First Author: Shumei Kato, Moores Cancer Center, La Jolla, CA*

Background: Carcinoma of unknown primary (CUP) is a rare, difficult-to-treat malignancy. To further understand the genomic landscape of CUP, next-generation sequencing (NGS) of circulating tumor DNA (ctDNA) from patient plasma was performed. To our knowledge, this is the largest cohort of patients with CUP interrogated by liquid biopsy. **Methods:** We evaluated the molecular alterations of 442 patients with CUP using clinical-grade NGS of ctDNA isolated from patient plasma. The test detects single nucleotide variants in 54-70 genes, as well as copy number amplifications, fusions and indels in selected genes. **Results:** Eighty percent of patients (353/442) had ctDNA alterations with 66% (290/442) harboring at least one characterized alteration; 43.9% (194/442) $\geq$ 2 characterized alterations. *TP53*-associated genes were most commonly altered (37.8% [167/442]) followed by genes involved in the MAPK pathway (31.2% [138/442]), PI3K signaling (18.1% [80/442]) and the cell cycle machinery (10.4% [46/442]). Among patients harboring at least one characterized alteration, most (87.9% [255/290]) had distinct genomic profiles, and 99.7% (289/290) had alterations theoretically targetable with either an FDA-approved or investigational agent. The mean number of potentially actionable alterations per patient was 1.7 (range, 0 to 10). Illustrative patients who had dynamic changes in ctDNA content during the course of therapy and responding patients matched on the basis of ctDNA to targeted therapies or immunotherapy will be presented. **Conclusions:** Evaluation of ctDNA was feasible among individuals with CUP. Most patients harbored a unique somatic profile. The majority of patients had potentially actionable alterations. Serial ctDNA showed dynamic changes in molecular alterations in response to therapy, and several patients have attained responses to targeted or immune therapies chosen on the basis of ctDNA findings. The current report suggests that non-invasive liquid biopsies merit investigation in next generation clinical trials.

Genomic profiling of squamous malignancies across anatomic sites. *First Author: Christine H. Chung, Moffitt Cancer Center, Tampa, FL*

Background: Primary squamous cell carcinomas (SCCs) have diverse etiologies, but can share genomic features. We reviewed the genomic profiles of a series of SCC cases of differing anatomic origin. **Methods:** Hybrid-capture based genomic profiling of 182 or 236 or 315 genes was performed on 4783 squamous malignancies in the course of clinical care, with baits for HPV6, 11, 16, and 18, and assessment of tumor mutation burden (TMB; mutations/Mb) and microsatellite instability. **Results:** Sites of origin were head and neck (HNSCC, n = 1300), cervical (cSCC; n = 318), anal (aSCC, n = 248), esophageal (n = 242), lung (lSCC, n = 2386), and cutaneous (sSCC, n = 289) SCC cases. For HNSCC, cSCC, and aSCC (collectively termed HCA SCC), 395 (30%), 215 (68%), and 211 (83%) were HPV positive, respectively. For HCA SCC, the most common GA were in *TP53* (45%), *CDKN2A* (29%), *PIK3CA* (24%), *TERT* (21%), and *FAT1* (14%). The most frequent GA differentially associated with HPV status were in *PIK3CA* (34.9% versus 16.0%), *CYLD* (11.4% versus 1.4%) and *PTEN* (14.8% versus 6.1%) for HPV+ cases, and *TP53* (3.8% versus 76.5%), *CDKN2A* ()1.4% versus 49.8%), and *TERT* (4.3% versus 33.0%) for HPV- cases. Mean TMB for HPV+ and HPV- cases were 6.6 (STDEV 7.3) and 13.7 (STDEV 29.7), respectively. TMB of all SCC cases was significantly different ($p < 10^{-12}$) when stratified by HPV status. For lSCC and eSCC, the most common GA were found in *TP53* (86%) *CDKN2A* (40%), and *PIK3CA* (26%) and mean TMB was 11.6 with HPV found in 3.1% of cases. In sSCC, the most common GA were in *TP53* (85.5%), *CDKN2A* (54.3%), and *TERT*(44.0%), and mean TMB was 59.5 with HPV in 3.1% of cases. Subsets of SCC cases had defining and targetable GA including bi-allelic deletion of *SMARCB1* ($<$ 0.3%), amplification of *PD-L1* (~2%), and various kinase fusions. Cases demonstrating radiologic response to immunotherapy and matched targeted therapies, as well as subsequent development of multiple mechanisms of acquired resistance, will be presented. **Conclusions:** HPV driven SCC have similar genomic profiles regardless of of site origin, and have a significantly lower median TMB than HPV negative SCC. Early consistency of responses of SCC to matched therapies may strengthen the case for site independent genomic predictors of therapy response.

Whole exome analysis of patients (pts) with metastatic GIST (mGIST) demonstrating exceptional survival with imatinib (IM) therapy compared to those with short term benefit. *First Author: Eytan Ben Ami, Dana-Farber Cancer Institute, Boston, MA*

Background: Most patients with mGIST initially benefit from IM therapy with durable disease control (DC), i.e. objective responses and stable disease, with median duration of approximately two years. We reported exceptional long-term benefit (LTB) with DC and overall survival (OS) >14 years in a subset of mGIST pts treated with IM. We aimed to characterize tumor and normal genomes of exceptional LTB pts treated with IM and compare with short-term benefit (STB) pts. **Methods:** Among 87 mGIST pts enrolled between July 2000 and June 2001 in the B2222 trial of IM and followed prospectively at the Dana Farber Cancer Institute, we identified 10 LTB (>14 years of DC) pts, and 6 STB (<2 years of DC) pts on IM. Targeted genotyping (*KIT/PDGFRA*)was performed in all tumors (n=16). Whole exome sequencing (WES) was performed on archival FFPE tumor samples from LTB and STB pts prior to any IM treatment. We compared WES results from LTB with STB pts to identify unique features of long-term DC and OS with IM. **Results:** *KIT* mutation in LTB pts were as follows: exon 11(6 pts), exon 9 (3 pts), and SDH-deficient with *KIT/PDGFRA* wild type (1 pt). In STB pts, mutated *KIT*was found 4 pts (exon 11) and 2 pts (exon 9). WES was successful in six LTB (five exon 11, one exon 9) and three STB (two exon 11, one exon 9) pts. A total of 1211 somatic mutations were observed (546 missense, 37 nonsense, 256 silent, 285 indels, 36 splice mutations). The mean somatic mutational burden was 3.42 mutations/Mb (range 1.18-4.93) and 3.34 mutations/Mb (range 1.06-6.68) among LTB and STB, respectively. Genes mutated in LTB but not in STB were MUC7 (4 pts), H1F0 (3 pts), ZKSCAN1 (3 pts), SLC24A1 (3 pts) and USP4 (2 pts). **Conclusions:** KRAB domain containing zinc finger (KRAB-ZNF) gene expression signatures have been associated with prediction of response to IM, and a possible role in response modulation to tyrosine kinase inhibitors in GIST. We found variants in ZKSCAN1, a gene encoding a transcriptional regulator of the KRAB subfamily of zinc finger, to be present in LTB but not in STB. KRAB-ZNF family of genes may be linked to LTB and exceptional survival with IM in mGIST; functional analyses will be important to test such hypotheses.

Molecular signatures and responses to targeted therapies in over 300 relapsed and therapy-refractory young adult (AYA) and childhood cancers. *First Author: Erin Haag Breese, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Contemporary chemotherapy-based regimens provide cures for most pediatric & AYA cancers. However, for patients with relapsed/refractory malignancies, outcomes are poor & imply a distinct and aggressive biology. Identifying common themes in the molecular architecture & oncogenic mechanisms in these patients is a critical priority for drug development. We hypothesized that the molecular signature of cancers in these patients would be independent of histology. We also assessed the response to molecular alteration (MA)-targeted therapies. **Methods:** IRB-approved analysis of MAs in 306 relapsed/refractory pediatric & AYA malignancies (116 hematologic malignancies, 68 sarcomas, 46 neuroblastomas, 36 CNS, 14 liver, 9 renal, 17 other) was performed. DNA was analyzed for MAs (Foundation Medicine, Cambridge, MA; Univ of Washington, Seattle, WA); additional MAs were identified by cytogenetic & fluorescent *in situ* hybridization analyses. **Results:** Median age was 8 years (range birth - 44 yrs). MAs were identified in 90.1% of patients & included a median of 2 mutations (range 0-18) in 133 cancer-related genes. In contrast to genomic analyses of *de novo* malignancies in children, a high frequency of TP53 MAs was identified (20.4% of patients) and was associated with inferior survival. MAs were identified in targetable pathways including cell cycle regulation (32.6%), DNA repair (7.2%), epigenetic (28.6%), RAS/RAF/MEK (24%), tyrosine kinase (TK; 18.4%), PI3K/AKT/mTOR (11.8%), and NOTCH/WNT (8.9%). A higher number of MAs was associated with inferior survival. Patients with alterations in epigenetic & TK pathways also had inferior outcomes. MAs were frequently independent of histology & the spectrum of mutations was similar to adult cancers. Exceptional responses were observed with MA-based assignment of therapies (epigenetic, NTRK, RAS/RAF/MEK & ALK). **Conclusions:** Relapsed/refractory pediatric & AYA cancers have frequent MAs independent of histology. The spectrum of MAs is distinct from *de novo* disease & potentially reflects tumor evolution & resistance mechanisms. These findings support MA-guided approaches to new drug development paired with adult trials.

SHIVA: Randomized phase II trial comparing molecularly targeted therapy based on tumor molecular profiling versus conventional therapy in patients with refractory cancer—Overall survival (OS) analysis. *First Author: Sylvain Dureau, Institut Curie, Paris, France*

Background: The SHIVA trial is a multicentric randomized phase II trial comparing molecularly targeted therapy among 11 drugs based on tumor molecular profiling versus conventional therapy in patients with any type of cancer that is refractory to standard of care (NCT01771458). Only patients who had a druggable molecular alteration (DMA) identified on a mandatory tumor sample from a metastatic site using targeted sequencing, CGH and IHC were randomized. Cross-over was allowed at disease progression. The trial did not show any difference for its primary endpoint (PFS) *[Le Tourneau et al., Lancet Oncol 2015]*. We report here the OS of randomized and non-randomized patients. **Methods:** OS was estimated in the 4 following groups: 1) randomized patients, 2) patients for whom a DMA was identified but who were not subsequently randomized because they did not meet the randomization criteria (PS of 0 or 1, adequate organ function), 3) non-randomized patients because of the absence of DMA, and 4) non-randomized patients because no genomic analyses were performed. Since 70% of patients randomized into the standard arm eventually crossed over to the targeted therapy arm, all randomized patients were analyzed in group 1. The groups were compared in terms of patient characteristics using student and $\chi 2$ tests. OS was estimated using the Kaplan Meier method. **Results:** Among 741 patients included in SHIVA, 8 patients were included twice. Follow-up data were available for 680 out of the 733 patients. 197, 78, 222 and 183 patients belonged to groups 1 to 4, respectively. Median OS of the whole cohort was 7.9 months [95% CI: 7.0–9.1].As compared to non-randomized patients due to the absence of identified DMA, non-randomized patients with a DMA had a significantly worse prognosis: HR = 2.3 [95% CI: 1.7–3.0] ($p > 0.0001$) whereas randomized patients had a non-significant trend toward a better prognosis: HR = 0.85 [95% CI: 0.7–1.1] ($p = 0.18$). **Conclusions:** A statistically significant difference in OS was only observed in patients with a DMA who were not randomized. However, our analysis does not allow showing an intrinsic prognostic value of the DMA on OS.

Characterization of tumor mutation load (TML) in solid tumors. *First Author: Mohamed E. Salem, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Rapid advances in immunotherapy have created a need for biomarkers to improve patient treatment selection. TML is proposed as a potential predictive biomarker due to its association with tumor immunogenicity. **Methods:** TML was assessed in 8020 tumors from 14 different cancers using somatic nonsynonymous missense mutations sequenced with a 592-gene panel. High TML was set at $\geq$ 17 mutations per megabase (mt/MB) based on an established concordance ($>$ 99%) with MSI-High in colorectal cancer (CRC). **Results:** Mean TML was highest in melanoma (Mel; 21 mt/MB), NSCLC (11 mt/MB), and bladder cancer (BLC; 11 mt/MB), whereas prostate cancer (PC), pancreas adenocarcinoma (PA), and renal cell carcinoma (RCC) had the lowest levels (all 6 mt/MB). High TML was seen most frequently in Mel (36%), NSCLC (15%), BLC (15%), and anal cancer (SCCA; 9%); and least frequently in PA (1.6%) and RCC (0.5%). Primary NSCLC carried lower TML than its brain metastases (11 vs. 16 mt/MB, $p < 0.001$). Older age was associated with higher TML in Mel ($p = 0.001$), CRC ($p = 0.009$), breast cancer (BC; $p = 0.01$), and NSCLC ($p = 0.02$). Higher TML was seen in males than in females for Mel ($p = 0.002$) and NSCLC ($p < 0.001$). Presence of mutations in oncogenic driver genes such as EGFR, ALK, ROS1 RET fusions, cMET exon 14 skipping correlated with lower TML in NSCLC (6.9 vs. 12 mt/MB, $p < 0.001$), as did BRAF and NRAS mutations in Mel (17 vs. 26, $p = 0.003$). Conversely, mutations in tumor suppressor genes such as ARID1A (CRC, NSCLC, and BLC) and NF1 (BC, CRC, Mel, BLC, and NSCLC) were associated with higher TML ($p < 0.05$). MSI-high was correlated with high TML in CRC and gastric cancers ($p < 0.05$). **Conclusions:** TML varied significantly among different cancers. High TML was associated with older age, absence of oncogenic mutations and presence of tumor suppressor gene mutations. Future studies will assess the impact of TML on clinical outcome and establish its role in selecting patients for immunotherapy.

	N = 8020	Mean TML	High TML %	PD-L1 %	TML ≥ 17 & PD-L1 %

Changes in computer extracted features of vessel tortuosity on CT scans post-treatment in responders compared to non-responders for non-small cell lung cancer on immunotherapy. *First Author: Vamsidhar Velcheti, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Immune-checkpoint blockade treatments demonstrate promising clinical efficacy in patients with non-small cell lung cancer (NSCLC). Nivolumab is a PD-1 inhibitor that is FDA approved for treatment of patients with chemotherapy refractory advanced NSCLC. The current standard clinical approach to evaluating tumor response is sub-optimal in defining clinical benefit from immunotherapy drugs. We sought to evaluate whether computer extracted measurements of vessel tortuosity significantly and differentially change post treatment between NSCLC patients who do and do not respond to immunotherapy. **Methods:** A total of 50 NSCLC patients including pre- and post- treatment CT scans were included in this study. The patients were either responders or non-responders to Nivolumab. Patients who did not receive Nivolumab after 2 cycles due to lack of response or progression as per RECIST were classified as 'non-responders'. A total of 35 tortuosity features of the vessels around the lung nodules were investigated. In the training cohort (N = 25), the features were ranked based on the degree of change between pre- and post- treatment CT. The top 4 features were used for training a Support Vector Machine (SVM) classifier to identify which patients did and did not respond to immunotherapy on a validation cohort of N = 25 patients. **Results:** The top features identified were the ones associated with the curvature of the vessel branches. The AUC for the SVM classifier was 0.75 for the training and 0.79 for the test set. **Conclusions:** Changes in specific vessel tortuosity features between baseline and post-treatment CT scans following nivolumab were different between NSCLC patients who did and did not respond. Multi-site validation of the vessel tortuosity features is needed to establish it as a predictive biomarker for NSCLC patients treated with immunotherapy.

11519 Poster Discussion Session; Displayed in Poster Session (Board #219), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Change in metabolic tumor activity on ^{18}F-FDG PET after a single dose of cetuximab to predict for treatment benefit, PFS, and OS in patients with advanced colorectal cancer. *First Author: Erik Jacobus Van Helden, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Despite RAS selection, one third of patients with metastatic RAS wild-type colorectal cancer (mCRC) do not benefit from anti-EGFR inhibitors. Therefore, an additional or more accurate predictive biomarker is needed to identify patients with primary resistant mCRC. **Methods:** In the IMPACT-CRC trial (NCT02117466) patients with chemotherapy refractory mCRC received 500 mg/m^2 cetuximab every 2 weeks. Before the first dose and just before the second dose, patients underwent a ^{18}F-FDG PET/CT (FDG PET). PET scans were quantitatively assessed by manual tumor delineation of $\leq$ 5 lesions, 2 per organ. Outcome is reported in total lesion glycolysis (TLG), defined as metabolic tumor volume times mean standard uptake value of the tumor. An optimal threshold to assess metabolic response was defined as decrease in TLG $\geq$15%. Quantitative data were correlated with CT evaluation after 8 weeks of treatment according to RECIST v1.1. **Results:** Out of 35 patients, 1 was excluded due to an infusion reaction. Median age was 64 years, 74% was male, 4 patients had a BRAF mutated tumor and 9 patients had right-sided primary tumors. 62% of patients had stable disease or partial response on CT after 8 weeks. At the time of this analysis, 88% of patients had progressive disease and 71% had died. Of the patients with right-sided tumors 11% had treatment benefit, compared to 80% in the left-sided group ($p = 0.001$). None of the 9 metabolic non-responders had treatment benefit, whereas 83% of the metabolic responders had treatment benefit according to RECIST v1.1. After adjustment for age, WHO score, BRAF mutation, sex and primary tumor site, FDG PET response remained correlated with PFS and OS ($p = 0.002$ and $p = 0.014$). **Conclusions:** Early evaluation of metabolic response after 1 dose of cetuximab is highly and independently predictive for treatment benefit with a 100% negative predictive value. Implementation of early FDG-PET evaluation in daily clinical practice can prevent unnecessary toxicity, costs of ineffective treatment and allows timely treatment adjustment for patients with mCRC undergoing anti-EGFR treatment. Clinical trial information: NCT02117466.

ACRIN 6698 trial: Quantitative diffusion-weighted MRI to predict pathologic response in neoadjuvant chemotherapy treatment of breast cancer. *First Author: Savannah C. Partridge, University of Washington Seattle Cancer Care Alliance, Seattle, WA*

Background: Diffusion-weighted (DW) MRI is a non-contrast technique that can reflect treatment-induced alterations in tumor microstructure and cellularity. ACRIN 6698 was performed as a sub-study of the I-SPY 2 TRIAL to evaluate quantitative DW MRI for early assessment of breast cancer response to neoadjuvant chemotherapy (NAC) in a multisite, multiplatform trial. **Methods:** The IRB-approved trial was performed at ten institutions. Of 406 enrolled breast cancer patients, 272 were randomized to treatment (12 weekly cycles paclitaxel+/-experimental agent, followed by AC) and underwent breast DW MRI at four time points: pre-NAC (T1), early-NAC after 3 cycles paclitaxel (T2), mid-NAC between paclitaxel and AC (T3) and post-NAC (T4). Tumor apparent diffusion coefficient (ADC) was measured at each time point and compared for patients with and without complete pathologic response (pCR) by Wilcoxon signed rank test. Exploratory analyses were performed across subtypes defined by hormone receptor (HR) and HER2 expression. Performance for predicting pCR was assessed by calculating the area under the ROC curve (AUC). **Results:** Of 272 treated patients, 227 comprised the final cohort (14 were excluded for missing MRI exams, 31 for poor image quality). Median patient age was 48 (range, 25-77) years, and 71/227 (31.3%) achieved pCR. Subtype groups were HR+/HER2+ (n = 38), HR+/HER2- (n = 95), HR-/HER2+ (n = 20), and HR-/HER2- (n = 74). For the full cohort (all subtypes and treatments), both ADC and change in ADC from T1 were significantly predictive of pCR at T3 (AUC = 0.63, 95% CI 0.55-0.71; AUC = 0.62, 95% CI 0.53-0.70, respectively), and also at T4. ADC measures were not predictive of pCR at either T1or T2. Stratifying by subtype showed change in ADC at T3 was more predictive in HR-/HER2+ (AUC = 0.86) and HR+/HER2- (AUC = 0.75) tumors than HR-/HER2- and HR+/HER2+ tumors (AUC = 0.59 and 0.56, respectively). **Conclusions:** DW MRI reflects cytotoxic effects of chemotherapy, and mid-treatment ADC was a predictive marker of pCR. The predictive value of ADC varied across biologic subtypes. Further work is needed to determine the comparative predictive value of ADC to other imaging metrics. Clinical trial information: NCT01564368.

11521 Poster Session (Board #221), Sat, 1:15 PM-4:45 PM

Inter-tumor validation, through advanced MRI and circulating biomarkers, of plasma Tie2 as the vascular response biomarker for bevacizumab. *First Author: Gordon C. Jayson, CRUK Manchester Institute, Manchester, United Kingdom*

Background: VEGF inhibitor (VEGFi) use is compromised by lack of predictive/ response biomarkers. Previously, we identified plasma Tie2 (pTie2) as a vascular response biomarker (VRB) for bevacizumab (bev) in ovarian cancer (OC). Here, we applied dynamic contrast-enhanced MRI (DCE-MRI) and circulating biomarkers in colorectal cancer (CRC), to validate pTie2 as the first tumor VRB. **Methods:** Seventy patients were recruited, with untreated, mCRC and ≥1 lesion of 3-10cm diameter for DCE-MRI. Patients received bev 10mg/kg for 2 weeks to elicit a biomarker response and then FOLFOX6/bev until progressive disease (PD) Thirteen circulating and 6 imaging biomarkers were measured before and during treatment and at PD. Unsupervised correlation analysis identified bev-induced biomarker correlations. Biomarkers were evaluated by clustered parameter-time course studies to determine their epithelial or vascular origin. Clinical significance was determined by relating the biomarker data to tumor 3D volumetric change assessed by MRI and PFS. The emergent vascular biomarker signal was modelled with epithelial biomarkers to assess the independent contribution of the vascular compartment to PD. **Results:** Bev induced significant correlations between pTie2, Ang2 and K^{trans}. Cluster analysis of Tie2 concentration-time course curves showed that pTie2 reflected tumor K^{trans}but not CK18, an epithelial antigen, i.e. changes in pTie2 reflected tumor vascular biology Patients who had the greatest area under the pTie2-time curve had tumors with high $K^{trans}$and/or low pVEGFR2, pre-treatment. They also had the greatest reduction in tumor volume and longest PFS. Fusion of pTie2 and CK18 data significantly improved modelling of PD. **Conclusions:** Bev impacts tumor vasculature causing proportional changes in pTie2. Information from pTie2 adds clinical value to that derived from the epithelial compartment. Thus (i) pTie2 is the first vascular response biomarker for bev and probably all VEGFi and (ii) demonstration of separate vascular and epithelial compartments in ovarian and CRC validates the vascular compartment as a target. This work identifies the first assay that could optimise use of VEGFi. Clinical trial information: 2009-011377-33.

11522 Poster Session (Board #222), Sat, 1:15 PM-4:45 PM

Effect of mast cells on efficacy of anti-angiogenic therapy by secreting matrix-degrading granzyme b. *First Author: Mark Wroblewski, Department of Hematology and Oncology with Sections BMT and Pneumology, University Medical Center Hamburg-Eppendorf; Department of Tumor Biology, University Medical Center Hamburg-Eppendorf, University Hospital Hamburg-Eppendorf, Hamburg, Germany*

Background: Resistance towards anti-angiogenic therapy (AAT) still represents a substantial clinical challenge. As mast cell (MC) density is known to correlate with tumor angiogenesis, we analyzed if inhibition of MC holds potential to increase efficacy of AAT in mice and cancer patients. **Methods:** C57BL/6J (WT), NSG or MC-deficient $Kit^{W\text{-}sh}$(Wsh) mice were subcutaneously injected with Panc02, EL4 or BxPC3 cells with or without bone marrow-derived MC. Tumors were treated with 20 mg/kg of anti-VEGFR2 antibodies (DC101) or 25 mg/kg cromoglicic acid. Tissue microarrays from n = 299 breast cancer patients from the GeparQuinto Phase 3 clinical trial were stained for MC and MC numbers were correlated with clinical data. **Results:** We observed that absence of MC reduced tumor growth and increased the efficacy of AAT in different tumor models. Intriguingly, AAT only initially reduced microvessel proliferation but this was abrogated over time as a result of MC-mediated resistance. We show that MC secrete increased amounts of granzyme b upon therapy, which mobilizes alternative pro-angiogenic factors from the tumor matrix. These factors act beside the targeted VEGFA-VEGFR2-axis and reinduce angiogenesis despite the presence of AAT. Importantly, MC-mediated resistance could be overcome using the FDA-approved MC inhibitor cromoglicic acid. In line with our preclinical data, high intratumoral MC density correlated with disease progression in HR+ breast cancer patients when Bevacizumab was added to standard neodjuvant chemotherapy (HR 8.45, p = 0.006). Accordingly, Kaplan-Meier curves indicated that disease free survival of patients with high tumoral MC density was numerically shorter in the whole cohort and significantly shorter in the HR+ cohort upon addition of AAT to chemotherapy (p = 0.168 and p = 0.004, respectively). **Conclusions:** Here we unravel a novel resistance mechanism, by which MC hamper efficacy of AAT in mice and cancer patients. In preclinical models this effect could be overcome by combining AAT with an FDA-approved MC inhibitor indicating high clinical relevance. Thus, combination of FDA-approved MC inhibitors with AAT might be a suitable approach to increase efficacy of AAT in the clinic.

11523 Poster Session (Board #223), Sat, 1:15 PM-4:45 PM

VEGFR2 cytoplasmic expression (VEGFR2ce) in relation to survival in metastatic breast cancer (MBC) patients (pts) treated with bevacizumab (Bev). *First Author: Roseana Melo Borba, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Bev is a monoclonal antibody that binds to VEGFA that demonstrated improved progression free survival (PFS) in MBC clinical trials. VEGFR2, NOTCH1, Integrin a1b2 and ILK are angiogenesis-related proteins possibly related with Bev efficacy. The correlation of these proteins expression and Bev survival variables was evaluated. **Methods:** We retrospectively analyzed 1st line chemotherapy in two HER2 negative MBC cohorts. Pts were treated between May-07 and July-14. Cohort 1 (C1) was treated with paclitaxel and Cohort 2 (C2) with paclitaxel and Bev. Expression of biomarkers was determined by immunohistochemistry. Tumor samples were arranged on a tissue microarray. Survival curves were calculated by Kaplan-Meier method and log-rank test. Cox model was used in multivariate analysis. **Results:** C1 had 42 pts. Median age was 63y. Tumor subtypes were divided in luminal (92.9%) and triple negative (TN) (7.1%). Visceral metastasis (mets) were present in 71.4%. Median follow-up (mFUP) time was 32.1m. mPFS was 8.0m and mOS was 33.5m. C2 had 29 pts. Median age was 57y. Luminal 79.3%; TN 20.7%; Visceral mets 79.3%; mFUP 38m. mPFS was 10.5m and mOS was 47m. In C2, high VEGFR2ce was correlated with improved PFS (high VEGFR2 16.5m x low VEGFR2 6.8m, p = 0.025). Breast cancer subtype, metastasis pattern and VEGFR2 expression were included in the multivariate analysis for PFS. VEGFR2 remained as independent factor (HR 0.35; IC95% 0.14 – 0.85, p = 0.021). In C1, VEGFR2 was not correlated with improved PFS (high VEGFR2 8.6m x low VEGFR2 8.0m, p = 0.24). Other markers were not associated with PFS. **Conclusions:** High VEGFR2ce was associated with increased PFS in patients treated with Bev. In MBC VEGFR2 may have a role as a predictive tool on benefit of antiangiogenic therapy.

11524 Poster Session (Board #224), Sat, 1:15 PM-4:45 PM

Circulating tumor cell status and benefit of radiotherapy in stage I breast cancer. *First Author: Chelain Rae Goodman, Northwestern Memorial Hospital, Chicago, IL*

Background: Circulating tumor cell (CTC) status has been shown to be prognostic of decreased survival in non-metastatic breast cancer. While up to 20-30% of patients with early breast cancer have detectable CTCs, less is known regarding the role of CTC-status in guiding clinical management. **Methods:** An observational cohort study was performed on women with stage I breast cancer evaluated for CTCs from the 2004-2014 National Cancer Database. Logistic regression was used to explore clinicopathological associations with CTC-status. Kaplan-Meier and multivariable Cox proportional-hazards survival analyses were used to estimate associations of CTC-status with overall survival using a propensity score-adjusted and inverse probability-weighted matched cohort. **Results:** Of the stage I breast cancer women evaluated for CTCs, 23.1% (325/1,407) were CTC-positive. Age, histology, receptor status, and nodal stage were associated with CTC-status. CTC-status was an effect modifier of the radiotherapy-survival association: CTC-positive women who did not receive radiotherapy had an increased hazard of death compared to CTC-negative women who also did not receive radiotherapy (four-year survival: 85.7% vs. 93.3%, HR = 2.92, CI = 1.43-5.98, P = 0.003). CTC-positive patients treated with radiotherapy did not have decreased survival compared to CTC-negative patients not treated with radiotherapy (HR = 0.67, CI = 0.28-1.65, P = 0.40). From the matched cohort analysis, CTC-positive women who did not receive radiation had a 4.82-fold increased hazard of death compared to CTC-positive women treated with radiotherapy (four-year survival: 83.2% vs. 96.6%; CI = 2.62-8.85, P < 0.001). **Conclusions:** Treatment with adjuvant radiotherapy was associated with improved survival in CTC-positive women with stage I breast cancer. If prospectively validated, CTC-status may be valuable as a predictor of benefit of radiotherapy in early stage breast cancer.

11525 Poster Session (Board #225), Sat, 1:15 PM-4:45 PM

CD4+ T cells in PBMC to predict the outcome of anti-PD-1 therapy. *First Author: Hiroshi Kagamu, Niigata University, Niigata, Japan*

Background: Antibody blockade of programmed death 1 (PD-1), has led to durable responses and significant prolongation of overall survival in metastatic cancers including non-small cell lung cancer (NSCLC). However, in clinical trials, response rates were as low as 20 %, and approximately 50 % of the patients did not achieve benefits to prolong progression free survival. These results bring us a hypothesis that there are subgroups with distinct pre-existing anti-tumor immunity resulting in different responses to anti-PD-1 therapy. We reported that effector T cells, which are capable of mediating antitumor reactivity, are primed in LNs draining growing tumors and that these T cells exclusively belong to the T cells that down-regulated CD62L ($CD62L^{low}$) subpopulation. In the absence of purified tumor antigenic proteins or peptides on many tumors, the expression of the homing molecule CD62L on T cells may serve as a surrogate marker for identifying tumor-specific immune cells. **Methods:** We analyzed the peripheral blood mononuclear cells (PBMC) of 50 consecutive NSCLC patients who were planned to be treated with anti-PD-1 Ab, Nivolumab after obtaining written informed consent. The patients received Nivolumab at a dose of 3 mg per kilogram of body weight every 2 weeks. Tumor response was assessed with the use of the Response Evaluation Criteria in Solid Tumors (RECIST), version 1.1, at week 8 and every 8 weeks thereafter. **Results:** The NSCLC patients who achieved partial response (PR) or stable disease (SD) had significantly ($p = 4.1x10^{-7}$) more $CD62L^{low}$ $CD4^+$ T cells in PBMC than progressive disease (PD) patients. The percentages of $CD62L^{low}$ in $CD4^+$ T cells provided sensitivity 92.9 %, and specificity 96.7 % to predict the patients who had PD. Moreover, SD patients had significantly ($p = 0.0067$) less regulatory T cell subpopulation than PR patients, thus, it was possible to predict PR from SD. **Conclusions:** These results show that the major differences in pre-existing immunity among PR, SD, and PD patients to anti-PD-1 Ab existed in $CD4^+$ T cell balance between primed effector and regulatory T cells. Further characterization of $CD62L^{low}$ $CD4^+$ T cells including mRNA microarray, checkpoint molecules, and chemokine receptors is going on.

11526 Poster Session (Board #226), Sat, 1:15 PM-4:45 PM

Cell-free DNA (cfDNA) mutations from clonal hematopoiesis: Implications for interpretation of liquid biopsy tests. *First Author: Pedram Razavi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A large fraction of cfDNA fragments are derived from hematopoietic sources. Somatic alterations in cfDNA can be tumor-derived but also could represent somatic changes associated with clonal hematopoiesis. We performed deep sequencing of both plasma cfDNA and matched white blood cell (WBC) genomic DNA (gDNA) to determine the contribution of clonal hematopoiesis to the variants observed in cfDNA. Four cohorts were investigated: metastatic breast (BC), non-small cell lung (NSCLC), castration-resistant prostate cancer (CRPC), and non-cancer participants (pts). **Methods:** Metastatic cancer pts with *de novo* or progressive disease were prospectively enrolled. Non-cancer pts were blood bank donors. Plasma cfDNA and matched WBC gDNA were sequenced using a targeted 508-gene panel (2 Mb) to $>$ 60,000X raw depth. Variant calling used a novel pipeline that employed molecular barcoding for error suppression followed by *de novo* assembly and graph-based variant calling. **Results:** Of 151 metastatic cancer pts (48 BC, 49 NSCLC, 54 CRPC), median age was 64 (30-87) with 53% female and 33% treatment naive. Of 47 non-cancer pts, median age was 61 (20-78) with 51% female. Analysis of cfDNA identified 1072 variants (AF $>$ 0.1%, $>$ 2 mutant reads, passing bioinformatic quality filters) which were also detected in WBC gDNA as non-germline ($<$ 35% allele frequency [AF]) non-synonymous variants. For these cfDNA variants, AF ranged from 0.1-14.4% and correlated with AF in WBC gDNA ($r^2 = 0.47$, $p < 0.001$). Mutated genes were consistent with clonal hematopoiesis, with the most frequently mutated genes being DNMT3A, TET2, PPM1D, and TP53 (215, 77, 45, and 36 variants, respectively). For both cancer and non-cancer pts (age $>$ 45), median number of overlapping variants was 5 per pt (range 0-22). The number of WBC gDNA and cfDNA variants per individual was positively associated with age ($p < 0.001$) in both cancer and non-cancer pts (interaction $p = 0.08$). **Conclusions:** Somatic cfDNA variants are frequently derived from clonal hematopoiesis and increase with age. Accurate assessment of somatic alterations in cfDNA should account for this phenomenon to distinguish between tumor-derived and WBC-derived variants.

11527 Poster Session (Board #227), Sat, 1:15 PM-4:45 PM

Circulating tumor DNA profiling to reveal heterogeneity of EGFR-TKI resistance mechanisms in lung adenocarcinoma patients. *First Author: Rongrong Chen, Geneplus-Beijing, Beijing, China*

Background: EGFR-TKI therapy has significantly improved prognosis of NSCLC patients with *EGFR* sensitive mutation. However, almost all patients ultimately develop PD while receiving TKI treatment. Circulating tumor DNA (ctDNA) is promising as a minimally-invasive liquid biopsy for comprehensive analysis of molecular abnormalities. **Methods:** A total of 254 advanced lung adenocarcinoma patients with signs of EGFR-TKI resistance were enrolled in the study. ctDNA was analyzed using next-generation sequencing based ER-Seq method, which enables simultaneously assess single-nucleotide variants, insertions/deletions, rearrangements, and somatic copy-number alterations across 59 genes. **Results:** ctDNA profiling was possible for all patients, 172 patients had $\geq$ 1 ctDNA alteration(s). Median number of plasma somatic mutations was 2, predominantly located in *EGFR* and *TP53*, with *MET*, *ERBB2* and *PIK3CA* followed. Of that, 30.6% of mutations detected in ctDNA were at a frequency below 1%. In exploring the mechanisms of TKI-resistance, we found TKI-sensitizing mutations were not detected in plasma of 138 patients (54.3%). Known mechanisms such as *EGFR* T790M/C797S mutation, activating mutations of *PI3K-AKT-mTOR* signaling, amplification of *MET*, activating mutation / amplification of *ERBB2*, activating mutation of *KRAS*, *BRAF* or mutations in *EGFR* EX20 other than T790M/C797S were identified in 59, 16, 8, 7, 3, 2, and 2 patients respectively. T790M/C797S was detected in 50.8% of patients with plasma positive for TKI-sensitizing mutations. Of note, C797S was only detected in patients treated with AZD9291. *EGFR* amplification were identified in 15 patients, though whether it would result in TKI-resistance was still controversial. Co-occurrence of resistance mechanisms were observed in 22 patients including 13 patients without TKI-sensitizing mutations. **Conclusions:** There was a high frequency of inter and intra-patient heterogeneity of resistance mechanisms after EGFR TKI therapy. ctDNA can be used as a 'liquid biopsy' to facilitate the broad exploration of potential resistance mechanisms.

11528 Poster Session (Board #228), Sat, 1:15 PM-4:45 PM

Association of circulating tumor DNA clearance during treatment with improved progression-free survival in advanced non-small cell lung cancer patients. *First Author: Shun Lu, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: Currently, response assessment of patients with non-small cell lung cancer (NSCLC) primarily relies on imaging scans, which do not reflect biological processes at the molecular level. We utilized circulating tumor DNA (ctDNA) coupled with capture-based ultra deep next generation sequencing to conduct dynamic monitoring of treatment response, thus evaluating the ability of ctDNA as a tumor clonal response biomarker. **Methods:** We performed capture-based sequencing on longitudinal plasma samples, including baseline and a minimum of 2 evaluation points, obtained from 88 patients with advanced NSCLC using a ctDNA panel, spanning 160KB of human genome and consisting of critical exons and introns from 168 genes. This real world study comprises a highly heterogeneous cohort with a mixture of prior treatment exposure. **Results:** At baseline, treatment-naïve patients often harbor solo driver mutation; in contrast, patients with prior treatments are more likely to harbor concurrent driver mutations. Patients who received molecular targeted therapy according to the baseline sequencing results have a longer progression-free survival (PFS) ($p = 0.0001$), demonstrating the value of ctDNA in directing treatment. During subsequent evaluations, we observed 74% concordance rate between molecular and radiographic responses. Furthermore, our data revealed that during follow-up, patients with at least one time of undetectable ctDNA are associated with a longer PFS ($p = 5.52e^{-6}$), regardless the type of treatment commenced. Among 44 patients who had at least one time of undetectable ctDNA, 39 achieved partial response or stable disease as their best response. Collectively, this phenomenon reflects clonal response, thus demonstrating the biological nature underlying the clinical response assessed by imaging modalities. **Conclusions:** This real world study demonstrates that patients with at least one time of ctDNA clearance during subsequent evaluation are associated with a longer PFS. Our study warrants further investigations to explore the value of ctDNA clearance as a surrogate endpoint of efficacy and as a risk stratification factor.

11529 Poster Session (Board #229), Sat, 1:15 PM-4:45 PM

Early detection of competing resistance mutations using plasma next-generation sequencing (NGS) in patients (pts) with *EGFR*-mutant NSCLC treated with osimertinib. *First Author: Nicolas Marie Guibert, Dana-Farber Cancer Institute, Boston, MA*

Background: In pts with *EGFR*+ NSCLC, genotyping of plasma cell-free DNA (cfDNA) has become a routine option for non-invasive detection of *EGFR*T790M. We hypothesized that serial NGS of cfDNA would allow early detection of co-existent resistance mutations during osimertinib treatment. **Methods:** Serial plasma samples were collected from pts with advanced *EGFR*+ NSCLC and T790M+ acquired resistance treated with osimertinib. Up to 4 specimens were analyzed, blinded to tumor genotype: baseline, initial 2 follow-ups, and progression. Plasma NGS was performed using enhanced tagged amplicon sequencing of hotspots and coding regions from 36 genes. Diagnostic accuracy was compared to tumor genotype (including NGS when available) and droplet digital PCR (ddPCR) of cfDNA. **Results:** 94 specimens from 26 pts underwent plasma NGS. Studying 26 baseline specimens, plasma NGS was more sensitive than ddPCR for known *EGFR* driver mutations (100% vs 88.5%). In 8 pts with pretreatment tumor NGS, 5 of 6 TP53 mutations were detected; one plasma positive/tissue negative result was seen across 36 genes, a *PIK3CA* mutation (0.6% AF) which was confirmed using ddPCR (99.6% specificity). Quantitative concordance of AF compared to ddPCR was high (R = 0.94). 21 pts had detectable *EGFR* driver mutations at resistance. Among 6 pts with maintained T790M, 4 acquired C797S and 2 of these additionally acquired low level *KRAS* mutations (G13D, Q61K). Among 15 pts with loss of T790M, 7 had competing non-*EGFR* alterations identified: *MET* amp, *PIK3CA* E545K, *BRAF* V600E (n = 2), *HER2* amp, *KRAS* G12S, and *FGFR1* amp. Resistance mutations detected at AF $>$ 0.3% were confirmed with ddPCR. In 3 pts, a competing resistance mutation (1 *KRAS*, 2 *BRAF*) could be detected in plasma NGS pretreatment and reemerged as putative drivers at time of resistance. **Conclusions:** In this retrospective blinded validation, tagged amplicon-based plasma NGS was more sensitive than ddPCR with high specificity and quantitative concordance. In a subset of cases, serial plasma NGS can detect emergence of competing resistance mutations, creating an opportunity for the study of osimertinib-based targeted therapy combinations.

11530 Poster Session (Board #230), Sat, 1:15 PM-4:45 PM

Prevalence and heterogeneity of androgen receptor splice variants and intra-AR structural variation in patient with castration-resistant prostate cancer. *First Author: Luc Yves Dirix, Department of Oncology, GZA Hospitals Sint-Augustinus, Antwerp, Belgium*

Background: Androgen receptor splice variant 7 (AR-V7) is linked to *a priori* resistance to abiraterone acetate and enzalutamide. However, AR-V7 negativity does not necessarily indicate responsiveness and up to 20% of AR-V7 positive patients do demonstrate moderate response to these second-line endocrine therapies. **Methods:** Peripheral blood samples from patients with CRPC (n = 30) starting a new line of systemic therapy were subjected to comprehensive profiling of AR. AR splice variant (ARV) profiling for eight isoforms was performed by targeted RNA-Seq on CellSearch-enriched circulating tumour cells. Low-pass whole-genome and targeted sequencing of the entire AR gene in plasma-derived circulating cell-free DNA allowed the assessment of copy number status and structural rearrangements, respectively. ARV expression, structural variation, copy number alterations and ligand-binding domain mutations were combined and correlated to clinicopathologic parameters. **Results:** Twenty-five out of 30 patients (83%) demonstrated an aberration in AR. Twenty out of 30 patients (66.7%) demonstrated AR amplifications. Interestingly, 15/30 patients had intra-AR structural variants, of whom 14 expressed ARVs. In the context of endocrine treatment, 15/26 (57.7%) patients were ARV-positive with 13/15 patients having less than 6 months benefit from their therapy (Fisher's exact test, p = 0.0115). ARV expression was heterogeneous with 10/15 ARV-positive patients expressing several ARV. Notably, AR-V7 was most frequently detected, however AR-V3 was 3.5x more abundant (Wilcox signed rank, p = 0.0029). In 17 patients, a baseline AR profile was available and demonstrated how having any ARV was associated with progression-free survival (HR: 4.53, 95%CI: 1.424–14.41; p = 0.0105). In the poor response group, 6/17 (35.2%) were AR-V7 negative, of whom 4 carried other AR aberrations. **Conclusions:** Comprehensive AR profiling on liquid biopsies is feasible and provides new insights into the mechanisms driving endocrine resistance. Clinical validation, by means of a non-interventional, prospective and multicentric study, is essential and currently ongoing.

11531 Poster Session (Board #231), Sat, 1:15 PM-4:45 PM

Prognostic impact of *PD-1*, *PD-L1,* and *CD8* genes expression in peripheral blood in gastric cancer. *First Author: Shuhei Ito, Kyushu University, Fukuoka, Japan*

Background: Programmed death 1 (PD-1)/PD-1 ligand (PD-L1) blocking agents to gastric cancer (GC) in the clinical setting show significant therapeutic promise. However, since these agents are enormously expensive and potentially toxic, it is crucial to identify predictive biomarkers for detecting the best candidate who would benefit from these agents by less invasive and simpler method, such as liquid biopsy. **Methods:** Expression levels of genes coding for *PD-1*, *PD-L1* and *CD8* (CD8+ T cells are closely associated with cellular immune responses to tumors) were assessed in peripheral blood (PB) samples using quantitative RT-PCR. Samples were obtained from 407 GC patients (392 patients with neoadjuvant chemotherapy [NAC] and 15 patients without NAC) before surgery and 23 PB from normal controls (NC). Flow cytometric analysis was performed to identify PD-1-expressed cells in PB mononuclear cells. **Results:** *PD-1*, *PD-L1* and *CD8* mRNA levels of GC patients were significantly higher than those of NC: 4.2-, 3.0- and 6.1-fold increases, respectively ($P < 0.0001$, $P = 0.0001$ and $P < 0.0001$). *PD-1* mRNA levels were significantly lower in GC patients with NAC than in GC patients without NAC ($P < 0.01$). GC patients with low *PD-1*, high *PD-L1* and low *CD8* mRNA levels had significantly poorer overall survival (OS) than those with high *PD-1*, low *PD-L1* and high *CD8* mRNA levels, respectively ($P < 0.05$, $P < 0.05$ and $P < 0.05$). Multivariate analysis showed that *PD-1* low/*PD-L1* high mRNA levels was independent risk factors for OS (OR 2.15, 95%CI 1.29-3.45, $P < 0.01$). Flow cytometric analysis demonstrated the proportion of CD3 (T cell marker)-positive cells in the PD-1-positive fraction were 95.4 $\pm$ 6.9% in GC patients. Thus, most PD-1 protein expression occurred on T cells. Taken together, *PD-1*, *PD-L1* and *CD8* mRNAs in PB were overexpressed in GC patients, and *PD-1* mRNA levels which was mostly expressed on T cells in protein levels in PB were decreased in GC patients with NAC. Furthermore, relative levels of *PD-1*, *PD-L1* and *CD8* were associated with prognosis, respectively. **Conclusions:** Preoperative *PD-1*, *PD-L1* and *CD8* mRNA levels in PB may reflect antitumor immune response, and *PD-1* low/*PD-L1* high mRNA levels in PB are markers of poor prognosis in GC patients.

11532 Poster Session (Board #232), Sat, 1:15 PM-4:45 PM

Evaluation of liquid biopsies for molecular profiling in patients with advanced non-small cell lung cancer (NSCLC) in the relapse treatment setting. *First Author: Jordi Remon, Medical Oncology Department, Gustave Roussy, Villejuif, France*

Background: Molecular profiling is limited by access to sufficient tumor tissue for comprehensive analysis and due to tumor heterogeneity, the complete range of tumor DNA abnormalities may not be represented nor accurately reflect the clinical evolution of disease. Circulating tumor DNA (ctDNA) can be used as a minimally-invasive liquid biopsy for the detection, quantification and monitoring of molecular abnormalities for personalized treatment strategies. **Methods:** In a prospectively designed program, to date, we have recruited 227 advanced NSCLC patients having received prior therapy, with unknown molecular profile at time of blood collection. Blood collections (10ml K2-EDTA) were performed to assess molecular profile prior to or at time of relapse. Repeat samples were performed on patients initiated on treatment and followed for up to 18months. Patient samples were analyzed with InVision (enhanced tagged-amplicon sequencing) using a 34 gene panel. Interim analysis performed with full descriptive summary statistical analyses to be presented at conference. **Results:** ctDNA profiling detected somatic mutations in 182pts (80.2%), predominantly located in *TP53 (46%), EGFR* (28%), *KRAS (11%)* and STK11 (7%, half of which had concurrent KRAS). Of note, clinically actionable mutations were detected: T790M (25pts, median 1.4% AF), ERBB2 (8 pts), MET (8pts) and BRAF (4pts) providing eligibility for new therapy options. 20pts including 12 EGFR/T790M+ve were evaluated for ctDNA monitoring up to 18 months (median 10m); correlation between dynamic change in mutation allele fraction and clinical response was observed, especially predictive of relapse to treatment. 10 patients demonstrated SD/PR response to osimertinib treatment with T790M detection at low allele fraction (7/10 $<$ 1% AF with 1pt at 0.08% AF). **Conclusions:** ctDNA can be used as a non-invasive 'liquid biopsy' for molecular profiling of NSCLC patients to detect clinically relevant and actionable mutations when tissue biopsy is unavailable. Liquid biopsies can be repeated as needed where tissue is not feasible, providing real-time information to support personalised treatment.

11533 Poster Session (Board #233), Sat, 1:15 PM-4:45 PM

Prospective characterization of circulating tumor cells using a nanotechnology-based capture system in oligometastatic patients undergoing definitive radiation therapy. *First Author: Daniel Paul Lindsay, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Circulating tumor cells (CTCs) can provide prognostic information in select patients with advanced cancers. We have developed a sensitive and specific CTC capture system (Oncosensor) which may predict clinical outcomes in patients undergoing definitive radiation for head and neck cancers. There is increasing interest in utilizing potentially curative metastasis-directed therapy for patients with oligometastatic solid-tumor malignancies. There is currently no biomarker to predict the success of this approach in most patients. The purpose of this prospective study is to investigate the potential utility of CTCs as a predictive biomarker for patients with oligometastatic cancer undergoing potentially curative therapy. **Methods:** Eligible patients had a metastatic solid-tumor malignancy with 3 or fewer metastases. All sites of disease were treated with definitive radiation or surgery. Concurrent chemotherapy was allowed. Peripheral blood (7 ml) was collected prior to starting, first week, mid-point, end RT, and every 4 to 12 weeks post RT. CTCs were quantified using the Oncosensor platform. We then assessed correlations between CTCs (baseline, end treatment, and changes during treatment) and clinical outcomes using multivariate analysis. **Results:** Baseline CTCs were detected in 20/20 enrolled patients with a mean baseline of 32/ml which decreased to a mean of 14/ml at the end of treatment. There was no association between pretreatment CTCs and clinical outcomes ($p = 0.81$). There was a significant association between post-RT CTCs and PFS ($p = 0.039$, HR 1.07 per CTC). Our data also suggest that post-treatment CTC monitoring may be able to detect early disease recurrence. Among the 4 patients with documented clinical failures and post-treatment CTC monitoring, all 4 had increases in CTCs with or prior to clinical or radiographic disease progression, with 1.6 to 7.3 fold increase at the time of progression compared to the prior time point. **Conclusions:** Our pilot data suggest CTCs may provide a predictive biomarker for patients with oligometastatic disease and could potentially provide a novel marker of disease recurrence.

11534 Poster Session (Board #234), Sat, 1:15 PM-4:45 PM

Bim and soluble PD-L1 (sPD-L1) as predictive biomarkers of response to anti-PD-1 therapy in patients with melanoma and lung carcinoma. *First Author: Roxana Stefania Dronca, Mayo Clinic, Rochester, MN*

Background: To date, there are no validated blood-based biomarkers of predicting response to PD-1 blockade. We previously reported that Bim is a downstream signaling molecule of the PD-1 pathway, and that measurement of Bim levels in circulating T-cells may predict and monitor responses to anti–PD-1 therapy in melanoma. We have identified the existence of sPD-L1 in cancer patients and showed that the sPD-L1 is biologically active and capable of triggering apoptosis in activated T-cells. Here we evaluated T cell Bim and sPD-L1 in the peripheral blood (PB) as biomarkers of response in a cohort of patients with metastatic melanoma and lung cancer undergoing anti-PD1 therapy. **Methods:** 60 pts treated with anti-PD-1 had PB collected at baseline and at radiographic tumor evaluation. Frequencies of Bim^+ T cells and Bim median fluorescence intensity (MFI) were measured by flow cytometry in gated tumor-reactive $CD11a^{high}PD1^+$ $CD8^+$ T cells. We also measured levels of sPD-L1 at baseline and serially during treatment with sPD-L1 ELISA. Baseline Bim and sPD-L1 levels and percent change in Bim levels in patients (pts) who had a radiographic response (CR/PR) were compared to those who had progressive disease (PD) at 12 wks. **Results:** Similarly to previously reported preliminary data, pts with objective response (CR/PR, 15/60) after 4 cycles of anti-PD1 therapy had higher frequency of Bim T cells at baseline compared to pts with PD (16/60) (mean 43% vs. 30%, $P = 0.0484$). The frequencies of Bim+ T cells decreased significantly after the first 3 months of treatment in responders compared with progressors (mean -16% vs. + 40% $P = 0.0111$). High baseline sPD-L1 were associated with progression on anti-PD1 therapy (mean 2.8 ng/mL vs. 0.7 ng/mL, $p = 0.07$, $n = 13$) and the levels increased by the first tumor assessment in patients resistant to anti-PD-1. **Conclusions:** Measurements of Bim and sPD-L1 levels may help to select patients who are likely to benefit from anti-PD1 monotherapy versus combinatorial strategies, and provide a new non-invasive way to monitor response to anti-PD-1 blockade. A larger validation study is underway.

11535 Poster Session (Board #235), Sat, 1:15 PM-4:45 PM

Monitoring of circulating tumor DNA in non-small cell lung cancer patients treated with EGFR-inhibitors. *First Author: Remy B Verheijen, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Epidermal growth factor receptor (EGFR) inhibitors such as erlotinib and gefitinib are routinely used in the treatment of non-small cell lung cancer (NSCLC). Monitoring of EGFR mutations in circulating tumor DNA (ctDNA) derived from plasma has been proposed as an alternative for repeated tumor biopsies. Our aim was to investigate the dynamics of ctDNA in a cohort of NSCLC patients and explore the roles of EGFR driver and resistance mutations in predicting disease progression and progression free survival (PFS). **Methods:** NSCLC patients treated with either erlotinib or gefitinib as first-line anti-EGFR therapy were included. Clinical data was collected retrospectively from medical records. Plasma samples collected as part of routine care were analyzed. First DNA was isolated from plasma using the QIAsymphony SP (Qiagen). Then EGFR driver (L858R and exon 19 deletions) and resistance (T790M) mutations were quantified using the X100 Droplet Digital PCR and analyzed using QuantaSoft software (Bio-Rad). The dynamics of ctDNA mutations over time and the relationship between copy numbers and progression free survival were explored. **Results:** 68 NSCLC patients and 249 plasma samples (1-13 per patient) were included in the analysis. In 33 patients, the T790M mutation was detected. The median (range) T790M concentration in these samples was of 7.3 (5.1 - 3688.7) copies/mL. In 30 patients, the L858R or exon 19 deletion driver mutations were found in median concentrations of 11.7 (5.1 – 12393.3) and 27.9 (5.9 – 2896.7) copies/mL, respectively. Using local polynomial regression, the copies/mL of EGFR driver mutations increased several weeks prior to progression on standard response evaluation. In Kaplan-Meier analysis, patients with a detectable T790M mutation during the first 8 weeks of treatment had a shorter PFS (7.6 versus 14.4 months, $p < 0.01$, log-rank test). **Conclusions:** Early detection of the T790M mutation in plasma ctDNA is related to poor PFS. Furthermore, an increase in the copies/mL of the EGFR driver mutation over time may predict clinical progression.

11536 Poster Session (Board #236), Sat, 1:15 PM-4:45 PM

Liquid biopsy in the clinic: A prospective study of plasma circulating tumor DNA (ctDNA) next generation sequencing (NGS) in patients with advanced non-small cell lung cancers to match targeted therapy. *First Author: Joshua K. Sabari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Liquid biopsy for plasma ctDNA NGS is a rapidly evolving science. Plasma ctDNA assays are commercially available and are increasingly adopted in the community with a paucity of evidence-based guidance. We set out to study the optimal timing and utility of plasma ctDNA NGS in clinic. **Methods:** Pts with advanced NSCLC who were driver unknown, defined as not having prior tissue NGS or clinical concern for tumor heterogeneity that may affect treatment decisions, were eligible. Peripheral blood was collected in a Streck tube (10mL), DNA extracted, and subjected to a bias-corrected hybrid-capture 21 gene targeted NGS assay in a CLIA lab with unique reads at 3000x and sensitive detection at variant allele frequency above 0.1% (ResolutionBio *Bellevue, WA*). Pts also had concurrent tissue NGS via MSK IMPACT. Clinical endpoints included detection of oncogenic drivers in plasma, ability to match pts to targeted therapy, concordance and turnaround time of plasma and tissue NGS. **Results:** Forty-one pts were prospectively accrued. Plasma ctDNA detected an oncogenic driver in 39% (16/41) of pts, of whom 17% (7/41) were matched to targeted therapy; including pts matched to clinical trials for *HER2* exon 20 insertionYVMA, *BRAF* L597Q and *MET* exon14. Mean turnaround time for plasma was 7 days (4-12) and 28 days (20-43) for tissue. Plasma ctDNA was detected in 56% (23/41) of pts; detection was 40% (8/20) if blood was drawn on active therapy and 71% (15/21) if drawn off therapy, either at diagnosis or progression (Odds ratio 0.28, 95% CI 0.06 - 1.16; $p = 0.06$). All pts had concurrent tissue NGS; of the 10 samples resulted, there was 100% driver concordance between tissue and plasma in pts drawn off therapy. **Conclusions:** In pts who were driver unknown or who had clinical concern for tumor heterogeneity, plasma ctDNA NGS identified a variety of oncogenic drivers with a short turnaround time and matched them to targeted therapy. Plasma ctDNA detection was more frequent at diagnosis of metastatic disease or at progression. A positive finding of an oncogenic driver in plasma is highly specific, but a negative finding may still require tissue biopsy.

11537 Poster Session (Board #237), Sat, 1:15 PM-4:45 PM

Association of circulating tumor DNA (ctDNA) tumor mutational burden (TMB) with DNA repair mutations and response to anti-PD-1/PD-L1 therapy in non-small cell lung cancer (NSCLC). *First Author: Andrew A. Davis, Northwestern University, Chicago, IL*

Background: Identifying optimal biomarkers for response to anti-PD-1/PD-L1 therapies in NSCLC is critical. TMB is a potential biomarker of genomic instability and neoantigen binding sites to activated effector T cells. The goal of this study was to derive a measure of ctDNA TMB and to examine the association between TMB and clinical variables, DNA repair mutations, and response to checkpoint blockade. **Methods:** We retrospectively examined 136 patients with NSCLC who had undergone ctDNA next-generation sequencing (NGS) in our institution. The ctDNA testing, performed by Guardant360, is not currently clinically indicated for TMB. We derived ctDNA TMB using coding base substitutions and indel alterations both including and excluding potentially functional variants, but excluded rearrangements, fusions, and copy number variants. In addition, survival data were obtained for 17 patients who were treated with anti-PD-1/PD-L1 therapy and had ctDNA before first line therapy or within 90 days of therapy initiation. **Results:** ctDNA TMB was associated with the number of direct and indirect DNA repair gene mutations (t-test, $p < 0.05$). Smoking was also associated with higher TMB when including functional variants (chi-square test, $p = 0.034$). Driver mutations (EGFR, KRAS) and prior radiation therapy were not correlated with TMB. Lower ctDNA TMB (below the median, 15 mutations/MBp) was associated with longer PFS and OS (Kaplan-Meier log-rank test, $p < 0.05$). **Conclusions:** ctDNA TMB was derived and was significantly associated with greater number of DNA repair mutations. Smoking predicted higher TMB score. However, in a small subset of patients, lower ctDNA TMB predicted response to checkpoint blockade. Potential reasons include the small sample size, the possibility of ctDNA reflecting tumor burden, and the limited length of DNA sequenced (~78,000-138,000 bp). Larger, prospective studies are necessary to validate these findings.

11538 Poster Session (Board #238), Sat, 1:15 PM-4:45 PM

Association of early reduction in circulating tumor DNA (ctDNA) with improved progression-free survival (PFS) and overall survival (OS) of patients (pts) with urothelial bladder cancer (UBC) treated with durvalumab (D). *First Author: Michael Kuziora, MedImmune, Gaithersburg, MD*

Background: Mutation variant allele frequencies (VAFs) in ctDNA indicate the frequency of cancer clones harboring the specific variant in the primary lesion and metastases, thus providing a surrogate for tumor burden. We previously reported that early reduction in VAF in ctDNA was associated with improved survival on durvalumab in NSCLC subjects. Here we replicated this association in UBC pts treated with durvalumab. **Methods:** CP1108/NCT01693562 was a nonrandomized phase 1/2 trial evaluating D in pts with advanced UBC or other solid tumors. By 24OCT2016, 103 UBC pts received 10 mg/kg Q2W of D with median 8.4 mos follow up. A panel of 70 genes was assayed for DNA variants using the Guardant360 cancer panel in plasma ctDNA from 33 UBC pts pre-treatment and 29 pts pre and 6 wks on-treatment. The mean VAF pre or on treatment of patient single nucleotide variants (SNVs) and insertion/deletions was correlated with clinical outcomes. Objective response rate (ORR) was calculated according to RECIST v1.1 and a Cox proportional hazard ratio (HR) was calculated adjusting for baseline ECOG, sex, age, and smoking status. **Results:** Complete and partial responders (CR/PRs) showed a significant decrease ($\Delta = -2.4\%$, $p = 0.02$) in ctDNA mean VAF post-treatment with D (i.e. reduction in tumor burden) compared to an increase in mean VAF (i.e. increase in tumor burden) in progressive disease (PD) pts ($\Delta = +2.7\%$, $p = 0.31$). This correlation was also observed in total mutation count in CR/PR ($\Delta = -4.6$, $p = 0.003$) compared to PD pts ($\Delta = +2.8$, $p = 0.44$). Pts with a decrease in ctDNA VAF at week 6 had longer median PFS (9.3 mos, 95%CI = [3.0, not reached(NR)] and OS (median NR, 95% CI = [20.3,NR]) compared to those with an increase in VAF (median PFS = 1.4 mos, 95%CI = [1.3,NR];HR = 0.29; $p = 0.05$ and median OS = 8.2 mos, 95% CI = [2.3,NR]; HR = 0.12; adjusted $p = 0.04$). DCR was 85%/14% for pts with a decrease/increase in VAF ($p = 0.002$). **Conclusions:** CtDNA VAFs were reduced in responders but not non-responders after six wks of D. A decrease in VAFs 6 wks following treatment with D correlated with longer PFS and OS, suggesting utility as an early indicator of clinical benefit. Clinical trial information: NCT01693562.

11539 Poster Session (Board #239), Sat, 1:15 PM-4:45 PM

CK19 combined with contrast-enhanced ultrasound: A prediction model for non-sentinel lymph node involvement in early breast cancer. *First Author: Xingfei Yu, Zhejiang Cancer Hospital, Hangzhou, China*

Background: According to Z0011 and AMAROS trials, patients with breast cancer stage cT1~2cN0 and sentinel lymphnode (SLN) 1~2 involvement can avoid axillary lymphnode dissection (ALND). But the risk of non-sentinel lymphnode (nSLN) involvement in those early stage patients is still unclear and it is difficult to predicting the risk before surgery. Our previous study showed CK19 mRNA in peripheral blood had predicative value of nSLN involvement. Also, contrast-enhanced ultrasound (CEUS) is a new effective method exmaming axillary lymph node. We aim to establish a prediction model for nSLN involvement in early breast cancer using CK19 combined with CEUS score. **Methods:** We identified 119 cases diagnosed early breast cancer (stage cT1~2cN0 and 1~2 SLNs involvement as in Z0011 and AMAROS trials) from Oct 2015 to Nov 2016 in Zhejiang Cancer Hospital. The CK19 mRNA of peripheral blood by RT-PCR and CEUS score of axillary lymph nodes were acquired before surgery. We used logistic regression analysis for filtering out valuable predictive clinical parameters and establishing formulas to calculate the probability of nSLN involvement. Our model was compared with Memorial Sloan Kettering Cancer Center (MSKCC) nomogram, which is one of the most reliable and validated methods for predicting of nSLN. **Results:** The histological grade, CK19 and CEUS score were screened by logistic regression analysis into the formula to calculate the probability of nSLN involvement. The sensitivity, specificity, total accuracy of this model was 89.13%, 80.82% and 84.03%, respectively. The false negative rate was 10.87%. The model had high quality of consistency (Kappa 0.675, $p < 0.01$) and goodness of fit (likelihood-ratio test, -2log liklihood = 84.607). The area under curve (AUC) of ROC was significantly higher ($P < 0.01$) in our model (0.914, 95%CI, 0.863~0.965) than in MSKCC nomogram (0.563, 95%CI, 0.459~0.667). **Conclusions:** The prediction model based on CK19 and CEUS score has satisfying sensitivity, specificity and accuracy, more effective than MSKCC nomogram. It is a valuable model of evaluating the risk of nSLN involvement in early breast cancer before surgery, picking out the patients who can truly avoid ALND.

11540 Poster Session (Board #240), Sat, 1:15 PM-4:45 PM

Evaluation of liquid biopsies for molecular profiling in untreated patients with stage III/IV non-small cell lung cancer (NSCLC). *First Author: Benjamin Besse, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Molecular profiling is limited by tumour heterogeneity and access to sufficient tissue for comprehensive analysis. Circulating tumour DNA (ctDNA) can be used as a minimally-invasive liquid biopsy for mutation detection, quantification and monitoring for personalised treatment strategies. **Methods:** We recruited 110 patients into a prospectively-designed study for Stage III/IV NSCLC patients intended to initiate 1stline platinum-based chemotherapy. Blood collections (10ml K2-EDTA) were performed prior to treatment and analysed by InVision (enhanced tagged-amplicon sequencing) using a 34-gene panel. Tissue biopsies, when available, were analysed by NGS (Ion-Torrent, Sanger) for concordance analysis. To evaluate correlation with outcome, repeat blood collections were performed in selected patients. **Results:** 110 NSCLC pts were included (61% male, 14% never-smoker, and 70% adenocarcinoma). ctDNA profiling detected mutations in 83 pts (79%). TP53 (44%), KRAS (17%), STK11 (18%; 11/19 with KRAS/STK11) and EGFR (10%) were the commonest abnormalities detected. Additionally, MET (6%), ERBB2 (6%), PIKC3A (6%) and BRAF (4%) mutations and EGFR, MET, ERBB2 amplifications were detected in 2% of patients, respectively. 20% of the mutations detected in ctDNA were observed at $< 0.5\%$ allele fraction, with 6% between 0.03%-0.25% AF. Tissue was available in 44 pts; somatic mutations were detected in 73%. Tissue & liquid concordance was 92.3%. 10 pts (23%) reported as tissue negative had a positive liquid biopsy. 33 advanced NSCLC patients were evaluated for longitudinal serial ctDNA monitoring up to cycle 4 of chemotherapy; the ratio of mutated molecules between D1 and D42 was significantly correlated with change in RECIST 1.1 measurement at D42 (p-value = 0.002625 CI 95% 0.298, 0.875). **Conclusions:** ctDNA can be used as a 'liquid biopsy' for molecular profiling of NSCLC patients to detect clinically relevant and actionable mutations when tissue biopsy is unavailable. Liquid biopsies can be used longitudinally and may provide an early surrogate for response evaluation by radiographic RECIST.

11541 Poster Session (Board #241), Sat, 1:15 PM-4:45 PM

Predictive impact of PD-L1-expressing circulating tumor cells in NSCLC patients treated with nivolumab. *First Author: Ryota Shibaki, Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan*

Background: PD-L1 expression on tumor tissue is associated with response to PD-1 blockade in NSCLC. Here, we conducted a serial evaluation of PD-1-expressing circulating tumor cells (CTCs) as a potential real-time diagnostic modality in NSCLC patients treated with nivolumab. **Methods:** Advanced NSCLC patients after failure of at least one prior chemotherapy regimen received nivolumab monotherapy (3mg/kg, q2W) until progressive disease (PD) or unacceptable toxicity. Peripheral whole blood (3 mL) was collected for CTC evaluation at baseline and at week 4. CTCs were detected using microcavity array system (Hitachi Chemical Co., Ltd, Chikusei, Japan). PD-L1 expression was immunohistochemically examined on both tumor tissues and CTCs. This study was registered at UMIN (ID: 000024414). **Results:** Thirty patients were registered in the study between January 2016 and September 2016 at Wakayama Medical University Hospital and 29 were included in the analysis. Demographics of the patients were as follows: median age 70 (range, 49 to 86); male 73 %; stage IV, 100 %; squamous/non-squamous, 27/73 %. At baseline, CTCs were detected in all patients (median, 15; range, 1 to 90) and PD-L1-expressing CTCs were detected in 87% of patients. Tumor proportion score (TPS) of PD-L1 expression on CTCs ranged from 6% to 100%, indicating intrapatient heterogeneity. Matched tumor tissues were available from 14 patients and 7 showed the PD-L1 TPS $\geq$ 50%. No positive correlation was observed on PD-L1 expression between tumor tissues and CTCs based on TPS (R2 = 0.0035). Overall response rate was 25% (7/29), and disease control rate was 54% (15/29). Total CTC count was significantly decreased after nivolumab treatment at week 4 ($p < 0.05$), but no significant change was observed in PD-L1 TPS on CTC. Patients harboring CTCs with PD-L1 TPS 50% or more at baseline were significantly more likely to achieve non-PD than those harboring CTCs with TPS less than 50% ($p < 0.05$). **Conclusions:** This is the first report on a serial monitoring of PD-L1 expression on CTCs in patients treated with nivolumab. PD-L1-expressing CTCs are suggested to hold potential for predicting clinical benefit. Clinical trial information: 000024414.

11542 Poster Session (Board #242), Sat, 1:15 PM-4:45 PM

Dynamics of soluble programmed death-ligand 1 (soluble PDL1) during chemotherapy and its prognostic implication in cancer patients. *First Author: Hyerim Ha, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea*

Background: The soluble form Programmed Death-Ligand 1(sPDL1) is suggested to have immunosuppressive activity and under investigation as candidate biomarker for immuno-oncology drug development. In this study, we measured the serum sPDL1 at pre-and post-chemotherapy and evaluated its prognostic implication and dynamics during chemotherapy in biliary tract cancer (BTC) patients. **Methods:** From 90 advanced BTC patients (training cohort 42 patients, validation cohort 48 patients) who were candidates for palliative 1st-line chemotherapy, blood was collected at pre-and post-chemotherapy. sPDL1 was measured using an enzyme-linked immunosorbent assay. Response to chemotherapy, overall survival (OS) and other prognostic factors including neutrophil-lymphocyte ratio (NLR) were also obtained. **Results:** OS of all patients was 11.5 months (95% CI; 9.7-16.2). The best response was CR in 7 patients (7.8%), PR 20 patients (22.2%), SD 52 patients (57.8%) and PD 11 patients (12.2%). Median sPDL1 at pre-chemotherapy was 0.97 ng/mL (range 0.6-1.9). Patients with high pre-chemo sPDL1 ($\geq$ 1.30 ng/mL) showed worse OS than patients with low pre-chemo sPDL1 (9.1 vs. 12.5 months, p =0.003). In multivariate analysis, high pre-chemo sPDL1 (HR 1.96, 95% CI; 1.2-3.9, p = 0.011) and pre-chemo NLR (HR 1.82, 95% CI; 1.1-3.0, p = 0.020) were independent poor prognostic factors for OS. Post-chemotherapy sPDL1 and its changes compared with pre-chemotherapy were not significantly different across tumor response groups. However, at the time of disease progression, sPDL1 was increased significantly compared with pre-chemo sPDL1 (1.59 ng/mL vs 0.72 ng/mL, p = 0.003). In PR group, sPDL1 at pre-chemo, post-chemo, and PD was 1.19, 0.98, and 2.77 ng/mL, respectively. In SD group, sPDL1 at pre-chemo, post-chemo, and PD was 1.16, 1.19, and 1.83 ng/mL, respectively. In PD group, sPDL1 at pre-chemo and PD was 0.62, and 1.04 ng/mL. **Conclusions:** sPDL1 at pre-chemotherapy confers the prognostic value for OS in BTC patients under palliative chemotherapy. The dynamics of sPDL1 during chemotherapy correlates with disease progression.

11543 Poster Session (Board #243), Sat, 1:15 PM-4:45 PM

Assessing tumor heterogeneity using circulating tumor DNA to predict and monitor therapeutic response in metastatic breast cancer. *First Author: Fei Ma, Department of Medical Oncology, National Caner Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Within metastatic breast cancer (mBC), tumor heterogeneity limited efficacy and duration of response to treatment. In this study, circulating tumor DNA (ctDNA) was used to evaluate tumor heterogeneity as a prognostic factor and monitor therapeutic response in patients with mBC. **Methods:** We collected plasma samples from 37 *HER2*-positive mBC patients treated with pyrotinib. Target-capture deep sequencing was performed to detect somatic mutations in plasma ctDNA. Clonal population structures were identified based on variations from ctDNA using Bayesian cluster with PyClone. Molecular tumor burden index (mTBI) was calculated with the mean variant allele frequency of mutations in trunk clonal population. **Results:** Mutations in *TP53* and genes of PI3K/Akt/mTOR pathway were associated with drug resistance for pyrotinib. The result showed that patients with resistant mutations occurring as a truncal event, who receiving monotherapy of pyrotinib, presented worse therapeutic effect (HR, 4.52; P = 0.03). The median PFS of patients with versus without resistant mutations in trunk clonal population was 7.8 weeks (95% CI 7.4 to 26.8 weeks) versus 31.6 weeks (95% CI 15.7 to 60 weeks), respectively. Patients with high heterogeneity (clonal population $\geq$3) had a significantly worse PFS (HR, 2.79; 95% CI 1.23 to 6.34; P = 0.014). The median PFS among patients with high versus low heterogeneity was 30.0 weeks (95% CI 13.9 to 53.5 weeks) versus 60.0 weeks (95% CI 31.4 to 84 weeks), respectively. Longitudinal monitoring of 21 patients during treatment showed positive correlation between mTBI in ctDNA and tumor size evaluated by CT imaging ($P < 0.0001$). Monitoring the mTBI in serial ctDNA increased sensitivity for prediction of progressive disease in 6 of 21 patients, with a mean time of 12.7 weeks earlier than using CT scan. ROC curve analysis showed an area under the curve value was 0.97 ($p < 0.0001$). **Conclusions:** Assessing tumor heterogeneity in ctDNA provides genetic predictors of treatment outcome. Molecular tumor burden in ctDNA is a potential indicator of therapeutic response. These observations might be supplements for the current therapeutic response evaluation.

11544 Poster Session (Board #244), Sat, 1:15 PM-4:45 PM

Early TKI-pharmokinetics and circulating tumor DNA (ctDNA) to predict outcome in patients with EGFR-mutated non-small cell lung cancer (NSCLC). *First Author: Frederic Bigot, Department of Medical Oncology, Paris Descartes University, Hopital Européen Georges Pompidou, AP-HP, Paris, France*

Background: Erlotinib (E) and gefitinib (G) are indicated as first-line therapy of *EGFR*-mutated NSCLC patients (pts). Many studies highlighted TKI pharmacokinetic (PK) impact on toxicities. However, data about the relationship between PK and efficacy are sparse. Recently, ctDNA has been shown to be a strong prognostic factor for metastatic NSCLC pts undergoing specific treatment. Thus, we underwent an observational study to determine plasma drug concentration and ctDNA impact on outcomes in NSCLC pts treated with E or G. Then, we explored the correlation between PK and ctDNA in order to improve management of pts treated with *EGFR*-TKI. **Methods:** We analyzed consecutive pts with *EGFR*-mutated NSCLC treated with TKI in Cochin and European Georges Pompidou hospitals (APHP, Paris) from April 2010 to March 2016. Plasma samples were collected 2 to 6 weeks after TKI initiation. Steady state trough concentration (Cssmin) was assessed by high performance chromatography. CtDNA was analyzed using Next-Generation Sequencing (Ampliseq ColonLungV2 panel, BPER method). Therapeutic ranges obtained from previous studies were between 1200 to 2000 ng/mL and $>$ 200 ng/mL for E and G, respectively. **Results:** Out of 77 pts, 56 had Cssmin analysis, 40 ctDNA analysis and 31 both. Median age was 70 years (range: 31-90), 49 were treated with E, 24 with G. Median follow-up was 19 months. Whatever *EGFR* TKI, pts with Cssmin into therapeutic ranges had longer PFS than pts over or under-exposed (median: 17.5 vs 7.5 months, p = 0.002). Those with early indetectable ctDNA had significantly better PFS (median 13 vs 5.8 months, p = 0.01) and OS (median: 21.4 vs 14.3 months, p = 0.02). No correlation was found between ctDNA and Cssmin. Occurrence of toxicity $>$ grade 2 in pts treated with E was associated with higher plasma concentration (mean 1991 vs 1184 ng/mL, $p < 0.01$). **Conclusions:** Early Cssmin and ctDNA assessment appear as markers to predict outcomes. Our observational study is the proof of concept that pts undergoing *EGFR*-TKI therapy could be monitored with Cssmin and ctDNA to define optimal personalized treatment strategies. A prospective study is planned to evaluate dose adaptation of TKI based on those 2 tools.

11545 Poster Session (Board #245), Sat, 1:15 PM-4:45 PM

Progastrin: A new specific early cancer screening biomarker. *First Author: Alexandre Prieur, ECS-Screening, Lausanne, Switzerland*

Background: One in two people will be diagnosed with cancer during his/her lifetime. Because we are lacking effective screening tests, most cancers are detected in late stages, when survival rates are very low. Here, we show the development of the first early cancer screening test for multiple cancers using progastrin (PG) as biomarker. The gene coding for PG is a target gene of the Wnt oncogenic pathway that is activated in almost all type of cancers, at the earliest stages of development. We showed that the neutralization of PG by a specific humanized antibody could be used for colorectal cancer treatment. Moreover, as PG is secreted by cancer cells, we can specifically detect it in the blood of persons having a cancer at early stage. **Methods:** Antibodies directed against PG were produced and selected for target specificity and affinity. ELISA is the most reliable assay to detect biomarker on the blood. Hence, selected antibodies were used to set up an ELISA sandwich to detect PG in the blood of patients with various types of cancers and at various stages. **Results:** We first set up a prototype ELISA using polyclonal antibodies. We validated our test using 223 blood samples from patients with polyps and colorectal cancers at various stages for which we observed an increased levels of PG. Then, we showed the presence of PG in the blood of 212 patients with other types of cancer, including liver, pancreatic and breast cancers, confirming that PG could be used as a biomarker for multiple types of cancers. Next, we set up our industrial ELISA using polyclonal and monoclonal antibodies called DECODE Lab and tested 245 new blood samples from patients with various types of cancer including early stages. Strikingly, using our test we were able to detect breast (AUC = 0.9638; sensitivity 70%), colorectal (AUC = 0.9635; sensitivity 73%), melanoma (AUC = 0.9882; sensitivity 87%) and cervix utery (AUC = 0.9827; sensitivity 84%) all stages combined with a high specificity of 97.5%. Finally, for early stage patients with melanoma and breast cancer, we had a sensitivity of 68% and 81% respectively. **Conclusions:** Taken together, the results presented here show that PG is a reliable biomarker for early cancer screening. The ELISA test that we developed is very efficient and now available for the clinic.

11546 Poster Session (Board #246), Sat, 1:15 PM-4:45 PM

Biomarker modulation in patients treated with TRC105 in combination with anti-VEGF therapy. *First Author: Yingmiao Liu, Duke University Medical Center, Durham, NC*

Background: TRC105, an endoglin-targeting monoclonal antibody with anti-angiogenic and anti-tumor activity, is being evaluated in multiple diseases. Here we report on pharmacodynamic and prognostic biomarkers in patients (pts) treated with both TRC105 and anti-VEGF agents. **Methods:** Plasma samples were collected from pts on three phase 2 trials combining TRC105 with an anti-VEGF agent: axitinib in metastatic renal cell carcinoma (mRCC), pazopanib in advanced soft tissue sarcoma, and bevacizumab in glioblastoma (GBM). Baseline and on-treatment levels of 22 soluble protein biomarkers were assessed. **Results:** Soluble endoglin markedly increased after TRC105 treatment in all pts ($p< 0.001$) as previously reported. BMP9 (a ligand for endoglin) and TGFβR3 (a type III TGFβ receptor) decreased in sarcoma pts at Cycle 2 Day 1 (C2D1) and generally remained below baseline throughout the course of treatment (BMP9, $p= 0.004$; TGFβR3, $p= 0.003$). Although TGFβR3 was decreased at C2D1 in mRCC (p = 0.030), no clear patterns were observed over time. Overall BMP9 levels did not change in response to therapy in either mRCC or GBM. Osteopontin (OPN) levels, a downstream effector of TGFβ signaling, were increased in sarcoma pts [$p=$ 0.002 at C2D15, $p< 0.001$ at C4D1 and end of study (EOS)]; however, in mRCC ($p= 0.010$) and GBM ($p= 0.003$), OPN was only elevated at EOS. Increases in PlGF and VEGFD, and decreases in VEGFR2 were observed across all studies, as previously noted for VEGF inhibitors. In the mRCC trial, 5 of 18 pts exhibited a ≥30% tumor reduction. Lower OPN ($p= 0.026$) and higher TGFβR3 ($p= 0.003$) levels at baseline correlated with radiographic response to treatment. In the sarcoma trial, 6 of 19 pts responded (CHOI criteria) in which lower baseline levels of ICAM1 ($p= 0.018$) and TSP2 ($p=$ 0.042) correlated with stable disease. **Conclusions:** In these trials, increases of soluble endoglin in response to TRC105 were observed, independent of the presence of any specific VEGF inhibitor. Differential regulation of BMP9, TGFβR3, and OPN suggests potential disease-specific modulation of key TGFβ signaling molecules in response to dual therapy. Baseline levels of OPN and TGFβR3 showed potential prognostic value in mRCC. Confirmation in larger trials is needed.

11547 Poster Session (Board #247), Sat, 1:15 PM-4:45 PM

Pre-treatment hematological markers as a predictive biomarker for survival in patients with non-small cell lung cancer treated with nivolumab. *First Author: Pradnya Dinkar Patil, Cleveland Clinic, Cleveland, OH*

Background: The absolute neutrophil count (ANC), absolute monocyte count (AMC) and neutrophil to lymphocyte ratio (NLR) are known markers of inflammation. We evaluated whether ANC, AMC and NLR are prognostic for overall survival (OS) and evaluated change in NLR as a predictive marker of response per RECIST in non -small cell lung cancer (NSCLC) patients treated with nivolumab. **Methods:** A total of 115 patients with NSCLC treated with nivolumab were included. ANC, AMC and NLR were examined at initiation of nivolumab therapy and after two cycles. The prognostic role of ANC, AMC and NLR on OS and changes in NLR ratio in responders was assessed using Cox regression model. **Results:** ANC > 6, AMC > 0.5 and NLR > 2.8 at baseline were independently associated with shorter OS (Hazard ratio (HR) 1.17 (1.08-1.27), p = .00001; HR 4.53 (1.99-10.31), p = 0.04 and HR 1.09 (1.04-1.13), p = 0.0002 . Responders had a decrease in NLR by (median (range) -0.93 (-14.7-52.95), p = 0.03) whereas non-responders had an increase in NLR by (median (range) 0.85 (-8.6-132.9), p = 0.03). **Conclusions:** ANC, AMC andNLR are independent prognostic factors in NSCLC patients treated with nivolumab. Changes in NLR can be an early biomarker for response with nivolumab in NSCLC patients.

Exosomal Del-1 as a potent diagnostic marker for breast cancer: A prospective cohort study. *First Author: Soo Jung Lee, Department of Oncology/ Hematology, Kyungpook National University Medical Center, Kyungpook National University School of Medicine, Daegu, South Korea*

Background: The authors recently reported exosomal Del-1 as a diagnostic marker for breast cancer (Moon PG *et al*, Clin Cancer Res. 2016). Therefore, the current study aimed to confirm the diagnostic role of exosomal Del-1 in a prospective cohort with breast cancer by comparing plasma exosomal Del-1 levels before and after curative surgery. **Methods:** To identify the optimal time of sampling after surgery, blood samples were serially collected at day 1, 3, 5, and 7 after surgery from 22 patients with breast cancer. Thereafter, one hundred fourteen breast cancer patients who underwent curative surgery were prospectively enrolled and then their exosomal Del-1 levels before and after surgery were compared using ELISA with both anti-Del-1 and anti-CD63 antibodies. **Results:** Among 22 patients for identifying the optimal sampling time, all the exosomal Del-1 levels were normalized at post-operative day (POD) 1 (0.5 or less), and therefore POD 3 or later was accepted for the sampling time for 114 prospective patient cohort.At diagnosis, exosomal Del-1 levels of 110 (96.5%) patients were higher (> 0.5) and 109 (99.1%) patients showed a normalization of Del-1 after surgery including four patients with the borderline Del-1 (between 0.4 and 0.5). During the mean follow-up duration of 21.8 (range, 5.9 – 58.4) months, nine (7.9%) patients experienced relapses (4 loco-regional and 5 distant), where 3 out of 6 in high group (> 0.5), 2 out of 4 in borderline group, and 4 out of 105 in normalized group (≤0.4). In particular, patients who relapsed in higher Del-1 group showed earlier relapse compared to the relapsed patients in lower Del-1 group. **Conclusions:** As the current prospective cohort study demonstrated a normalization of exosomal Del-1 after curative surgery, exosomal Del-1 can be confirmed as a potent diagnostic biomarker for breast cancer. Plus, a high Del-1 level after surgery seems related with early relapse suggesting a potential prognostic marker by identifying the existence of residual tumor.

Cerebrospinal fluid circulating tumor cells (CSF CTC) for real-time patient monitoring and response to treatment. *First Author: Rachna Malani, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The validated CellSearch system (Janssen Diagnostics, LLC), utilizing an immunomagnetic CTC selection method based on EPCAM antibody conjugated ferroparticles, is an FDA-approved methodology for enumerating CTC from blood in pts with breast, prostate and colon cancers. The CellSearch system has been used to evaluate CSF CTC of pts with leptomeningeal metastasis (LM) and has demonstrated potential as a diagnostic marker and response to cancer treatment. We explored the use of CSF CTC enumeration in the follow-up of pts with LM from HER2+ cancers receiving intrathecal (IT) therapy, aimed at characterizing changes over time as a potential biomarker of treatment response. **Methods:** CSF from pts participating in an IRB-approved phase I/II dose escalation trial of IT trastuzumab for LM in HER2+ cancer (NCT01325207) was evaluated by CellSearch system. 3 ml CSF from a ventricular reservoir was collected for CSF CTC enumeration at pre-treatment Day 1 of each cycle and correlated with CSF cytology from the same sample, and with clinical and radiographic response. LM progression was defined as clinical, CSF cytologic or radiographic worsening. **Results:** 15 pts with HER2+ LM (14 breast, 1 colon) were enrolled; 13 were women. At baseline 7 pts had positive CSF cytology, the other patients had a diagnosis by MRI. Of the 15 pts, 10 had greater than 1 cycle of treatment to be evaluable; 5 pts progressed during cycle 1 (Table). Mean CSF CTC at baseline was 82 per 3ml (range 0-200); 2 pts had no detectable CSF CTCs. A numerical decrease in CSF CTC was observed in 5 pts after cycle 1 and remained low (mean =9.5, range 0-92) while disease was stable. 3 pts (pts.3, 4 and 7) demonstrated a rise in CSF CTCs roughly 1 month prior to disease progression. **Conclusions:** Changes in CSF CTCs enumeration in response to treatment may allow quantitative surveillance of treatment response. CSF CTCs may serve as a platform to assess treatment response or as an early biomarker of LM progression and should be further investigated. Clinical trial information: NCT01325207.

11550 Poster Session (Board #250), Sat, 1:15 PM-4:45 PM

Correlation of cell-free circulating DNA, RNA, and PD-L1 from plasma with clinical response in patients with metastatic lung and breast cancers. *First Author: Luis E. Raez, Memorial Cancer Institute, Pembroke Pines, FL*

Background: There is an unmet need to evaluate tumor response by other means than radiology tests. Changes in gene expression, allele-fractions of mutations, PDL-1 expression and levels of cell free DNA [DNA] or RNA [RNA] in plasma might be useful for monitoring disease state and predicting outcome to anti-tumoral therapy. **Methods:** We measured serial levels of plasma DNA/RNA in metastatic patients (pts) with NSCLC and breast cancers undergoing treatment and correlated them with response (CR/PR/SD/PD) seen by CT scans. We also monitored PD-L1 expression in NSCLC pts treated with immunotherapy. DNA/RNA were extracted from plasma. RNA was reverse transcribed with random primers to cDNA. Levels of DNA/RNA were determined by RT-qPCR. **Results:** 52 pts were enrolled (28 breast/24 NSCLC). Breast group: 39% (11/28) were Caucasian (NHW) and 36% (10/28) Hispanic (H). 20 pts completed first two cycles of therapy: 2 pts had PR and showed no change (NC) or decrease (DEC) in levels of DNA/RNA. 11pts achieved SD, 9 had NC levels of DNA/RNA. Pts with PD: 5/6 underwent significant increase (INC) in DNA/RNA levels. Overall, among breast pts, there was an 84% (16/19) agreement between response and levels of DNA/RNA. These were correlated with one another ($r = 0.7002$, $p < 0.0001$). NSCLC group: 71% (16/24) were NHW and 25% (6/24) H. Non-SQCC were 87% (21/24). 20 pts had CT scans. One pt had PR with DEC levels of DNA/RNA. 10 pts achieved SD, all showed DEC or NC levels of DNA/RNA. 8 pts had PD, 6 of them had INC in DNA/RNA levels even 7 weeks prior to PD. Among NSCLC pts, there was a 90% (17/19) agreement in response and levels of DNA/RNA. These were correlated with one another ($r = 0.6231$, $p < 0.0001$). In 5 pts PD-L1 expression remained stable when CT scans showed SD or PR. **Conclusions:** There is a strong correlation between clinical responses with changes in plasma levels of DNA/RNA in pts with NSCLC (90%) and breast cancer (84%). Some of these were documented weeks before imaging was done. cfRNA is as effective as cfDNA as predictive tool for response. Plasma PDL-1 expression is a new tool to monitor immunotherapy response.

11551 Poster Session (Board #251), Sat, 1:15 PM-4:45 PM

Liquid biopsies of plasma exosomal nucleic acids, plasma cell-free DNA, and survival of patients with advanced cancers. *First Author: Lino Moehrmann, Department of Translational Oncology, National Center for Tumor Diseases (NCT) Heidelberg and German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: Blood-based liquid biopsies offer easy accessible genomic material for molecular diagnostics in cancer. Commonly used cell-free DNA (cfDNA) originates from dying cells. In contrast exosomal nucleic acid (exoNA) originates from living cells, which can better reflect underlying cancer biology. **Methods:** We isolated exoNA (EXO52) and cfDNA (QIAamp Circulating Nucleic Acid kit) from plasma of patients with progressing advanced cancers and tested for $BRAF^{V600}$, $KRAS^{G12/G13}$, and $EGFR^{exon19del/L858R}$ mutations using next-generation sequencing (EXO1000), droplet digital PCR (ddPCR, QX200) and BEAMing digital PCR. The results were compared to clinical testing of archival tumor tissue and correlated with survival. **Results:** Of the 43 patients (colorectal cancer, 20; melanoma, 8; non-small cell lung cancer, 6; ovarian cancer, 2; papillary thyroid cancer, 2; other cancers, 5) 41 had a mutation in the tumor tissue (20 [47%] *BRAF* mutation, 17 [40%] *KRAS* mutation and 4 [9%] EGFR mutation). Mutation testing of plasma exoNA from all 43 patients detected 39 (95%) of 41 mutations present in tumor tissue with 100% specificity. Mutation testing of plasma cfDNA from 39 patients using ddPCR detected 33 (89%) of 37 mutations present in tumor and testing of plasma cfDNA from 37 patients using BEAMing detected 34 (97%) of 35 mutations present in tumor tissue; however, both cfDNA methods reported an additional *KRAS* mutation not present in tumor tissue. Patients with high mutation allele frequency (MAF, > median) had shorter median survival compared to patients with low MAF (< median) when using exoNA (5.9 vs. 11.8 months, $P = 0.006$), but not cfDNA ddPCR (6.0 vs. 7.4 months, $P = 0.06$) or cfDNA BEAMing (6.5 vs. 7.4 month, $P = 0.07$). High MAF in exoNA was an independent prognostic factor for survival in multicovariate analysis (HR 0.13, $P = 0.017$). **Conclusions:** Mutation testing of plasma exoNA for common *BRAF*, *KRAS*, and *EGFR* mutations has high sensitivity compared to clinical testing of archival tumor tissue and better specificity than PCR testing of plasma cfDNA. High MAF in exoNA is the independent prognostic factor for shorter survival.

11552 Poster Session (Board #252), Sat, 1:15 PM-4:45 PM

Tetrahydrouridine-decitabine for non-cytotoxic epigenetic therapy of NSCLC to enhance immunotherapeutic effect of anti-PD1 in vivo. *First Author: Kai Kang, Cleveland Clinic, Cleveland, OH*

Background: NSCLC response to anti-PD1 therapy is ~20%, largely because most NSCLC avoids immune-recognition in the 1stplace, e.g., by epigenetics to suppress neo-antigen expression. DNA methyltransferase (DNMT1) mediates this repression and is depleted by decitabine (Dec). Unfortunately Dec has trivial distribution into solid cancer tissues because of rapid deamination by cytidine deaminase (CDA). Therefore, to improve tissue-distribution of Dec with the low Cmax/long Tmax profile needed for DNMT1-depletion without cytotoxicity, we combined Dec with a CDA inhibitor tetrahydrouridine (THU). **Methods:** C57/BL6 mice were inoculated with LL3-luc cells via tail vein. After documentation of lung invasion by live-imaging, mice (n = 5/group) were randomized to PBS, THU-Dec (10/0.1 mg/kg sc 3×/wk), anti-PD1 (5 mg/kg ip q5d, DX400 from Merck) or THU-Dec/anti-PD1 combination. Antigen presentation, PD, MDSCs, and T-cells were measured in blood and tumor. **Results:** THU-Dec or anti-PD1 alone decreased tumor by imaging and increased survival, however, THU-Dec/anti-PD1 combination extended median survival the most and completely regressed tumor in 2/5 mice (median survival days PBS 37, THU-Dec 56, anti-PD1 62, THU-Dec/anti-PD1 77). Rechallenge of cured mice with LL2-luc confirmed immune-memory effect, with no engraftment vs expected engraftment in controls. Consistent with the pharmacologic rationale, THU-Dec produced > 2-fold more DNMT1-depletion in tumor vs PBS. Consistent with non-cytotoxic effect, absolute lymphocyte counts were preserved with THU-Dec, while numbers of G-MDSC decreased (2.9 k/μL PBS vs 0.3 k/μL THU-Dec/anti-PD1, $p < 0.01$). Expression of neoantigens MAGE-A1 and MAGE-A3 increased > 4-fold with THU-Dec vs PBS ($p < 0.01$). THU-Dec/anti-PD1 increased tumor infiltrating lymphocytes 6-fold vs PBS ($p < 0.01$) and decreased regulatory T-cells 2.5-fold vs PBS ($p < 0.01$). IFNγ expression in tumor increased 2.4-fold with THU-Dec/anti-PD1 vs PBS ($p < 0.01$). **Conclusions:** THU-Dec/anti-PD1 produced marked survival improvements and cures in tumor-bearing mice, scientific validation of our clinical trial NCT02664181 combining THU-Dec/nivolumab in 2nd line for NSCLC.

11553 Poster Session (Board #253), Sat, 1:15 PM-4:45 PM

***CCL5* expression and tumor infiltrating immune cells in triple negative breast cancer.** *First Author: Jhajaira Araujo, Oncosalud-Auna, Lima, Peru*

Background: CCL5 is a chemo-attractant of regulatory T cells, promoting tumor immune avoidance and related to a poor outcome in several malignancies; however, in triple negative breast cancer (TNBC), it is related to a better outcome. Our aim was to evaluate the correlation between *CCL5* and tumor infiltrating immune cells and their prognosis value. **Methods:** We evaluated 72 TNBC patients with residual disease after neoadjuvant chemotherapy with matched data of tumor infiltrating lymphocytes (TILs) count and *CCL5* expression (profiled with NanoString). *CCL5* expression levels were log2 transformed and median centered. Correlation between TILs (log2 transformed) and *CCL5* was evaluated with the Spearman's rank test. Cox PH model was used to investigate the effect of *CCL5* (median as cutoff) and TILs ($<$ 20% and $\geq$20%) in distant-recurrence free survival. We used the CIBERSORT platform to evaluate the immune cells composition according to the expression of *CCL5* (higher vs. lower or equal than median) in 3 independent TNBC datasets (GSE25066, GSE58812 and GSE76124). **Results:** There was a significant correlation between TILs and residual tumor size (P = 0.017) and *CCL5* (ρ = 0.347, P = 0.003). In univariate analysis, TILs (HR = 0.276, 95%IC: 0.128-0.593; P = 0.001) and *CCL5* (HR = 0.401; 95%CI: 0.206-0.781; P = 0.007) were both associated with outcome. In a multivariate analysis with *CCL5* expression and TILs count, TILs was the only significant marker with a P = 0.008 (HR = 0.336; 95%CI: 0.150-0.753), in contrast to *CCL5* (HR = 0.573; 95%CI: 0.285-1.154; P = 0.124). CIBERSORT analysis suggested that high *CCL5* expression is associated with recruitment of CD8 cells (13% v 6%, P $<$ 0.001; 6% v 1%, P $<$ 0.001 and 12% v 8%, P = 0.003), activated CD4 memory T cells (4% vs. 2%, P $<$ 0.001; 5% vs. 0%, P $<$ 0.001; 3% vs. 0%, P $<$ 0.001) and Macrophages M1 (9% vs. 7%, P = 0.022; 13% vs. 8%, P = 0.005; 11% vs. 5%, P $<$ 0.001) in GSE25066, GSE58812 and GSE76124 datasets, respectively. **Conclusions:** TILs was the stronger and more significant prognostic immunological marker, even than *CCL5* expression. High *CCL5* expression was associated with enrichment of CD8 cells, activated CD4 memory T cells and Macrophages M1. Role of these cells in TNBC should be explored more deeply.

11554 Poster Session (Board #254), Sat, 1:15 PM-4:45 PM

Analysis of T-cell repertoires in early-stage breast carcinomas to evaluate tumor immunogenicity. *First Author: Javier Carrasco, Grand Hôpital de Charleroi, Charleroi, Belgium*

Background: Breast carcinomas (BC) are often considered to be weakly immunogenic and thus poorly sensitive to immunotherapy. **Methods:** We analyzed the repertoire of tumor-infiltrating T cells (TILs) in 41 early BC by sequencing their T cell receptor β genes (TCRβ). Libraries were built using a digital sequencing approach, barcoding each sequenced molecule to improve accuracy and quantification. T cell repertoires were also obtained from paired blood samples allowing identification of T cell clones enriched in the tumors as compared to blood. For 5 patients, $CD8^+$ TILs were cloned *ex-vivo* from a tumor sample and screened for recognition of autologous predicted neoepitopes. **Results:** T cell infiltration differed from one tumor to another. Its amount varied of more than 30 fold and its diversity ranged from $<$ 100 to $>$ 5000 different clonotypes. In 34% of the tumors, there was an important T cell infiltration and we detected several clonotypes with a $\geq$500 fold enrichment as compared to blood. In 22% of the tumors, an important T cell infiltration was observed but without significantly enriched clonotypes. In 43% of the tumors the T cell infiltration was very limited. For 5 tumors with a high T cell infiltration, we screened *ex-vivo* isolated $CD8^+$ T cell clones for recognition of predicted neoepitopes. In 4 of these tumors, with no enriched clonotypes, no recognition was observed. In 1 of these tumors, with enriched clonotypes, 6 different $CD8^+$ T cell clones recognized 4 predicted neoepitopes. Three of these clones were $>$ 100 fold more frequent in the tumor as compared to blood. **Conclusions:** About 30% of early BC were infiltrated by T cell clonotypes significantly enriched relative to blood. In one of these tumors some of the most enriched clonotypes recognized neoepitopes, demonstrating that some primary BC are spontaneously immunogenic. About 20% of the tumors had an important T cell infiltration without enriched clonotypes. None of the TIL clones isolated from 4 such tumors recognized predicted neoepitopes. Our results suggest that the detection of intratumorally enriched T cell clonotypes could identify immunogenic tumors, which may be sensitive to treatment with immunostimulatory antibodies.

11555 Poster Session (Board #255), Sat, 1:15 PM-4:45 PM

Tumor kinetic modeling and identification of predictive factors for tumor response to durvalumab in patients with non-small cell lung cancer (NSCLC). *First Author: Yanan Zheng, MedImmune, Mountain View, CA*

Background: Durvalumab is a human monoclonal antibody that binds to PD-L1 and blocks its interaction with PD-1 and CD80. The primary objectives of this analysis were to describe the longitudinal tumor size profiles and identify the key factors predicting tumor growth and regression following durvalumab. **Methods:** Longitudinal tumor size data obtained from NSCLC patients in study 1108 (all lines of therapy) and ATLANTIC (third line and beyond) following durvalumab treatment were modeled using nonlinear mixed effect modeling. Tumor kinetics were described by four key parameters: tumor growth and killing rate constants, fraction of durvalumab-sensitive tumor cells, and delay time for tumor killing. Potential predictive factors for tumor growth and regression were evaluated in a multi-variable covariate analysis. The model was used to simulate response rates at different tumor PD-L1 expression cutoffs. **Results:** Tumor kinetic modeling accurately described the longitudinal tumor response profiles from NSCLC patients in both studies. The factors associated with more rapid tumor growth were liver metastases, ECOG score $>$ 0, high neutrophil-to-lymphocyte ratio and EGFR/ALK mutation. Tumor cell PD-L1 expression, baseline tumor size and smoking history were identified as significant predictive factors for tumor killing or the fraction of sensitive tumor cells. Simulations using the tumor kinetic model showed increased response rates in patients with higher tumor cell PD-L1 expression (increased by 9-11% and 10-14% with 25% and 50% cutoff, respectively), patients receiving durvalumab as first-line therapy (increased by 12% vs. 2nd line/above), and patients with smoking histories (increased by 4-5% vs. non-smokers). **Conclusions:** Tumor kinetic modeling identified factors that predict tumor progression and response following durvalumab in NSCLC patients. The multivariate analysis accounts for various predictive factors within predictive biomarker strata, allowing better interpretation of different biomarker cutoffs. The modeling technique can potentially guide patient selection/enrichment, clinical trial design strategies and tumor biology. Clinical trial information: NCT02087423 and NCT01693562.

11556 Poster Session (Board #256), Sat, 1:15 PM-4:45 PM

Prognostic value of NK and T-lymphocytes markers in operable non-small cell lung cancer (NSCLC). *First Author: Marcin Tomasz Skrzypski, Medical University of Gdańsk, Department of Oncology and Radiotherapy, Gdańsk, Poland*

Background: Therapies aimed at activation of T and NK cells are developed to expand NSCLC treatments options. It is conceivable that markers of 'immune ignorant', 'immune excluding' or 'inflamed' tumor phenotypes could be prognostic or predictive of benefit from specific immune-targeting therapies. Aim: To assess the prognostic value of expression of T and NK cells mRNA markers and immune-related genes in early stage NSCLC. **Methods:** qRT-PCR was used to assess 48 mRNAs levels in frozen cancer tissue sections and matched normal lung parenchyma from 56 surgically treated stage I-IIIA NSCLC patients. The mRNA expression (normalized vs. 4 reference genes) was compared between the groups that did (44%) or did not relapse, as well as clinicopathological features (33% never-smokers, 75% lung adenocarcinoma). **Results:** Low expression of *FAS-L* (p.adj. = 0.048), *TIGIT* and *LAG3* was correlated with shorter distant metastasis free survival (DMFS) (p $<$ 0.04). Expression of *PD-1* (p = 0.024) and *CTLA4* (p = 0.04) was significantly lower in relapsed vs. non-relapsed NSCLCs, whereas there was no difference for *PDL-1* and *PDL-2*. Expression of NK activation markers: *NCR3* and *NCR1*, but not *NCR3-ligand 1* was significantly lower in relapsed vs. not relapsed NSCLCs. Other NK cell markers: *CD96* and *NKG2D* were expressed at lower levels (p = 0.02) in relapsed vs. not relapsed NSCLCs, whereas there was no difference for *NKG2C* and *NKG2A*. Expression of *CXCR3* was lower in relapsed NSCLCs (p = 0.03), however, the expression of its ligands (chemoattractants for lymphocytes) - *CXCL9, CXCL10* or *CXCL11* or *endothelin receptor type B* was not different according to metastatic status. *GITR* and *FOXP3* expression was significantly higher in cancers vs. normal lung parenchyma (p.adj. $<$ 0.003). There were no differences in expression according to gender, smoking or NSCLC histological types. **Conclusions:** Non-inflamed NSCLC phenotype is associated with higher risk of dissemination after primary resection. Neoplastic tissue is characterized by higher level of immune tolerance in comparison to normal lung tissue.

11557 Poster Session (Board #257), Sat, 1:15 PM-4:45 PM

Effect of chemoradiation for cervical cancer on transient decrease and variable expansion in T-cell infiltrate and diversity of T-cell repertoire. *First Author: Lauren Elizabeth Colbert, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The effect of fractionated radiation on intratumoral immune infiltrate is unclear. The purpose of this study was to characterize local immune changes and treatment response during chemoradiation (CRT). **Methods:** Cervical cancer patients underwent cisplatin based CRT over 5 weeks with brachytherapy. Cervical DNA swabs and cytology brushings were collected at baseline, one week, three weeks and five weeks. Deep T cell receptor β sequencing (TCR; Adaptive, Seattle WA) and multiparametric flow cytometry (MPFC) were performed for each time point. T cell density (TCD) and productive clonality (PC) were analyzed. Cells separated from the tumor brushings were stained and fixed with antibodies to T cell subsets with activation and suppressor markers including CD3, CD4, CD8, Ki67, PD-1, CTLA-4, and ICOS. Changes in T cell subsets were evaluated as percentage of live lymphocytes. **Results:** Eight patients were evaluated using MPFC. CD4 and CD8 percentages were lowest at one week and subsequently expanded. The percentage of proliferating CD4 (CD4+ Ki67+) was highest at week 5 (1.19%). There was no change in percentage of CD8+ cells expressing PD1, CTLA4 or ICOS over the course of treatment. TCR diversity was assessed for 9 patients. At baseline, week 1, week 3 and week 5, median TCD for all patients were 0.046 (IQR 0.008 to 0.097), 0.021 (IQR 0.005 to 0.043), 0.035 (IQR 0.015 to 0.083), and 0.033 (IQR 0.017 to 0.110). Median productive clonality at each point was 0.05 (IQR 0.06 to 0.02), 0.03 (IQR 0.06 to 0.02), 0.04 (IQR 0.05 to 0.02) and 0.03 (IQR 0.01 to 0.05). PC fold count increased (1.69, SD 1.3) for complete response (CR) patients and decreased 0.3 (SD 0.008) for patients with recurrent (REC) disease ($p = 0.1$). One TCR sequence was common in 4/9 patients at the end of treatment and six sequences were common in 3/9 patients. **Conclusions:** Chemoradiation induces a transient decline in tumor infiltrating CD8+ and CD4+ cells, followed by a variable expansion in T-cells at the end of treatment with an increase in proliferation phenotypes. TCR sequencing revealed increase in productive clonality during radiation for patients with a complete response to treatment.

11558 Poster Session (Board #258), Sat, 1:15 PM-4:45 PM

Adjuvant radiation therapy to induce a transitory adaptive up-regulation of programmed death ligand 1 (PD-L1) on circulating epithelial tumor cells (CETCs) to affect the anti-tumor immune response in primary breast cancer patients. *First Author: Dorothea Schott, Transfusion Center, Bayreuth, Germany*

Background: Radiation therapy (RT) is an integral part of the treatment of breast carcinoma but unfortunately many patients experience local recurrence. During the inflammatory response that accompanies radiation tumor cells may develop multiple resistance mechanisms for example the up-regulation of PD-L1 on tumor cells which leads to immune evasion. Since CETCs arise from the tumor it is conceivable that under evolutionary pressure they might share some of the immune escape mechanism inherent to tumor cells. In this study we demonstrate that RT leads to a transitory adaptive up-regulation of PD-L1 expression on CETCs. **Methods:** CETCs and the expression of PD-L1 and Ki-67 were analyzed from 25 patients with primary non-metastatic breast cancer using the maintrac method. The fraction of PD-L1 and Ki-67 positive CETCs were assessed at baseline, 3 and 6 weeks after start of RT and 6 weeks after end of therapy. Additionally, copy number status of PD-L1 was determined using FISH. **Results:** Fractionated-dose RT leads to a significant increase in PD-L1 expression on CETCs with the highest expression level midterm of irradiation as compared to baseline (49% vs. 74%, $p < 0.01$). 6 weeks after end of RT the number of PD-L1 positive CETCs returned to baseline value. The up-regulation of PD-L1 was dose dependent. Patients who received higher total dose had significantly more PD-L1 positive CETCs as compared to patients treated with lower total dose midterm of RT (64% vs. 43, $p < 0.05$). Before start of therapy there was a correlation between the fraction of PD-L1 and Ki-67 positive CETCs ($r = 0.6$, $p < 0.01$). PD-L1 copy number gains were significantly associated with PD-L1 expression ($r = 0.6$, $P < 0.05$). **Conclusions:** RTleads to an up-regulation of PD-L1 expression on CETCs, which could be a possible mechanism of acquired radioresistance. Combining immunomodulatory agents with radiation might have the potential to overcome this resistance and could improve clinical outcome in breast cancer.

11559 Poster Session (Board #259), Sat, 1:15 PM-4:45 PM

Breast cancer-related paraneoplastic neurologic disease. *First Author: Brittany L. Murphy, Mayo Clinic Department of Surgery and Robert D. and The Patricia E. Kern Center for the Science of Health Care Delivery, Rochester, MN*

Background: Paraneoplastic neurologic disease (PND) is an aberrant immune-mediated response against the nervous system triggered by occult malignancy. Given the rarity of this disease, a paucity of data exists describing breast cancer (BC)-related PND; thus, we sought to further examine this specific population of patients. **Methods:** Using an institution specific clinical search tool, we identified all patients at our institution from 1997-2016 with a diagnosis of BC-related PND, verified by an international expert. Retrospective review was used to record tumor and treatment factors associated with PND and BC. A descriptive analysis was performed of the characteristics associated with BC-related PND. **Results:** BC-related PND was diagnosed in 58 female patients. Average age at BC diagnosis was 54.0±10.3 years. Most had invasive cancer of Stage II or higher [Stage 0 (10.3%), I (10.3%), II (44.8%), III (13.8%), IV (6.9%), unknown (13.8%)]. Most patients were hormone receptor (HR)+ (63.8%), while 4 (6.9%) were HR-, and 17 (29.3%) were unknown. Of the 34 patients where Her2/neu (Her2) data was available, 7 (20.6%) were Her2+ and 27 (79.4%) were Her2-. The majority (62.1%) had neurological symptoms prior to BC, 5.2% were concurrent, and 32.7% developed PND after initial BC. The interquartile range for time from PND to BC diagnosis was -8.5 to 10.5 months. Of the 58 patients, 29 (50%) had autoantibodies detected: Purkinje Cell Cytoplasmic Autoantibody Type-1 (PCA-1[anti-Yo]) (10), amphiphysin-IgG (n = 9), Anti-Neuronal Nuclear Autoantibody Type-2 (ANNA-2[anti-Ri]) (n = 5), and other (n = 5). The most common syndromes were cerebellar ataxia (n = 14), myelopathy (n = 11), and myopathy (n = 11). Immunotherapy was used for PND in 53 of 58 (91.4%) patients; benefit from immunotherapy was assessed as complete 0 (0%), robust 11 (20.8%), mild to moderate 28 (52.8%), none 9 (17%), and indeterminate 5 (9.4%). **Conclusions:** BC-related PND is rare, with only 58 cases over 20 years at a large academic institution. Paraneoplastic symptoms often present prior to BC diagnosis and BC characteristics are typical of the general population. Over 75% of patients benefit from immunotherapy. These data may provide helpful information to providers treating this population of patients.

11560 Poster Session (Board #260), Sat, 1:15 PM-4:45 PM

Metabolic barriers to immunotherapy in renal cell carcinoma. *First Author: Katy Beckermann, Vanderbilt University, Nashville, TN*

Background: Cancer cells can inhibit effector T cells through both immunomodulatory receptors and alteration of the tumor microenvironment as a result of cancer metabolism. A majority of patients treated with immune checkpoint inhibitors recently approved by the FDA fail to exhibit a clinical response. The extent to which metabolic conditions within the tumor impede T cell activation and anti-tumor effector function in renal cell carcinoma (RCC) are unknown. **Methods:** Under the IACUC protocol M1600005-00, BALB/c or Rag mice were subcutaneously injected with 100,000 Renca cells obtained from ATCC and growth monitored by caliper measurements in 3 dimensions every 3 days. *In vivo*PD-1 blockade was performed by 200 mcg/i.p. injection every 3 days using purified mPD-1 (BioXcell, J43). Deidentified tissue donations from patients with RCC were collected under the IRB protocol #151549 and processed into single cell suspensions following mechanical dissociation for the functional assays indicated below. **Results:** Through work with Rag deficient mice lacking functional B and T cells, we have established that tumor growth is regulated in a T cell dependent manner as evidenced by earlier formation and faster tumor growth. In a syngeneic mouse model of RCC (RenCa), we find that inhibition of PD-1 delays tumor growth and size. Tumor infiltrating lymphocytes (TILs) were abundant in patient-derived RCC, but are phenotypically distinct and are impaired both functionally and metabolically from healthy control. Instead of efficient use of aerobic glycolysis, TILs fail to increase glucose metabolism, and instead display increased reactive oxygen species (ROS) and mitochondrial dysfunction. CD8 effector cells found in tumors have notable differences in mitochondrial morphology compared to healthy control CD8 T cells by electron microscopy and immunofluorescence where CD8 TIL are punctate and dispersed throughout the cell while healthy control CD8 mitochondria are fused in networks. Thus bypassing metabolic defects may partially restore TIL activation. **Conclusions:** Preclinical data suggests that improved understanding of metabolic dysfunction in TILs of RCC may allow for combined therapies to improve response rates of checkpoint inhibition in this disease.

Cell surface GRP78 expression on T and NK cell sub-populations of breast cancer patients. *First Author: Rinat Yerushalmi, Davidoff Cancer Center, Petah Tikva, Israel*

Background: The targeting of unfolded protein response (UPR) in tumor cells has received much attention. However, data are sparse on the impact of UPR on T and NK cells. The master regulator of UPR is the glucose-regulated protein 78 (GRP78) that is expressed in some tumor cells or normal stressed cells. There are few studies concerning GRP78 expression on T and NK cells in cancer and its relationship to stress induction by chemotherapy. We aimed to reveal the effect of UPR activation on the peripheral T and NK cells of breast cancer patients by the evaluation of cell surface GRP78 expression on T and NK cells before and after neoadjuvant chemotherapy. **Methods:** Forty-seven patients with triple negative, ER positive/Her2 negative and Her2 positive breast cancer were included. FACS analysis of their blood specimens before and after neoadjuvant treatment was performed. For multicolor FACS analysis, anti-CD3, CD4, CD8, CD56, CD16, NKG2D, CD45RA, CD45RO, CCR7 CD62L and anti-GRP78 antibody (AF488) were added to one of the tubes. A second tube was incubated with IgG-AF488 as isotype control. Analysis of the different T and NK subpopulations that expressed cell surface GRP78 were analyzed with the Gallios Flow cytometer and Kaluza Flow Analysis Software (Beckman Coulter, Inc.). **Results:** The percentage of cell surface GRP78 baseline expression in CD3 (1.8±0.9), CD8 (2.9±1.5), NKG2D (4.8±2) and CD45RO/CD62L/CCR7 active T memory cells (2.1±0.5) in Her2 positive patients were significantly higher than in triple negative and ER positive/Her2 negative patients. GRP78 expression on CD56, CD16 and NKG2D cells measured after neoadjuvant treatment was significantly higher in patients with complete response (CR) compared to patients without CR. 89% of the CR patients presented with Her2+ subtype. The non-CR patients include triple negative and Her2 negative subtypes. **Conclusions:** GRP78 was found to be expressed in the different T and NK sub-populations. The level of expression changed with each breast cancer subtype and response to chemotherapy. These novel findings suggest that GRP78 may be used as a new predictive biomarker. It sets the stage for understanding the mechanism of UPR activation on the immune system in breast cancer.

11562 Poster Session (Board #262), Sat, 1:15 PM-4:45 PM

Fatty-acid-binding proteins as a novel target for the treatment of anti-PD-1-resistant tumors. *First Author: James William Welsh, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The mechanisms underlying immunosuppression and resistance to PD1 inhibitors in cancer are not well understood. We attempted to fill this gap with an integrated transcriptome analysis in an anti-PD1-resistant lung adenocarcinoma mouse model. The model was created by in vivo passage of 344SQ murine lung cancer cells ($p53^{R172H\Delta g}/+K\text{-}ras^{LA1/+}$) in a syngeneic host repeatedly dosed with anti-mouse PD1 antibodies. Anti-PD1-resistant 344SQ (344SQ_R) and 344SQ parental (344SQ_P) cells were then inoculated into syngeneic 129Sv/ev mice, which were then dosed twice with anti-PD1 or control IgG antibodies. **Methods:** Tumor tissues were collected and analyzed as follows: transcriptome with Affymetrix; protein levels by reverse phase protein array analysis; signature enrichment by gene set enrichment analysis; metabolome by mass spectrometry; and lipid content with fluorescent probes Oil O and BODIPY. We also isolated tumor-infiltrating immune cells for flow cytometry and gene expression analyses. **Results:** We identified lipid-related metabolic pathways as being the most highly enriched in anti-PD1-resistant tumors (344SQ_R) vs. their 344SQ_P counterparts; the resistant cells also had more lipid droplets than the 344SQ_P cells. The anti-PD1-resistant tumors overexpressed several genes involved in lipogenesis and fatty acid pathways, including fatty acid binding proteins (FABPs). Specifically, FABP overexpression promoted fatty acid uptake and lipid-droplet accumulation in resistant tumors. 344SQ_R tumors promoted immune suppressive cells by upregulating FABPs expression in M2-like macrophages, marked by increased fatty acid intake and fatty acid oxidation. Conversely, percentages of CD4+ and CD8+ tumor-infiltrating lymphocytes were reduced in the resistant tumors. **Conclusions:** These results suggest that lipid metabolic rewiring drives resistance PD1 inhibitors supporting the accumulation of immunosuppressive cells, including M2-like macrophages, preventing type I immune responses elicited by T cells. Collectively, these findings reveal new potential lipid-related targets for drug development or new treatments combining inhibitors of these targets with anti-PD1 therapy.

11563 Poster Session (Board #263), Sat, 1:15 PM-4:45 PM

Combining chemotherapy and programmed death 1 (PD-1) blockade to induce a T-cell response in patients with metastatic triple negative breast cancer (mTNBC). *First Author: Elias Obeid, Fox Chase Cancer Center, Philadelphia, PA*

Background: Correlative studies to determine the effect of combining chemotherapy (CT) simultaneously with checkpoint inhibition on the peripheral immune response are planned as part of a clinical trial in MTNB. The trial design is a Safety run-in, into a randomized phase II trial of combination pembrolizumab (P) with carboplatin (C) and gemcitabine (G) in patients with mTNBC. One key concern is that CT may suppress immune cell function, thereby diminishing the efficacy of PD-1 blockade. **Methods:** Patients with a diagnosis of mTNBC are recruited to this trial with a Safety Run-in (N = 6-12 subjects), followed by a randomized design of C + G with/without P (2:1 randomization, N = 75). Safety run-in consists of P 200 mg on day 1 of each 21-day cycle, and C (AUC2) + G (800mg/m^2) on days 1 and 8. Patients are consented for a peripheral blood (PB) collection pre-cycle 1 and on day 1 of cycle 3, in order to phenotype immune system changes by flow-cytometry. **Results:** Six patients have been recruited as of this interim analysis. Data from PB analysis of 3 on-treatment patients is available. In 2 subjects, the activation marker CD69 increased on CD4+ and CD8+ T cells from baseline, indicating enhanced T cell function. Also the ratio of CD8+ T cells to regulatory T cells ($CD25^{high}$ $CD127^{low}$) has increased. Both patients expressed PD-1 on T cells at baseline. The 2 subjects with evidence for enhanced immune response have a continued clinical benefit (12 cycles subject 1, 8 cycles subject 2). In contrast, subject 3 (who discontinued P and received corticosteroids for grade a 2 immune-related hepatitis during cycle 2) lacked expression of PD-1 on T cells and did not exhibit these immune changes, and her disease clinically progressed after 4 cycles of CT. **Conclusions:** Although comprising a very limited number of patients, early analysis from our correlative studies of combining CT with the PD-1 blockade revealed evidence for effective immune stimulation in two subjects. Furthermore, immune changes accompanied a lasting clinical response. Although early, we conclude that combining CT with checkpoint blockade can achieve its goal of unleashing an anti-tumor immune response in mTNBC patients. Clinical trial information: NCT02755272.

11564 Poster Session (Board #264), Sat, 1:15 PM-4:45 PM

Genetic variants in CCL5 and CCR5 genes and serum VEGF-A levels to predict efficacy of bevacizumab in metastatic colorectal cancer patients receiving first-line chemotherapy. *First Author: Mitsukuni Suenaga, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Early VEGF-A reduction by targeting abundant VEGF-A is a potential predictive marker of bevacizumab (BV). CCL5/CCR5 axis modulates VEGF-A production via endothelial progenitor cells migration. We tested whether genetic polymorphisms in CCL5/CCR5 pathway will predict outcomes in metastatic colorectal cancer (mCRC) patients (pts) receiving BV in first-line setting. **Methods:** Genomic DNA was extracted from 215 samples of three independent cohorts: 61 pts receiving FOLFOX+BV (median age 60 yrs, median follow-up 39.2 mos); 83 pts receiving FOLFOX (median age 61 yrs, median follow-up 57.6 mos); 71 pts receiving FOLFOX/XELOX+BV as exploratory for serum biochemistry assay (median age 60 yrs, median follow-up 28.9 mos). Single nucleotide polymorphisms of genes in CCL5/CCR5 pathway were analyzed by PCR-based direct sequencing. Serum VEGF-A levels at baseline and day 14 were measured using ELISA. **Results:** In univariate analysis for the FOLFOX cohort, pts with the *CCL5* rs2280789 G/G variant or any *CCR5* rs1799988 T allele had shorter overall survival (OS) compared to the those with any A allele or the C/C variant (18.7 vs. 29.4 mos, HR 1.93, 95%CI: 1.05−3.53 P= 0.025; 22.0 vs. 31.2 mos, HR 1.74, 95% CI: 0.98-3.90, P= 0.055). The trend remained in multivariable analysis (P= 0.090 and P= 0.026). The differences were not confirmed in the FOLFOX+BV cohort. Pts with any *CCL5* rs2280789 G allele had longer progression-free survival (PFS) and OS when receiving FOLFOX+BV than FOLFOX (PFS: 19.8 vs. 11.0 mos, HR: 0.44, 95%CI: 0.25-0.78, P= 0.002; OS: 41.8 vs. 21.1 mos, HR: 0.43, 95%CI: 0.24-0.77, P= 0.002); pts carrying any *CCR5* rs1799988 T allele had longer PFS and OS (P= 0.025 and P= 0.008, respectively). No significant difference was shown in pts with either A/A or C/C variant. In the exploratory cohort, any *CCL5* rs2280789 G allele was associated with higher VEGF-A levels at baseline and greater decrease of VEGF-A levels at day 14 compared with the A/A variant. **Conclusions:** CCL5 and CCR5 impact the angiogenic environment. Our data suggest the genotypes may identify specific populations who benefit from BV-based chemotherapy in first-line treatment for mCRC.

11565 Poster Session (Board #265), Sat, 1:15 PM-4:45 PM

Algorithmic prediction of response to checkpoint inhibitors: Hyperprogressors versus responders. *First Author: Shipra Gandhi, Roswell Park Cancer Institute, Buffalo, NY*

Background: Predicting response to checkpoint inhibitors (CPIs) using biological knowledge-based decision processes with machine learning (ML) has a great potential to predict rapid progression in patients treated with checkpoint inhibitors (CPIs) (hyperprogressive disease (HPD)) as well as responders. ML models risk overfitting data and do not always evaluate the underlying biology, thus performing well in the initial training cohort but lack generalizability when extended to other cohorts. Biology-based decision may not perform as well initially due to limited understanding and a simplified rule set, but often perform equally well when extended to larger similar cohorts of patients. **Methods:** A custom NGS cancer immune gene expression assay compared 87 patients treated with CPIs classified as CR, PR, or SD versus 12 HPD. A ML-based polynomial regression model based on 54 immune-related genes combined with mutational burden was optimized for prediction of response. A biological 4-gene decision tree model was constructed independently based on ML. A second biological decision tree incorporated the weighted average relative rank of the expression of multiple genes in 4 different immune functions including immune cell infiltration, regulation, activation, and cytokine signaling. Bayesian model average (BMA) incorporated all three models' results into the final prediction. **Results:** For87 patients classified as CR, PR, or SD the PPV >96% for responders and a NPV >90% for non-responders was achieved with the regression model, however with response indeterminate for 24% of the population. While the two biological decision tree models' PPV were in the 70% range, they accurately revealed the critical genes' roles in immune response with strong literature support. BMA process integrated these three models resulted in a PPV >96% and a NPV >90% and eliminated the indeterminate group. For HPD a unique biology related to priming of short term memory T-cells was identified. **Conclusion:** Prediction of response to CPIs is best attained by combining ML with biological knowledge. Decision tree models using a large panel of immune related genes in the context of archival samples from patients treated with CPIs can be used to better understand the biology of responders versus non-responders and provides new insights into HPD.

11566 Poster Session (Board #266), Sat, 1:15 PM-4:45 PM

Computer extracted measurements of vessel tortuosity on baseline CT scans to predict response to nivolumab immunotherapy for non-small cell lung cancer. *First Author: Monica Khunger, Cleveland Clinic, Cleveland, OH*

Background: Immune-checkpoint blockade treatments, particularly drugs targeting the programmed death-1 (PD-1) receptor, demonstrate promising clinical efficacy in patients with non-small cell lung cancer (NSCLC). We sought to evaluate whether computer extracted measurements of tortuosity of vessels in lung nodules on baseline CT scans in NSCLC patients(pts) treated with a PD-1 inhibitor, nivolumab could distinguish responders and non-responders. **Methods:** A total of 61 NSCLC pts who underwent treatment with nivolumab were included in this study. Pts who did not receive nivolumab after 2 cycles due to lack of response or progression per RECIST were classified as 'non-responders', patients who had radiological response per RECIST or had clinical benefit (defined as stable disease >10 cycles) were classified as 'responders'. A total of 35 quantitative tortuosity features of the vessels associated with lung nodule were investigated. In the training cohort (N=33), the features were ranked in their ability to identify responders to nivolumab using a support vector machine (SVM) classifier. The three most informative features were then used for training the SVM, which was then validated on a cohort of N=28 pts. **Results:** The maximum curvature (*f1*), standard deviation of the torsion (*f2*) and mean curvature (*f3*) were identified as the most discriminating features. The area under Receiver operating characteristic (ROC) curve (AUC) of the SVM was 0.84 for the training and 0.72 for the validation cohort. **Conclusions:** Vessel tortuosity features were able to distinguish responders from non-responders for patients with NSCLC treated with nivolumab. Large scale multi-site validation will need to be done to establish vessel tortuosity as a predictive biomarker for immunotherapy.

AUC values of the top ranked tortuosity features on training and validation cohorts.

11567 Poster Session (Board #267), Sat, 1:15 PM-4:45 PM

Pathogenic variants in DNA damage response (DDR) genes in patients with advanced solid tumors. *First Author: Ecaterina Elena Ileana Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Deleterious mutations in DDR genes are frequently associated with response to poly(ADP-ribose) polymerase (PARP) inhibitors and platinum chemotherapy. However, much remains unknown about their association with specific molecular signaling pathways. We report the prevalence of pathogenic variants in DDR genes and their co-alteration with other somatic variants. **Methods:** Targeted exome sequencing of 201 genes was performed in 1,189 patients (pts) with advanced solid tumors enrolled in a molecular testing protocol (NCT01772771), using matched normal and tumor DNA. We assessed germline and somatic alterations in 15 cancer-related DDR genes, their co-occuring genomic alterations and the tumor mutation burden (TMB), defined as number of somatic non-synonymous mutations. **Results:** A total of 124 pathogenic or likely pathogenic variants in DDR genes were identified in 111/1189 (9%) pts with 57% of these alterations being somatic. These variants were found in the following genes: ATM 17 pts (1.4%); BAP1 5 pts (0.4%); BRCA1 18 pts (1.5%); BRCA2 17pts (1.4%); CHEK1 8 pts (0.7%); CHEK2 16 pts (1.3%); ERCC3 4 pts (0.3%); ERCC4 2 pts (0.2%); ERCC5 3 pts (0.2%); MLH1 4pts (0.3%); MSH2 8 pts (0.7%); MSH6 6 pts (0.5%); PALB2 3 pts (0.2%) and RAD51 1pt (0.1%). DDR alterations were found more frequently in the following tumor types tested: breast 14%, colorectal 12%, melanoma 8%, glioblastoma 6% and ovarian 6%. The most relevant somatic co-alterations with DDR mutations were activation of the PI3K/AKT/mTOR pathway through mutations or copy-number variations in AKT1, MTOR, NF1, PIK3CA, PIK3R1, PTEN, TSC1 and TSC2 ($p = 0.008$). Patients with deleterious variants in mismatch excision repair genes (MLH1, MSH2 or MSH6) had a significantly higher TMB than all other patients enrolled (median TMB = 62 vs 5, $p = 0.002$). Patients with somatic pathogenic DDR variants had a significantly higher TMB (median = 13) compared to patients with germline DDR variants (median = 5) ($p = 0.004$). **Conclusions:** The association of DNA repair mutations with alterations in signaling pathways provide rationale for novel therapeutic combinations. Variations in TMB based on distinct types of DDR gene alterations may have implications for immunotherapy.

11568 Poster Session (Board #268), Sat, 1:15 PM-4:45 PM

SEER study of breast cancer specific mortality (BCSM) in patients with lobular tumors treated based on recurrence score results. *First Author: Frederick L. Baehner, Genomic Health, Redwood City, CA*

Background: Linking the 21-gene assay RS result to the SEER Registries demonstrated very low 5-y BCSM with low RS and high 5-y BCSM with high RS across subgroups, such as nodal status, age, tumor size and grade (npj Breast Cancer 2016). Given the large sample size and interest in outcomes as a function of tumor characteristics, we characterized the relationship between RS results and BCSM in patients reported by SEER with lobular morphology. **Methods:** Patients with RS and lobular morphology based on the registry ICD-O-3 code 8520 were eligible if node negative (N0) or node positive up to 3 positive nodes (N+mic,1-3), HR+, HER2- negative, no prior malignancy, and diagnosed between Jan 2004 and Dec 2012. No information in SEER is available regarding lobulars, ie., trabecular, alveolar, solid and pleomorphic. 5-y BCSM was estimated using actuarial methods. **Results:** There were 6,075 eligible patients reported with lobular morphology (11% of cases). Median age was 59 years; 88%/12% were N0/N+; 31%/62%/7% grade 1/2/3; 61%/39% ≤2 cm/>2 cm. Median follow-up was 44 months. A minority (8%) had RS >25. Chemotherapy (CT) use and BCSM increased with increasing RS. In multivariable analysis in N0 disease, continuous RS result and tumor size predicted BCSM (p=0.003 and p=0.04, respectively), whereas age and tumor grade were non-significant. In multivariable analysis in N+ disease, continuous RS result alone predicted BCSM (p=0.002). **Conclusions:** In these analyses the prognosis of patients with lobular breast cancer treated based on RS results depends on both nodal status and the RS result. The 5-y BCSM for lobular breast cancer is excellent with RS of 25 or less, and increases for RS >25.

11569 Poster Session (Board #269), Sat, 1:15 PM-4:45 PM

Baseline cell-free DNA (cfDNA) and metabolic tumor volume (MTV) independently predict outcome in metastatic chemorefractory colorectal cancer (mCRC). *First Author: Erwin Woff, Nuclear Medicine Department, Institut Jules Bordet - Université Libre de Bruxelles (ULB), Brussels, Belgium*

Background: No validated prognostic biomarker is currently available for mCRC. This trial assessed cfDNA and MTV before treatment with regorafenib as prognostic biomarkers for progression-free survival (PFS) and overall survival (OS) in mCRC. **Methods:** After signed informed consent, mCRC patients were enrolled in a prospective non-randomized trial aiming to define unlikelihood to benefit from regorafenib (EudraCT number: 2012-005655-16) and assessed for cfDNA and FDG PET/CT MTV at baseline. cfDNA was extracted from 3mL of plasma and quantified using the Qubit 2.0 fluorometer. All target lesions were delineated on FDG PET/CT using a PERCIST-based threshold and their volumes were summed to obtain total MTV. MTV and cfDNA optimal cutoffs for OS and PFS prediction were determined by the Contal and O'Quigley's method. MTV, cfDNA, age, gender, Body Mass Index (low, normal, high, obese), ECOG PS, number of chemotherapy lines (NCL), previous use of bevacizumab and presence of a KRAS mutation were included in a multivariate analysis. **Results:** MTV and cfDNA of 132 evaluable/141 eligible patients were well correlated (Spearman's correlation coefficient = 0.70; $p < 0.001$) and risk groups for both PFS and OS were identified on the basis of cfDNA (cfDNA < 1 μg/mL; cfDNA≥ 1 μg/mL) and MTV (MTV < 100 cm^3; 100-300 cm^3; > 300 cm^3). The multivariate analysis retained cfDNA, MTV, NCL, and obesity as independent parameters for PFS prediction, and cfDNA, MTV, NCL, BMI, and previous use of bevacizumab as independent parameters for OS prediction. Prognostic scores for PFS and OS were developed based on regression coefficients from the final Cox proportional hazards models. Prognostic scores for PFS (1.8 vs 5.3 months, HR: 3.15 for score $\geq$-3 vs $<$ -3, (95% CI, 2.08-4.76); $p < 0.001$) and for OS (4.2 vs 13.9 months, HR: 4.59 for score $\geq$-6 vs $<$ -6: (95% CI, 2.92-7.21); $p < 0.001$) both identified patients with much contrasted outcomes. **Conclusions:** Baseline cfDNA and MTV along with BMI parameters predict outcome in patients with mCRC before regorafenib onset. These parameters not related to treatment should be considered, if validated in further studies, as stratification factors in future clinical trials. Clinical trial information: 2012-005655-16.

11570 Poster Session (Board #270), Sat, 1:15 PM-4:45 PM

FDG PET/CT and N0 mediastinal nodal status in early stage non-small cell lung cancer: A single institution retrospective experience. *First Author: Shashank Reddy Cingam, Louisiana State University Health Sciences Center, Shreveport, LA*

Background: The increasing use of CT and now low-dose screening CT scans for at-risk patients have led to increasing detection of lung cancer at early stages. FDG PET/CT is used as an adjunct to conventional imaging to assess loco-regional lymph node spread. However, there is a potential for false-negative results, especially in smaller lesions or early nodal involvement. The main objective of this study was to study the value of PET/CT scan to evaluate for true negative mediastinal nodes in patients with early stage NSCLC. Accurate determination of N0 status can have a significant impact on the cost-effectiveness and timely management of early stage NSCLC. **Methods:** Of a total of 404 patients with NSCLC managed at our facility between 2008 to 2015, 29 adult patients whose PET scan showed no or equivocal mediastinal nodal involvement and subsequently underwent surgical exploration of mediastinal lymph nodes were included in the study. Data variables that were collected included the cancer site, date of PET, node status on PET, type and date of surgery, cancer histology, and the tissue diagnosis of the sampled nodes. SAS software was used for the analysis of the data. **Results:** Of the 29 patients with N0 or equivocal nodes on FDG PET/CT, 7 (24.13%) had evidence of malignancy on biopsy of the surgically resected lymph nodes. No statistically significant differences were noted between the site of the neoplastic lesion, cancer histology, duration between the date of PET and the date of surgery in the true negative (TN) and false negative (FN) groups. The recurrence rate was higher in the FN group 60 % (3/5) compared to 21 % (4/19) in the TN group who had follow up for atleast 2 years. **Conclusions:** Our findings suggest incidence of false negative results of FDG PET/CT for evaluation of N0 nodes in early stage NSCLC is 24.13%. This is comparatively higher than false negatives rates with mediastinoscopy (5-10%) reported in other studies. Although our sample size is small, if confirmed, such a relatively high incidence of false negative results on FDG PET/CT for N0 disease supports the current recommendations for exploratory mediastinoscopy and/or surgery for definitive staging in early stage NSCLC.

11571 Poster Session (Board #271), Sat, 1:15 PM-4:45 PM

Clinical utility of molecular testing to select therapy in relapsed/refractory non-Hodgkin lymphoma: Mayo Clinic Center for Individualized Medicine experience. *First Author: Nabila Nora Bennani, Mayo Clinic, Rochester, MN*

Background: Relapsed/refractory (R/R) non-Hodgkin lymphomas (NHL) have a poor prognosis with limited treatment options. Our expanding knowledge of molecular alterations seen in R/R NHL allows identification of patients that potentially may benefit from a precision medicine approach. However, experience in routine clinical implementation of precision medicine has been limited. Here, we summarize our clinical experience in molecular characterization of RR NHL targeted therapy (TT) using next-generation sequencing (NGS), and selection of targeted therapy (TT) based on molecular profile. **Methods:** We conducted a prospective study in RR NHL through the Center for Individualized Medicine at Mayo Clinic. Consenting patients underwent NGS using FoundationOne Heme panel from biopsies done at time of relapse. Results of NGS were discussed at the Genomic Tumor Board and recommendations for TT were given based on matching specific molecular alteration(s) with potential agent(s) predicted to be active based on NGS. The agents could include FDA-approved, off-label use and clinical trial therapies. **Results:** 28 cases were enrolled: 18 aggressive NHL, 10 follicular lymphoma (FL). Molecular alterations were present in all cases. In aggressive B-cell NHL, CDKN2A/B gene cluster alterations were seen in 73% (8/11), while seen in only 1/7 T-cell lymphomas (TCL), and 1/10 FL. TP53 deletions were second most common genomic alterations in DLBCL (57%) and seen in 40% FL. JAK-STAT and ERBB pathways were altered in TCL (2/7 each). IGH-BCl-2 gene rearrangement were common in FL (70%), followed by MLL gene alterations (50%). Targetable mutations were present in 86% (24/28) of cases. A TT was recommended in all 24 cases, but received by 2 patients only. Remaining patients did not due to benefit from current therapy (10/24), ineligibility or lack of clinical trial (7/24) or interim clinical deterioration (5/24). **Conclusions:** Targetable mutations were identified in most cases of RR NHL with TT recommended for all cases. However, access to TT limits potential clinical benefit of molecular-based matching strategy. More studies are needed to assess impact on clinical outcomes.

11572 Poster Session (Board #272), Sat, 1:15 PM-4:45 PM

The use of ^{18}F-fluoroestradiol (FES) and ^{18}F-fluorodeoxyglucose (FDG) PET in the evaluation of breast cancer heterogeneity. *First Author: Lanell M Peterson, University of Washington Seattle Cancer Care Alliance, Seattle, WA*

Background: ^{18}F-Fluoroestradiol (FES) is an estrogen analogue that has been shown to be a promising biomarker in ER imaging of breast cancer. FES uptake correlates to ER expression, provides qualitative and quantitative assessment of multiple tumor sites simultaneously, and can predict response to endocrine therapies. Tumor heterogeneity is a known feature of metastatic breast cancer. Our work and others has shown that patients that have tumors with high FDG-PET SUV and low FES-PET SUV uptake have a poorer prognosis. Biopsies of metastatic disease may be done initially for diagnosis of metastatic disease, but are generally only performed in the setting of target identification for clinical trials. A change in ER or HER2 expression, however, can result in a change in therapy. FES-PET imaging offers a virtual biopsy and can reveal heterogeneity of the entire tumor burden. **Methods:** We reviewed our prior evaluations of tumor heterogeneity with FES-PET from 3 different studies. 46 breast cancer patients with metastatic disease (de novo or recurrent) who had biopsy proven ER+ primary breast cancer underwent FES-PET and FDG-PET imaging and a biopsy of a metastatic lesion prior to therapy initiation. ER and HER-2 expression was reviewed. **Results:** Of the 46 patients, 5 (11%) had ER- metastatic biopsies. One (2%) biopsy changed from ER+/HER-2 neg to ER-/HER-2+, and one (2%) biopsy changed from ER+/HER-2+ to ER+/HER-2-. All 5 patients (11%) with changes in ER/HER2 expression underwent a change in therapy due to the unexpected findings by metastatic biopsy. FDG findings helped to guide selection of biopsy sites. FES quantitative measures correlated with biopsy findings. **Conclusions:** Biopsy resulted in a change in therapy for $>$ 10 % of patients enrolled in trials of FES imaging. Imaging can help identify heterogeneous tumor locations to assist identification of evolving tumor targets in breast cancer. In addition, FES imaging may reveal a change in tumor phenotype that can ultimately affect choice of therapy. Research Support: P01CA42045, R01CA72064

11573 Poster Session (Board #273), Sat, 1:15 PM-4:45 PM

Contribution of microarrays of gene expression (MAGE) to the definition of PET/CT as a qualified biomarker of early response in metastatic patients. *First Author: Manuel Sureda, Plataforma de Oncologia, Hospital Quironsalud Torrevieja. Catedra Oncologia Multidisciplinar-UCAM, Torrevieja, Spain*

Background: Proliferating cancer cells consume elevated quantity of glucose, converted into lactate regardless the presence of oxygen (Warburg effect). This effect has been useful for imaging metabolically active tumors with FDG-PET, although its use in early response is controversial. Molecular mechanisms of FDG uptake are not fully understood. We have used MAGE to determine the most relevant genes involved in FDG uptake. **Methods:** Fresh-frozen tumor biopsies and quantitative basal FDG-PET/CT were obtained from metastatic lesions in cancer patients. Total tumor RNA was hybridized to a whole human genome oligonucleotide microarray. Gene expression signature-based prediction, using the most relevant genes involved in FDG uptake measured by SUV, was finally determined by Partial Least Squares (PLS). The interpretation of biological phenomena (IBP) derived from the selected genes was made by means of different public statistical bioinformatics resources. **Results:** 71 patients with different histological diagnosis were included in the training cohort and 13 in the validation one. 909 probes correlated significantly with SUV: 333 positively and 576 negatively. A predictive signature based on these 909 probes was built using PLS-3, with an RMSE in the validation set of 0.645 (within the 95% CI of RMSE determined in the training set). In IBP, other biological processes were more relevant than glycolysis in FDG uptake: RNA processing, ribosome biogenesis, protein processing, cell adhesion, cytoskeleton organization, angiogenesis and autophagy. **Conclusions:** This PLS-3-built signature is the first reported one that can accurately predict SUV. FDG uptake is a complex phenomenon that involves multiple biological processes, confirming the value of PET/CT in early response.

11574 Poster Session (Board #274), Sat, 1:15 PM-4:45 PM

The mutational landscape of gastrointestinal malignancies as reflected by circulating tumor DNA. *First Author: Paul Riviere, University of California San Diego Moores Cancer Center San Diego School of Medicine, La Jolla, CA*

Background: Liquid biopsy of circulating tumor DNA (ctDNA) is a novel method of detecting genetic alterations in cancer patients without tissue acquisition. **Methods:** Our analysis surveyed the genomic landscape of 213 patients with various gastrointestinal malignancies using next generation sequencing of plasma ctDNA across a 68 gene panel (www.guardanthealth.com/guardant360/). Data analysis was performed following UCSD IRB guidelines for de-identified database (NCT02478931). **Results:** The most common cancer types were colorectal adenocarcinoma (N = 55 (26%)), appendiceal adenocarcinoma (N = 46 (22%)), hepatocellular carcinoma (N = 31 (15%)), and pancreatic ductal adenocarcinoma (N = 25 (12%)). 70% of patients had discernible alteration(s), and 58% of patients had $\geq$1 characterized alterations. The median number of characterized alterations per patient was 1 (range 0-13). The number of detected alterations per patient varied between cancer types: in hepatocellular carcinoma, 74% of patients (23/31) had $>$ 1 characterized alteration(s), whereas 76% of patients (35/46) with appendiceal adenocarcinoma had no characterized alterations. Overall, of 123 patients with characterized alterations, $>$ 99% (122/123) had $\geq$1 hypothetical (experimental or approved) treatment options available. Potentially targetable alterations varied between cancer types, proportionally to the detection rate of characterized alterations. The median percent ctDNA of characterized alterations was 2.50% (IQR 0.76-8.96%). Of interest, 95% of patients (117/123) had distinct molecular portfolios. Altogether, there were 143 unique characterized alterations within 56 genes. Overall concordance rates of 96%, 94%, 95%, and 91%, respectively, were found between ctDNA and tissue biopsy (105 patients) (https://www.foundationmedicine.com/) in the four most common alterations (*KRAS* amplification, *MYC* amplification, *KRAS* G12V, and *EGFR* amplification). **Conclusions:** Our observations suggest that many patients with gastrointestinal tumors have discernible and pharmacologically tractable ctDNA alterations. Hence, ctDNA assessment through non-invasive liquid biopsy may have an important role in clinical practice.

11575 Poster Session (Board #275), Sat, 1:15 PM-4:45 PM

Targeted next-generation DNA sequencing of paired tumor and normal DNA to reveal frequent actionable germline alterations. *First Author: Wolfgang Michael Korn, University of California, San Francisco, San Francisco, CA*

Background: Targeted next-generation DNA sequencing of paired tumor and normal DNA samples allows for detection of biologically relevant variants in the tumor with significantly greater accuracy than tumor-only sequencing. In addition, this approach presents with the opportunity of unveiling previously unknown cancer predisposition traits in a patient's germline DNA. **Methods:** We sought to determine the rate of pathogenic germline alterations in 546 consecutive pediatric and adult patients who underwent molecular profiling using the UCSF 500 assay, a hybrid capture-based DNA sequencing assay targeting the coding regions of ~500 cancer-related genes, TERT promoter, select introns from 40 genes (for detection of gene fusions and other structural variants), and intergenic regions at regular intervals along each chromosome (for chromosomal copy number and LOH assessment). **Results:** Pathogenic germline alterations were found in 89/546 patients (16.3%), including 25 pediatric and 64 adult cases. Germline variants were identified in 37 genes with MUTYH (n = 15, 17%), CHEK2 (n = 10, 11%), BRCA2 (n = 9, 10%), BRCA1 (n = 5, 6%), TP53 (n = 5, 5%), and APC (n = 4, 5%) being altered most frequently. Loss of heterozygosity of genes affected in the germline was seen in tumor DNA 37 (42%) cases, highlighting their likely role as drivers of tumorigenesis. Clinically relevant germline findings not associated with increased cancer risk were identified in 6 (7%) of the cases, for example a COL1A1 mutation associated with Ehlers-Danlos Syndrome. In In 73 (82%) of the cases, pathogenic germline alterations were new findings and genetic counseling was recommended. A possible, previously unknown, role of germline mutations was found in some instances, including a TSC2 germline mutation in a patient with hybrid oncocytoma/chromophobe tumor (HOCT) with loss of the normal TSC2 allele in the tumor. **Conclusions:** Our data suggest that paired tumor/normal DNA analysis uncovers actionable heritable traits in a substantial fraction of patients and represents the preferred approach to analyzing malignancies in children and adults.

11577 Poster Session (Board #277), Sat, 1:15 PM-4:45 PM

Function and expression of checkpoint inhibitors and immune agonists on immune cells in monoclonal gammopathy of undetermined significance (MGUS), smoldering multiple myeloma (SMM) and MM and tumor-specific T lymphocytes. *First Author: Jooeun Bae, Dana-Farber Cancer Institute, Boston, MA*

Background: Characterization of expression and function of immune regulatory molecules in tumor microenvironment will provide the framework for developing novel therapeutic strategies. **Methods:** We evaluated the expression and functional impact of various immuno-regulatory molecules, PD-1, PDL-1, PDL-2, LAG3, TIM3, OX40 and GITR, on the $CD138^+$ tumor cells, myeloid derived suppressor cells (MDSC), and T cell subsets from patients with MGUS, SMM and active MM (newly diagnosed, relapsed, relapsed/refractory), and the myeloma-specific cytotoxic T lymphocytes (CTL) induced with XBP1/CD138/CS1 peptides. **Results:** PDL-1/PDL-2 was more highly expressed on $CD138^+$ myeloma cells in active MM than SMM or MGUS. G-type MDSC ($CD11b^+CD33^+HLA\text{-}DR^{low}CD15^+$). Treg cells ($CD3^+CD4^+/CD25^+FOXP3^+$) numbers were increased and expressed higher levels of PD1/PD-L1 in active MM than in MGUS, SMM or healthy donors. Among the checkpoint molecules (PD-1, PDL-1, PDL-2, LAG3, OX40, GITR) evaluated, PD-1 showed the highest expression on $CD3^+CD4^+$ and $CD3^+CD8^+$T cells in BMMC and PBMC from patients with active MM. Functionally, T cells from MM patients showed increased proliferation upon treatment with an individual immune agonist ($>$ 150%) or checkpoint inhibitor ($>$ 100%). Interestingly, each individual anti-checkpoint molecule induced proliferation of T cells expressing other checkpoint molecules. In addition, the blockade of PD1, LAG3 or TIM3 enhanced MM antigen-specific cytotoxicity, assessed by parameters including CD107a, granzyme B and IFN-g production, which was most prominent within the memory CTL subset of MM antigen-specific T cells. **Conclusions:** These results demonstrate an increased frequency of immune regulatory cells, which highly express checkpoint inhibitors in active MM. Direct stimulation with an immune agonist or blockade of a checkpoint inhibitor increased MM patients' T cell proliferation and myeloma-specific CTL function, supporting development of combination immune regulatory therapies to improve patient outcome in MM.

11578 Poster Session (Board #278), Sat, 1:15 PM-4:45 PM

Rare tumor clinic: The UCSD Moores Cancer Center experience with a precision therapy approach. *First Author: Shumei Kato, Moores Cancer Center, La Jolla, CA*

Background: Rare tumors have an incidence of < 15/100,000 per year; ultra-rare, prevalence < 2000 in the USA. Patients (pts) may lack approved treatments and clinical trial access. Although each rare tumor is uncommon, cumulatively they account for > 20% of cancers. We recently initiated a Rare Tumor Clinic that emphasized a precision medicine strategy (genomic and proteomic analysis and individualized therapy). We report our preliminary experience. **Methods:** We investigated outcome among the first 40 pts presenting to the Rare Tumor Clinic at UC San Diego Moores Center for Personalized Cancer Therapy. Whenever possible, next-generation sequencing (NGS) of tissue and plasma-derived circulating tumor DNA (ctDNA) as well as proteomic markers were assessed. **Results:** Median age was 58 (range, 31 – 78 yo); 70% (28/40) were women; median number of previous systemic therapies, 2 (range, 0-7). The most common diagnoses were sarcoma (N = 7) for solid tumors; Erdheim-Chester disease (N = 5), for hematologic malignancies. Twenty distinct diagnoses were seen. Examples of ultra-rare tumors included ameloblastoma, yolk sac liver tumor, ampullary cancer, Castleman's disease, and desmoid tumor. 82.5% of pts (33/40) had tissue NGS (182 to 405 genes); 7.5% (3/40), inadequate tissue. The median number of characterized tissue alterations was 3 (range, 0 to 24); 32 pts (80%) had ≥1 characterized genomic alteration. 33 pts (82.5%) had ctDNA analysis; 15 pts had ≥1 characterized alteration. Among those 15 pts, median number of characterized alterations was 3 (range, 1 to 14). 92.5% (37/40) of pts had ≥ 1 actionable target based on either genomic (32 pts) or proteomic markers (27 pts) (FDA-approved [mostly off-label] or investigational agent). 52.5% (21/40) received matched therapy; 52.4% (11/21) achieved SD≥6 months (N = 3)/CR (N = 2)/PR (N = 6). Matched therapy resulted in significantly longer PFS compared to last prior unmatched therapy (HR: 0.26, 95% CI: 0.10 – 0.71 [p = 0.008]). **Conclusions:** Identifying genomic and proteomic markers in pts with rare and ultra-rare tumors was feasible. When therapies were matched, > 50% of pts attained SD≥6 months/CR/PR. Further clinical investigations focusing on rare and ultra-rare tumors are urgently needed.

11579 Poster Session (Board #279), Sat, 1:15 PM-4:45 PM

Persistence of AKT1 low quiescent cancer cells after neoadjuvant chemotherapy in triple negative breast cancer patients. *First Author: Sheheryar Kairas Kabraji, Massachusetts General Hospital, Boston, MA*

Background: The mechanisms that allow triple negative breast cancer (TNBC) tumors to survive neoadjuvant chemotherapy (NACT) are incompletely understood. Evidence suggests that proliferative heterogeneity may contribute to primary chemotherapy resistance in patients with localized triple negative breast cancer. However, the detailed characterization of a drug-resistant cancer cell state in residual TNBC tissue after NACT has remained elusive. $AKT1^{low}$quiescent cancer cells (QCCs) are a quiescent, epigenetically plastic, and chemotherapy resistant subpopulation initially identified in experimental cancer models. Here, we asked whether $AKT1^{low}$ QCCs actually exist in primary tumors from patients with TNBC and persist after treatment with NACT. **Methods:** We identified QCCs in primary and metastatic human breast tumors using automated, quantitative, immunofluorescence microscopy coupled with computational and statistical analysis. We obtained pre-treatment biopsy, post-treatment mastectomy, and metastatic specimens from a retrospective cohort of TNBC patients treated with neoadjuvant chemotherapy at Massachusetts General Hospital (n = 25). Using automated quantitative immunofluorescence microscopy, QCCs were identified as AKT^{low} / $H3K9me2^{low}$ / $HES1^{high}$ cancer cells using pre-specified immunofluorescence intensity thresholds. QCCs were represented as 2D and 3D digital tumor maps and QCC percentage (QCC-P) and QCC cluster index (QCC-CI) were determined for each sample. **Results:** We found that QCCs exist as non-random and heterogeneously distributed clusters within primary tumors. In addition, these QCC clusters are enriched after treatment with multi-agent, multi-cycle, neoadjuvant chemotherapy in both residual primary tumors as well as nodal and distant metastases in patients with triple negative breast cancer. **Conclusions:** Together, these data qualify QCCs as a non-genetic mechanism of chemotherapy resistance in triple negative breast cancer patients that warrants further study.

11580 Poster Session (Board #280), Sat, 1:15 PM-4:45 PM

Clinicopathologic features of non-small cell lung cancer (NSCLC) harboring an *NTRK* gene fusion. *First Author: Anna F. Farago, Massachusetts General Hospital, Boston, MA*

Background: Gene fusions involving *NTRK1/2/3* can generate oncoproteins containing the kinase domains of TRKA/B/C, respectively. Inhibition of TRK signaling has led to dramatic responses across tumor types with *NTRK* fusions. An estimated 0.1 – 1% of NSCLCs harbor *NTRK* fusions. To date, clinical and radiographic responses to TRK inhibitors have been reported for 2 *NTRK* fusion-positive NSCLCs (Farago et al., 2015; Hong et al., 2016). Despite the potential benefit of identifying these fusions, the clinicopathologic features of *NTRK* fusion NSCLCs are not well characterized. **Methods:** Physicians across multiple institutions contributed deidentified cases to an *NTRK* fusion NSCLC database. A central pathologist (M.M.) reviewed tumor histology in cases with available tissue. **Results:** 10 NSCLC cases with *NTRK* gene fusions were identified. Of these, TRK kinase domain-containing potentially activating fusions were verified by next-generation sequencing (NGS) in 7, forming the study cohort. Fusions involved *NTRK1* (6) and *NTRK3* (1) with 6 different partners. Four (57%) patients were male. Median age at diagnosis was 47.6 years (range 27.9 – 86.0). The average smoking pack year history was 8.9 (range 0 to 30). Five (71%) presented with metastatic disease. No concurrent alterations in *KRAS*, *EGFR*, *ALK*, *ROS1*, or other known drivers were identified in the study cohort cases. On pathologic review of 4 cases, all were adenocarcinoma, including 2 invasive mucinous adenocarcinomas and 1 adenocarcinoma with neuroendocrine features. Of the 3 remaining non-study cohort cases, 1 was a non-kinase domain-containing *NTRK1* fusion with a concurrent *KRAS G12C* mutation, 1 was an *NTRK2* intragenic deletion disrupting the exon 18 3' splice site, and 1 was an *NTRK1* alteration detected by FISH but not verified by NGS and with a concurrent *HER2* L755P mutation. **Conclusions:** *NTRK* fusions occur in both men and women across wide ranges in age and smoking history. We therefore suggest that all NSCLC adenocarcinomas without other oncogenic driver alterations be screened for *NTRK* fusions. Notably, not all *NTRK* alterations are activating, requiring validation of the specific position of the fusion.

11581 Poster Session (Board #281), Sat, 1:15 PM-4:45 PM

Molecular profiling comparison of breast cancer subtypes in young women and older women. *First Author: Antoinette R. Tan, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC*

Background: Young women with breast cancer (YWBC; ≤40 years) have a more aggressive clinical course and is associated with a poorer prognosis. In this analysis, we explore molecular features in tumors of YWBC and older women with breast cancer (OWBC; ≥65 years) by subtype. **Methods:** Somatic genomic profiles of 1879 breast tumors collected from 2013-2017 were assessed retrospectively and included in a de-identified data analysis if ER, PR and HER2 (immunohistochemistry [IHC] and/or *in situ* hybridization [ISH]) were available. Testing included IHC, ISH and massively parallel sequencing assays (next-generation sequencing [NGS]) at a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). Pearson's chi-square was utilized for comparisons and significance defined as $p < 0.05$. **Results:** Frequency of subtypes in YWBC (n = 536) and OWBC (n = 1343) were 45% and 55% HR+HER2-, 38% and 36% triple-negative (TN), 7% and 5% HER2+HR-, and 10% and 4% in HER2+HR+, respectively. Specimens tested were breast (53%, 43%) and a metastatic site (43%, 57%) in YWBC and OWBC, respectively. HR+HER2- YWBC exhibited higher rates of pathogenic mutations in TP53 (34%, 24.4%; n = 748; p = 0.008), BRCA1 (9%, 4.5%; n = 503; p = 0.047), BRCA2 (14.8%, 8.4%; n = 501; p = 0.032), gene amplifications in FGF3 (26.7%, 10.4%; n = 107; p = 0.034), FGF4 (26.7%, 9.1%; n = 107; p = 0.019), FGF19 (29.6%, 11.6%; n = 96; p = 0.033), CCND1 (36.7%, 18.2%; n = 107; p = 0.042), and overexpression of EGFR (18.6%, 8%; n = 364; p = 0.004). TN YWBC had higher rates of alterations in TP53 (80.2%, 67.4%; n = 577; p = 0.002) and BRCA1 (13.3%, 5.9%, n = 375; p = 0.015). YWBC that was HER2+HR+ exhibited a higher rate of APC mutations (10%, 0%; n = 84; p = 0.03). In OWBC, there were higher rates of PD-L1 expression in HER2+HR- (22.7%, 0%; n = 70; p = 0.009) and TN (13%, 6.3%; n = 458; p = 0.035). There were also higher PIK3CA mutations in HER2+HR+ (43.4%, 18.8%; n = 101; p = 0.008) and CDH1 mutations (12.8%, 0%; n = 85; p = 0.022) in TN. **Conclusions:** There were distinct molecular aberrations and significantly different frequency of alterations in subtypes of YWBC compared to OWBC. These molecular changes may contribute to increased understanding of breast cancer tumor biology and refinement of treatment strategies in YWBC and OWBC.

11582 Poster Session (Board #282), Sat, 1:15 PM-4:45 PM

Restoration of tumor suppression in vivo by systemic delivery of chemically-modified PTEN mRNA nanoparticles. *First Author: Mohammad Ariful Islam, Center for Nanomedicine and Department of Anesthesiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: The onset and maintenance of cancer frequently involves gain of oncogenic function along with loss of tumor suppression. *PTEN* is a well-characterized tumor suppressor gene that is lost or mutated in many human cancers including ~50% of metastatic castration-resistant prostate cancer (mCRPC). Reintroduction of functional PTEN for mCRPC treatment has proven difficult. **Methods:** PTEN mRNA was synthesized by *in vitro* transcription method and modified with ARCA capping and enzymatic polyadenylation, and then substituted with Pseudo-UTP, 5'-Methyl-CTP. A robust self-assembly approach was employed to prepare PTEN mRNA nanoparticles (NPs) using cationic lipid-like compound G0-C14 and PLGA polymer coated with lipid-PEG shell. PTEN expression in tumors and PI3K-AKT pathway were confirmed by IHC and western blot, respectively. Apoptosis was checked by flow cytometry and Tunel assays. *In vivo* toxicity was studied by hematologic and histologic tests, and immune response. **Results:** We successfully restored PTEN mRNA to PTEN-null prostate cancer (PCa) cells *via* systemic delivery of mRNA NPs. These mRNA NPs are stable in serum, demonstrate minimal toxicity, and provide highly effective transfection in PCa cells (substantially higher HA-PTEN expression than plasmid PTEN transfection) and PCa xenograft tumors, leading to ~85% inhibition of tumor cell growth *in vitro* and *in vivo*. We also confirm mRNA NP-mediated systemic restoration of PTEN function in PTEN-null PCa and delineate its tumor suppression through inhibition of the PI3K-AKT pathway and enhancement of apoptosis. **Conclusions:** The work provides proof of principle for the systemic reintroduction of mRNA-based tumor suppressor genes to tumors *in vivo*. Because PTEN loss is frequent in late-stage PCa, this approach may have feasibility in this patient population. Considering the strong potential of mRNA therapy and the lack of systemic studies of *in vivo* mRNA transfection of tumors, this study sheds light on the useful application of NP-mediated mRNA delivery for validating tumor suppressors (e.g., *PTEN*) as a therapeutic target in cancer treatment where loss of a tumor suppressor contributes to the underlying genetic mechanism of cancer.

11583 Poster Session (Board #283), Sat, 1:15 PM-4:45 PM

Role of ERBB signaling in RET-rearranged lung cancer and contribution of EGFR amplification to cabozantinib resistance. *First Author: Roger Smith, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Lung cancers driven by oncogenic *RET* fusions have lower response rates to targeted monotherapy such as cabozantinib (28%) relative to response rates typically observed in *ALK*- or *ROS1*- rearranged lung adenocarcinomas (60-80%). **Methods:** To identify targetable co-dependencies or cooperating pathways for *RET* fusion-positive lung cancers, we performed high-throughput chemical and genetic screens to find FDA-approved drugs or genes that when inhibited, would synergize with cabozantinib in *RET* fusion-positive lung cancer cell lines. In addition we performed NGS of a pair of pre-treatment and post-cabozantinib progression samples. **Results:** We identified *EGFR* siRNAs and anti-EGFR drugs as synergistic with cabozantinib. Combinations of drugs that target EGFR (cetuximab, afatinib, erlotinib, gefitinib, neratinib) and RET (cabozantinib, CEP-32496, lenvatinib, vandetanib) were more effective at reducing growth of RET cell lines than any single agent *in vitro* and in xenograft models. Cabozantinib treatment of *RET* fusion-positive cell lines inhibited EGFR and RET phosphorylation, an observation not seen in *RET* wild-type cell lines. Co-immunoprecipitation studies reveal that RET and EGFR interact. Ectopic expression of *CCDC6-RET* in NIH-3T3 or human bronchial epithelial cells resulted in upregulation of multiple ERBB receptors and ligands (not seen in a *ROS1* fusion-positive cell line) and a concomitant increase in EGFR stability. Treatment with ERBB pathway ligands or overexpression of EGFR decreased sensitivity to cabozantinib in two *RET* fusion-positive cell lines. Finally, sequencing of a pair of pre-treatment and post-progression samples from a lung cancer patient treated with cabozantinib revealed acquired amplification of *EGFR* in the latter sample. **Conclusions:** Taken together, these results suggest that the tumorigenic potential of RET fusion oncogenes is dependent on deregulation of ERBB-activated pathways and that a combination of RET and EGFR drugs could be more effective in treating *RET* fusion-positive tumors. Moreover, amplification of *EGFR* is a potential driver of resistance to cabozantinib in *RET*-rearranged lung cancers.

11584 Poster Session (Board #284), Sat, 1:15 PM-4:45 PM

Alterations in the B-catenin pathway in non-small cell lung cancer to define a distinct molecular subtype with prognostic and therapeutic implications. *First Author: Saveri Bhattacharya, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: The treatment of non-small cell lung cancer (NSCLC) has been revolutionized by the development of targeted therapy for distinct molecular subsets. Activation of the β-catenin pathway is essential for colorectal carcinoma tumorigenesis and has been implicated in hepatocellular, thyroid and ovarian cancer. The β-catenin pathway is involved in the cell adhesion complex and Wnt signaling. While mutations in this pathway have been reported in NSCLC and β-catenin overexpression correlates with worse survival, its role in lung tumorigenesis is poorly understood. **Methods:** We performed targeted next generation sequencing using the Ion Torrent Hotspot Cancer Panel v.2 on tumor tissue from 244 NSCLC patients in which we have defined key demographic and clinical parameters including stage and survival. This cohort contained 91 Stage I cases with mRNA expression data using an Illumina platform. Co-occurrence of genes in the β-catenin pathway and 27 other genes in the panel were assessed by Fisher's exact test, with Benjamini-Hochberg adjustment for multiple comparisons. **Results:** Seventeen of 244 tumors had mutations in the β-catenin pathway (APC, CTNNB1, and NOTCH1): 10/170 non-squamous NSCLC (6%, 95% CI 3%-10%), and 7/70 squamous NSCLC (10%, 95% CI 5%-19%). The rate of EGFR and RB1 mutations was higher in tumors with b-catenin pathway mutation (5/17 and 2/17) than in those without (13/227 and 0/227, adjusted $p = 0.06$ for both). The presence of an APC mutation was also associated with higher mRNA expression of the pro-survival protein, BCL2 ($n = 91$; 5/41 vs. 0/50, unadjusted $p = 0.022$, adjusted $p = 0.3$). Furthermore, APC mutations were more frequently observed in tumors with higher levels of EMT markers (high VIM 8% vs. low VIM 0%, unadjusted $p = 0.16$) and EMT transcription factors (10% vs. low expression 2%, unadjusted $p = 0.16$). Finally, we observed a trend toward worse overall survival in non-squamous tumors with mutations in the β-catenin pathway ($n = 170$, log rank test $p = 0.07$). **Conclusions:** These studies suggest that tumors with b-catenin pathway alterations are defined by a more mesenchymal and potentially drug resistant subtype which portends a poor prognosis.

11585 Poster Session (Board #285), Sat, 1:15 PM-4:45 PM

Identification of novel fumarate hydratase gene alterations in prostate cancer. *First Author: Sherri Z. Millis, Foudation Medicine, Inc., Phoenix, AZ*

Background: Fumarate hydratase (FH), an enzyme involved in the Krebs cycle, plays a crucial role in the generation of energy and oxygenation of cells. Genomic alterations (GAs) of FH, a tumor suppressor gene, have been shown to cause chronic hypoxia that encourages tumor formation and have been linked to hereditary leiomyomatosis and renal cell cancer. Only few reports have associated FH mutations with other cancers, and none in prostate cancer. **Methods:** Identification of an FH V435M pathogenic alteration, which likely changes fumarate binding kinetics, in a prostate cancer patient, with negative family history for renal cancer and cutaneous leiomyomatosis, led to review of a database of 1781 prostate cancer patients, whose tissue was assayed by hybrid-capture based comprehensive genomic profiling (CGP) in the course of clinical care to evaluate genomic alterations (GA: base substitutions, indels, amplifications, copy number alterations, fusions/rearrangements) and targeted therapy opportunities. Tumor mutational burden (TMB) was calculated from a minimum of 1.11 Mb sequenced DNA and reported as mutations/Mb. **Results:** Profiling identified 49 prostate adenocarcinoma patients (3%) with FH gene alterations, 2 of which harbored the V435M GA identified in the original prostate patient. Ten of 40 alterations were H476_k477 insertions, in the C terminus domain, and 14 were amplifications. The rest were variants of unknown significance (VUS). **Conclusions:** A FH GA, known to impact other cancers, found in a prostate cancer, led to the discovery of a frequency that suggests deregulation of metabolic pathway activation may contribute to prostate cancer pathogenesis for a subset of patients. The somatic FH GA's are likely to be substantially more common than germline mutations, and identifying metabolic-enzyme mutations that are pathogenic in prostate cancer could lead to pharmacologic manipulations that are more effective and less toxic than existing therapies. No FDA approved therapies currently exist for this patient's tumor type nor of any other tumor type with FH GA's. In our case, alterations in the C-terminal binding domain of FH might inform drug development.

11586 Poster Session (Board #286), Sat, 1:15 PM-4:45 PM

Induction of a BRCAness state by oncometabolites and exploitation by PARP inhibitors. *First Author: Ranjit Bindra, Department of Therapeutic Radiology, Yale School of Medicine, New Haven, CT*

Background: 2-Hydroxyglutarate (2HG) exists as two enantiomers, R-2HG and S-2HG, and both are implicated in tumor progression via their inhibitory effects on α-ketoglutarate (aKG)-dependent dioxygenases. The former is an oncometabolite induced by isocitrate dehydrogenase-1 and -2 (IDH1/2) mutations, while the latter is produced under pathologic processes such as hypoxia. Recurring IDH1/2 mutations were first identified in gliomas and acute myeloid leukemia (AML). **Methods:** Our group recently reported that IDH1/2 mutations induce a homologous recombination (HR) defect which renders tumor cells exquisitely sensitive to Poly (ADP-Ribose) polymerase (PARP) inhibitors. Remarkably, this "BRCAness" phenotype can be completely reversed by mutant IDH1/2 inhibitors, and it can be entirely recapitulated by treatment with either 2HG enantiomer in cells with intact IDH1/2. We performed a comprehensive series of studies that directly implicate two aKG-dependent dioxygenases, KDM4A and KDM4B, as key mediators of the observed phenotype. **Results:** Using the methodology and preliminary data obtained above as a basis for further inquiry, here we have extended these findings to several related gene mutations, which similarly induce profound synthetic lethality with PARP inhibitors in these tumors, and our data suggest a similar mechanism of action via which HR is suppressed. Finally, we provide additional evidence that suppression of 2HG production with small molecule inhibitors of mutant IDH1/2 function does not lead to any detectable decreases in cell growth or viability in several unique models. **Conclusions:** Small molecule inhibition of oncogenic kinases is a pillar of precision medicine in modern oncology, and this approach has been extrapolated to treat IDH1/2-mutant and other oncometabolite-producing cancers with inhibitors blocking the neomorphic activity of the mutant proteins. The findings present here directly challenge this therapeutic strategy, and they instead provide a novel approach to treat these tumors with DNA repair inhibitors. Based on these findings, we are planning a multi-center Phase II trial testing the efficacy of olaparib for the treatment of recurrent IDH1/2-mutant tumors later this year.

11587 Poster Session (Board #287), Sat, 1:15 PM-4:45 PM

Impact and correlation of mutational load (ML) and specific mutations (mts) assessed by limited targeted profiling (LTP) with PD-L1 tumour expression (exp) in resected non-small cell lung carcinoma (NSCLC). *First Author: Jane Sze Yin Sui, Department of Medical Oncology, St. James's Hospital, Dublin, Ireland*

Background: The advent of immunotherapy represents a paradigm shift in the treatment of NSCLC compared to conventional chemotherapy. Recent studies have shown higher mts burden assessed by exome sequencing are associated with improved objective response and clinical benefit. We performed this study to evaluate the impact of ML assessment by LTP, correlating with PD-L1 exp and clinicopathological variables in resected NSCLC. **Methods:** NSCLC patients (pts) who underwent curative resection between 1998 and 2006 at our institution were included. PD-L1 status was assessed using Ventana SP124 antibody on archival FFPE surgical tumour specimens cores. PD-L1 was scored positive if membranous staining was present in >1% of tumour cells aggregated across the replicate cores to address heterogeneity. In collaboration with the Lung Cancer Genomics Ireland Study a targeted panel of 49 genes were assessed by Sequenom MassArray including genes in MAPK and PI3K pathways. Clinical data was obtained from hospital electronic database. **Results:** Ninety-one pts were included, of which 51 (56.0%) were males, with a median age of 65 years (range: 42 – 82). 51.6%, n=47 with squamous histological subtypes, 46.2%, n=42 were ex-smoker and 49.5%, n=45 had Stage I disease. 23.1%, n=21 had PD-L1 positivity. 149 mts were identified of which, 32(21.5%) with PHLPP2, 31(20.9%) with PIK3R1 and 21(14.1%) with TP53. The presence of PI3K and TP53 mts are associated with positive PD-L1 status (see table). An inverse correlation of PD-L1 positivity with ML of (1 vs 2 vs 3: 53.8% vs 30.8% vs 15.4%) was noted. **Conclusions:** We did not identify higher PD-L1 exp with higher ML assessed by a LTP widely used in clincial practice. However, positive PD-L1 exp was correlated with PIK3R1 and TP53 mts , warranting further investigation as potential modulators or surrogates of positve PD-L1 expression.

PD-L1 exp with driver mts.

Mts	PD-L1 positive, n=21	PD-L1 negative, n=70
TP53	29%	14%

11588 Poster Session (Board #288), Sat, 1:15 PM-4:45 PM

Antitumor activity of indenoisoquinoline inhibitors of topoisomerase 1 (TOP1) via apoptosis and autophagocytosis pathways in animal models. *First Author: Robert J. Kinders, Clinical Biomarkers Program, Laboratory of Human Toxicology and Pharmacology, Applied/Developmental Directorate, Leidos Biomedical Research, Inc., Frederick, MD*

Background: We performed pharmacodynamic biomarker analysis for response to a panel of three indenoisoquinolines (LMP776, LMP400 and NSC706744, J. Med. Chem. 49:7740, 2006) that have demonstrated antitumor activity in dogs. In preclinical xenograft models treated with indenoisoquinolines, we observed that gH2AX was not a useful biomarker for the biological activity of compound 706744, but was a reasonable biomarker of drug activity (Clin. Canc. Res. 16:5447, 2010) for the other two compounds, even though *in vitro* data indicated that all 3 compounds inhibited TOP1 and killed tumor cells. It has been reported that irinotecan activates autophagy (Pharm. Rev. 65:1162, 2013) which correlated with its metabolism to SN-38; we therefore developed, validated and tested an immunofluorescence microscopy assay for LC3 as a marker of autophagy. **Methods:** Assays were developed to evaluate apoptosis by co-localization of cleaved caspase 3 and gH2Ax, and autophagy by LC3 immunofluorescence on formalin fixed, paraffin-embedded tissue sections of xenografts models or lymphomas from outbred dogs. Percent positive cells containing LC3 puncta were quantitated using a spot morphology algorithm. Analysis of gH2AX and cleaved caspase 3 cellular co-localization was developed using a blebbing morphology algorithm (Definiens). **Results:** LC3 reported that indenoisoquinoline 706744 activates autophagy *in vitro* with the absence of cleaved caspase 3-dependent apoptosis while the -776 and -400 compounds do not activate autophagy, but instead demonstrate apoptosis in response to drug treatment. Results in animal models confirmed that both autophagy and apoptosis were active. Clinical readiness of the assays was confirmed on canine biopsy FFPE slides. **Conclusions:** 1,Structurally-related TOP1 inhibitors may trigger alternative pathways of cell destruction; 2,Autophagy may report drug anti-tumor activity or tumor drug resistance according to current literature. This assay may be useful for determination of pharmacodynamic pathways associated with anti-tumor activity to elucidate mechanism of action of investigational agents used in clinical trials.

11589 Poster Session (Board #289), Sat, 1:15 PM-4:45 PM

Validation of an expanded neoantigen identification platform for therapeutic and diagnostic use in immuno-oncology. *First Author: Sean Michael Boyle, Personalis, Inc., Menlo Park, CA*

Background: Neoantigen identification is increasingly critical for clinical immuno-oncology applications including predicting immunotherapy response and neoantigen-based personalized cancer vaccines. Although standard research pipelines have been developed to aid neoantigen identification, building a robust, validated neoantigen identification platform suitable for clinical applications has been challenging due to the complex processes involved. **Methods:** To improve neoantigen identification, we extended standard sequencing and informatics methods. We developed an augmented and content enhanced (ACE) exome sequenced at 200X to increase sensitivity to SNPs and indels used for neoantigen identification as well as HLA performance. To accurately identify fusions and variants from RNA, we optimized our ACE transcriptome for FFPE tissue. To improve neoantigen pipelines based on MHC binding algorithms, we developed peptide phasing, high accuracy HLA typing, TCR interaction predictors, and transcript isoform estimation tools to detect neoantigens from indel and fusion events. We performed comprehensive analytical validation of the platform including the ACE Exome, somatic SNV/indel calls, RNA based variant and fusion calls, and HLA typing. This was followed by an overall in silico validation of neoantigen identification using 23 experimentally validated immunogenic neoepitopes spiked into exome data. **Results:** Analytical validation of our ACE exome platform showed > 97% sensitivity for small variants with a specificity of > 98% at minor allele frequency > 10%. From the ACE transcriptome we achieved a fusion sensitivity of > 99% and RNA based variant calls sensitivity of > 97%. Our ACE exome based HLA typing was 98% and 95% concordant with Class I and II HLA results (respectively) from clinical testing. Our in silico validation of neoantigen predictions resulted in identification of 22 out of 23 immunogenic neoepitopes. **Conclusions:** We developed sequencing and informatics improvements to standard approaches that can enhance neoantigen identification and demonstrated a comprehensive validation approach that may support neoantigen use in future clinical settings.

11590 Poster Session (Board #290), Sat, 1:15 PM-4:45 PM

Characterisation of CCS1477: A novel small molecule inhibitor of p300/CBP for the treatment of castration resistant prostate cancer. *First Author: Neil Pegg, CellCentric Ltd, Cambridge, United Kingdom*

Background: Targeted degradation of androgen receptor (AR) and AR variants (ARV) remains an attractive therapeutic opportunity for patients with castrate resistant prostate cancer (CRPC). E1A binding protein (p300) and CREB binding protein (CBP) are two closely related transcriptional activators of AR. We have developed CCS1477 which is a potent, selective and orally active small molecule inhibitor of the bromodomain of p300/CBP and investigated its role in regulating androgen receptor expression and function. **Methods:** Binding of CCS1477 to p300, CBP and BRD4, was measured in a surface plasmon resonance (SPR) assay. Potency and functional activity (proliferation and biomarker knockdown) was demonstrated in prostate cell lines *in vitro* (22Rv1, VCaP). Cross species *in vivo* pharmacokinetic (PK) properties were assessed, and *in vivo* efficacy, linked to inhibition of biomarkers, was determined in 22Rv1 and LNCaP xenograft models. **Results:** CCS1477 binds to p300 and CBP with high affinity (Kd = 1.3/1.7nM) and selectivity (Kd = 222nM; BRD4). It is a potent inhibitor of cell proliferation in prostate cell lines (IC50 = 96nM,22Rv1; 49nM,VCaP) with minimal effect in AR-ve lines. In 22Rv1 cells, p300/CBP inhibition down-regulates AR-FL, AR-V7 and c-Myc protein by Western, an effect not seen with the BET inhibitor, JQ1 at equivalent proliferation IC50s. Inhibition of p300/CBP also reduces c-Myc, KLK3 and TMPRSS2 gene expression (qPCR) in 22Rv1 cells *in vitro*. The *in vivo* PK properties of CCS1477 are consistent with qd or qod oral dosing in mouse. CCS1477 dosed at 10mg, 20mg/kg qd or 30mg/kg qod, caused complete tumour growth inhibition over 28 days in a 22RV1 xenograft model, including extended duration in the absence of the drug for a further 24 days. This was accompanied by complete inhibition of plasma PSA and significant knockdown of tumour AR-FL, AR-V7, and C-Myc protein as well as C-Myc and TMPRSS2 mRNA expression. **Conclusions:** Taken together these data support the clinical testing of CCS1477 in castrate resistant prostate cancer by down-regulation of AR, AR-SV and c-MYC expression and function.

11591 Poster Session (Board #291), Sat, 1:15 PM-4:45 PM

Co-amplification of *MET* and *PIK3CA* in NSCLC and data on a PDX mouse model. *First Author: Jin Kang, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Amplification of the mesenchymal-epithelial transition (*MET*) proto-oncogene or phosphatidylinositol3-kinase (*PI3K*) is common in non-small-cell lung cancer (NSCLC) and represents a potential therapeutic target. NSCLC with coexisting driver mutations or amplifications is a cause of great concern. **Methods:** From 2013 until now, fluorescence in situ hybridization was used to screen for *MET* amplified NSCLC patients.The amplification of the *MET* was defined as centromere 7 ratio $\geq$ 2.0 and the criterion of Cappuzzi. The amplification of the *PIK3CA* was copy numbers $\geq$ 4.0. We established the patient-derived exnograft (PDX) mouse model from a dual *MET/PIK3CA*-amplified patient. Preclinical efficacy of single versus dual inhibition was evaluated in vivo. Six groups were allocated to receive the treatment of vehicle control, bozitinib,crizotinib, taselisib (PI3K inhibitor), bozitinib+taselisib, or crizotinib+taselisib, respectively. **Results:** Totally, 568 (568/2321, 24.47%) patients harbored positive *MET* amplification and 6 (6/568,1%) were comfirmed with dual *MET/PI3K* amplification. The two stageIV patients received *MET* inhibitor treatment.One trial (NCT02896231) patient was treated with bozitinib and achieved confirmed PR, but with 3 months PFS and 5 months OS. The best response was PR and PFS was 5.6 months for the other one receiving the study drug capmatinib (NCT02276027). In the PDX mouse model experiment, we found three single-anget inhibitors monotherapy to be active but only transiently effective in controlling the growth of PDX. The PDX models showed more sensitivity to taselisib among the three single-anget groups. In contrast, the combination of the two inhibitors caused a stronger and long-lasting growth inhibition in PDX models. The addition of taselisib to bozitinib or crizotinib monotherapy provided obvious enhanced activity. Regretfully, two mice died because of the toxicities in the crizotinib+taselisib group. **Conclusions:** Patients with dual *MET/PIK3CA* amplification represent a rare molecular subtype of NSCLC and have a relatively short duration of response to *MET* inhibitors.The combination of *MET/PI3K* inhibitors is synergistic preclinically.

11592 Poster Session (Board #292), Sat, 1:15 PM-4:45 PM

Phosphopeptide mapping of DLC1 in ER+ breast cancer reveals AMOTL2, a key hippo pathway component, as an important target. *First Author: Yesim Gokmen-Polar, Indiana University School of Medicine, Indianapolis, IN*

Background: Metastases suppressor genes are believed to control tumor progression and metastases. Deleted in Liver Cancer 1 (DLC1) acts as a gatekeeper for tumor and metastasis suppression. Low expression of DLC1 correlates with poor prognosis in patients with ER+ breast cancer. It is essential to understand the impact of DLC1 and its functional network in preventing tumor and metastasis suppression. **Methods:** T47D cells with stable DLC1-Full-Length (DLC1-FL) were generated using mammalian expression cloning vector, pcDNA3.1+/C-(K)-DYK, and CloneEZ™ technology. Growth rate of control and DLC1-FL knock-in cells was assessed for 2 weeks using clonogenic assay. Proteomic and phosphopeptide enrichment assays (Pierce TiO2 enrichment kit) were performed in triplicates to examine the basis of altered growth phenotype. The PeakJuggler node in Proteome Discoverer was utilized for label-free quantitation of both protein and peptide MS peak areas. In addition, GO term enrichment analysis was performed in DAVID for the significantly changed phosphopeptides. **Results:** Stable knock-in of T47D-DLC1-FL inhibits cell growth significantly in vitro compared to T47D-control in clonogenic assay. The phosphopeptide enrichment proteomic analyses showed 199 phosphopeptides were identified only in T47D-DLC1-FL and 182 peptides were identified only in T47D-control cells. Pathway analysis using DAVID showed 3 main clusters of significantly differently identified phosphopeptides (p-values $\leq$ 0.01) involving cadherin binding (p = 4.9e-12), cell-cell adherens junction (p = 3.9e-10), and cell-cell adhesion (p = 9.4e-7). Analysis of specific phosphopeptides showed canonical pathways such as CTNNB1 (Thr552), and BCL2L13 (370-385). More importantly, phosphorylation of HIPPO-pathway component AMOTL2 at S766, critical for promoting YAP signaling and invasion was only identified in T47D-control but not T47D-DLC1-FL (p = 5.78e-5). **Conclusions:** This data suggest that the absence of DLC1 promotes phosphorylation of AMOTL2, and thereby activating YAP-TAZ signaling leading to invasiveness. This data provides mechanistic basis for targeting this pathway to prevent recurrence in ER+ breast cancer.

11593 Poster Session (Board #293), Sat, 1:15 PM-4:45 PM

Genomic alterations in 670 patients with diverse cancers analyzed by next-generation sequencing (NGS) of circulating tumor DNA (ctDNA). *First Author: Maria Clemence Schwaederle, Center for Personalized Cancer Therapy and Division of Hematology and Oncology, UCSD Moores Cancer Center, La Jolla, CA*

Background: NGS of blood-derived ctDNA allows non-invasive tumor profiling. Liquid biopsy studies with clinical correlation have so far been mainly limited to small size cohorts. **Methods:** We performed comprehensive plasma genomic testing of ctDNA (NGS) in 670 patients (pts) (54-70 genes); Guardant Health, Inc.; (Clinical Laboratory Improvement Amendment certified and College of American Pathologists accredited). **Results:** The most represented cancers were gastrointestinal (31.8%), brain (22.7%), and lung (20.7%) (Table). Sixty-three percent of pts (N = 423) had $\geq$1 alteration. The most frequent alterations (characterized and variants of unknown significance (VUSs)) were in *TP53* (32.5% of pts), followed by *EGFR* (13%), *KRAS* (12.5%), and *PIK3CA* (9.1%); for characterized alterations, the breakdown was 30.7% (*TP53*), 7.6% (*EGFR*), 12.2% (*KRAS*), and 7.7% (*PIK3CA*). Interestingly, 32% of brain tumors had $\geq$1 ctDNA alteration. Head and neck tumors were independently associated with a higher number of alterations (P=0.019). Forty-eight percent of pts (320/670) had potentially actionable alterations; in 241, (75% of 320), by an FDA-approved drug (mostly off label). Illustrative examples of clinical utility will be presented such as a patient with gastric cancer and *EGFR*amplification in ctDNA who received anti-EGFR treatment (60% regression), as well a patient with aggressive gynecologic malignancy who received immunotherapy based on a hypermutated ctDNA profile. **Conclusions:** Most pts, including a subset of those with brain tumors, demonstrated ctDNA alterations. Pts with head and neck tumors harbored higher numbers of alterations. Overall, three quarters of pts with alteration(s) had $\geq$1 aberration that could potentially be pharmacologically tractable, suggesting the need to further assess the utility of ctDNA in a therapeutic setting.

Characteristics	Total patients, N = 670
Turn over time (median, 95%CI; range)	15 days (15-16 ; 7-35)
Common Tumors	
Gastrointestinal	213 (31.8%)
Brain	152 (22.7%)
Lung	139 (20.7%)
Breast	55 (8.2%)
Head and neck	25 (3.7%)
No. of pts with ≥ 1 alteration*	423 (63.1%)
Median No. of alterations (range) *	1 (0-26)

*Characterized alterations and VUSs

11594 Poster Session (Board #294), Sat, 1:15 PM-4:45 PM

ABCG2 and TOP-1 mRNA expression as predictive biomarkers for adjuvant FOLFIRI treatment in stage III colon cancer patients: Results from the PETAAC-3 prospective randomized clinical trial. *First Author: Nils Brunner, University of Copenhagen, Frederiksberg, Denmark*

Background: FOLFIRI as adjuvant treatment in primary colon cancer was previously tested in two pivotal prospective randomized clinical trials (PETACC-3 and CALGB 89803), both of which failed to demonstrate significant beneficial effects when adding irinotecan to 5FU. As a consequence, FOLFIRI is presently not used as adjuvant treatment for colon cancer. **Methods:** The study included 580 patients with mRNA expression data performed on tumor samples (FFPE) from stage III colon cancer patients enrolled in the PETACC-3 study, which randomized the patients to 5FU plus Leucovorin +/- irinotecan. Primary end-points were recurrence-free survival (RFS) and overall survival (OS). Median ABCG2 and the 75 percentile TOP-1 mRNA expression data were used to allocate the patients into one of two groups: One with high ABCG2 expression (above median) and low TOP-1 expression (below 75 percentile) (n = 167) and another group including all other combinations of these two genes. Kaplan Meier curves and Cox proportional hazards model were used to visualize differences between groups and calculate p-values (log-rank test). **Results:** The survival statistics showed a significant difference for both RFS (HR: 0.63 (0.44-0.92); p = 0.017) and OS (HR: 0.6 (0.39-0.93); p = 0.021) between the two groups when the patients received FOLFIRI. In contrast, no significant differences were observed between the groups when patients received 5FU and Leucovorin alone (p-values: RFS: 0.58; OS: 0.75). **Conclusions:** We here show that the combination of two independent gene expression abundance with a strong association to irinotecan treatment (high ABCG2 drug efflux pump and low TOP-1, the latter being the target for irinotecan) identified a group of stage III colon cancer patients who will not benefit from FOLFIRI adjuvant treatment while patients with other combinations of expression of these two genes appear to significantly benefit from adjuvant FOLFIRI treatment. The lack of a similar effect in patients receiving treatment with 5FU and Leucovorin only, points to a predictive value of ABCG2 and TOP-1 measurements.

11595 Poster Session (Board #295), Sat, 1:15 PM-4:45 PM

Occurrence of ALK fusions in cancers other than non-small cell lung cancer in a wide variety of tumor types and response to anti-ALK targeted therapy. *First Author: Jeffrey S. Ross, Albany Medical College, Albany, NY*

Background: Genomic fusions of the anaplastic lymphoma kinase gene (*ALK*) are an established therapy target for patients with non-small cell lung cancer (NSCLC), but are not well-characterized in non-NSCLC malignancies. **Methods:** Comprehensive genomic profiling (CGP) of 92,784 clinically advanced malignancies was performed using a hybrid-capture, adaptor ligation based NGS assay to a mean coverage depth of >600X. Tumor mutational burden (TMB) was calculated from a minimum of 1.1 Mb of sequenced DNA. **Results:** 17,127/92,784 (18.5%) were NSCLC and 75,657 (81.5%) were non-NSCLC. Of the 697 (0.8%) of cases with *ALK* fusions, 554 (79%) were identified in NSCLC and 143 (21%) in non-NSCLC including 67 carcinomas; 39 sarcomas including 30 non-uterine and uterine leiomyosarcomas and inflammatory myofibroblastic tumors; 24 in hematolymphoid malignancies including non-Hodgkins lymphomas, myelomas and histiocytic malignancies; 3 in gliomas; 2 each in mesotheliomas, neuroblastomas and undifferentiated malignancies and 1 in melanoma. *ALK* fusions were significantly more frequently identified in NSCLC (3.2%) than in non-NSCLC ($p<0.0001$). The non-NSCLC *ALK* fusion positive patients were significantly older ($p<0.0001$) and more often female ($p<0.0001$) than the NSCLC *ALK* fusion positive patients. At 84%, the more frequent finding of *EML4* as the fusion partner in the NSCLC patients versus non-NSCLC patients at 31% was significant ($p<0.0001$). *ALK* fusion positive non-NSCLC had significantly lower TMB (mean 5.01 mutations/Mb) than non-*ALK* altered non-NSCLC (p=0.006). Non-NSCLC *ALK*fusion positive cases responding to ALK inhibitors will be presented. **Conclusions:** In non-NSCLC patients *ALK* fusions are rare and found in both epithelial and mesenchymal malignancies. Initial evidence strongly suggests that anti-ALK therapies can be effective in *ALK* fusion driven non-NSCLC .

11596 Poster Session (Board #296), Sat, 1:15 PM-4:45 PM

Rates of PD-L1 expression testing in U.S. community-based oncology practices (USCPs) for patients with metastatic non-small cell lung cancer (mNSCLC) receiving nivolumab (N) or pembrolizumab (P). *First Author: Sean Khozin, U.S. Food and Drug Administration, Silver Spring, MD*

Background: FDA approved N for previously treated squamous mNSCLC in 3/2015 and non-squamous mNSCLC in 10/2015 regardless of PD-L1 expression. P was approved for previously treated mNSCLC in 10/2015 for patients whose tumors express PD-L1 as determined by an FDA-approved companion diagnostic (CoDx). Post-FDA approval treatment patterns of N and P, including PD-L1 testing patterns, remain unclear. **Methods:** We conducted a retrospective analysis using de-identified patient-level electronic health record (EHR) data aggregated from USCPs by Flatiron Health in accordance to an institutional review board approved protocol. Data was abstracted using both structured and unstructured EHR content with 10% duplicate abstraction to confirm data quality. All patients in the database with clinically-confirmed mNSCLC diagnosed from 1/1/11 to 3/31/16 and documented order or administration of N or P were included in the analyses. PD-L1 expression testing results were abstracted from unstructured data in EHR documents. **Results:** Within the first year of FDA approval, 1,362 mNSCLC patients received N or P (96.2% N; 3.3% P, 0.5% N+P). The median duration of treatment was 113 days. Overall, 11.3% of patients were tested for PD-L1 expression, 42.2% of whom tested positive. PD-L1 expression testing increased quarterly (Q) from 3.0% in Q2 2015 to 12.8% in Q1 2016. An FDA-approved CoDx was used 30.5% of the time. Among patients who received N, 90.5% were not tested for PD-L1 expression, 3.2% tested positive, and 4.7% tested negative for PD-L1. Among patients who received P, 32.7% were not tested for PD-L1 expression, 50.0% tested positive, and 1.9% tested negative. **Conclusions:** We observed low rates of PD-L1 expression testing in USCPs for patients with mNSCLC receiving N or P. Testing rates increased quarterly following FDA-approval. The majority of patients were not tested using FDA-approved CoDx. Most patients who were not tested for PD-L1 expression or tested negative received N. Clinician education will be important as data on optimal PD-L1 testing strategies guiding immunotherapy treatment decisions accumulates.

11597 Poster Session (Board #297), Sat, 1:15 PM-4:45 PM

Programmed cell death ligands expression in pheochromocytomas (PCC) and paragangliomas (PGL): Relationship with the hypoxic response and malignant behaviour. *First Author: David James Pinato, Imperial College London, London, United Kingdom*

Background: The hypoxic response underlies the pathogenesis and malignant behaviour of PCC/PGL. Regulation of PD-1 receptor-ligand signalling, a therapeutically actionable driver of the anti-tumour immune response, is a hypoxic-driven trait across malignancies. We evaluated the prognostic role of PD ligands in association with biomarkers of hypoxia and angiogenesis in patients with PCC/PGL. **Methods:** Tissue microarrays sections including consecutive cases of PCC/PGL diagnosed between 1983-2011 were stained for PD-L1 & 2, Ki-67, hypoxia inducible factor 1a (Hif-1a), Carbonic Anhydrase IX (CaIX), Vascular Endothelial Growth Factor-A (VEGF-A). Candidate biomarkers were assessed for correlation with clinical variables including overall survival. **Results:** In total, 100 patients, 10% malignant, 64% PCC, 29% familial with a median tumour size of 4.7 cm (range 1-14) were included. Median follow-up was 4.7 years. PD-L1 expression was observed in 18% of cases and was independent of adverse pathological features including capsular (CI), vascular invasion (VI), necrosis (N) and expression of biomarkers of hypoxia. We observed a trend towards association with malignancy ($p = 0.08$). PD-L2 expression was found in 16% of tumors. PD-L2 overexpression strongly correlated with CI, VI, N ($p < 0.01$) and malignant behaviour ($p = 0.009$) and was associated with stronger Hif-1a and CaIX immunolabeling ($p < 0.01$). PD-L2 but not PD-L1 expression was predictive of shorter survival (162 versus 309 months, HR 3.1 95%CI 1.1-9.2, Log-rank $p = 0.03$). Gene set enrichment analysis on the TGCA PCC/PGL RNA-seq dataset (n = 184) revealed a positive correlation between PD-L2 and a number of transcripts involved in angiogenesis and immunity including Interleukin-6 (Pearson R = 0.57) and CD-8a (R = 0.56). **Conclusions:** We report for the first time PD-1 ligands expression in PCC/PGL with a distinctive prognostic and clinicopathologic role. These findings support a potential therapeutic role for PD-1/PD-L1 targeted checkpoint inhibitors in these tumors.

11598 Poster Session (Board #298), Sat, 1:15 PM-4:45 PM

Association of MLL2 mutation positive non-small cell lung cancer with prognosis. *First Author: Fatemeh Ardeshir-Larijani, University Hospitals Cleveland Medical Center, Case Western Reserve University, Cleveland, OH*

Background: Myeloid/lymphoid or mixed-lineage leukemia protein 2 (MLL2) is an epigenetic regulator expressed in many tissues. Although MLL2 mutations are associated with poor prognosis in different types of cancer, the clinical impact of this gene in lung cancer remains unclear. Here, we evaluated the clinical and genomic characteristics of MLL2 alteration in non-small cell lung cancer (NSCLC) and compared it to small cell lung cancer (SCLC) **Methods:** Between 2014 and 2016 tumor samples of 194 Stage III and IV NSCLC patients and 50 SCLC patients underwent targeted-exome sequencing. The association of MLL2 mutation with survival outcomes was measured using KaplanMeier methods (PFS, OS). Cox s proportional hazards regression model was performed for multivariate survival analyses with known clinical prognostic features. All tests were two-sided and p-values = 0.05 were considered statistically significant. **Results:** The MLL2 mutation rate was 17.5% (N=34) in NSCLC. Patients with mutant MLL2 had significantly lower overall survival (OS) (9.97 vs. 30.2 months, $p < 0.0001$) and progression-free survival (PFS) (8.46 vs. 24.1 month, $p = 0.0007$) compared to those with wild type MLL2. The median overall survival in the entire NSCLC cohort was 23.3 months (95% CI: 16.5 34.4). Interestingly, MLL2 mutation was significantly more common in females ($p = 0.017$). There was no significant association of MLL2 mutation status with age, smoking history, race or histology . Using a multivariate Cox regression model with adjustments based on tumor stage, smoking histology and chemotherapy, MLL2 mutation remained the most remarkable prognostic factor in NSCLC: OS Hazard Ratio 2.79, $p = 0.0001$ and PFS Hazard Ratio 1.99, $p < 0.001$. By comparison, the MLL2 mutation rate in SCLC was 24% (N=12) and showed no gender bias (p=0.874). There was no significant decrease in survival associated with MLL2 mutation in SCLC (OS $p = 0.966$, PFS $p = 0.641$). **Conclusions:** This study demonstrates that MLL2 mutation specifically impacts survival outcome only in NSCLC but not SCLC.

11599 Poster Session (Board #299), Sat, 1:15 PM-4:45 PM

Survival profile in breast cancer molecular subtypes without systemic and locoregional treatment. *First Author: Sherry X. Yang, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: It is unclear whether survival varies among breast cancer molecular subtypes without systemic and locoregional therapy. This study aims to evaluate the survival profile by molecular subtypes after surgery. **Methods:** In total, we evaluated 301 women with invasive breast cancer with stage I, II or III disease. Patients were classified into four major breast cancer subtypes by immunohistochemistry/FISH classifiers: luminal-A (ER+ and/or PR+/HER2-), luminal-B (ER+ and/or PR+/HER2+), HER2-enriched (HER2+/ER-/PR-) or basal-like (ER-/PR-/HER2-; triple-negative). Overall survival (OS) was analyzed by Kaplan-Meier analysis, and log-rank test for differences. Association between clinical outcome and subtype adjusting for breast cancer prognostic factors was assessed by multivariable Cox proportional hazards model. **Results:** All patients did not receive systemic chemotherapy and hormone therapy as well as radiation therapy. Luminal A was the most common subtype (N = 224), followed by basal-like (N = 43), luminal B (N = 21) and HER2-enriched (N = 13). Median follow-up for OS was 197 months (range: 1 – 273 months). Age at diagnosis was statistically different among the subtypes, with basal-like and luminal B having high proportions less than 50 years ($P = 0.047$). Patients with basal-like and HER2-enriched had more high grade tumors ($P < 0.001$). Notably, there was no difference in OS among the four subtypes (log-rank $P = 0.983$). In multivariable analysis, the adjusted hazard ratio (HR) was 1.1 for luminal A vs. luminal B ($P = 0.781$), 0.62 in luminal A vs. HER2-enriched ($P = 0.273$), or 0.67 in luminal A vs. basal-like ($P = 0.158$). In contrast, the adjusted HR were 2.2 in age less than 50 years ($P = 0.0017$), and 1.1 for number of positive nodes ($P = 0.00074$). **Conclusions:** OS, through long-term clinical follow-up, is not significantly different among molecular subtypes if not controlling for other prognostic factors in patients who only received surgery. Age and number of positive nodes are independent prognostic factors in patients with no systemic and locoregional treatments.

11600 Poster Session (Board #300), Sat, 1:15 PM-4:45 PM

***RASA1* and *NF1* co-mutated non-small cell lung carcinomas: Cancer genomic data and evaluation of sensitivity to MEK inhibition.** *First Author: Takuo Hayashi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ras-GTPase activating proteins (RasGAPs), notably NF1 and RASA1, mediate negative control of the RAS/MAPK pathway. While *NF1* mutations are enriched in non-small cell lung carcinomas (NSCLC) lacking *KRAS* alterations, they are not completely mutually exclusive. We evaluated clinical and molecular characteristics of NSCLC with *RASA1* mutations in comparison with *NF1*-mutated cases. **Methods:** Large genomic datasets of NSCLC [MSK-IMPACT™ dataset at MSKCC (n = 2004), TCGA combined lung cancer dataset (n = 1144)] were analyzed to define concurrent mutations and clinical features of *RASA1*-mutated NSCLCs. Functional studies were performed using immortalized human bronchial epithelial cells (HBECs) and NSCLC lines with RasGAP truncating mutations, in *RASA1* (RERFLCKJ), *NF1* (LCLC103H and H1838), or both (EPLC272H). **Results:** Overall, approximately 2% of NSCLCs had *RASA1* truncating mutations, and this alteration was statistically, but not completely, mutually exclusive with known activating *EGFR* ($p = .02$) and *KRAS* ($p = .02$) mutations. Unexpectedly, *RASA1* truncating mutations had a strong tendency to co-occur with *NF1* truncating mutations ($p < .001$), suggesting selection for loss of more than one RasGAP. Furthermore, all patients (16/16) with concurrent *RASA1/NF1* truncating mutations lacked other known lung cancer drivers, including *KRAS*. Knockdown of RASA1 in HBECs activated signaling downstream of RAS and promoted cell growth. Conversely, restoration of RASA1 expression in RERFLCKJ cells reduced MAPK and PI3K signaling. While growth of cell lines with inactivation of only one of these two RasGAPs showed moderate and variable sensitivity to inhibitors of MEK (trametinib) or PI3K (GDC0941, PI103), EPLC272H cells (with concurrent *RASA1/NF1* mutations) showed notably more profound sensitivity (IC_{50}: 0.040μM trametinib). Finally, simultaneous silencing of *RASA1* and *NF1* sensitized both HBECs and NSCLC cells to MEK inhibition. **Conclusions:** Cancer genomic and functional data nominate concurrent *RASA1/NF1* loss of function mutations as a strong mitogenic driver in NSCLC. Patients whose tumors show this distinctive genotype should be considered for trials of MEK inhibitors.

11601 Poster Session (Board #301), Sat, 1:15 PM-4:45 PM

Selecting patients with metastatic colorectal cancer for treatment with temozolomide using proteomic analysis of MGMT. *First Author: Sarit Schwartz, NantOmics, LLC, Rockville, MD*

Background: Temozolomide (TMZ) is a standard treatment for melanoma and glioblastoma and it has shown limited but encouraging activity in patients with metastatic colorectal cancer (mCRC). In multiple cancer types, the DNA repair protein O^6-methylguanine-DNA methyltransferase (MGMT) is a resistance marker for TMZ; MGMT promoter methylation is associated with loss of MGMT expression and response to TMZ. We hypothesized that mCRC patients whose tumors expressed quantities of MGMT protein below a pre-defined cutoff would have better outcomes on TMZ than patients with MGMT expression above the cutoff. To test our hypothesis, we assessed MGMT by mass spectrometry in the tumor samples of patients with refractory mCRC and MGMT promoter methylation receiving TMZ. **Methods:** Archived formalin-fixed, paraffin-embedded tissue sections were obtained from 24 patients from two phase 2 trials. A pathologist marked the tumor areas, which were microdissected and solubilized. In each tumor sample, multiple protein biomarkers including MGMT were quantified with selected reaction monitoring mass spectrometry. An MGMT cutoff of 200 amol/ug was based on the limit of quantitation from a concentration curve. The Mantel-Cox log-rank and the Fisher's exact tests were used for survival comparisons. **Results:** MGMT protein was detected in 13 of 24 (54.2%) colorectal tumor samples (range: 229.3-784.8 amol/μg). The overall response rate was 29%. Patients with MGMT protein levels below a cutoff of 200 amol/ug (n = 11) had a notably higher response rate than patients with MGMT levels above the cutoff (64% vs. 0%; $p = 0.001$ Fisher's test). Also a longer progression-free survival was observed (4.3 vs. 1.6 months, HR = 0.36, 95% CI = 0.13-1.10, $p = 0.054$). Results for overall survival were consistent but not statistically significant (8.9 vs 6.9 months, HR = 0.55, $p = 0.221$). **Conclusions:** Patients with mCRC whose tumors expressed low or undetectable levels of MGMT protein had a better outcomes following TMZ treatment than their counterparts. Quantitative proteomic analysis of MGMT could potentially be used to select CRC patients for TMZ treatment. The results of validation studies are forthcoming.

11602 Poster Session (Board #302), Sat, 1:15 PM-4:45 PM

Biomarker-driven indication selection in JTX-2011 ICONIC clinical trial. *First Author: Heather Anne Hirsch, Jounce Therapeutics, Cambridge, MA*

Background: ICOS (Inducible T cell CO-Stimulator) is a co-stimulatory molecule expressed primarily on T lymphocytes. Clinical and preclinical data suggest that ICOS mediates anti-CTLA-4 driven anti-tumor responses. JTX-2011 is an ICOS agonist antibody in clinical development in advanced solid tumors (ICONIC trial). JTX-2011 is designed to generate an anti-tumor immune response via stimulation of T effector cells and preferential reduction of intra-tumoral T regulatory cells. Single agent preclinical efficacy correlates with the percentage of ICOS-expressing T cells within the tumor. We report indication selection and patient enrichment strategy for ICONIC using *in silico* and IHC analysis and assessment of potential predictive biomarkers for JTX-2011 using *ex vivo* tumor histoculture. **Methods:** Integrated analysis was performed from the TCGA for ICOS expression in histologic and molecularly defined tumors and immune cell signatures. ICOS expression was analyzed by IHC in a subset of indications based on *in silico* analysis. ICOS expression on intra-tumoral Tregs and PD-L1 were analyzed in a cohort of 126 head and neck squamous cell carcinomas (HNSCC). *Ex vivo* histoculture assays of human HNSCC was treated with JTX-2011 and assessed for IFNg gene signature induction. **Results:** ICOS mRNA expression was analyzed in ~10,000 solid tumors samples across ~30 indications. ICOS expression in key indications was confirmed using IHC. Based on frequency of high ICOS expression, non-small cell lung cancer, HNSCC, triple negative breast carcinoma, gastric cancer, and melanoma were selected as indications for ICONIC. Results were confirmed in clinical samples using multiplex immunofluorescence and ICOS IHC. A wide range of ICOS expression was observed suggesting that identification of an ICOS "high" group may enrich for patients likely to benefit from ICOS agonist therapy. In *ex vivo* histoculture assays of human HNSCC tumors treated with JTX-2011, ICOS IHC and ICOS RNA gene signatures correlated to response endpoints. Comparison of ICOS and PDL1 expression identified subsets of tumors in multiple indications with high ICOS but low PDL1 expression. **Conclusions:** These data support prioritization of specific tumor types the ICONIC trial.

11603 Poster Session (Board #303), Sat, 1:15 PM-4:45 PM

Preliminary correlative analysis of PD-L1 expression from the SUNRISE study. *First Author: Nikoletta Lea Kallinteris, Peregrine Pharmaceuticals, Inc., Tustin, CA*

Background: SUNRISE, a global, double-bind, Phase III trial of docetaxel (D) plus bavituximab (B) or D plus placebo (P) in previously treated non-squamous non-small cell lung cancer, demonstrated similar overall survival (OS) in both treatment arms. Biomarkers including pre-treatment PD-L1 expression are being retrospectively assessed in on-going exploratory analyses. **Methods:** Archival tissue obtained at the time of diagnosis was requested but not required in the SUNRISE trial. FFPE slides were stained with a panel of lymphoid cell markers: CD3+, CD8+, FoxP3+, PD-L1+, CD163+, CK+ and DAPI using a 6-plex quantitative immunohistochemistry (IHC) assay (OPAL, PerkinElmer, Hopkinton, MA, USA). Baseline PD-L1 expression was retrospectively scored on tumor cells (TC) as a percentage of PD-L1 expressing tumor cells: TC3$\geq$50%, TC2$\geq$5% and $<$ 50%, TC1$\geq$1% and $<$ 5%, and TC0 $<$ 1%. Cox regression models for PD-L1 IHC subgroup populations were used for correlation with OS. **Results:** In the subset of patients with available diagnostic biopsies (110 out of 597 randomized patients), the prevalence of PD-L1 expression was 5% for TC3, 18% for TC2/3, 35% for TC1/2/3, 65% for TC0. Median OS (mOS) of the D+B arm is 11.5 months (TC0, $<$ 1%) and 6.0 months (TC1/2/3, $\geq$1%) with HR 0.38 (95% CI, 0.19-0.76); p-value = 0.004. mOS of the D+P arm is 11.1 months (TC0, $<$ 1%) and 10.4 months (TC1/2/3, $\geq$1%) with HR 0.93 (95% CI, 0.47-1.87); p value = 0.844. **Conclusions:** Baseline PD-L1 expression in a subset of SUNRISE patients demonstrated that PD-L1 expression (TC0) was associated with a significantly prolonged OS compared to positive PD-L1 expression (TC1/2/3) in patients receiving D+B. No difference in OS was observed in the D+P group by PD-L1 expression. These observations are consistent with the hypothesis that bavituximab may demonstrate more effect in PD-L1 negative or low expressing "immune cold" tumors. Clinical trial information: NCT01999673.

11604 Poster Session (Board #304), Sat, 1:15 PM-4:45 PM

A novel prognostic signature based on centrosome amplification-based genes to predict clinical outcomes in breast tumors. *First Author: Angela Ogden, Georgia State University, Atlanta, GA*

Background: A majority of breast tumors exhibit centrosome amplification (CA), which imparts aggressive phenotypes like chromosomal instability and invasive behavior. Nevertheless, it is unclear whether CA is associated with poor clinical outcomes after adjusting for potentially confounding factors, like stage and age at diagnosis. **Methods:** We developed a twenty-gene signature, "CA20," composed of genes related to centrosome structure and/or whose dysregulation induces CA and tested its prognostic value compared with that of CIN25, a chromosomal instability (CIN) signature, in combined multivariable Cox models using the METABRIC and TCGA microarray breast datasets. The n = 1,969 primary breast cancers of the METABRIC dataset were split randomly and approximately equally into training and validation sets, unlike the n = 524 primary invasive breast cancers of the TCGA dataset, which could not be split to preserve power $\approx$ 0.80, so bootstrapping was instead used. CA20 and CIN25 were dichotomized by average scores and optimal cutpoints based on the log-rank test. **Results:** In both discovery and validation METRABRIC sets, CA20 was a significant independent predictor of worse breast cancer-specific survival (HR = 2.9, $p < 0.001$ and 2.4, $p < 0.001$, respectively, using average scores as cutpoints; similar results obtained using optimal cutpoints) in multivariable Cox models, unlike CIN25. CA20 score was highly correlated with CIN25 score ($\rho = 0.93$, $p < 10^{-6}$). In the TCGA dataset, high CA20 score was associated with 3.8- and 3.7-fold worse overall survival (bootstrap-p = 0.001 and 0.002, respectively, for average and optimal cutpoints) after adjusting for tumor stage and age at diagnosis, unlike CIN25. Also in the TCGA dataset, CA20 correlated very strongly with CIN25 ($\rho = 0.95$, $p < 10^{-6}$). Finally, using the TCGA dataset, we identified processes and pathways enriched in the CA20-high group ($q < 0.05$) that may be potential therapeutic targets, such as DNA repair processes, the DNA integrity checkpoint, and regulation of microtubule dynamics. **Conclusions:** CA20 is a novel signature with robust prognostic value in breast cancer and identifies patients who might respond to centrosome declustering drugs.

11605 Poster Session (Board #305), Sat, 1:15 PM-4:45 PM

Comprehensive analysis of potential immunotherapy genomic biomarkers by profiling paired tumor/normal exome of 1,000 Chinese cancer patients. *First Author: Qiang Xu, GenomiCare, Shanghai, China*

Background: With the broadening landscape of immunotherapy use, it is important to identify patients who are likely to benefit from the therapy. We reported the comprehensive analyses of potential predictive biomarkers for PD1/PD-L1 inhibitors based on Chinese patients' exome profiling data. **Methods:** Over 1,000 cancer patients from 70 hospitals across 20 provinces in China were recruited and the whole exome of tumor/normal samples of each patient were sequenced. Four potential genomic biomarkers: tumor mutation burden (TMB), mismatch repair deficiency (MMR), microsatellite instability (MSI), and PD-L1 (CD274) amplification (PD-L1 AMP) were analyzed in this Chinese cohort and compared with the mainly Caucasian cohort in TCGA database. **Results:** At least one of the four preselected genomic biomarkers was identified in 40.8% of this Chinese cancer patient cohort by clinical whole exome sequencing (CWES) analysis. Similar to TCGA cohort, the top 3 high TMB tumor types are lung, esophagus and colorectal cancer. Chinese hepatocellular carcinoma (HCC) patients showed higher TMB than the TCGA cohort (Median: 106 vs. 65 non-synonymous mutations per tumor NMT), which might be due to different etiologies. Five late stage cancer patients (3 lung, 1 melanoma and 1 gallbladder) using PD1/PD-L1 blockade with high TMB showed durable clinical benefit (SD$\geq$6months/PR/CR). Comparing with TCGA data, Chinese colorectal cancer cohort (252 patients) had relative lower MSI-high or MMR related mutations (8.33% vs. 12.5%, and 3.97% vs. 10.0% respectively). PD-L1 AMP most frequently occurred in lung squamous (14.3% VS 9.8% TCGA), HER2-positive breast cancer (8.8% VS 6.8% TCGA with unknown HER2 status) and sarcoma (6.0% VS 9.4%TCGA). One Chinese renal cell carcinoma patient with PD-L1 AMP received anti-PD-1 treatment and on-going PFS is 7 months by far. **Conclusions:** Our CWES analysis and limited clinical follow-up observations suggested that about 40% Chinese cancer patients had at least one of the 4 potential immunotherapy predictive biomarker mutations. Long-term follow-up is needed to verify the validity of those markers.

11606 Poster Session (Board #306), Sat, 1:15 PM-4:45 PM

Case-control study of PD-1, PD-L1 and B7-H3 expression in lung cancer (CA) patients (pts) with and without human immunodeficiency virus (HIV) infection. *First Author: Katherine Ann Scilla, University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD*

Background: PD-1, PD-L1 and B7-H3 are co-signaling molecules involved in CA immunology. There are limited data on expression of these molecules in HIV-infected (HIV+) lung CA pts and these pts are routinely excluded from immunotherapy trials. **Methods:** We reviewed archived lung CA tissue samples from HIV+ cases (n = 13) and HIV-uninfected controls (n = 13) from 2001-2015. Cases and controls were matched by histology and stage. Baseline demographics were collected for all pts. CD4 count and HIV RNA viral load (VL) were collected for HIV+ pts. Immunostained tumor sections were analyzed for percent of tumor cells expressing PD-L1 and B7-H3 (Abcam), and percent of tumor-infiltrating lymphocytes (TIL) expressing PD-1 and PD-L1 (Abcam). Positive expression was defined as $>$ 5%. Statistical analysis was performed using the non-parametric Mann-Whitney test and the chi-square test. Proportions are specified as percentage with 95% confidence limits in parentheses. **Results:** Lung CA HIV+ case pts were predominantly male (62%), black race (100%), adenocarcinoma histology (77%), stage 4 disease (62%), and had a median age of 48 years. Of case pts with available data, mean CD4 count was 307 (range 37-617) and mean HIV VL was 29,400 (range 0-100,000). PD-L1 expression on tumor cells was positive in 23% (8%, 50%) of cases and 46% (23%, 71%) of controls. B7-H3 expression on tumor cells was positive in 92% (67%, 99%) of cases and 69% (42%, 87%) of controls. PD-1 expression on TIL was positive in 69% (42%, 87%) of cases and 54% (29%, 77%) of controls. PD-L1 expression on TIL was positive in 31% (13%, 58%) of cases and 69% (42%, 87%) of controls (p = 0.05). B7-H3 percent expression on tumor cells was significantly higher in cases vs controls (median 90% vs 20%, p = 0.005), but there were no significant differences in percent expression of PD-L1 on tumor cells, PD-1 on TIL or PD-L1 on TIL. **Conclusions:** HIV+ lung CA pts had significantly higher B7-H3 tumor percent expression compared to HIV-uninfected controls, with similar rates of PD-L1 tumor percent expression, PD-1 TIL percent expression and PD-L1 TIL percent expression. These results support inclusion of HIV+ lung CA pts in future immunotherapy trials.

11607 Poster Session (Board #307), Sat, 1:15 PM-4:45 PM

A technical feasibility report on correlative studies from the investigator-initiated phase II study of pembrolizumab (Pembro) immunological response evaluation (INSPIRE). *First Author: Derek L. Clouthier, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Validated biomarkers of response to immune checkpoint inhibitors are needed. **Methods:** INSPIRE (NCT02644369) is a biomarker-driven study to comprehensively evaluate changes in genomic and immune landscapes in tumors and blood of patients (pts) treated with pembro at 200 mg IV Q3W. It consists of 5 histological cohorts of 20 evaluable pts each: head and neck squamous cell cancer (SCCHN), triple negative breast cancer (TNBC), high grade serous ovarian cancer (HGSOC), melanoma (MM) and mixed solid tumors (MST). All pts undergo pre- and on-treatment (week 6-9) fresh tumor biopsies (bx), and at progression for responders. The first core bx is for immunohistochemistry and subsequent cores are pooled to create single cell suspension for 5 prioritized biomarker assay groups: (1) whole exome/RNA-/TCR-sequencing; (2) T/B/NK, APCs, and/or Treg phenotyping; (3) patient-derived xenografts; (4) RNA-seq on viably sorted immune populations; (5) TIL expansion and characterization. Serial blood samples for immunophenotyping, chemokines/cytokines and ctDNA are collected. **Results:** 53 pts were enrolled from March 21, 2016-January 16, 2017 (5 SCCHN, 8 TNBC, 17 HGSOC, 7 MM, 16 MST). 84 tumor bx (53 pre-, 30 on-treatment, 1 progression) and 244 blood-based biomarker samples have been collected. The most common sites of tumor bx were: lymph nodes (27%), liver (22%) and skin (14%) (see table). For the 5 cohorts, the % of tumor bx with sufficient cellularity for biomarker assay groups 1 and 2 are: SCCHN (33%), TNBC (9%), HGSOC (52%), MM (55%), MST (55%). **Conclusions:** This report provides robust technical feasibility data to plan immune and molecular characterization of tumor and blood-based biomarkers in pts receiving ICI. Clinical trial information: NCT02644369.

Technical feasibility parameters.

Tumour bx site	Average (range) # of cores	Average (range) # of cells per core	% of samples adequate for biomarker evaluations groups 1, 2, 3, 4, 5
Lymph node	3.2 (1-5)	3.0E5 (0.024–1.4E6)	74, 61, 39, 13, 9
Liver	3.5 (2-6)	1.9E5 (0.19–7.7E5)	74, 63, 10, 10, 5
Skin	3.2 (3-4) [punch/excisions]	5.1E5 (0.012–2.2E6) NA	100, 40, NA, 0, 20 86, 71, NA, 29, 14
Other	3.7 (1-8)	1.9E5 (0.002–1.6E6)	55, 55, 16, 6, 3

11608 Poster Session (Board #308), Sat, 1:15 PM-4:45 PM

Genetic variations in semaphorin/neuropilin signaling to predict clinical outcome in patients (pts) with metastatic colorectal cancer (mCRC) receiving bevacizumab-based chemotherapy. *First Author: Yuji Miyamoto, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Neuropilin (*NRP*) is known to be an important *VEGF* co-receptor that acts as a key mediator of angiogenesis. Its ligands, semaphorins (*SEMA*), compete with *VEGF* for NRP binding and can themselves have angiogenic activity. Plexins are also receptors of SEMAs, and have the GTPase activating proteins (GAPs) domain for *RAS*. NRPs are shown to signal through RAS pathways. We aimed to evaluate whether single nucleotide polymorphisms (SNPs) of genes involved in the *SEMA/NRP*pathways predict clinical outcome in bevacizumab-treated mCRC pts. **Methods:** Associations between nine SNPs in 7 genes (*SEMA3A*, *SEMA3D*, *SEMA3F*, *NRP1*, *NRP2*, *PLXNA1* and *PLXND1*) and clinical outcomes were evaluated in mCRC patients receiving first-line FOLFIRI-bevacizumab in a phase III trial: TRIBE (*N*= 228). Associations between genotype and RAS mutation status with clinical outcomes was also examined. Main characteristics were the following: male/female = 138/90; median age = 60; *RAS*-wildtype/mutant = 55/116; median PFS = 9.7 months; median OS = 26.1 months, median follow-up time = 49.3 months. **Results:** *NRP1* rs2228638 Any A (*N*= 40) showed a significantly longer PFS compared to G/G variant (*N*= 188) in the univariate (11.6 months (M) vs. 9.5 M, HR = 0.64, 95%CI = 0.43-0.95, p = 0.022) and the multivariate analysis (HR = 0.59, 95%CI = 0.38-0.90, p = 0.016). *SEMA3F* rs12632110 A/A (*N*= 20) showed a significantly shorter PFS compared to any G variant (N = 205) in the multivariate analysis (HR = 1.89, 95%CI = 1.02-3.49, p = 0.043). Among *RAS*-mutant pts, *SEMA3F* rs12632110, *SEMA3F* rs1046956, *SEMA3D* rs7800072, *NRP1* rs228638, *PLXNA1* rs4679323 and *PLXND1* rs2255703 polymorphisms were significantly associated with PFS in the univariate and multivariate analysis. *PLXNA1* rs4679323 was also significantly associated with OS in the univariate and multivariate analysis. There was no association between these polymorphisms and outcome in patients with *RAS*wildtype tumors. **Conclusions:** Genetic variants within *SEMA/NRP* pathways may be prognostic markers in *RAS* mutant mCRC patients treated with bevacizumab-based chemotherapy.

11609 Poster Session (Board #309), Sat, 1:15 PM-4:45 PM

Simultaneous molecular alterations in solid tumors with *IDH1* or *IDH2* mutations. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Somatic mutations in *IDH1* or *IDH2* genes are prevalent in diverse solid tumors and implicated in tumorigenesis. Therapeutic responses to IDH inhibitors are infrequent plausibly due to presence of simultaneous alterations activating compensatory molecular pathways. **Methods:** We retrospectively reviewed results from clinical genomic profiling with targeted next-generation sequencing in two independent data sets of archival formalin-fixed paraffin-embedded (FFPE) tumor samples (Ion Torrent $<$ 50 genes, 300; FoundationOne $<$ 343 genes, 30; Oncomine 128 genes, 4) and plasma liquid biopsies (Guardant360 $<$ 73 genes panel, 337 samples) from patients with solid tumors of all stages. **Results:** In 334 FFPE samples the most represented cancers were gliomas (50%), melanomas (14%), cholangiocarcinomas (11%), and non-small cell lung cancer (NSCLC, 6%). In 296 *IDH1*-mutated FFPE samples the most frequent simultaneous alterations were in *TP53* (45%), *BRAF* (11%), *KRAS* (9%), and *PIK3CA* (26, 9%). In the most represented *IDH1*-mutated tumor types commonly altered genes were *TP53* (66%) in gliomas, *BRAF* (53% [V600K/R 30%, V600E 19%]) in melanomas, *PIK3CA* (13%), *CDKN2A* (13%) in cholangiocarcinomas and *KRAS* (65%) in NSCLC. In 38 *IDH2*-mutated FFPE samples the most frequent simultaneous alterations were in *TP53* (32%), and *KRAS* (16%). In 337 plasma samples the most represented cancers were NSCLC (39%), cholangiocarcinoma (13%), and breast cancer (8%). In 172 *IDH1*-mutated plasma samples the most frequent simultaneous alterations were in *TP53* (40%), *KRAS* (23%), *EGFR* (16%) and *BRAF* (16%). In the most represented *IDH1*-mutated tumors commonly altered genes were *TP53* (48%), *KRAS* (37%) in NSCLC and *TP53* (37%), *KRAS* (24%), *BRAF* (18%) in cholangiocarcinoma. In 161 *IDH2*-mutated plasma samples the most frequent simultaneous alterations were in *TP53* (43%), *EGFR* (20%), and *KRAS* (19%). In the most represented *IDH2*-mutated tumors commonly altered genes were *TP53* (43%), *EGFR* (32%), *KRAS* (18%) in NSCLC and *TP53* (18%), *ESR1* (18%), *KRAS* (18%) in breast cancer. There were 4 tumors with *IDH1* and *IDH2*mutations. **Conclusions:** *IDH1* and *IDH2* mutations often coexist with simultaneous oncogenic alterations including these in potentially druggable molecular targets.

11610 Poster Session (Board #310), Sat, 1:15 PM-4:45 PM

Variable DNA mismatch repair-associated gene profiles in colorectal versus uterine cancers. *First Author: Tabari Baker, Caris Life Sciences, Phoenix, AZ*

Background: DNA mismatch repair (MMR) plays an important role in maintaining DNA synthesis fidelity in the genome. Mutation in MMR genes occurs in colorectal and uterine cancers and leads to increased mutation burden that is associated with response to immune checkpoint inhibitors. It is unknown if there is an MMR gene-specific mutation signature in MMR-deficient tumors, or whether mutations in MMR genes drive specific mutation patterns. **Methods:** The study cohort consisted of 1060 uterine cancer (UtCa), and 797 colorectal cancer (CRC) cases consecutively submitted to Caris Life Science for molecular profiling using multiple technologies, including next generation sequencing (NGS), immunohistochemistry (IHC), and in situ hybridization (ISH). Mutation, IHC-positive, and ISH-positive frequencies were compared using Fisher's exact test (p-value < 0.05 considered significant). **Results:** In total, 1,857 tumors were examined. Of the 797 CRC cases, 115 (14.4%) had at least one mutation in MLH1, MSH2, or MSH6. Nineteen (19; 2.3%) of the CRC cases had mutations in multiple MMR related genes. Of the 1060 UtCa cases, 52 (4.9%) had at least one mutation in MLH1, MSH2, or MSH6. Twenty-two (22; 2.1%) of the UtCa cases had mutations in multiple MMR related genes. Colorectal cancers that were MLH1, MSH2, and MSH6 mutated enriched for rare, lineage specific co-mutations, including KRAS A146T (4/32 MLH1-mutated cases; 12.5%). Uterine cancers that were MLH1, MSH2, and MSH6 mutated also enriched for several co-mutations, including ARID1A (8/9 MLH1-mutated cases; 88.9%), a SWI-SNF chromatin remodeling complex family member. Further analyses revealed differences in PD-L1 positivity between MMR mutated CRCs versus UtCa (8/131; 6.1% versus 8/51; 15.7%). Tumor mutational load (defined as the total number of non-synonymous mutations per Mb sequenced) was 35 mutations per Mb in CRC and 51 mutations per Mb in UtCa. **Conclusions:** There are differences in mutation signatures between uterine and colorectal cancer, and possible additional molecular targets for combination with immune checkpoint therapies. Further analysis of MMR gene-specific differences in molecular profiles is ongoing and will be discussed.

11611 Poster Session (Board #311), Sat, 1:15 PM-4:45 PM

Deficient necroptosis pathway as a negative prognostic factor in acute myeloid leukemia. *First Author: Silvia Lo Monaco, Bologna University School of Medicine, Bologna, Italy*

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (*RIPK3*, *RIPK2*, *RIPK1*) and the *MLKL* substrate. Losses of *RIPK3* or *MLKL*, as well as deficiency in apoptosis, could allow tumor cells to escape the immunomediated cells death (ICD). **Methods:** We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis. **Results:** We find that 18 patients presented a loss of *RIPK1* or *MLKL* (nobody presented losses in *RIPK3/RIPK2*) and 13/18 patients were older than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is significantly lower than control group, with a median OS of 3 vs 6 month respectively ($p<.0.001$). With Fisher Exact Test we further demonstrate that copy number loss of *RIPK1* or *MLKL* are associate to loss of *TP53* or *FANCA*genes, complex karyotype and advanced age. COXHR model with *RIPK1* or *MLKL* loss, *BRACA1* loss, *TP53* mutation, *FANCA* loss, secondary disease and diagnosis karyotype considered as categorical variable shows that necroptosis deficiency (HR 1.98, CI 95% 1.04-3.78), *TP53*mutation , and secondary AML are independent negative prognostic factors in an optimal model. **Conclusions:** Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that have high probability to be resistant at chemotherapy promoting ICD mechanism. HER3-EGFR score to predict clinical outcomes in triple-negative breast cancer. *First Author: Angela Ogden, Georgia State University, Atlanta, GA*

Background: Limited preclinical evidence suggests that the ErbB family member HER3 may have prognostic value in TNBC. However, HER3 is a pseudokinase that cannot homodimerize, so in order to signal it must bind to other ErbB family members such as HER2 or EGFR. EGFR is frequently overexpressed in TNBC; consequently, it may be necessary to consider HER3 levels in the context of EGFR levels in TNBC to derive clinically meaningful insights. **Methods:** Towards this end, we tested the prognostic value of a combined immunohistochemical HER3-EGFR score (the sum of the individual H-scores, with the median used as a cutpoint) in a multi-institutional study of n = 510 TNBC patients using Cox proportional hazards regression. We also compared the HER3-EGFR-high and low groups in terms of 105 immunohistochemical biomarkers using Mann-Whitney U tests as well as Ingenuity canonical pathways using gene expression data from RNA-seq. **Results:** Among chemotherapy-treated TNBC patients, high HER3-EGFR score conferred a 2.30-fold increased risk of dying from breast cancer and a 1.78-fold increased risk of distant metastasis ($p = 0.006$ and $p = 0.041$, respectively) after adjusting for age and stage. Individual HER3 and EGFR H-scores were not associated with outcomes in simple or multivariable models. We also found that tumors from chemotherapy-treated TNBC patients with high HER3-EGFR scores exhibited higher immunohistochemical expression of luminal cytokeratins, DNA damage response proteins, and P-cadherin compared with tumors from chemotherapy-treated TNBC patients with low scores ($q < 0.25$). The top canonical pathway whose components were overexpressed in HER3-EGFR-high TNBCs was Hepatic Fibrosis ($p = 0.008$), which is linked to distant metastasis, and the top upstream regulator was HNF4A ($p = 0.012$), a transcription factor for *ERBB3* with isoforms that promote liver and gut tumorigenesis. **Conclusions:** Collectively, our study reveals that HER3-EGFR score may identify chemotherapy-treated TNBC patients at increased risk for distant metastases and death whose tumors may be characterized by fibrotic processes. Our immunohistochemical test thus identifies high-risk TNBCs who may benefit from agents that inhibit HER3-EGFR signaling.

11613 Poster Session (Board #313), Sat, 1:15 PM-4:45 PM

Association of immune-related genes to neutrophil-lymphocyte ratio (NLR) with survival of cetuximab treatment for metastatic colorectal cancer (mCRC): JACCRO CC-05/06AR. *First Author: Yu Sunakawa, Division of Medical Oncology, Showa University Northern Yokohama Hospital, Yokohama, Japan*

Background: The antitumor activity of cetuximab (cet) may be affected by extracellular immune mechanisms. We have reported that immune-related genes are associated with survival in mCRC patients (pts) treated with cet (ASCO 2016 abstract#11591). NLR reflects cancer-related inflammation and is a validated prognostic maker in many types of cancers; however, it is not currently used for treatment decision-making. The association between NLR and clinical outcome of cet treatment for mCRC is unknown, and which genes are affecting the NLR remain to be identified. **Methods:** We enrolled 77 pts (57% males and 15% right-colon cancer) with *KRAS* exon 2 wild-type from 2 phase II trials (JACCRO CC-05 or CC-06) of 1st-line therapy with FOLFOX or SOX plus cet. All patients' tissues were measured for expression levels of 354 immune-related genes by *HTG EdgeSeq Oncology Biomarker Panel* using next generation sequencing for quantitative analysis of targeted RNAs. The association between the NLR and clinical outcome was evaluated using Spearman's rank correlation coefficient. In addition, the two-sample t-test was performed to investigate which genes had significantly different expression level between NLR-low and high groups in top 100 genes associated with survival among all measured genes. **Results:** Seventy-one of 77 pts were available for NLR data. The NLR was associated with progression-free survival (PFS) and overall survival (OS) ($r = 0.24$; $p = 0.04$, $r = 0.29$; $p = 0.01$, respectively). When stratified by median value of NLR, the Kaplan-Meier curve of NLR-low ($n = 36$) vs. high ($n = 35$) had a significant difference in both PFS (median 11.8 vs. 9.1 m, $p = 0.036$) and OS (median 42.8 vs. 26.7 m, $p = 0.029$). The two-sample t-test revealed that *LYZ*, *TYMP*, and *CD68* genes expressed significantly differently between NLR-low and high groups (t-test p-value < 0.005, FDR p-value < 0.150). **Conclusions:** NLR is significantly associated with survival of 1st-line cet treatment for mCRC. Genes encoding for activities on tissue macrophages and endothelial cells may affect the level of NLR associated with outcome of cet combination chemotherapy. Clinical trial information: UMIN000010635.

11614 Poster Session (Board #314), Sat, 1:15 PM-4:45 PM

Effect of Wnt5a on aggressiveness of ER-positive breast cancer and cancer cell migration through JNK-ALCAM pathway. *First Author: Yoshie Kobayashi, Department of Surgical Oncology, Hiroshima University, Hiroshima, Japan*

Background: Wnt5a is a representative ligand that activates β-catenin-independent pathways and involved in cell motility and cell polarity, and the like, being mediated by JNK. We elucidated the implication of Wnt5a expression in breast cancer. **Methods:** One hundred seventy eight breast cancer patients (mean age ± SD: 60.0 ± 13.2 years) with clinical Stage I-III between January 2011 and February 2014, were prospectively evaluated. We examined relationships between Wnt5a expression and clinicopathological factors by immunohistochemical analyses. 5-year relapse-free survival rates and sites of recurrence were analyzed. In addition, molecules induced by Wnt5a in cultured cells were identified by DNA microarray analysis. **Results:** Wnt5a expression was significantly more frequent when estrogen receptor (ER) was present, 68/153 (44%) than when ER was absent, 1/25 (4%) (P <0.001) (Table). In ER-positive breast cancer, a significant interaction between expression of Wnt5a with lymph node metastasis (P<0.001), high nuclear grade (P=0.004), and lymphatic invasion (P=0.001). 5-year relapse-free survival rates were 81.1% and 100% in Wnt5a-positive and Wnt5a-negative breast cancers, respectively (P = 0.024). All recurrent breast cancer patients in this study had bone metastasis. We established MCF7 stably expressing Wnt5a (Wnt5a/MCF7 cells) and microarray analyses identified several genes induced by Wnt5a (>3.0 fold), involving activated leukocyte cell adhesion molecule (ALCAM). ALCAM is known to be related with apoptosis, invasion and prognosis of breast cancer. We focused on ALCAM and investigated its protein expression by Western blotting, and found remarkable increase of ALCAM in Wnt5a/MCF7 cells. **Conclusions:** Wnt5a expresses in ER-positive breast cancer and is associated with high-grade malignancy and a poor prognosis through JNK-ALCAM pathway. Wnt5a could be a novel prognostic factor of ER-positive breast cancer.

Wnt5a expression in intrinsic subtypes.

ER status	Total	HER2 Positive	Status Negative	*P* value
Positive	68/153 (44%)	5/11 (45%)	63/142 (44%)	
Negative	1/25 (4%)	1/8 (13%)	0/17 (0%)	<0.001

11615 Poster Session (Board #315), Sat, 1:15 PM-4:45 PM

PD-L1 assessment in FNA (EBUS) dervied samples. *First Author: Andrew Lerner, Johns Hopkins School of Medicine, Department of Medicine Pulmonary Division, Baltimore, MD*

Background: Pembrolizumab therapy for non-small cell lung cancer requires PD-L1 immunohistochemistry (IHC). FDA approval was based on staining of resections or core biopsies. Little is known about PD-L1 expression in fine needle aspiration (FNA) specimens including EBUS of mediastinal lymph nodes. **Methods:** IHC was performed using the PD-L1 IHC 22C3 pharmDx test on formalin fixed paraffin embedded FNA cell blocks of 8 squamous cell carcinomas and 15 adenocarcinomas (ACA) (age: 42-84, mean: 63, median: 63; 11 female and 12 male). Mutation data (50 gene NGS panel, and ALK, ROS1, RET and MET FISH) was available for 14 ACA. Membranous PD-L1 staining of any intensity and extent was recorded in at least 100 tumor cells (tumor proportion score). The tumors were grouped as: no staining (<1%), low expression (1-49%) and high expression (50% or more). **Results:** Six (26%) tumors showed no staining, 6 (26%) low expression and 11 (48%) high expression (table 1). High PD-L1 expression was seen in 1 ALK, 1 braf, 1 EGFR, 1 Her2 exon20, 2 kras mutated tumors and 2 tumors with no or unknown mutation status, low PD-L1 expression in 1 braf and 1 EGFR mutated case and 1 tumor without mutation. No expression was seen in 1 ROS1, 1 kras mutated tumor and 1 tumor without mutation. One EBUS biopsy also had PD-L1 assessed on a transbronchial biopsy of the primary tumor showing similar staining (30% versus 20%). **Conclusions:** PD-L1 immunohistochemistry appears to be feasible using cell blocks of fine needle aspirates containing adeqaute number of viable tumor cells. The majority of ACA were also adequate for NGS mutation and FISH analysis. High PD-L1 expression was seen in approximately half the tumors, which is greater than has been observed in resections/core biopsies, this finding merits further study. High expression of PD-L1 was seen in both squamous cell carcinoma and adenocarcinoma, and tumors with and without common driver mutations.

PD-L1 Expression according to histologic type.

Histologic type	No expression	Low expression	High expression
Adenocarcinoma (n15)	4 (27%)	3 (20%)	8 (53%)
Squamous cell carcinoma (n8)	2 (25%)	3 (37.5%)	3 (37.5%)
Total (n23)	6 (26%)	6 (26%)	11 (48%)

11616 Poster Session (Board #316), Sat, 1:15 PM-4:45 PM

Development of a pan-cancer 15 gene expression signature to detect a subgroup driven by EMT/MAPK signalling. *First Author: Nuala McCabe, Almac Diagnostics, Craigavon, United Kingdom*

Background: Epithelial–mesenchymal transition (EMT) is the conversion of epithelial cells to mesenchymal cells and involves loss of cell–cell adhesion and cell polarity and increased motility, invasiveness and metastases. The EMT process has therefore been under investigation as a new target for anticancer drug discovery. The aim of this work was to develop an EMT biomarker suitable for formalin-fixed paraffin embedded (FFPE) tissue that could be used for patient treatment selection. **Methods:** Unsupervised hierarchical clustering of ovarian cancer gene expression data (TCGA. 2011) previously identified an EMT subgroup. We confirmed this EMT subgroup in FFPE tissue using 265 high grade serous ovarian cancer (HGSOC) FFPE samples. The analysis was extended to show existence of an EMT subgroup across a range of solid tumours including colon, lung, melanoma and prostate cancer. Further to this, a common gene list was generated to include only transcripts with high variability and expression across diseases, and used as a starting list for development of a 15 transcript assay which can be used to prospectively identify the EMT subgroup from archived tissue. **Results:** The 15 gene expression assay was a poor prognostic marker in Colorectal, (Relapse free survival: HR = 1.46 [95% CI:1.07-1.98]); Lung, (Relapse free survival: HR = 2.18 [95% CI:1.33-3.56]); Prostate cancer, (Biochemical recurrence: HR 2.49 CI: 1.43-4.34) and was associated with activated MAPK (phospho-MAPK) in preclinical models and clinical samples ($p < 0.05$). The assay score was reduced by MEK inhibition ($p < 0.05$) and elevated by KRAS, NRAS and MEK1 overexpression ($p < 0.05$). The assay predicted response to the MEK inhibitors Trametinib and Selumetinib in cell line models ($p < 0.001$). **Conclusions:** A 15 gene expression assay has been developed from FFPE samples across multiple diseases to detect an EMT molecular subgroup associated with MAPK signalling. The assay predicted sensitivity to MEK inhibitors in pre-clinical model systems. Further work aims to validate the assay as a predictive biomarker in clinical samples from patients treated with EMT or MEK targeted therapies.

11617 Poster Session (Board #317), Sat, 1:15 PM-4:45 PM

Comparing programmed death ligand-1 expression on tumor cells before and after acquiring resistance to tyrosine kinase inhibitor in EGFR harbouring non-small cell lung cancer. *First Author: Siwat Sakdejayont, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

Background: Although anti-PD1/PD-L1-targeting immunotherapy has been successful in the treatment of non-small cell lung cancer (NSCLC) patients, the benefit is unclear in EGFR mutation(mEGFR) NSCLC. To date, there are several clones of anti-PD-L1 antibody which provide different predictive values and the level of expression also dynamically changed after treatment. The study examined changes of PD-L1 expression in mEGFR harbouring NSCLC tissues, comparing between before and after treatment with tyrosine kinase inhibitors(TKIs) using an FDA-approved PD-L1 assay. **Methods:** We retrospectively reviewed tumor specimen from 24 patients with mEGFR NSCLC who had been treated with gefitinib, erlotinib, afatinib and received second tissue biopsy after acquiring resistance to TKIs. The collected FFPE specimens were stained with commercial anti-PD-L1 22C3 assay monoclonal antibody. Tumor proportion score(TPS) and H-score were measured before and after TKIs. **Results:** Of the study patients,54.2% patients were exon 19 deletion(n = 13), 41.7% were exon 21 point mutation(L858R) (n = 10), and 1 case was L858R/S761I. After TKIs resistance 10/13 (76.9%) of exon 19del and 8/10 (80%) of L858R revealed presence of +T790M. Pretreatment PD-L1 expression was positive(TPS≥1%) in 6 cases (25%). Mean TPS of positive cases was 34.0% and H-score was 78.2, All except 2 of 6 positive cases had adequate specimens from second biopsy(n = 22). Among 4 positive cases,PD-L1 expression tended to be higher after TKIs; mean TPS changed from 23.9 to 40.9 (p = 0.171) and H-score were from 49.3 to 91.1 (p = 0.172). 18/24 patients with TPS and H-score zero at the beginning remained zero after progression. Median TTP were similar in patients with positive PD-L1 expression and negative,13.8 m vs 14.5 m (n = 24,p = 0.644) with TKIs and 3.9 m vs 2.5 m (n = 14, p = 0.560) with chemotherapy. **Conclusions:** Prevalence of PD-L1 expression in mEGFR NSCLC was low. PD-L1 expression tended to be higher after TKIs for this with positive cases which may guide the sequences of treatment. Nevertheless no changes of PD-L1 expression for those with negative, hence re-biopsy may not be necessary.

11618 Poster Session (Board #318), Sat, 1:15 PM-4:45 PM

Nanomechanical profiling of human breast tumors as prognostic marker for breast cancer. *First Author: Rosemarie Anne Burian, Breast Center, University Hospital Basel, Basel, Switzerland*

Background: Assessment of tumor aggressiveness is crucial when making treatment decisions. Established prognostic markers may be insufficient to stratify cancer patients into treatment relevant risk groups. Emerging evidence indicates mechanical properties of cancer cells and their microenvironment play a vital role in cancer invasion and metastases. Detecting and measuring these nanomechanical changes could be a marker of cancer aggressiveness. **Methods:** We developed an atomic force microscope (AFM) based method: ARTIDIS (Automated and Reliable Tissue Diagnostics) for measuring nanomechanical properties of human tissue biopsies. These were performed on fresh, non-fixed tissue under physiological conditions. This novel method uses a micro-fabricated 20nm tip indenting and measuring stiffness of thousands of locations within 60-180minutes. This quantitative, biopsy-wide, nanomechanical profile strongly correlates to the tissue's biological composition. Post-AFM this biopsy is analyzed by pathology. We sought to differentiate benign from cancerous lesions based on nanomechanical properties; then link the cancerous nanomechanical profiles prospectively to the clinical outcomes. **Results:** Our results demonstrate the first AFM based nanomechanical profiling to detect aggressive breast cancer subtypes using fresh tissue in a clinical setting. We have shown that nanomechanical profiles of human breast cancer biopsies display stiffness profiles distinct from surrounding normal tissue. Breast cancer subtypes were distinguishable by their nanomechanical properties only. We have discovered specific nanomechanical profiles of tumor subtypes likely to metastasize. When the primary tumor displayed the same soft nanomechanical profile as adjacent tissue, this was associated with positive nodal status. **Conclusions:** Our results demontrate nanomechanical profiling is a fast and sensitive method to stratify malignant biopsies into relevant subgroups in a clinical setting. Relative stiffness and distribution values provide a nanomechanical profile indicating cancer aggressiveness. This will help optimize specific cancer diagnosis, orientate therapy choice and support patient follow up.

11619 Poster Session (Board #319), Sat, 1:15 PM-4:45 PM

Androgen receptor (AR) activation in breast cancer (BC) liver metastases. *First Author: Corinne Ramos, Theranostics Health, Inc., Rockville, MD*

Background: AR is expressed in the majority of BCs and its signaling may contribute to the development of BC metastases (mets). The expression pattern of AR, its phosphorylated form, p-AR S650, and correlations with other BC growth and survival pathways were evaluated in BC mets by reverse phase protein array (RPPA). **Methods:** RPPA was performed on 93 FFPE primary BCs and mets at a CLIA-certified laboratory. Immunostaining with 24 antibodies was directed against AR, p-AR S650, p-MET, and total and p-HER1/2/3 pathway proteins. Clinical and genomic data were obtained from pt chart review. Analysis of variance (ANOVA) was used to assess any statistically significant differences between the groups. **Results:** 35 tissues were primary BCs (38%); 58 were mets (62%). Sites of mets: liver (n = 41); lung (n = 8); chest wall (n = 9). Of the 41 liver mets, 2 were triple negative (TN), 32 were ER+/HER2-, and 7 were HER2+. AR expression was increased in chest wall (1.7-fold; p = 0.038) compared to primary BCs. p-AR was increased in liver (2.0-fold; p = 0.039) and chest wall (1.8-fold; p = 0.026) compared to primary BCs. ER+ liver mets especially showed strong liver-specific activation of AR along with overexpression of HER1, HER3, VEGFR, and activation of mTOR, S6 Ribo, 4EBP1, and STAT3. MEK/ERK pathway was not activated in ER+ liver mets. HER2+ liver mets had pan-HER1/2/3 activation along with MET, SRC, S6 Ribo, 4EBP1, and JAK2/STAT3. In the 2 TN liver mets, EGFR, VEGFR, mTOR, S6 Ribo, 4EBP1, and JAK2/STAT3 were activated while AR and MEK/ERK were not. The ER+ liver mets showed higher expression of p-AR (p = 0.079), p-HER3 (p = 0.002), p-HER2 (p = 0.010) and p-Jak2 (p = 0.002) compared to primary ER+ BCs whereas the HER2+ liver mets showed lower level of p-IGFR (p = 0.049) and p-MET (p = 0.010) compared to primary HER2+ BCs. Interestingly, TN chest wall mets had higher levels of AR and p-AR (p = 0.008 and 0.044 respectively) compared to TN BCs. **Conclusions:** ER+ liver mets have strong expression of AR and p-AR, and all liver met subtypes showed accumulation of S6 Ribo/4EBP1 and activation of JAK2/STAT3, but not the MAPK pathway. HER1/3 and HER1/2/3 were activated in ER+ and HER2+ liver mets, respectively. These data suggest that targeting AR, HER1/3, and mTOR in ER+ liver met would be of interest.

11620 Poster Session (Board #320), Sat, 1:15 PM-4:45 PM

Phosphoproteomic analysis of matched primary breast cancer (BC) and lymph node (LN) metastases. *First Author: Corinne Ramos, Theranostics Health, Inc., Rockville, MD*

Background: Therapeutic recommendations are often based on molecular markers expressed in primary BCs. However, LN metastases (mets) may more accurately reflect the lethal potential of the disease (Ries 2007). Whether activated oncogenic pathways in axillary LN mets can be reliably identified in the associated primary BCs is unknown. We evaluated the activation of key signaling pathways in pts' matched primary BC and axillary LN mets using reverse phase protein array (RPPA). **Methods:** 60 pts' matched FFPE primary BC and axillary LN mets (20 TN, 20 ER+/HER2-, 20 HER2+) are to be evaluated by RPPA at a CLIA-certified laboratory. The first 20 matched BC/LN (3 TN, 14 ER+/HER2-, 3 HER2+) and 7 unmatched (1 TN LN, 1 ER+/HER2- BC, 5 ER+/HER2- LN) results are reported here. Immunostaining of 14 HER1/2/3 and downstream pathway proteins was performed. Mann-Whitney U tests (p value) were utilized to compare BC vs LN mets protein level. **Results:** Increased expression of HER1 (6-fold) and p-Akt (2-fold) was observed in TN compared to Luminal (Lum) and HER2+ primary BCs. AR expression was upregulated in TN and HER2+ (2-fold) compared to Lum primary BCs. The LN mets showed higher expression of HER1 (p = 0.004), p-HER3 (p = 0.040), p-IGFR (p = 0.009), p-S6 (p = 0.033), p-4EBP1 (p = 0.027) and p-MEK1/2 (p = 0.023) compared to primary BCs. TN had higher level of p-Akt T308 (p = 0.077) in the LN mets compared to the primary BCs while HER2+ showed a downregulation of p-Akt T308 (p = 0.049) in the LN mets. HER2+ also had higher level of HER1 (p = 0.049), p-HER3 (p = 0.049), p-FGFR (p = 0.083), and p-4EBP1 (p = 0.049) in the LN mets compared to primary BCs. Higher levels of HER1 (p = 0.043) and p-MEK1/2 (p = 0.027) were observed in Lum B LN mets compared to p-IGFR (p = 0.041), p-Akt S473 (p = 0.088), p-S6 (p = 0.063) and p-4EBP1 (p = 0.097) in Lum A LN mets. **Conclusions:** In TNBC, preliminary results show that p-Akt is differentially upregulated in LN mets while HER1, p-HER3 and p-4EBP1 are overexpressed in HER2+ LN mets. Lum A LN mets showed higher levels of p-IGFR, p-Akt, p-S6 and p-4EBP1 vs Lum B LN mets which had higher levels of HER1 and p-MEK1/2. These data suggest different signaling pathways in BC LN mets compared to primary BCs. Analyses of 60 pts' matched primary BC/LN samples will be presented.

11621 Poster Session (Board #321), Sat, 1:15 PM-4:45 PM

Molecular landscape of BRAF mutations in large cell neuroendocrine carcinoma of lung: An analysis of BRAF mutations and a case report of a BRAF non-V600E mutated tumor responding to targeted therapy. *First Author: Keerthi Tamragouri, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: In advanced stages, large cell neuroendocrine carcinoma of the lung (L-LCNEC) mimics small cell lung cancer (SCLC) despite its traditional classification as a non-small cell lung cancer (NSCLC). Here we present a focused analysis of BRAF mutations in this population. **Methods:** Comprehensive genomic profiling of tumor tissues was performed from a cohort of 300 patients with biopsy proven L-LCNEC. Specimens were either from a primary lung lesion or metastatic site. **Results:** 14 unique BRAF alterations (amplifications, mutations) were identified in 13 patients. The importance of biomarker driven therapy is subsequently highlighted with our case of a 69 year-old male diagnosed with metastatic L-LCNEC that did not respond to cisplatin/etoposide. He then demonstrated a significant durable response with therapy targeted toward a BRAF non-V600E mutation (G469R) associated with biomarker response identified through circulating cell free tumor DNA analysis. A change in clonal allele frequency from nearly 50% to non-detectable was observed. **Conclusions:** Though uncommon, L-LCNEC does appear to contain activating and therefore actionable alterations. We thus highlight the value of pursuing NGS for these patients.

Specimen site	BRAF protein change	BRAF MAF (mean allele frequency?)	BRAF mutation characterization
Bone	G469A	0.41	Activating (Carter *et al.*, 2015)
Liver	K601N	0.45	Activating (Yao *et al.*, 2015)
Other	G469R	0.59	Activating (Damm *et al.*, 2014, Yao *et al.*, 2015)
Soft Tissue	G466V	0.32	Kinase impaired (Zheng *et al.*, 2015)
Liver	N581I	0.35	Uncharacterized
Lung	E220K	0.18	Unknown
Bone	E26_A27insAG	0.25	Unknown
Lymph Node	W210L, G9D	0.35, 0.2	Unknown
Soft Tissue	P149T	0.31	Unknown
Soft Tissue			amplification (CN = 9)
Liver			amplification (CN = 14)
Lymph Node			amplification (CN = 6)
Lung			amplification (CN = 8)

11622 Poster Session (Board #322), Sat, 1:15 PM-4:45 PM

Microarray analysis to identifiy novel copy number alterations in acute myeloid leukemia. *First Author: Maria Chiara Fontana, University of Bologna, Bologna, Italy*

Background: SNP microarray can detect Copy Number Alterations (CNAs) which could be predictive of response and can help define therapeutic strategies. Our aim is to improve conventional cytogenetic analysis and identify new genetic alterations relevant to leukemogenesis by a SNP array-based genotyping approach. **Methods:** We performed SNP 6.0/Cytoscan HD (Affymetrix) on 235 Acute Myeloid Leukemia (AML) patients at diagnosis. Seventy-eight/235 samples were also performed by Whole Exome Sequencing, WES (HiSeq,Illumina). SNP Array data were analyzed by Nexus Copy Number (BioDiscovery) and R Core Team. **Results:** We found several genes preferentially deleted, including *MRPS5* (14.8%), *PHF6* (9.3%), *SCAPER* (7.2%), *CASK* (5.9%), *WNK* (4.6%), *STAG2* (4.2%), *LRRK1* (3.4%), *PALB2* (3.4%), genes preferentially amplified were *RABL2B* (16.1%), *NF2* (10.2%), *NBPF9* (7.6%), *JAK2* (6.8%), *RB1*, *NF1* and *KMT2A* (4.2%), *PTEN* (3.4%), *TP73* and *SMAD2* (2.5%). Single-copy losses and deletions were enriched ($p < .001$) for genes mapping in these pathways: aberrant PD-1 signaling, loss of function of *SMAD4* in cancer and *SMAD4* MH2 Domain mutants in cancer. The pathways significantly ($p < .001$) deregulated in our cohort with single copy gain and homozygous amplification were: regulation of transcription and nucleic acid, negative regulation of metabolic processes, constitutive signaling by aberrant PI3K in cancer and PI3K/AKT network. In order to define driver alterations, we correlate deletions and losses with mutational data. We found losses are also targeted by mutations (*BRCA2*, *LRRK1*), while deleted genes, as *CASK*, *CDK6* and *MAPT*, were involved in pathways affected by genomic mutations (*CASK* deletion and *MPP6* mutation, *CDK6* deletion and *PPM1D* mutation, *MAPT* deletion and *SPAG5*mutation). **Conclusions:** We have identified new CNAs and pathways involving novel potential leukemia-related genes. The comparison between SNP and WES data could provide important findings on prognosis of AML patients. Minimal deleted regions of genes in deregulated pathways deserve further investigation in order to identify new genes which could be relevant AML biomarkers. Ackn**:** ELN, AIL, AIRC,prog. Regione-Università 2010-12 (L. Bolondi),FP7 NGS-PTL project,HARMONY.

11623 Poster Session (Board #323), Sat, 1:15 PM-4:45 PM

Parallel VENTANA IHC and RT-PCR of ALK status in non-small cell lung cancer and response to crizotinib. *First Author: Chunwei Xu, Fujian Cancer Hospital, Fuzhou, China*

Background: Advanced NSCLC patients who harbor (ALK) rearrangement were sensitive to crizotinib. However, not all ALK-positive patients benefit equally from crizotinib. A method for determining ALK rearrangement is RT-PCR, the Chinese FDA has approved RT-PCR to detect ALK rearrangement. In this regard, VENTANA IHC is a standard method to identify ALK protein overexpression in NSCLC. However, up to now, it is still largely unknown about the response to crizotinib for Chinese NSCLC patients having ALK overexpress detected by VENTANA IHC. To better clarify the clinical implication of VENTANA IHC to detect ALK rearrangement, we compared the curative effect and survival by the two methods in advanced NSCLC patients and analysis VENTNA IHC and RT-PCR inconsistent cases. **Methods:** A total of 1720 patients with NSCLC who had their ALK rearrangement detected by IHC and/or RT-PCR were included in this analysis. And we compared the efficacy and survival of patients with ALK positive detected by IHC and RT-PCR. We used next-generation sequencing (NGS) to detect patients whom two methods were not consistent. **Results:** 187/1720 patients were identified as ALK-positive by IHC and/or RT-PCR and 66 patient received crizotinib. We identified 172/1674 patients had ALK positive by IHC method, 41/322 patients had ALK rearrangements by RT-PCR method. And 29/276 patients with ALK positive were simultaneously analyzed by IHC and RT-PCR. The overall response rates (ORR) were 65.90% by IHC and 55.88% by RT-PCR, respectively. And the disease control rates (DCR) were 86.36% by IHC and 76.47% by RT-PCR. The median PFS of IHC was 8.5 months and RT-PCR was 9.2 months Targeted next-generation sequencing in the special type: Among 6 cases of 17 cases ALK positive patients were inconsistent by IHC and RT-PCR performed with NGS, 4 cases were identified to have EML4-ALK fusions, and 2 cases were KCL1-ALK (ND) and FBXO36-ALK (PFS 21.2 months). **Conclusions:** VENTANA IHC is a reliable and rapid screening tool in routine pathologic laboratories for the identification of suitable candidates for targeted therapy. It has a moderate sensitivity and a slightly higher curative effect, and some VENTANA IHC positive but RT-PCR negative cases may benefit from crizotinib.

11624 Poster Session (Board #324), Sat, 1:15 PM-4:45 PM

KRAS in non-small cell lung cancer: Single institution experience—What factors are involved? *First Author: Idoroenyi Usua Amanam, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Disease heterogeneity with variable molecular mutations is one of the main contributory factors in non-small cell lung cancer (NSCLC). The goal of this study was to better understand the *KRAS* patients with co-occurring mutations. **Methods:** We identified 60 patients with a diagnosis of NSCLC and a *KRAS* mutation in the COH Cancer Registry from 2009 to 2016. Next generation sequencing was performed. **Results:** Of the 60 patients identified, 42 (70%) were Stage IV at diagnosis, 7 (12%) Stage I and 7 (12%) stage II and 4 (6%) Stage III. 47 (78) patients were smokers. Caucasian was the most common (n = 44, 73%) racial group, followed by Asians (n = 9, 15%), African-Americans (n = 3, 5%), other (n = 3, 5%) and Pacific Islander (n = 1, 1.7%). The average age at diagnosis was 67 (median 69.50) years; 30 patients (50%) were over 70 years, 23 (38%) patients were 51-69 years, and 7 (12%) 50 years or below. Majority of the patients had metastatic disease (n = 52, 87%) with 20% (n = 12) having brain metastasis with average metastatic sites 1.6. An average of 1.97 (range = 0-5) lines of therapy including chemotherapy, biologic agents or immunotherapy were received. 12 (20%) patients received immunotherapy, radiation in 28 (47%) and surgery in 22 (37%) with a median overall survival at 15 months. The most frequent molecular alteration was codon 12 mutation (n = 47, 78%), followed by codon 13 (n = 7, 12%) and codon 61 (n = 6, 10%) mutations. The most common co-occurring mutations in this cohort were TP53 (n = 15, 25%), ATM (n = 9, 15%), LRP1B (n = 9, 15%), ARID1A (n = 8, 13%), STK11 (n = 8, 13%), ARID1B (n = 7, 12%), TERT (n = 7, 12%), EGFR (n = 6, 10%), RBM10 (n = 6, 10%), SPTA1 (n = 6, 10%). We are currently evaluating the relevance of the Circos plot analysis for these mutations, clinical response to immunotherapy and potential biomarkers. **Conclusions:** KRAS mutations are among the most common molecular alterations identified in NSCLC. Effective treatments targeting KRAS mutations have represented a challenge so far. Understanding the significance of co-mutations and their therapeutic implications, especially in response to immunotherapy and other agents represents an important step to develop better treatment options for KRAS mutated lung cancers.

TPS11625 Poster Session (Board #325a), Sat, 1:15 PM-4:45 PM

WINTHER: An international study to select rational therapeutics based on the analysis of matched tumor and normal biopsies in subjects with advanced malignancies. *First Author: Jean-Charles Soria, Gustave Roussy Cancer Campus and University Paris-Sud, Villejuif, France*

Background: Today, personalized cancer medicine implies matching the patient's tumor genomic characteristics with molecularly and immune targeted agents. Although there are an increasing number of DNA aberrations that can now be matched to a cognate therapy, some patients do not display such druggable oncogene drivers. **Methods:** WINTHER is an open non-randomized study involving 6 cancer centers in France, Spain, Israel, Canada and USA applying genomic and also transcriptomic assays to guide treatment decisions. The novelty of the WINTHER approach lies in the use of tumor and matched normal tissue biopsies together and an algorithm for predicting efficacy of therapies. The aim is to provide a rational therapeutic choice for all of the patients enrolled in the study whether or not they harbor actionable DNA alterations. The study endpoint is the comparison of the progression-free-survival (PFS) under the WINTHER selected therapy to the PFS of the last therapeutic line. Patients included have refractory metastatic cancer of any histological type, with at least one prior therapeutic regimen and performance status of 0 to 1. Patients who have received a matched treatment based on a molecular anomaly as their immediate prior therapy were excluded. After consent, patients undergo a tumor and histologically-matched normal tissue biopsy. Extracted DNA and RNA of both tumor and normal from frozen tissues at the local center under common standard operating procedures are sent to centralized laboratories for omics investigations. DNA is investigated at Foundation Medicine Inc. and RNA at Gustave Roussy using Agilent technology. For RNA, the WINTHER algorithm is applied on the differential RNA expression data between tumor and normal tissues and establishes the list of drugs with the presumed higher score of efficacy for each patient. Patients with actionable genomic events enter in ARM A, and patients without any druggable anomaly of the DNA enter in ARM B and are treated using the WINTHER algorithm RNA-based treatment decision tool. To date, the trial has recruited 303 patients. Clinical trial information: NCT01856296.

TPS11626 Poster Session (Board #325b), Sat, 1:15 PM-4:45 PM

A phase I, first-in-human, dose escalation study of intravenous TK216 in patients with relapsed or refractory Ewing sarcoma. *First Author: Noah Federman, University of California, Los Angeles, Los Angeles, CA*

Background: Ewing sarcoma (ES) is a rare cancer that affects children and young adults. Patients with recurrent/refractory ES have a poor prognosis (5-year survival 10-15%) with no improvement despite advances in cytotoxic and targeted therapies. Genomic rearrangements resulting in fusion proteins and over-expression of *ets* family transcription factors occur in 95% of ES. In particular, the EWS-FLI1 oncogenic fusion creates a constitutively active transcription factor that drives the malignant ES phenotype. Strategies to target the EWS-FLI1 fusion protein have been limited by lack of specificity. A promising approach is to target the interaction of the *ets* transcription factor with its critical protein partner, RNA helicase A (RHA). TK216 is a novel small-molecule that directly binds to EWS-FLI1 and inhibits its function by blocking binding to RHA. TK216 demonstrates potent anti-proliferative effects on ES cell lines and xenografts. **Methods:** We initiated a Phase 1, first-in-human, open-label, multi-center, dose-escalation/dose-expansion trial of TK216 in patients with recurrent/refractory ES who are ≥12 years of age (ClinicalTrials.gov: NCT02657005). TK216 is dosed based on body surface area and administered as a continuous intravenous infusion for 7 days followed by 14 days rest every 21 days. Treatment may continue in the absence of disease progression. One intrapatient dose escalation is allowed. Enrollment of 6 to 8 cohorts using a 3+3 dose-escalation design is anticipated. During dose expansion, a total of 18 patients with ES will be accrued at the recommended Phase 2 dose (RP2D). The primary objective of the study is to determine the maximum tolerated dose and RP2D of TK216. Secondary objectives are to assess the safety profile, pharmacokinetics, pharmacodynamics, and antitumor activity of TK216. Molecular assays will be performed to characterize EWS-FLI or EWS-ets abnormalities in archival tumor tissue. The overall response rate, duration of response, progression-free survival, and overall survival will be determined in the expansion cohort. Nine patients have been enrolled since June 2016. Accrual to cohorts 1, 2, and 3 completed and cohort 4 opened in January 2017. Clinical trial information: NCT02657005.

TPS11627 Poster Session (Board #326a), Sat, 1:15 PM-4:45 PM

CEA, CA15.3 and 18-FDG PET in the follow-up of early breast cancer (BC) patients (pts): A prospective, multicentric, randomized trial—KRONOS patient-oriented new surveillance study Italy. *First Author: Claudio Zamagni, Policlinico S. Orsola-Malpighi Hospital, Bologna, Italy*

Background: Current recommendations for breast cancer (BC) surveillance in asymptomatic patients (pts) include only mammography and physical examination and arise from two trials conducted in the 80's. Since then new findings about BC biology, treatment and the introduction of cutting-edge diagnostic technologies such as 18-FDG PET have deeply modified our clinical scenarios. The aim of this prospective randomized trial is to verify if the serial measurement of CEA and CA15-3 followed by 18-FDG PET can anticipate the diagnosis of BC recurrence compared to control arm by estimation of the difference of restricted mean survival time (RMST) between the two arms. If the end-point will be met a subsequent extension trial will investigate the impact of the earlier diagnosis of distant metastases on survival. **Methods:** Pts diagnosed with stage I-III BC, who underwent adequate surgery are eligible. Special histologies and low-risk cases according to St. Gallen criteria are excluded. The study includes pts at the beginning of the follow-up after the conclusion of primary treatment (cohort 1), and pts that have concluded without relapse the first 5 years of follow-up (cohort 2). Eligible pts will be randomized in a 1:1 ratio to follow-up according to local practice (control arm) or to three-monthly serial dosing of CEA and CA15-3 and subsequent 18 FDG-PET only in case of an increase of CEA and/or CA 15.3 greater than a critical difference compared to baseline (experimental arm). The following stratification factors will be used: node negative *vs* positive, HER2 negative *vs* positive, ER positive *vs* negative. Eight-hundred pts will be enrolled over 3 years. For such a calculation, we made the assumption of a 20% baseline 5-year incidence of relapse. The target reduction of three months in RMST implies a median time of diagnostic anticipation, conditional on having BC recurrence, of 10 months. The follow-up will continue until 10 years from surgery. Since 23rd October 2014 573 pts have been enrolled. The present trial was approved by the Ethical Committee of each participating centre and is registered on Clinical trial information: NCT02261389.

TPS11628 Poster Session (Board #326b), Sat, 1:15 PM-4:45 PM

A pharmacodynamic study of sirolimus and metformin in patients with advanced solid tumors. *First Author: Amikar Sehdev, Indiana University, Indianapolis, IN*

Background: Sirolimus is an inhibitor of the mammalian target of rapamycin (mTOR). Metformin has shown anti-cancer activity through its cellular (e.g., AMPK activation) and systemic effects (e.g., inhibition of IGF-1). We conducted a pilot study to test the hypothesis that metformin may potentiate mTOR inhibition by sirolimus. **Methods:** An open-label, randomized study was conducted in which eligible patients with advanced solid tumors were started on sirolimus (3mg daily) alone for the first 7 days. On day 8, patients were randomized to either receive metformin XL (500 mg daily) plus sirolimus (Arm A) or sirolimus alone (Arm B) for until day 21. From day 22 onwards, all patients recieved metformin XL plus sirolimus. The pharmacodynamic (PD) biomarkers were collected at baseline, day 8 and day 22 of cycle 1. The primary endpoint was to compare the change in PD biomarker phospho-p70S6K, using a two-sample t test (log ratio D22/D8 in arm A vs. arm B). The phospho-p70S6K was measured in peripheral blood T cells using Western blot. The secondary endpoints were to assess objective response rate (RECIST 1.1), toxicity (CTCAE V4.0) and changes in the serum levels of PD biomarkers: fasting glucose, triglycerides, insulin, C-peptide, IGF-1, IGF-1R, IGF-BP, leptin and adiponectin using two-sample t tests. **Results:** 24 patients were enrolled, at which time an interim futility analysis was conducted. 18 patients were evaluable for the primary endpoint (8 in arm A; 10 in arm B). The mean log ratios D22/D8 in phospho-p70S6K in arms A and B were -0.12 (SD = 0.13) and -0.16 (SD = 0.29), respectively (P = 0.64). Of the 17 pts evaluable for response, the best response was stable disease in 9 patients and progressive disease in 8 patients. There were no dose-limiting or unexpected toxicities. Of the 21 patients evaluable for serum PD biomarkers, there were no significant differences between arms A and B in fasting glucose, triglycerides, insulin, C-peptide, IGF-1, IGF-BP1, IGF-BP3, leptin and adiponectin ($P > 0.05$ for all). **Conclusions:** The addition of metformin to sirolimus, although well-tolerated, was not associated with significant changes in phospho-p70S6k and other PD biomarkers. Based on the results of the interim analysis, the trial was terminated. Clinical trial information: NCT02145559.

Publication-Only Abstracts

Publication-only abstracts, which are selected to be published in conjunction with the 2017 Annual Meeting, but not to be presented at the Meeting, can be found online in full-text, fully searchable versions at abstracts.asco.org and JCO.org.

The publication-only abstracts are not included in the print volume, but are citable to this *Journal of Clinical Oncology* supplement. Please refer to the following example when citing publication-only abstracts:
