Background: Programmed Death-1 Receptor (PD-1) and its ligand (PD-L1) downregulate T cell activation and suppress tumor killing. This study investigated the role of PD-L1 and tumor infiltrating lymphocytes (TILs) in response to neo-adjuvant therapy and prognosis in esophageal adenocarcinoma (EAC). **Methods:** Transcriptional profiling of 273 formalin fixed paraffin embedded pre-treatment endoscopic EAC biopsies was carried out using the Almac Diagnostics Xcel array and the expression levels of PD-L1 probesets corresponding to protein encoding extracted. Response was assessed by tumor regression grade (TRG; score ≤ 2 = response). Immunohistochemistry (IHC) for PD-L1 and CD8 was performed in matched resection specimens from 135 patients. All EAC patients were treated with cisplatin-based neo-adjuvant chemotherapy followed by surgical resection between 2003 and 2014 at four UK centers as part of the OCCAMS consortium. Associations between expression, protein levels and TRG were assessed by Kruskal-Wallis, Mann-Whitney Unpaired, Spearman rank correlation or chi-squared tests. Survival analysis was performed using Cox Proportional Hazards regression. **Results:** High PD-L1 gene expression in the pre-chemotherapy biopsies was associated with pathological response (TRG ≤ 2; $p = 0.02$) following neo-adjuvant chemotherapy. PD-L1 ($> 5\%$) was expressed in the tumor or stromal cells in 4% and 15% of resection specimens respectively. PD-L1 gene and IHC expression ($> 5\%$) were closely associated between the biopsies and both the tumor ($p = 0.032$) and stroma ($p = 0.019$) of the matched resection specimens. Patients with PD-L1 IHC positivity in tumor cells demonstrated improved relapse-free survival (HR 0.314; 95% CI 0.099-0.997; $p = 0.049$) and positive stromal PD-L1 IHC staining correlated with pathological response ($p = 0.05$). Biopsy gene expression of PD-L1 and CD8 was closely associated ($p = 0.024$) and the presence of CD8+ TILs in the microenvironment strongly correlated with tumor ($p < 0.001$) and stromal ($p < 0.001$) PD-L1 positivity. **Conclusions:** High PD-L1 expression in the pre-treatment biopsies in EAC is predictive of response to neo-adjuvant chemotherapy and may aid selection of conventional and immune-targeted agents.

4024 Poster Session (Board #16), Sat, 8:00 AM-11:30 AM

VIKTORY trial: Report on AZD1775/paclitaxel in TP53 mutation (+) GC, selumetinib/paclitaxel in ras aberrant GC, AZD5363/paclitaxel in PIK3CA mt and biomarker negative, savolitinib/docetaxel in met (+), and vistusertib/paclitaxel in RICTOR(+) GC. *First Author: Jeeyun Lee, Samsung Medical Center, Seoul, Republic of Korea*

Background: The VIKTORY trial is a biomarker-based umbrella trial in GC. **Methods:** See table below. **Results:** From June 2014 to Jan 2017, 432 metastatic gastric cancer patients were enrolled. 124 (28.7%) were treated on one of the associated study protocols. At January 2017, 25 pts were allocated to selumetinib/paclitaxel arm, 25 to AZD1775/paclitaxel arm, 16 to AZD5363/paclitaxel arm, 16 to vistusertib/paclitaxel arm, 4 to savolitinib monotherapy, 19 to savolitinib/docetaxel arm, 19 to phase I AZD6738/paclitaxel arm. Initial efficacy signals have been seen in several arms (selumetinib/paclitaxel, 6 of 21 evaluable patients in PR). Correlative analyses between molecular signatures and treatment response are ongoing and will be presented at the meeting. For vistusertib/paclitaxel in the biomarker negative arm, we found RICTOR amplification as a promising predictive biomarker for response. Two (of three) GC patients with RICTOR amplification achieved PR to vistusertib/paclitaxel. **Conclusions:** This is one of the first attempts to undertake a biomarker-driven trial in metastatic GC. 28.7% of the patients were guided to one of the parallel arms based on molecular screening outcomes. We were able to identify potential molecular targets in the biomarker-negative arm, for further assessment in new protocols. Clinical trial information: 02299648.

Biomarker	Treatment arm
RAS amp/mt or MEK signature	selumetinib(AZD6244, ARRY-142886, licensed from Array BioPharma), 75 mg bd continuous/docetaxel 60mg/m^2 q 3 wks
PIK3CA amp/mt	AZD5363, 400 mg bd 4d on 3d off/paclitaxel 80 mg/m^2 D1,8,15 q28d
MET amp or MET overexpression	1) savolitinib (AZD6094, HMPL504), 600 mg qd/docetaxel 60 mg/m^2 q 3wk; 2) savolitinib 800mg OD q 3 wks
TP53 mt	AZD1775, 225 mg BD (x 5 doses) days 1~3 q3w paclitaxel 80 mg/m^2 D1,8,15
Biomarker negative (non-actionable)	vistusertib 50 mg bd 3 d on 4 d off, of a 7 d/paclitaxel 80 mg/m^2 D1,D8, D15 q 28 d
RICTOR amplification	vistusertib 50 mg bd 3 d on 4 d off, of a 7 d / paclitaxel 80 mg/m^2 D1,D8,D15 q 28 d
TSC1 TSC2 null	vistusertib 50 mg bd 3 d on 4 d off, of a 7 d/paclitaxel 80 mg/m^2 D1,D8, D15 q 28 d

4025 Poster Session (Board #17), Sat, 8:00 AM-11:30 AM

Correlation of benefit from immune checkpoint inhibitors with next gen sequencing (NGS) profiles in esophagogastric cancer (EGC) patients. *First Author: Geoffrey Yuyat Ku, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immuno-oncology (IO) with anti-PD-1 and –PD-L1 antibodies (Abs) is active in EGC but only benefits a minority of Pts. Biomarkers are needed to identify responders. **Methods:** We reviewed our experience of Pts treated with anti-PD-1/PD-L1 Abs and correlated their outcomes with PD-L1 and mismatch repair protein (MMR) status by immunohistochemistry (IHC), as well as MSK-IMPACT (≥340-gene) NGS profile. MSIsensor from IMPACT assesses microsatellite instability phenotype, while ≥20 mutations (or 17 mutations/Mb) strongly correlates with MMR-deficiency (dMMR) by IHC (J Clin Oncol 2016;34:2141). Progression-free (PFS) and overall survival (OS) were analyzed from the start of IO. **Results:** 71 Pts were identified, with 3 Pts receiving 2 IO regimens. 66 had adenoCAs and 5 had squamous CAs. Median age 58, 77% male, 96% had received ≥2 prior chemo regimens. 39 (55%), 18 (25%) and 17 Pts (24%) respectively received anti-PD-1, anti-PD-L1 and anti-CTLA-4 plus anti-PD-1/PD-L1 Abs. 6 Pts (8%) had objective response (2 complete responses or CRs) and the median PFS and OS are 1.6 and 4.7 mos; 2-yr OS is 17%. PD-L1 IHC was performed in 16 Pts (23%; 7 +ve), MMR was tested in 20 Pts (28%; 4 dMMR) and IMPACT was obtained in 44 Pts (62%). All 4 dMMR tumors were also MSI by MSIsensor and had a median of 46 mutations (range, 29-63) or, equivalently, 33 mutations/Mb (range, 21-46); 2 of 2 dMMR tumors tested PD-L1 +ve. 3 of the 4 Pts with dMMR/MSI tumors had a response (including 1 CR) and the median OS of these 4 Pts is not reached with 23+ months of follow-up. Finally, a patient whose tumor is MMR-proficient, not MSI but has 15 mutations (including in *POLD1*), achieved an ongoing CR at 37+ mos. For the 44 Pts with IMPACT testing, there appeared to be improved OS for tumors with ≥10 vs. <10 mutations/Mb (2-yr OS 80% vs. 12%, p=0.03). **Conclusions:** Pts with tumors that are MSI or have ≥10 mutations/Mb on MSK-IMPACT appear to derive significant benefit from IO. MSK-IMPACT can offer novel information, identify novel mutations (e.g. *POLD1*) and may be used to help select Pts for IO. We are seeking to define a mutation no. cut-off that can serve as a biomarker and updated data will be presented.

4026 Poster Session (Board #18), Sat, 8:00 AM-11:30 AM

Association of a DNA damage response deficiency (DDRD) assay with prognosis in resected esophageal and gastric adenocarcinoma. *First Author: Richard C. Turkington, Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom*

Background: Current strategies to guide the selection of neo-adjuvant or adjuvant therapy in esophageal and gastric adenocarcinomas (EAC/GAC) are inadequate. We assessed a clinically validated 44 gene DNA Damage Response Deficiency (DDRD) assay to predict prognosis following neo-adjuvant DNA damaging chemotherapy (CT) in EAC and adjuvant CT or chemoradiotherapy (CRT) in GAC. **Methods:** Transcriptional profiling of 273 formalin fixed paraffin embedded pre-treatment endoscopic EAC biopsies was performed using the Almac Diagnostics Xcel array. All EAC patients were treated with cisplatin-based neo-adjuvant chemotherapy followed by surgical resection between 2003 and 2014 at four UK centers in the OCCAMS consortium. Further validation was performed using a publically available dataset of 270 resected gastric cancers treated with adjuvant platinum-based CT, CRT or surgery alone at the Samsung Medical Centre, Seoul, Korea. The association between the DDRD score and prognosis was assessed by Kaplan-Meier analysis and Cox Proportional Hazards regression. **Results:** A total of 66 EAC samples (24%) were characterized as DDRD positive with the remaining 207 samples (76%) being DDRD negative. DDRD assay positivity was associated with improved DFS (HR 0.58; 95% CI 0.36-0.93; p = 0.024) and OS (HR 0.56; 95% CI 0.34-0.92; p = 0.023) following multivariate analysis. DDRD positive patients had a higher pathological response rate (p = 0.033) and a higher rate of loco-regional versus distant relapse (30% vs 20%; p = 0.013). For GAC, 132 samples (49%) were characterized as DDRD positive with the remaining 138 (51%) being DDRD negative. DDRD positivity was associated with improved DFS (HR 0.48; 95% CI 0.25-0.96; p = 0.037) following D2 gastrectomy and adjuvant CT or CRT. DDRD status was not associated with DFS in the surgery alone cohort (HR 0.87; 95% CI 0.55-1.38; p = 0.562). **Conclusions:** The DDRD assay is strongly predictive of benefit from DNA damaging neo-adjuvant CT and esophagectomy in EAC and gastrectomy and CT/CRT in GAC and can be applied to routine diagnostic material.

4027 Poster Session (Board #19), Sat, 8:00 AM-11:30 AM

A randomized, double-blind, multi-center phase III study evaluating paclitaxel with and without RAD001 in patients with gastric or esophagogastric junction carcinoma who have progressed after therapy with a fluoropyrimidine/platinum-containing regimen (RADPAC). *First Author: Sylvie Lorenzen, Third Department of Internal Medicine (Hematology/Medical Oncology), Klinikum rechts der Isar, Technische Universitat Munchen, Munich, Germany*

Background: There is a need for effective treatments in the second- or further line setting in advanced gastric cancer, especially for new agents. In the current trial we evaluated paclitaxel with RAD001 (everolimus) in patients with gastric carcinoma who have progressed after therapy with a fluoropyrimidine/platinum-containing regimen. **Methods:** This is a randomized, double-blind, multi-center phase III study. Patients with gastric carcinoma or adenocarcinoma of the esophagogastric junction (EGJ) who have progressed after treatment with a fluoropyrimidine/platinum-containing regimen were randomly assigned to receive Paclitaxel (80 mg/m2) on day 1, 8 and 15 plus placebo (arm A) or RAD001 (10mg daily, arm B) d1-d28, repeated every 28 days as 2nd, 3rd or 4th line therapy. Primary end point was overall survival (OS), secondary endpoints were best overall response, disease control rate, progression free survival (PFS) and toxicity. **Results:** 300 patients (median age: 62 years; median lines prior therapy: 2; 47.7% of patients had prior taxane therapy) were randomly assigned (Arm A, 150, Arm B, 150). In the intention to treat population, there was no significant difference in median PFS (placebo, 2.07 vs. RAD001, 2.2 months, HR 0.88, p = 0.3) or median OS (placebo, 5.0 vs. RAD001, 6.1 months, HR 0.93, p = 0.54). For patients with prior taxane use, RAD001 improved PFS (placebo 1.8 vs. RAD001, 2.7 months, HR 0.69, p = 0.03) and OS (placebo 3.9 vs. RAD001, 5.8 months, HR 0.73, p = 0.07). Combination of paclitaxel and RAD001 was tolerable, but the RAD001 arm was associated with significantly more grade 3-5 mucositis (13.3% vs. 0.7%; p < 0.001). **Conclusions:** The addition of RAD001 to paclitaxel/RAD001 did not improve outcomes in pretreated metastatic gastric/EGJ cancer. Of note, activity was seen in the taxane pretreated group. Additional biomarker studies are planned to look for subgroups that may have a benefit. Clinical trial information: 2009-018092-14.

4028 Poster Session (Board #20), Sat, 8:00 AM-11:30 AM

Results of interim analysis of the multicenter randomized phase III SENORITA trial of laparoscopic sentinel node oriented, stomach-preserving surgery versus laparoscopic standard gastrectomy with lymph node dissection in early gastric cancer. *First Author: Keun Won Ryu, Gastric Cancer Branch, Research Institute and Hospital, National Cancer Center, Goyang, South Korea*

Background: The benefits and hazards of laparoscopic sentinel node oriented stomach-preserving surgery, compared to those of laparoscopic standard gastrectomy with lymph node dissection in early gastric cancer (EGC), are unknown. The SENORITA trial investigated the clinical impact of laparoscopic sentinel node oriented stomach-preserving surgery in EGC. **Methods:** Other than those with absolute indication for endoscopic resection, eligible patients had EGC confined to the mucosa and submucosa, with diameter ≤ 3cm, regardless of histology on preoperative evaluation. Patients were randomized for laparoscopic standard gastrectomy or laparoscopic stomach-preserving surgery. Patients were stratified based on depth (mucosa vs. submucosa) and size (≤ 2cm vs. 2 < ≤ 3cm) of the EGC and by participating institution. The primary endpoint was 3-year disease-free survival (3yDFS). The expected 3yDFS was 97% and non-inferior margin was 5%. 580 patients and 24 events were needed to show non-inferiority with 80% power. One interim analysis was planned after 12 events (50%) occurred. Using the O'Brien-Fleming error spending function, the two-sided nominal significance level for the interim analysis would be 0.0054. **Results:** From March 2013 to May 2016 462 patients were randomized; analysis was performed in 421 after a dropout of 41 patients. Laparoscopic stomach-preserving surgery was possible in 75.6% by study protocol. Interim analysis was conducted based on 12 events (median follow-up: 15.89 months). The 3yDFS in the laparoscopic standard gastrectomy arm was 96%; the 3yDFS in the laparoscopic stomach-preserving surgery arm was 93%, (99.46% CI: -3.18%, 9.18%). The postoperative complication rates were 15.0% and 12.9%, respectively (p = 0.542). **Conclusions:** In this interim analysis, laparoscopic sentinel node oriented stomach-preserving surgery did not show non-inferiority for 3yDFS. The follow-up time was not mature enough to evaluate non-inferiority. Further follow-up will elucidate the role of laparoscopic sentinel node oriented stomach-preserving surgery. Clinical trial information: NCT01804998.

4029 Poster Session (Board #21), Sat, 8:00 AM-11:30 AM

Short-term outcomes from a multi-institutional, phase III study of laparoscopic versus open distal gastrectomy with D2 lymph node dissection for locally advanced gastric cancer (JLSSG0901). *First Author: Sang-Woong Lee, Osaka Medical College, Osaka, Japan*

Background: The safety of laparoscopic gastrectomy for advanced gastric cancer is controversial. We conducted a multi-institutional, randomized controlled trial to compare short- and long-term outcomes of laparoscopic distal gastrectomy (LAP) with D2 lymph node dissection for advanced gastric cancer in comparison to open distal gastrectomy (OP) in Japan (UMIN000003420). We herein demonstrate short-term outcomes of this trial. **Methods:** Patients with potentially curable gastric cancer (T2-T4, N0-2 and M0) by distal gastrectomy were eligible for inclusion. Between November 2009 and July 2016, 507 patients were randomly assigned to either the LAP group (n = 252) or the OP group (n = 255). Only credentialed surgeons in both the procedures from 37 Japanese institutions participated in the study. The primary endpoint was 5-year relapse free survival. Secondary endpoints were 5-year overall survival, adverse events and short-term clinical outcomes. **Results:** According to study protocol, 47 patients among the total eligible patients were excluded because of distant metastasis or tumor extension intraoperatively. The remaining 460 patients underwent distal gastrectomy with D2 lymph node dissection and were analyzed as per protocol. Estimated blood loss was lower in LAP than in OP (30 vs. 150 ml, $P < 0.001$) and operative time was longer in LAP than in OP (291 vs. 205 min, $P < 0.001$). Post-operative analgesics use was less in LAP than in OP (38.3 vs. 53.6 %, $P = 0.001$), and first day of flatus was shorter in LAP than in OP (2 vs. 3 days, $P < 0.001$). There were no significant differences in all grade intra-operative complications (LAP 0.9% vs. OP 2.6%, $P = 0.285$). In addition, there were no significant differences in grade 3 and higher post-operative complications between the two groups (LAP 3.1% vs. OP 4.7%, $P = 0.473$). Hospital mortality was 0.4 % in each group. **Conclusions:** Credentialed surgeons could safely perform laparoscopic distal gastrectomy with D2 lymph node dissection for locally advanced gastric cancer. The laparoscopic approach could be accepted without increasing major surgical complications in this setting. Clinical trial information: 000003420.

4030 Poster Session (Board #22), Sat, 8:00 AM-11:30 AM

Assessment of conditional survival probability in resected esophageal adenocarcinoma. *First Author: Donna M. Graham, Queens University of Belfast, Belfast, United Kingdom*

Background: Prognostication for cancer patients is based upon factors determined at baseline and becomes less relevant over time. Conditional survival (CS) estimates future prognosis based upon survival to a specific time point after treatment. We analyzed CS for patients in the United Kingdom (UK) undergoing surgery and neoadjuvant chemotherapy (NAC) for gastro-esophageal junction (GEJ) or esophageal adenocarcinoma (EAC). **Methods:** 1409 patients with GEJ/EAC treated with NAC and surgical resection at 7 centers across the UK from 2002-2014 were identified. Clinicopathological and survival data was collected as part of the Oesophageal Cancer Clinical and Molecular Stratification (OCCAMS) consortium. A multivariable Cox survival model was used to analyze the association of factors such as node positivity (N+), lymphovascular invasion (LVI+), tumor differentiation, circumferential resection margin involvement (CRM+) and pathological response by tumor regression grade (TRG ≤ 2) with risk of relapse (RR) or death from time of surgery. **Results:** Of 1409 patients, 726 (51.5%) were aged <65 years, and 1195 (84.8%) were male. Hazard ratios (HR) for RR conditional on recurrence-free (RF) years to date are detailed below. N+ was the most robust predictor of relapse and mortality over time. LVI+ and moderate to poor differentiation influenced relapse in the first 2 years whereas CRM+ and TRG≤ 2 had their greatest effect in the year following surgery. Age, sex, and year of surgery had no association with RR or mortality. Similar patterns were observed for risk of death. **Conclusions:** CS provides a more dynamic estimate of future RR and survival among patients who have accrued survival time, especially in patients with high-risk features. CRM+ and LVI+ govern early survival events but as time from surgery increases these factors become less relevant.

Probability of relapse within timeframe conditional on RF status.

	0-1yr		1-2yr		2-3yr		3-5yr	
	HR	p-value	HR	p-value	HR	p-value	HR	p-value
N+	2.06	<0.001	2.76	<0.001	2.91	0.002	2.81	0.012
LVI+	1.80	0.001	1.63	0.009	0.62	0.242	0.85	0.722
Mod/poor diff	1.73	0.001	1.50	0.033	0.91	0.826	1.97	0.187
CRM+	1.68	<0.001	1.00	0.986	1.14	0.664	1.41	0.432
TRG ≤2	2.38	0.015	1.22	0.488	1.47	0.447	4.20	0.058

4031 Poster Session (Board #23), Sat, 8:00 AM-11:30 AM

Impact of chemoradiotherapy on PD1/PDL1 expression and clinical outcomes in gastroesophageal cancers. *First Author: Arsen Osipov, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Expression of the immune modulating proteins, programmed death receptor-1 (PD1) and its ligand (PDL1), in gastrointestinal malignancies is associated with poor prognosis. PD1/PDL1 expression levels have also been identified as predictors of response to checkpoint inhibition. Minimal data is available on how expression of PD1 and PDL1 is influenced by chemoradiotherapy (CRT). In this study, we investigated the relationship between PDL1/PD1 expression, CRT, and clinical outcomes in gastro-esophageal (GE) cancer. **Methods:** With IRB approval, we identified 28 patients with gastric cardia or GE junction tumors who underwent neoadjuvant standard CRT followed by surgical resection. Pre-CRT biopsies and post-CRT surgical specimens were analyzed using quantitative immunohistochemistry for the expression of PDL1 and PD1. Samples were categorized as trace-low (TL) or moderate-high (MH) expressors of PDL1 and PD1. The impact of these and other clinical and pathologic variables on overall survival (OS) was assessed using multivariate cox proportional hazards modeling. Co-expression of PDL1 and PD1 in matched samples was determined by regression analysis. **Results:** Following CRT, PDL1 and PD1 expression increased in 54% and 32% of patients, respectively. On multivariate analysis, patients with MH expression of PD1 after CRT irrespective of pre-CRT expression levels had a significant decrease in OS compared to those with TL expression (median survival 23.1 vs 74.1 months; HR,3.31; CI,1.05-10.35; $p = 0.039$). In patients with gastric confined tumors, an increase in PD1 expression from TL to MH after CRT was associated with significantly lower OS rates ($p = 0.003$). Regression analysis of PD1 to PDL1 was significant ($p < 0.01$) both before and after CRT, with a correlation coefficient of 0.34 in pre-CRT and 0.49 in post-CRT specimens. **Conclusions:** Elevated expression of PD1 is associated with poor OS in patients with GE cancer. Neoadjuvant CRT upregulates both PDL1 and PD1. In gastric cancer patients, this led to significantly worse survival. These data identify potential mechanisms of resistance and suggest a role for checkpoint inhibitors in combination with CRT.

4032 Poster Session (Board #24), Sat, 8:00 AM-11:30 AM

Current trends and survival in patients with esophageal squamous cell carcinoma: An analysis of the National Cancer Database from 2007 to 2013. *First Author: Brandon C. Chapman, University of Colorado School of Medicine, Aurora, CO*

Background: Although surgical resection is the treatment of choice for patients with esophageal squamous cell carcinoma (ESCC), some evidence suggests that definitive chemoradiation (CR) may have equivalent survival compared to surgery alone. The objective of this study was to evaluate current trends in the treatment of ESCC and its impact on overall survival (OS). **Methods:** Using the NCDB (2004-2013), patients with non-metastatic/loco-regional ESCC were categorized into definitive CR, neoadjuvant CR/surgery, surgery alone, and surgery/adjuvant therapy. Multivariate Cox proportional hazard models by stepwise selection were applied to estimate hazard ratios (HR) of predictors of OS. **Results:** We identified 11,229 patients with ESCC undergoing definitive CR (n = 8855, 78.9%), neoadjuvant therapy/surgery (n = 953, 8.5%), surgery alone (n = 1130, 10.1%), and surgery/adjuvant therapy (n = 291, 2.6%). The distance of primary tumor from incisors was comparable for all four groups. On multivariable analysis, treatment modality had the largest impact on OS followed by AJCC stage, age and annual surgical volume. Compared to neoadjuvant therapy/surgery, both surgery only (HR 1.17, 95% CI 1.04-1.32) and definitive CR (HR 1.51, 95% CI 1.37-1.66) were associated with increased long-term mortality. However, there was no difference in mortality in the surgery/adjuvant therapy group (HR 1.10, 95% CI 0.94-1.30) compared to the neoadjuvant therapy/surgery group. Patients treated at facilities performing more than 20 esophagectomies per year, regardless of whether they underwent surgical resection, had improved OS compared to facilities performing 10-19 per year (HR 1.47, 95% CI 1.29-1.68), 5-9 per year (HR 1.44, 95% CI 1.29-1.62), and < 5 per year (HR 1.53, 95% CI 1.38-1.70). **Conclusions:** Patients receiving either neoadjuvant therapy or adjuvant therapy and esophagectomy for ESCC have improved OS compared to patients undergoing esophagectomy alone and definitive CR. These findings suggest that patients with ESCC should be considered for multimodality treatment at high-volume centers and surgery should be included in the treatment plan whenever possible.

4033 Poster Session (Board #25), Sat, 8:00 AM-11:30 AM

Enteral nutrition to improve nutritional status, treatment tolerance, and outcomes in patients with esophageal cancer undergoing concurrent chemoradiotherapy (CCRT): Results of a prospective, randomized, controlled, multicenter trial (NCT 02399306). *First Author: Tao Li, Department of Radiation Oncology, Sichuan Cancer Hospital and Institution, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China*

Background: Patients with esophageal cancer undergoing CCRT are at high risk of malnutrition. The aim of this study was to investigate the influence of enteral nutrition on nutritional status, treatment tolerance and outcomes in esophageal cancer patients undergoing CCRT. **Methods:** Patients with inoperable esophageal cancer were randomly assigned (2:1 ratio) to the enteral nutrition group (EN group) or the control group. Patients in the EN group were supported with individual enteral nutrition intervention according to the nutritional status assessment results. The control group was treated with conventional diet guidance. The primary endpoint was the change in body weight from baseline after treatment. Secondary endpoints were nutrition related blood parameter changes, treatment tolerance and outcomes. **Results:** Between Mar. 2015 and Jan. 2017, 158 patients from ten hospitals were randomised into the EN group (n = 106) and the control group (n = 52). Following CCRT, patients in EN group lost only 0.72±3.27 kg of body weight compared with 2.10±2.89 kg in the control group ($P < 0.001$). Participants who received EN had less decline than controls in serum albumin (2.66±5.05 g/L and 4.75±4.94 g/L, $P < 0.001$) and hemoglobin (10.29±15.78 g/L and 18.48±14.66 g/L, $P < 0.001$). Grade 3/4 leukopenia in the control group was significantly more frequent than the EN group (33.3% vs. 20.0 %, P = 0.011). Patients supported on EN experienced greater chemoradiotherapy completion rates (92.5% vs. 67.3%, P = 0.001) and lower infection rates (18.8% vs 31.7%, P = 0.021). There was significant difference in tumor response between two groups (EN group: 81.1%, control group: 67.3%, P = 0.004). The 1- and 2-year OS rates in the EN group were significantly greater (89.6% and 75.4%, respectively) compared with the control group (78.5% and 57.9%, respectively). **Conclusions:** Enteral nutrition may be advantageous in patients with esophageal cancer undergoing CCRT by improving nutritional status, treatment tolerance and outcomes. Clinical trial information: NCT 02399306.

4034 Poster Session (Board #26), Sat, 8:00 AM-11:30 AM

How many lymph nodes is enough? Defining the optimal lymph node dissection in stage I-III gastric cancer using the National Cancer Database. *First Author: Karna Tushar Sura, Beaumont Health, Department of Radiation Oncology, Oakland University William Beaumont School of Medicine, Royal Oak, MI*

Background: Gastric cancer is one of the most causes of cancer-related death worldwide. Surgical resection with lymph node dissection is the primary therapeutic modality. However, the appropriate extent of lymph node dissection remains controversial. Herein, the National Cancer Database (NCDB) was used to determine the optimal number of lymph nodes (LNs) to be dissected for resectable gastric cancer. **Methods:** The NCDB was queried from 2004-2013 for patients with invasive gastric cancer who underwent surgical resection with negative margins. The optimal number of LNs dissected was determined using a univariate $\chi 2$ cut-point analysis. Actuarial survival was determined using the Kaplan Meier method, and comparisons of survival estimates were completed with log-rank tests. Multiple sensitivity analyses were utilized to decrease bias. **Results:** 17,851 patients were included. The mean (±SD) number of LNs examined was 16 ± 11. For all patients, the optimal number of LNs needed to be examined was 20+ nodes. When correcting for stage migration (< 7 LNs removed), the optimal cut-off value was 20+ LNs. When stratifying by pathologic nodal stage, the cutpoint was 10+ LNs for pN1 and pN2. The 5-year survival was 30.6 ± 1.6% for 0-9 removed LNs compared to 48.2 ± 1.2% for 10+ removed LNs ($p < 0.001$) in pN1 disease and 18.3 ± 1.7% for 0-9 removed LNs compared to 32.6 ± 1.2% for 10+ removed LNs ($p < 0.001$) in pN2 disease. For pN3 disease, the optimal cut-off point was 20+ LNs; the 5-year survival was 17.2 ± 1.3% for 0-19 removed LNs compared to 28.5 ± 1.7% for 20+ removed LNs ($p < 0.001$). Moreover, the outcome was inferior among patients who had > 10% positive dissected LNs ($p < 0.05$). **Conclusions:** The optimal number of dissected LNs of 20+ LNs was associated with superior survival. Extended LN dissection is to be considered especially in patients with > 10% positive dissected LNs.

4035 Poster Session (Board #27), Sat, 8:00 AM-11:30 AM

Patterns of care and treatment outcomes of patients with stage I esophageal cancer: A National Cancer Database analysis. *First Author: Amy Catherine Moreno, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The aim of this study was to examine current patterns of care and associated outcomes for patients with stage I esophageal cancer (EC) treated in the United States. **Methods:** The National Cancer Data Base (NCDB) was queried for patients diagnosed with clinical stage T1-2N0 EC from 2004-2012. Patients were categorized into four treatment groups: observation without definitive therapy (Obs), chemoradiotherapy (CRT), local excision (LE), and esophagectomy (Eso). Patient, tumor, and treatment parameters were compared between groups. Kaplan-Meier 5-year overall survival (OS) estimates, postoperative 30- and 90-day mortality comparisons, and multivariate Cox proportional hazards modeling are reported. **Results:** A total of 5,460 patients met the criteria. Of these, 21% were observed, 14% underwent CRT, 23% LE, and 42% Eso. Median age and follow up were 67 years and 28 months, respectively. Eso was the primary treatment for patients of age ≤ 80 while 48% of patients age > 80 were observed. Age, race, comorbidity score, tumor location within the esophagus, type of medical insurance, median income, type of facility (academic vs. non-academic), and distance from treating facility were significant factors for predicting receipt of local therapy over observation. Postoperative 30-day mortality between the LE and Eso groups was 0.5% and 2.9%, respectively ($P < .001$), which increased to 1.4% and 5.5% at 90 days ($P < .001$). Five-year OS was 21% for Obs, 26% CRT, 64% LE, and 63% Eso ($P < .001$). Multivariate analyses demonstrated improved OS with any form of local definitive therapy: CRT (*HR*: 0.54, 95% CI [0.48 - 0.61], $P < .001$), LE (*HR*: 0.24, [0.20 - 0.27], $P < .001$), Eso (HR: 0.31, [0.28 - 0.35], $P < .001$). Age, comorbidity score, facility type, distance, median income quartile, and insurance status were also independently associated with OS. **Conclusions:** Management of stage I EC is influenced by several demographic and socioeconomic factors. Clinical observation yields suboptimal outcomes compared to any local therapy, and a surgical approach should be considered over CRT whenever feasible.

4036 Poster Session (Board #28), Sat, 8:00 AM-11:30 AM

Three-field versus two-field lymphadenectomy for carcinoma of the middle and lower esophagus: Short-term results of a randomized controlled trial. *First Author: Bin Li, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The safety and efficacy of esophagectomy with 3-field lymphadenectomy remain controversial. **Methods:** We did this randomized trial in Fudan University Shanghai Cancer Center in China. Between March 2013 and November 2016, 400 patients with cancer located in the middle and lower esophagus were recruited and randomly assigned to receive 3-field or 2-field lymphadenectomy at a 1:1 ratio. Postoperative complications between the 3-field group (n = 200) and 2-field group (n = 200) were compared on the basis of the intention-to-treatment principle. **Results:** There was no significant difference between the two arms in terms of gender, age, BMI, FEV1, and tumor location. Median operative time was 183 minutes (range 125 to 331) in 3-field group versus 168 minutes (range 116 to 375) in 2-field group, $P < 0.001$. Overall morbidity was 28% (56/200) in the 3-field group and 30.5% (61/200) in the 2-field group, $P = 0.583$. The mortality rate was 0% (0/200) for the 3-field group and 0.5% (1/200) for the 2-field group, $P = 1.000$. Although more reintubation occurred in the 3-field group than in the 2-field group (3% [6/200] vs. 0% [0/200], $P = 0.030$), the distribution of severity (stratified according to the Clavien-Dindo classification) and hospital stay were similar between the two groups. A significantly higher number of lymph nodes were retrieved in the 3-field group (median 37, range 3 to 85) compared to those in the 2-field group (median 24, range 7 to 61) ($P < 0.001$). 44 patients (22%) had positive cervical nodes in the 3-field group. **Conclusions:** Morbidity after esophagectomy with 3-field lymphadenectomy is comparable with that after 2-field lymphadenectomy. Cervical lymphatic involvement is common in patients with middle and lower esophageal cancer. 3-field lymphadenectomy may offer more accurate tumor staging related to cervical lymphatic metastasis. TABLE. Regions of lymph nodes metastases Clinical trial information: NCT01807936.

4037 Poster Session (Board #29), Sat, 8:00 AM-11:30 AM

Exclusive chemoradiotherapy with or without dose escalation in locally advanced esophageal carcinoma: The CONCORDE study (PRODIGE 26). *First Author: Gilles Crehange, Georges-François Leclerc Center, Dijon, France*

Background: In esophageal cancer (EC), 20 to 45% of patients suffer from local failure after 50Gy concomitant chemoradiation (cCRT). Improvements in staging together with target definitions led us to test dose escalation in the modern era of new technologies. **Methods:** Patients were randomly assigned cCRT to 40Gy elective nodal irradiation with either a 10Gy boost (Arm A) or 26Gy boost (Arm B) combined with FOLFOX-4. The primary endpoint of this phase II was acute toxicity according to the NCIC-CTCAE (version 4.0). Quality of life according to the EORTC QLQ-C30 and OG25 was a secondary endpoint. All analyses were performed in intent-to-treat. **Results:** 160 patients were randomized between Jun 2011 and Feb 2016: 81 patients in arm A and 79 patients in arm B. The mean age at diagnosis was 61.9 (7.9) years and 62.1 (7.8) years, respectively. Seventy patients in each arm had squamous cell carcinoma (86.4% in arm A and 88.6% in arm B) and 59 patients (72.8%) and 58 patients (73.4%) had stage III disease in arms A and B, respectively. IMRT was performed in 57 (70.4%) and 55 (69.6%) patients in arms A and B. The rates of grade ≥3 (G3+) non-hematological toxicity were not significantly different between arms A and B (76.5% vs 86.0%, p = 0.12). The rates of G3+ hematological toxicity were not significantly different between arms A and B (82.7% vs 88.6%, p = 0.29). The rates of G3+ non-hematological toxicity were not significantly different between patients treated with 3DRT (83.3%) and IMRT (81.3%) (p = 0.77). The mean global health scores at baseline and 3 months were 63.9 (sd = 21.4) vs 69.6 (sd = 23.1) in arm A (p = 0.10) and 65.27 (sd = 19.54) vs 58.8 (sd = 19.9) in arm B (p = 0.16). The presence of dysphagia was neither significantly different between arm A (89.23%) and arm B (86.21%) (p = 0.61) at baseline nor at 3 months (77.78% vs 86.84%, p = 0.29). Odynophagia was present at baseline in 78.46% in arm A and 75.86% in arm B (p = 0.73) while the rates observed at 3 months were 68.18% and 73.68%, respectively (p = 0.59). **Conclusions:** Dose escalated cCRT in patients with EC is feasible with no increased acute toxicity and no deterioration of QOL. A phase III trial is on-going to conclusively address the issue of local control with cCRT. Clinical trial information: NCT01348217.

4038 Poster Session (Board #30), Sat, 8:00 AM-11:30 AM

Expression of Claudin 18.2 and HER2 in gastric, gastroesophageal junction, and esophageal cancers: Results from the FAST study. *First Author: Martin H. Schuler, University Hospital Essen, Essen, Germany*

Background: Claudin 18.2 (CLDN18.2), a gastric mucosa tight junction protein, is aberrantly expressed in various cancers. In the FAST Phase 2 trial (NCT01630083), IMAB362, an anti-CLDN18.2 monoclonal antibody, administered in combination with EOX chemotherapy, prolonged survival compared to EOX alone in patients with advanced/recurrent gastric, gastroesophageal junction (GEJ), and esophageal cancers ineligible for trastuzumab. The aim of the present analysis was to assess tumor CLDN18.2 expression and co-expression with HER2 in the FAST population. **Methods:** Tumor tissue samples from patients screened for inclusion into the FAST trial were analyzed for CLDN18.2 expression using a CE-marked, validated immunohistochemistry (IHC) assay. CLDN18.2 expression was centrally scored based on staining intensity and percentage of stained tumor cells. In a subset of tissue samples with known HER2 status, overall HER2 expression and co-expression with CLDN18.2 were determined. **Results:** Tissue samples from 730 patients with gastric, GEJ, and esophageal cancer were screened for the FAST study. Of these 730 samples, 685 (94%) were assessed by central IHC; 49% (n=333/685) met the FAST CLDN18.2 expression criterion (≥2+ intensity in ≥40% of tumor cells) for inclusion. Across the 154 tissue samples with known HER2 status, the majority (84%; n=129/154) were $HER2^-$. Furthermore, 94 of these 154 samples (61%) met the FAST CLDN18.2 expression criterion, of which 14% (n=13/94) co-expressed HER2 (Table). **Conclusions:** In tissue samples from patients screened for the FAST trial, nearly half met CLDN18.2 expression inclusion criterion. In samples with known HER2 status, co-expression of CLDN18.2 and HER2 occurred in 14% of the samples that met study eligibility. These data suggest CLDN18.2 may serve as a non-HER2 overlapping targetable alteration in a distinct subpopulation of patients with gastric, GEJ, or esophageal cancers. Clinical trial information: NCT01630083.

	Eligible for FAST* (n=94)	Not eligible for FAST* (n=60)	Total (N=154)
$HER2^+$, n (%)	13 (13.8)	12 (20.0)	25 (16.2)
$HER2^-$, n (%)	81 (86.2)	48 (80.0)	129 (83.8)

*Based on CLDN18.2 expression criterion.

4039 Poster Session (Board #31), Sat, 8:00 AM-11:30 AM

Phase II study of intraperitoneal docetaxel plus capecitabine/cisplatin for gastric cancer with peritoneal metastasis: XP+IP DOC trial. *First Author: Ryoji Fukushima, Teikyo University, School of Medicine, Tokyo, Japan*

Background: Intraperitoneal (IP) chemotherapy with taxanes provides sustained high local concentrations, and the efficacy of IP paclitaxel (PTX) has been shown in ovarian cancer. We previously reported the safety and efficacy of IP PTX plus systemic chemotherapy in clinical trials. Capecitabine/cisplatin (XP) is one of the standard regimens for the first-line treatment of advanced gastric cancer worldwide. We designed a new regimen combining IP docetaxel (DOC) with XP, and the recommended dose of IP DOC was determined to be 10 mg/m^2 in a phase I study. A phase II study of XP plus IP DOC was performed in gastric cancer patients with peritoneal metastasis. **Methods:** Gastric cancer patients with peritoneal metastasis confirmed by diagnostic imaging, laparoscopy or laparotomy were enrolled. DOC was administered intraperitoneally at 10 mg/m^2 on days 1 and 8. Cisplatin was administered intravenously at 80 mg/m^2 on day 1, and capecitabine was administered at 1000 mg/m^2 bid for 14 consecutive days, repeated every 21 days. The primary endpoint was the 1-year overall survival (OS) rate. Secondary endpoints were response rate, negative conversion rate on peritoneal cytology and safety. **Results:** Out of 50 patients enrolled, 48 patients received protocol treatment, and were evaluated for OS and toxicity. The median number of courses was 6 (range 1-15). The 1-year OS rate was 75% (95% confidence interval, 60-85%). The best overall response was stable disease in all the three patients with target lesions. Cancer cells ceased to be detected by peritoneal cytology in 28 (76%) of 37 patients. Nineteen patients underwent gastrectomy after response to chemotherapy. The incidences of grade 3/4 hematological and non-hematological toxicities were 42% and 48%, respectively. The frequent grade 3/4 toxicities included neutropenia (21%), leukopenia (8%), anemia (29%), anorexia (25%) and nausea (17%). Infection of the intraperitoneal port was observed in one patient. There were no treatment-related deaths. **Conclusions:** Combination chemotherapy of XP plus IP DOC regimen is well tolerated and active in gastric cancer patients with peritoneal metastasis. Clinical trial information: UMIN000016469.

4040 Poster Session (Board #32), Sat, 8:00 AM-11:30 AM

Clinicopathological features of program death ligand-1 expression with mismatch repair, Epstein-Barr virus status, and cancer genome alterations in metastatic gastric cancer. *First Author: Akihito Kawazoe, Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Chiba, Japan*

Background: Recently, anti-programmed death 1 (PD-1) or its ligand (PD-L1) antibodies have shown promising activities in metastatic gastric cancer (MGC). However, little is known about detailed clinicopathological features of PD-L1 expression in patients (pts) with MGC. **Methods:** Pts with histologically confirmed MGC were eligible for this prospective observational study. PD-L1 expression on tumor cell (TC) or inflammatory cell (IC) and mismatch repair (MMR) were analyzed by immunohistochemistry (IHC). Epstein–Barr virus (EBV) was detected by in situ hybridization. The expressions of tyrosine kinase receptors (RTKs) such as HER2, EGFR and MET and cancer genome alterations were also evaluated by IHC or next generation sequencing. **Results:** A total of 237 pts were enrolled from September 2015 to December 2016. Samples of 199 (84.0%) pts were obtained from biopsy. PD-L1 expression on TC and IC was positive in 27 (11.4%) and 167 pts (70.5%), respectively. One hundred and seventy-one pts (72.2%) had positive PD-L1 expression on either TC or IC. MMR deficient (D-MMR) and EBV was detected in 14 (6.9%, n = 203) and 14 pts (5.9%, n = 237), respectively. PD-L1 expression on TC was more frequently observed in pts with D-MMR ($P < 0.001$) and KRAS mutation ($P < 0.001$), while that on IC was more frequently observed in pts with EBV+ (P = 0.045), lymph node metastasis (P = 0.001), and lung metastasis (P = 0.045). In contrast, pts with peritoneal metastasis were associated with less frequent PD-L1 expression in IC (P = 0.003). A significant association was not observed between PD-L1 expression and RTKs expression or presence of other gene alterations. D-MMR was significantly associated with intestinal type (P = 0.026) and absence of liver metastasis (P = 0.022). PD-L1 expression on either TC or IC was not prognostic factor (hazard ratio ; 0.92, P = 0.741). Seven pts with D-MMR and seven pts with EBV+ MGC were enrolled in clinical trials of anti-PD-1/PD-L1 antibodies. **Conclusions:** PD-L1 expression in MGC was associated with some clinicopathological features. Impact of these characteristics on efficacy of anti-PD-1/PD-L1 antibody warrants further evaluation.

4041 Poster Session (Board #33), Sat, 8:00 AM-11:30 AM

The Nationwide Cancer Genome Screening Project in Japan SCRUM-Japan, GI-screen: Efficient identification of cancer genome alterations in advanced gastric cancer. *First Author: Shigenori Kadowaki, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in advanced non-colorectal gastrointestinal (GI) cancer (aNon-CRC), called as the SCRUM-Japan GI-SCREEN. **Methods:** This study is ongoing with 20 major cancer centers. Patients with aNon-CRC, who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutation, copy number variant (CNV) and fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to whether genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase. In this presentation, we show the results of advanced gastric cancer (aGC) cohort. **Results:** As of October 31st in 2016, a total of 565 aGC samples were analyzed. The sequence with the OCP was successfully performed in 425 (75.2%). Out of 475 patients except for the 90 patients in which precise data is not collected, the proportion of histology type is followed; intestinal type 44.6%, diffuse type 54.5%, other 0.6%, unknown 0.2%. Out of 406 samples of which results were available, the frequently detected mutations were *TP53* (47.8%), *PIK3CA* (8.6%), *KRAS* (5.4%), *SMAD4* (4.9%), *TET2* (4.4%), *APC* (3.9%), *ERBB2* (3.7%) and CNVs were *ERBB2* (10.8%), *CCNE1* (9.4%), *KRAS* (3.7%), *ZNF217* (3.2%), *FGFR2* (2.7%), and *MET* (2.5%). *FGFR3-TACC3* fusion, *WIPF2-ERBB2* fusion and *EGFR* vIII were detected in 2, 1, and 2 cases, respectively. **Conclusions:** This nationwide screening system is efficient to detect rare gene alterations in aGC. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine. Clinical trial information: UMIN000016344.

4042 Poster Session (Board #34), Sat, 8:00 AM-11:30 AM

A phase II study of early FDG-PET evaluation after one-cycle chemotherapy in patients with locally advanced esophageal squamous cell carcinoma treated with neoadjuvant chemoradiotherapy: Final report. *First Author: Ta-Chen Huang, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

Background: The optimal use of the metabolic tumor response measured by ^{18}fluorodeoxyglucose positron emission tomography (FDG-PET) in the treatment of esophageal cancer is currently unknown. We launched a phase II clinical trial to evaluate the early metabolic response to one-cycle chemotherapy in locally advanced esophageal squamous cell carcinoma (ESCC) patients, who subsequently received neoadjuvant chemoradiation (neo-CRT) followed by surgery. **Methods:** ESCC patients with stage T3 or N1M0 or M1a (AJCC, 6th edition) were enrolled to receive one-cycle chemotherapy, day 1 and 8 doses of paclitaxel, cisplatin, and 24-hour infusional 5-fluorouracil and leucovorin, followed by paclitaxel/cisplatin- based 40Gy neo-CRT and surgery. FDG-PET was performed at baseline and day 14 of the one-cycle chemotherapy. The primary endpoint is pathological complete response (pCR) to neo-CRT. We hypothesized that early PET responders, defined as $>$ 35% reduction of maximum standardized uptake value (SUV_{max}) from the baseline, would significantly improve pCR. **Results:** Between Feb 2008 and Mar 2012, 66 patients (M: F = 61: 5) were enrolled. Their clinical stages were: II or III, 56; IVA, 10. Forty seven received surgery. The pCR rate per surgical population was 34.0%. The median progression-free survival (PFS) and overall survival (OS) for the whole study group was 16 months (95% CI 9-27) and 22 months (95% CI 16-40), respectively. A total of53 patients were evaluable for PET response. The early PET response was not associated with high pCR rate or better survivals. However, in an exploratory analysis, the post-chemotherapy SUV_{max} was an independent prognostic factor for pCR, PFS and OS. A predictive model for pCR composed of weight loss and the post-chemotherapy $SUV_{max}$was established with an AUC of 0.84. **Conclusions:** Our study failed to validate the predictive value of predefined early PET response to one-cycle chemotherapy for pCR to neo-CRT in locally advanced ESCC patients. However, the FDG-PET SUV_{max} after one-cycle chemotherapy may have prognostic and predictive significance, and may be explored in further studies. Clinical trial information: NCT01034332.

4043 Poster Session (Board #35), Sat, 8:00 AM-11:30 AM

Is surgical resection beneficial in recurrent or metastatic gastric cancer? *First Author: Yong Won Choi, Department of Hematology-Oncology, Ajou University School of Medicine, Suwon, South Korea*

Background: Although chemotherapy is currently established as a standard treatment in recurrent or metastatic gastric cancer, the role of palliative surgical resection is still controversial. We investigated the survival benefit of surgical resection in patients (pts) with recurrent or metastatic gastric cancer who received systemic chemotherapy. **Methods:** A retrospective review was conducted on 698 pts who received palliative chemotherapy for recurrent (n = 307) or primary metastatic (n = 391) gastric cancer. Overall survival (OS) of pts who underwent surgical resection followed by chemotherapy was compared to that of pts who received chemotherapy alone. **Results:** Among 140 pts (primary metastatic: 97, recurrent: 43) with surgical resection, gastrectomy, metastasectomy, and gastrectomy with metastasectomy were performed in 83 (primary metastatic: 81), 44, and 13 pts, respectively. Higher surgical resection rate was observed in pts with young age ($<$ 70) (p = 0.010), ECOG PS 0 or 1 (p = 0.010), primary metastatic ($p < 0.0001$), absence of liver metastasis (p = 0.002), and signet ring cell histology (p = 0.002). The median OS of pts who underwent surgical resection before chemotherapy was significantly longer than that of pts who received chemotherapy alone (19 vs. 9 months, $p < 0.0001$). The OS benefit of surgical resection was consistent across subgroups in terms of baseline characteristics including age, ECOG PS, disease status (primary metastatic vs. recurrent), peritoneal metastasis, and first-line chemotherapy regimen (single vs. combination). In multivariate analysis, surgical resection was independently associated with favorable OS (hazard ratio = 0.41, $p < 0.0001$) along with ≥second-line chemotherapy ($p < 0.0001$), whereas ECOG PS 2 or 3 (p = 0.013), signet ring cell histology ($p < 0.0001$), and peritoneal metastasis (p = 0.046) were independent prognostic factors of poor OS. **Conclusions:** The present study suggests that judicious use of surgical resection before chemotherapy in recurrent or metastatic gastric cancer pts may result in favorable outcome, although large scale phase III trials are essential to establish this treatment approach as a standard practice.

4044 Poster Session (Board #36), Sat, 8:00 AM-11:30 AM

The prognostic role of metastatic lymph node ratio-staging system in gastric cancer patients: Analysis of the National Cancer Database. *First Author: Rand Naffouje, Weiss Memorial Hospital, Chicago, IL*

Background: The NCCN recommends retrieval of at least 15 lymph nodes for adequate nodal staging in gastric cancer. There is an ongoing debate about the accuracy of the classification systems for nodal involvement based on the absolute number of positive nodes (AJCC-N) vs. the ratio of positive nodes (rN). In this study, we aim to assess the accuracy of each system in the prediction of 5-year survival using the National Cancer Data Base (NCDB) for gastric cancer. **Methods:** The database included 168,377 gastric cancer patients between 2004-2014. Patients who were approached with palliative intent, or had metastatic disease were excluded from the analysis. Only patients who had at least one regional node examined were included. A univariate and multivariate regression analysis were conducted to identify significant predictors of the 5-year survival among the perioperative patients' characteristics. Bayesian Information Criterion (BIC) was used to compare the model fitting when the AJCC nodal staging is applied to that of the ratio nodal staging. **Results:** 48,126 patients were included in the final analysis. 23,102 (48%) patients had ≥15 nodes examined. The univariate and multivariate regression analysis identified age, male gender, Caucasian race, and presence of comorbidities as significant demographic predictors. TNM T-stage, N-stage, and rN-stage were significant predictors with worsening prognosis as the stage increases. Overall, BIC demonstrated that the model using rN had a better fit (rN = 30321 vs. AJCC-N = 30619). However, subgroup analysis showed that the AJCC-N functioned better when $<$ 15 nodes were examined (rN = 17367 vs. AJCC-N = 17311), whereas rN functioned better when ≥15 nodes were collected (rN = 16776 vs. AJCC-N = 16831). **Conclusions:** Both AJCC-N and rN are valid systems for nodal staging in terms of survival prediction in gastric cancer. When at least 15 nodes are resected in line with the current NCCN guidelines, the rN staging system for nodal metastasis appears to function more accurately in survival prediction. It might be advisable to consider the ratio of positive lymph nodes when a large number of nodes are collected to avoid over-staging and stage migration.

4045 Poster Session (Board #37), Sat, 8:00 AM-11:30 AM

Nomogram for lymph node metastasis prediction with early gastric cancer patients: To decide additional gastrectomy after endoscopic dissection. *First Author: Su Mi Kim, Samsung Medical Center, Seoul, Republic of Korea*

Background: Accurate prediction of metastatic lymph node is critical to avoid unnecessary gastrectomy and improve quality of life for patients with early gastric cancer. The aim of this study was to develop and validate a nomogram for prediction of lymph node metastasis in early gastric cancer patients. **Methods:** We reviewed the clinicopathological data of 10595 patients who underwent curative resection for early gastric cancer from 2001 to 2015 at Samsung Medical Center. This model was externally validated by 2100 patients who underwent curative resection for gastric cancer in National Cancer Center. Multivariate analysis using the Cox proportional hazard regression model was performed to develop the nomogram, and discrimination and calibration were evaluated by external validation. Overall survival, disease free survival, and recurrence free survival were compared between gastrectomy groups of 6641 patients and endoscopic dissection group of 999 patients who was performed the treatment in Samsung Medical Center for early gastric cancer by risk on nomogram to demonstrate the efficacy of nomogram. **Results:** Multivariate analyses revealed that age, tumor size, lymphatic invasion, depth of invasion, and histologic differentiation were significant prognostic factors for lymph node metastasis. The nomogram had good discrimination with a concordance index of 0.845 [95% confidence interval 0.832-0.858], supported by an external validation point of 0.813 [95% confidence interval 0.786-0.84]. In low risk on nomogram, endoscopic dissection group had similar overall survival (P = 0.319), disease free survival (P = 0.469) and recurrence free survival (P = 0.091) compared to gastrectomy group. **Conclusions:** We developed and validated a nomogram predicting lymph node metastasis for early gastric cancer based on a large database. This personalized nomogram is useful to avoid unnecessary gastrectomy after endoscopic dissection resulting in improved quality of life for early gastric cancer patients.

4046 Poster Session (Board #38), Sat, 8:00 AM-11:30 AM

Ramucirumab (R) plus pembrolizumab (P) in treatment naive and previously treated advanced gastric or gastroesophageal junction (G/GEJ) adenocarcinoma: A multi-disease phase I study. *First Author: Ian Chau, Royal Marsden Hospital, Sutton, United Kingdom*

Background: Angiogenesis and immunosuppression are hallmarks of tumor growth. This is the first study to combine R (anti-VEGFR2) with P (anti-PD-1) to simultaneously target both processes in the tumor microenvironment. **Methods:** Ongoing, multi-cohort, phase 1a/b trial enrolled pts with G/GEJ adenocarcinoma, measurable disease, ECOG PS 0-1, previously treated (Cohorts A and B) or untreated (Cohort A2) for advanced disease. PD-L1 was positive (tumor proportion score [TPS] $\geq$1%) or negative (TPS $<$ 1%) using the DAKO PD-L1 22C3 IHC pharmDx assay. R was administered at 8 mg/kg on Days 1&8 (Cohorts A and A2) or 10 mg/kg on Day 1 (Cohort B) with P 200 mg on Day 1 q3W. Primary objective- assess safety and tolerability of R+P; preliminary efficacy will be examined. **Results:** As of 21-Nov-2016, 41 previously treated G/GEJ pts were enrolled. Median age was 58 y, 76% male, 66% had ECOG PS of 1, 46% were PD-L1+, and 59% received study treatment as third or subsequent line. Median duration on therapy was 2.8 mo and 4.1 mo for A and B, respectively. Overall, 33 (80%) pts experienced a treatment-related AE (TRAE) and similar between cohorts A and B. Ten (24%) pts experienced grade 3-4 TRAEs, most commonly colitis (7%) and hypertension (7%). One treatment-related death occurred (pneumonitis and pulmonary sepsis). Responses occurred in 3 (7%) pts with 46% disease control rate (DCR). Progression-free and overall survival rates at 6 mo were 22.4 % (95% CI, 9.8-38.0) and 51.2% (95% CI, 33.9-66.1) respectively. Nine (22%) pts remain on treatment. Eighteen of 25 planned treatment naïve G/GEJ pts were enrolled. Median age was 70 yr, 83% male, 56% had ECOG PS of 0, and PD-L1 status is pending. Median duration on therapy was 2.1 mo. Twelve (67%) pts experienced a TRAE. Grade 3 TRAEs occurred in 5 (28%) pts (hypertension [n = 3], diarrhea, and acute kidney injury). No grade 4-5 events occurred. Preliminary efficacy data showed 3 (17%) pts responded with 50% DCR. Median PFS is immature and 89% of pts remain on treatment. **Conclusions:** R+P generated no new safety signals and demonstrated encouraging antitumor activity in treatment naïve and previously treatedadvanced G/GEJ adenocarcinoma. Clinical trial information: NCT02443324.

4047 Poster Session (Board #39), Sat, 8:00 AM-11:30 AM

Meaningful changes in quality of life (QoL) in patients with gastric cancer: Exploratory analyses from RAINBOW and REGARD. *First Author: Ian Chau, Royal Marsden Hospital, London, United Kingdom*

Background: EORTC QLQ-C30 is a well-established QoL instrument for cancer patients (pts), but there is limited information for gastric cancer. To identify priority domains and describe meaningful changes, we explored data from 2 randomized ramucirumab phase 3 trials in pts with previously treated gastric or gastroesophageal junction cancer. **Methods:** Pts completed QLQ-C30 v3.0 at baseline and Q6W while on study. Data from all treatment arms were pooled (N=1020). Changes from baseline in QoL domains were compared by best overall response (BOR) and ECOG performance status (PS) using analysis of covariance. Odds ratios (ORs) for BOR and PS outcome groups per QoL unit (point) change were estimated by cumulative logit regression modeling, with OR$\leq$0.85 considered meaningful. **Results:** Changes from baseline in QoL domains were significantly associated with BOR and PS outcomes (Table). ORs for BOR and PS outcomes for these domains were statistically significant ($p<0.05$) and suggested changes of 10-15 points predict clinical outcomes. **Conclusions:** QLQ-C30 is sensitive to clinical outcomes in advanced gastric cancer patients, particularly in global QoL, functional status and disease symptoms of fatigue, pain, and appetite loss. These analyses can inform trial designs and interpretation of results.

Mean (std dev) change from baseline at Wk 6 (0-100 scale with positive change reflecting improvement).

Prognostic and predictive factors for overall survival (OS) in metastatic esophagogastric cancer (EGC): A meta-analysis. *First Author: Emil ter Veer, Department of Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background: Prognostic and predictive factors for metastatic EGC are important to estimate prognosis, inform clinical decision-making and design future trials. We performed a systematic review with meta-analysis to identify these factors. **Methods:** We searched Medline, EMBASE and CENTRAL for phase 2/3 randomized controlled trials (RCTs) until January 2016 on palliative chemotherapy and targeted therapy for metastatic EGC. Prognostic and predictive factors were identified from respectively multivariate cox regressions and stratified treatment comparisons. Hazard Ratio's (HR) for OS were extracted and pooled with meta-analysis if possible. Prognostic factors were considered independent if the multivariate HR was significant (P$\leq$0.05). Predictive factors were clinically relevant if P for subgroup interaction was $\leq$0.20 and the HR in one of the subgroups was significant (P$\leq$0.05). **Results:** We identified 47 RCTs (14,853 patients), wherein 54 potential prognostic and 40 predictive factors were reported. Eight independent prognostic factors for poor OS reported in $\geq$2 RCTs based on $\geq$300 patients were: performance status of $\geq$1 vs 0 (pooled HR, 95% confidence interval: 1.47, 1.25-1.73) or 2 vs 0-1 (1.52, 1.32-1.76); metastatic vs locally advanced disease (1.55, 1.39-1.72); diffuse vs intestinal/other histology (1.38, 1.12-1.71); $\geq$3 vs $<$ 2 metastatic sites (1.35, 1.07-1.70); presence of metastases in peritoneum (1.24, 1.01-1.51) or liver (1.45 (1.28-1.64); measurable vs non-measurable disease (1.31, 1.04-1.66); and no prior vs prior surgery (1.33, 1.16-1.53). Predictive factors for specific treatment comparisons based on $\geq$300 patients were: age ($\geq$65 vs $<$ 65); performance status; tumor location (GEJ vs stomach); disease stage; number of metastatic sites; peritoneal metastasis; measurable disease; histology; HER2; KRAS; VEGF A; and Neuropilin-1 for first line treatments; and time to progression on first line therapy ($<$ 3, 3-6 or $\geq$6 months) for second-line treatments. **Conclusions:** Eight independent prognostic factors for OS and thirteen clinically relevant predictive factors for treatment efficacy of EGC were found.

4049 Poster Session (Board #41), Sat, 8:00 AM-11:30 AM

Cardiac death rates after irradiation for esophageal cancer: An epidemiologic study among esophageal cancer survivors. *First Author: Remco Jurriaan Molenaar, Academic Medical Center, Amsterdam, Netherlands*

Background: Esophageal cancer is frequently treated with radiation in addition to surgery and/or chemotherapy. Long-term survivors that received radiation may be at risk for radiation-induced cardiotoxicity. **Methods:** Esophageal cancer survivors (defined as surviving > 5 yrs after diagnosis) from all 18 Surveillance Epidemiology and End Results (SEER) registries from 1973 to 2013 were queried for irradiation status, cause of death and survival using SEERaBomb, a package for the R statistical programming language. **Results:** 6,514 esophageal cancer survivors were identified, of whom 2,892 (44%) received no radiation therapy and 3,448 (53%) received external beam radiotherapy. Mean age at the time of esophageal cancer diagnosis was 64.0 yrs in the no radiation group and 63.0 yrs in the radiation group. Median person years of follow up after esophageal cancer diagnosis was 8.6 yrs (interquartile range [IQR]: 7-12) in pts receiving no radiation and 7.9 yrs (6-11) in pts receiving radiation. A total of 590 esophageal cancer survivors died of cardiac disease; 254 received no radiation and 336 did receive radiation. Median time to cardiac death after esophageal cancer diagnosis was 32.2 yrs (IQR: 19-38) in pts that received no radiation and 25.3 years (15-30) in pts that received radiation (log-rank $P< 0.001$). Compared with unirradiated pts, irradiated pts had an increased risk of dying of cardiac disease (hazard ratio [HR] = 1.47; 95% confidence interval [CI]: 1.2-1.7, Cox regression $P< 0.001$). The association between radiation and cardiac death was the strongest in esophageal cancer pts diagnosed before 1995 (HR = 1.75; 95% CI: 1.4-2.2, $P< 0.001$) and in squamous cell carcinoma of the esophagus (HR = 1.9; 95% CI: 1.4-2.6, $P< 0.001$) but not in adenocarcinoma (HR = 1.04; 95% CI: 0.8-1.4, $P= 0.8$). **Conclusions:** 5-year esophageal cancer survivors that were treated with radiotherapy have an increased risk of dying of cardiac disease, compared with unirradiated counterparts. This association was strongest in pts treated before 1995 and in squamous cell carcinoma pts. This may be due to late radiation-induced cardiotoxicity, decreasing with the use of heart-sparing radiation techniques after 1995.

4050 Poster Session (Board #42), Sat, 8:00 AM-11:30 AM

Pathophysiology and therapeutic strategies for peritoneal recurrence after gastric cancer surgery. *First Author: Satoshi Murata, Department of Surgery, Shiga University of Medical Science, Otsu, Japan*

Background: We recently showed that cancer cells, with proliferative and tumorigenic potential, can spill into the peritoneal cavity during curative (R0) gastric cancer (GC) surgery, which is associated with peritoneal recurrence (PM). To elucidate the pathophysiology of PM, the relationship between spilled cancer cells and cancer stem cells was evaluated. Furthermore, to identify a therapeutic strategy for PM, the prognostic impact of hyperthermic intraperitoneal chemotherapy (HIPEC) following GC surgery with spillage of cancer cells was evaluated. **Methods:** Patients with advanced GC (≥pT2 [MP]) who underwent R0 gastrectomy between 2010 and 2015 were enrolled. Ninety-four consecutive patients with negative results in peritoneal cytology and cancer cell culture (CCC [-]) following peritoneal washing (PW) before GC surgery were included. Spilled cancer cells in PW after GC surgery (PW-Post) were examined to identify any CD44-positive cancer stem-like cells associated with cancer metastasis. Based on the PW-Post CCC results, associations between HIPEC and recurrence-free survival (RFS), or overall survival (OS) were evaluated. HIPEC was performed following GC surgery using CDDP, MMC, and 5-FU in 5 L saline maintained at 42˚C for 30 min. **Results:** Spilled cancer cells included $CD44^+$ cancer stem-like cells. In 48 patients with PW-Post positive CCC (CCC [+]), the number of patients with pStage I, II, and III were 4, 7, and 15, respectively, in those who received HIPEC (n = 26), and 3, 9, and 10, respectively, in those who did not (n = 22). Among patients with CCC (+), the 5-year peritoneal RFS, hepatic RFS, and lymph node RFS rates were 93.3%, 100%, and 68.5%, respectively, in patients who received HIPEC, and 56.7%, 35.6%, and 66.7%, respectively, in those who did not (P = 0.008, P = 0.008, and P= 0.24, respectively). Among patients with PW-Post CCC (-), none developed recurrence, regardless of whether they received HIPEC (n = 28) or not (n = 18). **Conclusions:** The results show that PW-Post CCC is a promising predictive biomarker for recurrence after R0 GC surgery. Adjuvant HIPEC performed with R0 GC surgery showed preventive effects on peritoneal and hepatic recurrence and survival benefits for patients with PW-Post CCC (+).

4051 Poster Session (Board #43), Sat, 8:00 AM-11:30 AM

Phase II study of afatinib in recurrent and/or metastatic esophageal squamous cell carcinoma (R/M ESCC) (KCSG HN14-18). *First Author: Min Hee Hong, Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Yonsei University Health System, Seoul, Republic of Korea*

Background: Afatinib, an irreversible pan-ErbB kinase inhibitor showed anti-tumor activity against esophageal cancer in phase I trial. In this multicenter, open-label, single arm phase II study, we aimed to evaluate the activity and safety of afatinib in R/M ESCC. **Methods:** Patients (pts) who had ECOG PS 0-2 and had progressed on platinum-based chemotherapy for R/M ESCC were enrolled. Pts were treated with afatinib 40mg/day until disease progression, unacceptable toxicity, or patient's refusal. Primary endpoint was objective response rate (ORR) per RECIST 1.1. The estimated sample size was 49, using a two-stage minimax design to evaluate incremental response rate from 5 to 15%. Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and safety profile. Additionally, we try to identify biomarker to predict efficacy of afatinib with target capture sequencing and gene expression profile as exploratory endpoints. **Results:** In a total of 49 enrolled pts (median age 60; range 44 -84), ORR and DCR were 14.3 % and 73.3%, respectively. With a median follow-up of 6.6 months, median PFS and OS was 3.4 months (95% CI 2.2-4.6) and 6.6 months (95% CI 5.2-8.0). Median treatment duration and duration of response were 2.8 months (range, 0.4-15.3) and 7.1 months (range, 2.5-13.9), respectively. Dose reduction and interruption occurred in 19 (38.8%) and 15 (30.6 %) pts. Treatment-related adverse events (TRAE) occurred in 33 pts (67.3%) with most common TRAEs being diarrhea (n=22, 44.9%) and acneiform rash (n=12, 24.5%). G3-4 TRAEs were rare, occurring in 7 pts (14.3 %). **Conclusions:** Afatinib demonstrated modest efficacy with manageable toxicity in platinum-resistant R/M ESCC patients. Given the modest response rate, identification of predictive biomarkers is essential for further clinical investigation of afatinib in R/M ESCC. Those biomarkers are being analyzed and will be presented in the conference (NCT02353936). Clinical trial information: NCT02353936.

Efficacy	Total (n=49)	%
Best response		
Complete response	0	0.0
Partial response (confirmed)	7	14.2
Stable disease	29	59.1
Progressive disease	11	22.4
Not evaluable	2	4.0
ORR (95% CI)		14.2 (4.4 – 24.0)
DCR (95% CI)		73.3 (61.1 – 85.9)

4052 Poster Session (Board #44), Sat, 8:00 AM-11:30 AM

Early presence of antiangiogenesis-related adverse events as a potential biomarker of antitumor efficacy in patients with metastatic gastric cancer treated with apatinib. *First Author: Xinyang Liu, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: Reliable biomarkers of apatinib response in gastric cancer (GC) are lacking. We investigated the association between early presence of common adverse events (AEs) and clinical outcomes in metastatic GC patients. **Methods:** We conducted a retrospective cohort study using data on 269 apatinib-treated GC patients in two clinical trials. AEs were assessed at baseline until 28 days after the last dose of apatinib. Clinical outcomes were compared between patients with and without hypertension (HTN), proteinuria or hand and foot syndrome (HFS) in the first 4 weeks using Kaplan–Meier methods, Cox proportional hazard regression and logistic regression models. Landmark analyses were performed as sensitivity analyses. Predictive model and risk scores were analyzed to predict overall survival (OS). **Results:** Presence of AEs in the first 4 weeks was associated with prolonged median OS (169 vs. 103 days, log-rank p=0.0039; adjusted hazard ratio [HR] 0.64, 95% confidence interval [CI] 0.64-0.84, p=0.001), prolonged median progression-free survival (PFS, 87 vs. 62 days, log-rank p=0.0309; adjusted HR 0.69, 95%CI 0.53-0.91, p=0.007), and increased disease control rate (54.67% vs. 32.77%; adjusted odds ratio 2.67, p<0.001). Results remained significant in landmark analyses. An AE-based prediction model and subsequently derived scoring system showed high calibration and discrimination in predicting OS. **Conclusions:** Presence of HTN, proteinuria or HFS during the first cycle of apatinib treatment was a viable biomarker of antitumor efficacy in metastatic GC patients.

Correlation between presence of at least one antiangiogenesis-related adverse event (AE) and antitumor efficacy of apatinib.

Clinical outcomes	With AE (n=150)	Without AE (n=119)	Unadjusted analysis		Multi-adjusted analysis[a]	
			HR (95% CI)	P-value	HR (95% CI)	P-value
Median OS (IQR), days	169 (96-255)	103 (58-201)	0.67 (0.51,0.88)	0.0039	0.64 (0.48,0.84)	0.001
Median PFS (IQR), days	87 (57-150)	62 (41-121)	0.75 (0.58,0.98)	0.0309	0.79 (0.53,0.91)	0.007

[a]Adjusted for sex, age, number of metastatic sites and ECOG PS. IQR: interquartile range.

4053 Poster Session (Board #45), Sat, 8:00 AM-11:30 AM

Comparison of chemoradiotherapy (CRT) using carboplatin/paclitaxel (CP) versus cisplatin/5-FU (CF) for esophageal or gastroesophageal junctional (GEJ) cancer. *First Author: Hao-Wen Sim, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: For resectable esophageal or GEJ cancer, trimodality therapy improves survival compared to surgery alone and represents the current standard of care. The optimal CRT regimen for neoadjuvant or definitive treatment of locoregional esophageal or GEJ cancer remains uncertain. **Methods:** A retrospective comparison of CF and CP for locoregional esophageal or GEJ cancer (2011-2015) was performed. Overall survival (OS) and disease-free survival (DFS) were assessed using multivariable Cox proportional hazards regression, controlling for age, performance status and Charlson comorbidity index. **Results:** 101 patients (pts) were identified (61 CF, 40 CP). 75% were male. Median age was 62 years (range 30-84). Primary sites were esophageal (52%, with 65% squamous histology) and GEJ (48%). Surgery was undertaken in 34 (56%) CF and 27 (68%) CP pts. Median follow-up was 43 months. Overall, there was a non-significant trend for improved OS with CF compared to CP (HR 0.61, 95% CI 0.33-1.14, p = 0.12). In the subgroup having surgery (N = 61), we found no significant difference in OS (HR 0.99, 95% CI 0.39-2.55, p = 0.99). In the subgroup without surgery (N = 40), CF was significantly superior to CP (HR 0.21, 95% CI 0.08-0.53, $p < 0.001$). Comparing only pts in this subgroup who received equitable radiation doses (N = 33), CF was still significantly superior to CP (HR 0.09, 95% CI 0.03-0.32, $p < 0.001$). OS was similar by histology (adenocarcinoma/squamous) in all-comers (p = 0.54), and in CF (p = 0.90) and CP subgroups (p = 0.63). DFS results corresponded with OS. There was a non-significant numerical difference in pCR rates between CF (31%) and CP (18%) (p = 0.35), which were lower than previously reported. **Conclusions:** Survival is similar for CF and CP CRT regimens in pts undergoing trimodality therapy, but for those who do not proceed to surgery, it appears that CF is more effective than CP. Clinicians may prefer CP for surgical candidates given its favourable toxicity profile. However, when treating with definitive CRT, CF may be preferable to CP as a standard regimen.

4054 Poster Session (Board #46), Sat, 8:00 AM-11:30 AM

A multicentre, phase II study with cabazitaxel in previously treated patients with advanced or metastatic adenocarcinoma of the oesophagogastric junction and stomach (CABAGAST). *First Author: Harald Schmalenberg, Krankenhaus Dresden-Friedrichstadt, IV. Medizinische Klinik, Dresden, Germany*

Background: This is a single-arm study to determine prolonged (> = 4 months) disease control rate with cabazitaxel administered in second- (or later) setting for patients with advanced or metastatic adenocarcinoma of the esophagogastric junction (EGJ) and stomach. **Methods:** 65 patients with advanced EGJ and stomach cancer were treated with 20mg/m^2 Cabazitaxel every 3 weeks for a maximum of 6 cycles. Main objective of the study was a prolonged Disease Control Rate (pDCR: CR, PR or SD lasting at least 4 months). Secondary Outcome Measures were overall survival (OS), progression-free survival (PFS), response rate by subgroup (with vs without previous treatment with a taxane) and toxicity. Patients were assessed for tumor response every 6 weeks during therapy and during follow-up (up to 12 months). **Results:** 65 patients (median age: 63, range 31-86 years) were assigned. Median no. of prior therapies was 2. 80% had received prior taxane therapy. Patients received a median of 2 cycles of cabazitaxel. Efficacy results are shown for the per protocol (PP) population. pDCR rate was 12.7%, (95%CI: 5,3%- 24.5%). pDCR was 20.0% in 2nd line patients (95%CI: 6.8%-40.7%) and 30.0% (95%CI: 6.7%-65.2%) in all lines in patients without prior taxane use. Response Rate was 5.5% (95%CI: 1.1%-15.1%) in total PP and 20.0% in the population without prior taxane use. Median OS was 4.6 months (7.4 months without prior taxane vs 3.8 months with prior taxane). Median PFS was 1.38 months (95%CI: 1.28- 1.87) with and 2.01 months (95% CI: 0.20- 4.67) without prior taxane use. Most common grade 3/4 toxicities were neutropenia in 13% of the patients, pain (12%), leucopenia (10%), anemia (10%), fatigue (10%) and nausea (10%). **Conclusions:** Cabazitaxel is active in heavily pretreated patients with metastatic and advanced esophagogastric junction and gastric adenocarcinoma. Toxicity is moderate. Patients without prior taxane use derived more benefit from Cabazitaxel. Clinical trial information: NCT01956149.

4055 Poster Session (Board #47), Sat, 8:00 AM-11:30 AM

Circulating tumor DNA analysis for outcome prediction in localized esophageal cancer. *First Author: Tej D. Azad, Stanford Cancer Institute, Stanford, CA*

Background: Blood-based biomarkers are not used in routine clinical practice in patients with esophageal carcinomas (ECs). Circulating tumor DNA (ctDNA) is an attractive biomarker that could be applied to ECs. We performed a study to explore pre- and post-treatment ctDNA analysis using the next generation sequencing-based CAPP-Seq method as a prognostic biomarker for localized EC. **Methods:** We prospectively enrolled 29 patients with localized EC treated with chemoradiotherapy (CRT) between June 2011 and October 2015. 12 (43%) patients were treated with CRT alone and 17 (57%) were treated with CRT followed by esophagectomy. Our cohort included patients with stage IB (1; 3.4%), II (7; 24.1%), and III (21; 72.4%) disease. Eight (27.6%) harbored squamous cell carcinoma (SCC) and 21 (72.4%) adenocarcinoma (AC). All patients received pre-treatment evaluation by thoracic CT, PET/CT, and esophagoduodenoscopy. ctDNA levels were quantitated in pre-treatment and post-treatment plasma samples using CAPP-Seq. **Results:** Median follow-up time was 21 months. We detected ctDNA pre-treatment in 72.4% of cases (N = 21) with a median concentration of 2.69 haploid genome equivalents per mL (hGE/mL; range 0.34-107.3). Pre-treatment ctDNA concentrations were strongly correlated with metabolic tumor volumes (MTV; R^2= 0.74; p = 1.7e-07) and were significantly higher in SCC than AC patients (28.2 vs. 2.1 mean hGE/mL; p = 0.002). Overall survival (OS) at 2 years for pretreatment ctDNA+ vs. ctDNA- patients was 47% vs. 86% (HR = 6.0; 95% CI = 0.74-49.2; $p < 0.05$) and trended toward significance when accounting for stage, histology, and age (p = 0.09). A single post-treatment plasma sample was collected within 3 months of treatment and was available for 19 patients. Post-treatment ctDNA was detected in 3 (15.7%) patients with a median concentration of 11.5 hGE/mL (range 2.2–11.9). Post-treatment ctDNA detection was strongly predictive of poor event-free survival ($p < 0.0001$) and time to distant metastasis ($p < 0.0001$). **Conclusions:** Our data suggest that pre- and post-treatment ctDNA levels may be prognostic for patients with localized EC and could potentially guide risk-adapted adjuvant therapy approaches.

4056 Poster Session (Board #48), Sat, 8:00 AM-11:30 AM

The impact of marital status on racial disparities in esophageal cancer care. *First Author: Alan Paniagua Cruz, University of Michigan Medical School, Ann Arbor, MI*

Background: It is well known that racial disparities exist in cancer treatment and outcomes. The present study examined the impact of marital status as a surrogate for social support on esophageal cancer (EsC) care. **Methods:** We performed a secondary analysis of data collected from a state cancer registry. We included individuals with an EsC diagnosis between January 1, 2000 and December 31, 2013. A Chi-square test and Fisher's exact test was used to analyze categorical variables and two-sample t-tests to compare continuous variables. **Results:** 8754 patients (Caucasian (C) or African American (AA) only) were included, with 88.4% C and 11.6% AA. Staging at diagnosis in C and AA patients revealed that 30.6% vs 28.6% had localized disease, followed by 33.8% vs 32.0% with regional, and 35.6% vs 40.0% with metastatic, respectively (p = .0155). Rates of chemotherapy (53.6% vs 53.5%) and radiation therapy (54.1% vs 56.2%) administration were found to be similar between C and AA patients. In contrast, surgery rates were significantly different between the two groups, with 29.7% of C undergoing surgical resection in comparison to only 12.0% of AA patients ($p < .0001$). When evaluating marital status, 63.3% of C were married, compared to 33.4% of AA patients ($p < .0001$). In the AA group, 20.1% of married patients underwent surgery in contrast to only 7.6% of single AAs ($p < .0001$). Similarly, in the C group, married patients underwent surgery at a rate of 34.5%, while single patients went to surgery at a rate of 22.2% ($p < .0001$). Surgery contraindication (CI) rates were found to be similar across all groups (5.6% married Cs, 5.2% married AAs, 6.6% single Cs, and 6.5% single AAs) along with surgery refusal rates (1.56% single Cs vs 2.68% married Cs (p = .052), and 1.04% single AAs vs 2.81% married AAs (p = .210)). **Conclusions:** African American patients receive chemotherapy and radiotherapy at comparable rates to Caucasian patients, but the rates of surgery are significantly lower. Being married was associated with an almost three-fold increase in surgery rates for AA patients, and cause a significant increase in Caucasians too.

4057 Poster Session (Board #49), Sat, 8:00 AM-11:30 AM

Association of the addition of cetuximab to preoperative chemoradiotherapy (CRT) for locally advanced esophageal squamous cell carcinoma (SqCC) with rate of long term survival: Mature results of a prospective phase Ib/II trial. *First Author: Baruch Brenner, Rabin Medical Center, Petah Tikva, Israel*

Background: Current treatment results in locally advanced esophageal cancer (LAEC) are far from being satisfying. This prospective phase IB/II study evaluated the safety and efficacy of the addition of cetuximab to standard preoperative CRT in this disease. **Methods:** Patients (pts) with potentially resectable LAEC (T2-4N0-1M0, T1-4N1M0 or T1-4N0-1M1A) received an induction cycle of cisplatin 100 mg/m^2, day 1, and 5-FU 1000 mg/m^2/day as a continuous infusion (CI), days 1–5, followed 4 weeks later by 50.4 Gy radiotherapy given concurrently with 2 cycles of cisplatin 75 mg/m^2 and escalating doses of CI 5-FU, days 1–4 and 29-32. Pts received also 10 weekly infusions of cetuximab, 250 mg/m^2, with a loading dose of 400 mg/m^2, starting from the induction. The phase II part of the study started when the 5-FU dose during CRT was defined. Surgery was planned 6-8 weeks after CRT. **Results:** 64 pts were enrolled and 60 completed CRT. Median age was 65 years (range: 38-84 years) and 66% were males. The SqCC/adenocarcinoma ratio was 39%/61% (25/39). Pts had very advanced tumors: 95% T3-T4, 67% N1 and 19% M1A. The most common grade $>$ 3 toxicities were leucopenia (45% of pts) and neutropenia (41%). There were two cases (3%) of fatal toxicities (neutropenic sepsis and sudden death). Among the 55 operated pts, R0 resection was achieved in 51 (93%). There were 8 cases (14.5%) of postoperative mortality, due to infection (3 pts), esophageal leak (2), bleeding (2) and pulmonary insufficiency (1). Pathological down-staging was noted in 72% of pts and pathological complete response (pCR) in 33%. 5y-local control, progression-free survival (PFS) and overall survival (OS) rates for all pts were 94%, 40%, 39%, respectively. Pts with SqCC had a significantly higher pCR rate (52% vs 15%, p = 0.007), 5y-PFS (67% vs. 21%, p = 0.008) and 5y-OS (64% vs. 20%, p = 0.019). **Conclusions:** This study suggests that the addition of cetuximab to standard preoperative CRT is safe. R0, pCR, local control and long term PFS and OS rates in pts with SqCC tumors are encouraging. Further evaluation of this approach in this population seems warranted.

4058 Poster Session (Board #50), Sat, 8:00 AM-11:30 AM

Safety in numbers? Gastric cancer survival varies with total retrieved lymph nodes. *First Author: Omidreza Tabatabaie, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Recently published AJCC 8thTNM-staging guidelines recommend a minimum of 16 lymph nodes be assessed in gastric cancer surgery with more lymph nodes (30) being desirable. However, the independent effects of greater numbers of lymph nodes excised on the overall survival of patients with gastric adenocarcinoma are understudied. **Methods:** National Cancer Database (NCDB) was reviewed from 2010 to 2014 for patients who underwent potentially curative surgery for gastric adenocarcinoma. Patients with zero or unknown number of harvested lymph nodes were excluded, as were those with metastatic or in-situ disease, or who received neoadjuvant chemo- or radiotherapy. Cox proportional hazards modeling was used for multivariate survival analysis. **Results:** Of the 12,507 patients who met selection criteria, 4,880 (39.0%) were female. The median age was 69 years [IQR: 59-77]. Median number of lymph nodes examined for each clinical T and N-stage is provided in the table. Overall, 51.0% of patients had $<$ 16 lymph nodes examined. After adjusting for clinical T and N-stages, sex, age, tumor size, grade, facility type, receipt of adjuvant chemotherapy, resection type and race, and compared to patients with $<$ 16 nodes examined, the hazard ratios for death in patients with 16-29, 30-44 and $\geq$45 examined lymph nodes were 0.87 (95% CI = 0.82-0.93), 0.79 (95% CI = 0.71-0.88) and 0.68 (95% CI = 0.56-0.83), respectively. **Conclusions:** Total lymph node count is an important independent predictor of overall survival in resectable gastric cancer, with an increased number of excised lymph nodes being associated with progressively decreased risk of death. These findings support the latest AJCC guidelines that higher number of lymph node retrieval is desirable. The recommended oncologic standard for at least 16 nodes to be assessed pathologically is not attained in more than half of upfront gastric resections performed for cancer.

N-stage	Number (%)	Median # nodes [IQR]	T-stage	Number (%)	Median # nodes [IQR]
0	7481 (59.8%)	15 [9-22]	1	2755 (22.0%)	14 [8-22]
1	1218 (9.7%)	17 [11-25]	2	1551 (12.4%)	16 [10-23]
2	533 (4.2%)	15 [10-22]	3	1924 (15.3%)	17 [10-25]
3	485 (3.8%)	21 [15-29]	4	855 (6.8%)	16 [10-24]
Unknown	2790 (22.3%)	15 [9-23]	Unknown	5422 (43.3%)	15 [9-22]

4059 Poster Session (Board #51), Sat, 8:00 AM-11:30 AM

A phase II study (KSCC/HGCSG/CCOG/PerSeUS1501B) of trastuzumab plus S-1 and oxaliplatin for HER2-positive advanced gastric cancer. *First Author: Katsunori Shinozaki, Division of Clinical Oncology, Hiroshima Prefectural Hospital, Hiroshima, Japan*

Background: A combination of S-1 and cisplatin (SP) has been the standard regimen for advanced gastric cancer (AGC) in East Asia. The combination of S-1 and oxaliplatin (SOX100) was demonstrated to be non-inferior to SP in the randomized phase III study. The ToGA study demonstrated that trastuzumab (T-mab) combination therapies with cisplatin and fluoropyrimidines improved the overall survival of patients with HER2-positive AGC. This multicenter study is the first phase II trial to assess the efficacy and safety of T-mab in combination with S-1 and oxaliplatin (HER-SOX130) in HER2-positive AGC. **Methods:** Patients with HER2-positive AGC or recurrent gastric cancer defined to be IHC 3+ or IHC 2+/FISH positive received 80 mg/m^2 S-1 per day orally on days 1–14, 130 mg/m^2 oxaliplatin intravenously on day 1, and T-mab (8-mg/kg loading dose and 6 mg/kg thereafter) intravenously on day 1 of a 21-day cycle until one of the criteria for withdrawal of the study treatment occurred. The primary end-point was the response rate (RR). Adverse events were recorded based on the NCI-CTCAE Vers.4.0. The threshold response rate was defined as 50%, and the expected rate was set at 70%, with an 80% power and a 1-sided alpha value of 0.05. The calculated sample size was 37 patients. **Results:** For this study, 42 patients (median age, 66 years) were enrolled from June 2015 to May 2016. Three patients were excluded owing to ineligibility. Efficacy and safety analyses were conducted in the full analysis set of 39 patients. The proportion of patients with IHC 3+ was 87%. The confirmed RR assessed by the independent review committee was 82.1(32/39) % (95% confidence interval [CI]: 67.3–91.0), and the disease control rate was 87.2(34/39) % (95% CI: 73.3–94.4). The incidence rates of grade 3 or 4 adverse events were as follows: neutropenia, 12.8%; thrombocytopenia, 17.9%; anemia, 10.3%; sensory neuropathy, 5.1%; anorexia, 17.9%; diarrhea, 7.7%; and teary eyes, 2.6%. **Conclusions:** HER-SOX130 demonstrated encouraging efficacy with a favorable safety profile. The survival benefit of this regimen needs to be validated by conducting further follow-up of patients. Clinical trial information: 000017552.

4060 Poster Session (Board #52), Sat, 8:00 AM-11:30 AM

Magnitude and duration of immune checkpoint up-regulation and changes in the immune microenvironment post chemo-radiation (CRT) in esophageal cancer. *First Author: Ronan Joseph Kelly, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: PD-1 inhibitors in metastatic gastroesophageal cancer have demonstrated response rates of approximately 25%. Unfortunately, the majority of patients do not respond. Therefore, a rationale strategy of combining immunotherapeutic agents with CRT in earlier stage esophageal cancer may prevent metastatic disease in a greater proportion of patients. This study assessed the impact of CRT on the immune microenvironment and the expression patterns of multiple immune checkpoints to optimally design neoadjuvant clinical trials. **Methods:** To determine the effects of CRT on resected esophageal adenocarcinomas (EAC), we examined the immune microenvironment pre and post CRT using IHC, LCM followed by qRT-PCR, and functional analysis of tumor-infiltrating lymphocytes. Additionally, to assess the duration and dependency of radiation-induced PD-L1 sensitization, esophagojejunostomy were performed on rats to induce gastroduodenoesophageal reflux and EAC formation. First, tumor bearing animals were dosed with single fraction 13 Gy or 16 Gy radiation to determine safety, dose correlation, and PD-L1 sensitization using qRT-PCR post-radiation. Next, longitudinal PD-L1 expression levels within individual tumor bearing animals were determined using serial endoscopic biopsies at baseline, 1, 5 and 9 weeks post 16 Gy radiation. **Results:** The majority of cancers displayed enhanced interferon γ and activated CD8+ T lymphocytes at the tumor stroma interface. These tumors also demonstrated enhanced upregulation of PD-L1 and multiple other immune checkpoints including – TIM3, GITR, IDO1, LAG3, CD137, OX40 and KIR. The animal model results indicated PD-L1 upregulation is dose dependent and transiently elevated post radiation exposure. **Conclusions:** Collectively, these findings provide insights into the evolving immune landscape after CRT and have significant implications for future neoadjuvant trial designs that will combine radiotherapy with immune checkpoint inhibitors. Currently, we are conducting a neoadjuvant trial assessing Nivolumab or Nivolumab/Ipilimumab in combination with CRT in stage II/III operable esophageal cancer.

4061 Poster Session (Board #53), Sat, 8:00 AM-11:30 AM

Treatment patterns for resected gastric cancer using the National Cancer Database. *First Author: Foluso Nelson Ogunleye, Beaumont Health, Department of Hematology and Oncology, Oakland University William Beaumont School of Medicine, Royal Oak, MI*

Background: The optimal management of patients with resected gastric cancer remains a therapeutic challenge. Although the benefit of peri-operative chemotherapy or adjuvant concurrent chemoradiotherapy for these patients is clearly established, recurrence and mortality rates remain high despite aggressive treatment. The goal of this study was to characterize the treatment patterns employed for patients with resected gastric cancer using the National Cancer Database (NCDB). **Methods:** The NCDB was queried between 2004-2013 for patients with invasive resected gastric cancer and negative margins, excluding those with metastatic disease. **Results:** We identified a total of 21,156 cases. The median age was 67 (range 55-79). A majority of patients were white (74%) followed by black (14%) and other (12%). Most patients had either insurance through the government (58%) or private insurance (37%). 47% of patients had surgery alone with approximately 53% of these patients diagnosed with stage I gastric cancer. The remainder of the patients had radiation alone (1.4%), chemotherapy alone (15.2%), or combined chemotherapy and radiation (36.7%). Table 1 includes the further breakdown of treatment. **Conclusions:** A majority of patients with resected gastric cancer had treatment with either radiation, chemotherapy, or a combination of both. However, it is interesting to note that in patients receiving adjuvant or neoadjuvant treatment, only a portion of the patients received treatment options with level 1 evidence such as the MAGIC or McDonald regimens.

4062 Poster Session (Board #54), Sat, 8:00 AM-11:30 AM

The Nationwide Cancer Genome Screening Project in Japan, SCRUM-Japan GI-screen: Efficient identification of cancer genome alterations in advanced esophageal cancer. *First Author: Yuichiro Nakashima, Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan*

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in advanced non-colorectal gastrointestinal (GI) cancer (aNon-CRC), called as the SCRUM-Japan GI-SCREEN. The objective is to evaluate the frequency of cancer genome alterations in aNon-CRC and to identify patients who are candidate for clinical trial for corresponding targeting agents. **Methods:** This study is ongoing with the participation of 20 major cancer centers. Patients with aNon-CRC, including advanced esophageal cancer (aEC), who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutation, copy number variant (CNV) and fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase. In this presentation, we show the results of aEC cohort. **Results:** As of October 31st in 2016, a total of 180 aEC samples were analyzed. The sequence with the OCP was successfully performed in 121 (67.2%). Out of 157 patients except for the 23 patients in which precise data is not collected, the proportion of sample and histology type is followed; surgical specimen 58.0%, squamous cell carcinoma 92.4%. The frequently detected mutations in 114 samples of which results were available were *TP53* (77.2%), *NFE2L2* (23.7%), *CDKN2A* (9.6%), *PIK3CA* (7.0%), *RB1* (6.1%), and CNVs were *CCND1* (37.7%), *EGFR* (7.9%), *MYC* (7.9%), *SOX2* (6.1%), *ATP11B* (5.3%), *NKX2-1* (5.3%). *ERBB2* amplification was identified in 3 cases (2.6%) and *FGFR3-TACC3*fusion was identified in one case (0.9%). **Conclusions:** This nationwide screening system is efficient to detect rare gene alterations in aEC. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine. Clinical trial information: UMIN000016344.

4063 Poster Session (Board #55), Sat, 8:00 AM-11:30 AM

A randomized, open-label, multicenter trial of the concurrent chemoradiotherapy of capecitabine with or without oxaliplatin versus cisplatin with 5-FU for Chinese squamous esophageal cancer: An interim report from CRTCOESC. *First Author: Ruinuo Jia, Henan Key Laboratory of Cancer Epigenetics, Cancer Hospital, The First Affiliated Hospital, College of Clinical Medicine, Medical College of Henan University of Science and Technology, Luoyang, China*

Background: CRT with 5- FU and cisplatin (PF) has shown greater clinical efficacy for local advanced esophageal cancer (EC) but with high rate of acute toxicities (ATs). CRTCOESC is a randomized, open-label, multicenter trial designed to evaluate the effect and safety of capecitabine with or without oxaliplatin versus PF with CRT in Chinese EC. **Methods:** Pts with biopsy-proven squamous EC (T2-4N0-2M0) were randomized to single capecitabine (Arm1), capecitabine plus oxaliplatin (Arm2), or PF (Arm3), while daily radiation 50Gy/2Gy for all. Pts were stratified by different regimens cycles. Both grade3-5 ATs and 2-year OS were the primary endpoint, with a planned accrual of 249 pts to detect a decrease in Grade3-5 ATs from 40% to 20%. The secondary endpoint included objective response rate (ORR) and 2-year progression free survival (PFS). Interim analysis of ATs and ORR was planned for the first 120 pts. **Results:** The study accrued 128 pts from 2014.10-2016.12, 118 were eligible. 86 patients were finished 16-weeks follow-up at least and analyzed in the interim report (Arm1: Arm2: Arm3 = 24: 37: 25). There was no difference between three arms on pts pretreatment characters (age, gender, weight, performance status, clinical stage, lymphonodus status, and pathology grade). Incidence of grade3-5 ATs in Arm1/2/3 were 25%: 32.4%: 64% ($p = 0.03$); it was significantly lower in Arm1/2 than Arm3 (Arm1 vs Arm3, $p = 0.041$; Arm2 vs Arm3, $p = 0.022$); and there no meaningful different between Arm1 and Arm2 ($p = 0.738$). The pCR rate and ORR were 50%: 48.6%: 48% and 87.5%: 83.8%: 100% in Arm1/2/3 ($p = 0.99$; $p = 0.133$). 56 patients had been finished 1 year follow-up (Arm1: Arm2: Arm3 = 12: 26: 18). The 1-year OS and PFS were 75%: 91.9%: 76% and 66.7%: 62.2%: 60% in Arm1/2/3 ($p = 0.166$; $p = 0.926$). **Conclusions:** Compared with PF, CRT with single capecitabine with or without oxaliplatin shown lower incidence of ATs and similar ORR and 1-year OS. The single capecitabine seemly carried out a benefit of lower ATs than it plus oxaliplatin; there was no meaningful difference for them on ORR and 1-year OS. Ruinuo Jia and Tanyou Shan did equal work. Clinical trial information: NCT02025036.

4064 Poster Session (Board #56), Sat, 8:00 AM-11:30 AM

Results of a phase II randomized study evaluating the potential benefit of a postoperative intraperitoneal immunotherapy after resection of peritoneal metastases from gastric carcinoma metastases (IIPOP- NCT01784900). *First Author: Diane Goere, Gustave Roussy, Villejuif, France*

Background: Prognosis of patients with peritoneal extension from gastric carcinoma remains poor. The aim of this multicentre, open-label, phase 2 randomized study was to analyze the potential survival benefit of an immediate postoperative intraperitoneal immunotherapy using a bi-specific (anti-EpCAM, anti-CD3), trifonctional agent named catumaxomab. **Methods:** Patients with limited synchronous carcinomatosis from gastric carcinoma (Peritoneal cancer index (PCI) $\leq$ 12), were treated after complete resection (gastrectomy plus all peritoneal deposits), by an intraperitoneal infusion of catumaxomab during 5 days. Patients were randomized between 2 arms according to the total doses administered of catumaxomab (100μg *vs* 140μg). The first end-point was the 2-year overall survival (OS). Forty randomized patients were required (20 in each arm), considering that a 2-year OS rate $\leq$ 30% would be considered as unacceptable, and $\geq$ 55%, a promising survival rate. The study was stopped prematurely due to the manufacturing stop of the catumaxomab. **Results:** Between March 2013 and September 2014, 26 patients were included in the study; among them, 11 were randomized, with a median PCI of 9 [1-12]. Seven patients received the whole planned treatment of catumaxomab; in the remaining 4 patients, interruptions were related to postoperative complications. One patient died postoperatively of multiorgan failure and grade 3-5 complications occurred in all the patients, without difference between the 2 groups. At the end of the follow-up, 3 were alive (25, 30, 36 months). The median OS was 19 months, and the 1 and 2- year OS rates were 63.6% and 36.4% respectively. **Conclusions:** This study has to be stopped prematurely; however, encouraging results regarding overall survival were observed. Intraperitoneal immunotherapy represents an innovative and promising treatment in patients with peritoneal metastases, considering the poor response to systemic chemotherapy and the "immunocompetence" of the peritoneum. The evaluation of a potential benefit of a local immunotherapy has to be pursued. Clinical trial information: NCT01784900.

4065 Poster Session (Board #57), Sat, 8:00 AM-11:30 AM

Incidence rate and clinical-pathological features of hereditary diffuse gastric cancer patients in China. *First Author: Miaozhen Qiu, Cancer Center of Sun Yat-Sen University, Guangzhou, China*

Background: Familial clustering is seen in 10 % of gastric cancer cases and approximately 1-3 % of gastric cancer arises in the setting of hereditary diffuse gastric cancer (HDGC). Little is known about the incidence rate and clinical-pathologic features of HDGC in Chinese patients. **Methods:** We retrospectively collected gastric adenocarcinoma patients who were diagnosed in Sun Yat-sen University Cancer Center between January 2002 and December 2014. All the patients had detailed record of family history and Lauren classification. All of statistical analyses were performed using the Intercooled Stata 13.0 (Stata Corporation, College Station, TX). **Results:** 7431 patients were enrolled for analysis. The incidence rate of HDGC was 3.97% (295/7431). There were 124 (42.03%) male and 171 (57.97%) female patients. The median age was 35 (Mean ±SD: 35.23± 7.50). The most common sites were gastric body (49.47%) and fundus (35.09%) . The distribution of AJCC 7thTNM stage was 47 (16.32%) stage I, 59 (20.49%) stage II, 88 (30.55%) stage III and 94 (32.64%) stage IV. Only 92 patients received the HER2 immunohistochemistry test. 4 (4.35%) patients were HER2 IHC +++ and 8 (8.70%) patients were ++. The median survival was 80 months for the whole population and 15 months for stage IV patients. **Conclusions:** The incidence rate of HDGC was 3.97% in China. About one third of the patients were diagnosed at stage IV. Early detection of HDGC was warranted in China.

4066 Poster Session (Board #58), Sat, 8:00 AM-11:30 AM

Safety results of a phase 3 study of comparing paclitaxel plus 5-fluorouracil versus cisplatin plus 5-fluorouracil in chemoradiotherapy for locally advanced esophageal carcinoma (ESO-Shanghai 1). *First Author: Yun Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Concurrent chemoradiotherapy (CCR) with cisplatin plus 5-Fu (PF) regimen is the standard modality for inoperable locally advanced esophageal squamous cell carcinoma (ESCC) patients. In this phase 3 trial, we aimed to assess the efficacy and safety of the paclitaxel plus 5-Fu (TF) regimen versus PF regimen in CCR for ESCC patients. **Methods:** ESCC patients presented with stage IIa to IVa were enrolled in a prospective multicenter phase 3 study. Patients were randomized to either PF group or TF group. Patients in PF group were treated with 2 cycles of CCR followed by 2 cycles of consolidation chemotherapy with PF (cisplatin 25 mg/m^2/d, d1-3, plus 5-Fu 1800 mg/m^2, civ 72h, q28d). Patients in TF group were treated with 5 cycles of weekly TF (5-Fu 300 mg/m^2, civ 96h plus paclitaxel 50 mg/m^2, d1) in CCR followed by 2 cycles of monthly TF (5-FU 1800 mg/m^2, civ 72h, plus paclitaxel 175 mg/m^2 d1) in consolidation chemotherapy. The radiotherapy dose in both groups was 61.2 Gy delivered in 34 fractions. Adverse events (AE) defined according to CTCAE 4.0. The primary end-point was 3-yr OS. The number and grade of participants with AE was analyzed by intention to treat. **Results:** Between April 2012 and July 2015, 436 ESCC patients in 7 centers were enrolled. TF group had a significant higher incidence of acute Grade 3/4 leukopenia (31.3% vs. 18.9%), hiccup (0.9% vs. 0.0%), dermatitis (17.5% vs. 7.5%), pneumonitis (9.8% vs. 2.3%), and esophagitis (6.0% vs. 3.2%), and lower incidence of anemia (0.5% vs. 1.9%), thrombocytopenia (0.5% vs. 13.8%), fatigue (5.6% vs. 17.3%), anorexia (0.5% vs. 14.1%), nausea (0.5% vs. 14.1%), and vomiting (0.9% vs. 17.7%) than PF group ($P < 0.05$). There were 3(1.4%) patients in TF group died of acute pneumonitis. For long-term AE, 1(0.5%) patient in each group died of pneumonitis. There was no significant difference in total numbers of incidence of ≥ Grade 3 AE between two groups. Until Jan 2017, the median survival has not reached. **Conclusions:** The safety results of this trial were acceptable. TF regimen showed a different AE profile compared with PF regimen used in CCR in ESCC patients. Clinical trial information: NCT01591135.

4067 Poster Session (Board #59), Sat, 8:00 AM-11:30 AM

Updated antitumor activity and safety of FPA144, an ADCC-enhanced, FGFR2b isoform-specific monoclonal antibody, in patients with FGFR2b+ gastric cancer. *First Author: Daniel V.T. Catenacci, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: FGFR2b-overexpressing gastric cancer is characterized by poor prognosis. FPA144, a humanized monoclonal IgG1 antibody that specifically binds to and blocks FGFR2b, has been engineered for enhanced antibody-dependent cell-mediated cytotoxicity (ADCC). FPA144-001 is a two-part Phase 1 study of FPA144 monotherapy in patients with advanced solid tumors, including gastric and gastroesophageal cancers (GEJ cancers). **Methods:** Part 1A was a 3+3 design to assess safety and PK and to establish a recommended dose (RD) of FPA144. Patients with gastric cancer were enrolled in Part 1B to assess PK in gastric cancer. Part 2 includes 4 cohorts of gastric cancer patients with either high, moderate, low or no FGFR2b overexpression based on a centralized immunohistochemistry (IHC) assay. Here, we describe results of gastric cancer patients that highly overexpress FGFR2b (FGFR2b+ High) enrolled in Parts 1 and 2 of the study. **Results:** As of October 28, 2016, 18 FGFR2b+ High (IHC 3+ ≥10% tumor membrane staining) patients were enrolled in the study. 12 of these patients received the RD of 15 mg/kg every 2 weeks. Enrolled patients received a median of 3 prior treatment regimens. Fatigue (22.2%, none ≥ gr 3) and infusion reaction (16.7%, 5.6% gr 3) were the most common treatment-related AEs. Treatment-related SAEs were reported in 2 patients: Grade 2 ulcerative keratitis and Grade 3 infusion reaction. There were 5 PRs, 4 confirmed and 1 unconfirmed. Disease control (PR+SD) was 55.6%, including a confirmed ORR of 22% with median DOR of 15.4 weeks. ctDNA analysis of a responding patient revealed baseline elevated FGFR2 gene copy (165 copies in the blood, mutation allele burden 66%) that decreased after monotherapy (nadir 75 copies, mutation allele burden 38.5%) corresponding with clinical response, serum tumor markers and near complete response on PET imaging. **Conclusions:** The demonstration of activity and an acceptable safety profile supports further development of FPA144 in patients with FGFR2b+ tumors. *FGFR2* gene amplification detected in ctDNA may provide a non-invasive diagnostic test for patient selection. Updated data will be presented. Clinical trial information: NCT02318329.

4068 Poster Session (Board #60), Sat, 8:00 AM-11:30 AM

Predicting survival in gastric cancer patients randomized to docetaxel with mass spectrometric quantitation of TUBB3. *First Author: Fabiola Cecchi, NantOmics, LLC, Rockville, MD*

Background: No predictive biomarker for chemotherapy has been validated for clinical use. A relationship between resistance to taxanes and expression of class III β-tubulin (TUBB3) protein has been suggested by small clinical studies, but not confirmed in randomized trials. Immunohistochemical definitions of "TUBB3 positive" vary widely between studies and depend on subjective measures of strong vs weak staining. We retrospectively evaluated the relationship between survival and TUBB3 protein quantitated by mass spectrometry in the tumor samples of 247 patients from the Intergroup Trial of Adenocarcinoma of the Stomach (ITACA-S). Patients had been randomized to a docetaxel-containing adjuvant regimen or to monotherapy with fluorouracil and leucovorin (5-FU/LV). **Methods:** Archived tumor tissues were microdissected and solubilized for proteomic analysis. TUBB3 and 44 other protein biomarkers were quantified with a mass spectrometry-based assay. A TUBB3 protein cutoff of 750 amol/ug was predetermined based on the assay's limit of detection. The Mantel-Cox log-rank test was used for survival comparisons. **Results:** Among gastric cancer (GC) patients treated with docetaxel-containing chemotherapy (n = 125), those with TUBB3 levels below the cutoff (750 amol/μg of total protein) had a longer median overall survival (mOS) than patients with TUBB3 levels above the cutoff (1563 vs 886 days, p = 0.04). TUBB3 level made no difference in survival among patients who received 5-FU/LV. Of note, among patients with high TUBB3 levels (> 750 amol), those treated with 5-FU/LV survived 3 years longer than patients in the docetaxel arm (mOS = 1991 vs 886 days, p = 0.048). **Conclusions:** Quantitative proteomic analysis of TUBB3 identified a subset of GC patients who benefitted from the addition of docetaxel to adjuvant chemotherapy. GC patients with TUBB3-expressing tumors had worse outcomes on a docetaxel-containing regimen than on 5-FU/LV. An ongoing study of triple-negative breast cancer patients treated with docetaxel suggests that proteomic TUBB3 may be predictive in other cancer indications. Personalized chemotherapy based on quantitated TUBB3 is promising and warrants broader evaluation.

4069 Poster Session (Board #61), Sat, 8:00 AM-11:30 AM

Phase II study of BKM120 in patients with advanced esophageal squamous cell carcinoma (EPOC1303). *First Author: Ken Kato, Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan*

Background: BKM120 is an oral pan-class I phosphatidylinositol-3-kinase (PI3K) inhibitor, which showed promising activity in breast cancer and squamous cell carcinoma of head and neck. We prospectively investigated clinical activity, safety and biomarkers of BKM120 in advanced esophagus squamous cell carcinoma (ESCC). **Methods:** We conducted a multicenter phase II study of BKM120 monotherapy in patients with pretreated advanced ESCC. All the patients had a treatment history of fluoropyrimidine and platinum. BKM120 of 100 mg/day was orally administered in a 28-day cycle. A primary end-point was a disease control rate (DCR). Using Simon's minimax two-stage design, total of 41 patients were required for primary analysis (promising DCR of 60%, non-promising one of 40%, one-sided alpha level of 10% and power of 90%). The response rate (RR), progression-free survival (PFS), overall survival (OS), and safety were also evaluated as secondary endpoints. Tumor samples for all the patients were required for gene alternation analysis in comprehensive genomic profiling assay (FoundationOne). **Results:** A total of 42 patients (median age, 62.5 years; performance status 0/1 = 28/14) were enrolled. One ineligible patient was excluded from primary analysis. Nineteen and two patients had SD and unconfirmed PR. DCR was 51.2% (95% CI, 35.1% to 67.1%), which met the primary endpoint of the study. Median PFS and OS was 2.0 months (95% CI, 1.8 to 3.2 months) and 9.0 months (95% CI, 6.4 to 11.7 months), respectively. Common grade 3 or 4 adverse events were anorexia, rash, hyponatremia, lipase increased, and abnormal hepatic function (including increased transaminase levels), which were profiles similar to previous studies of BKM120 monotherapy. No treatment-related deaths occurred. Further analyses of the gene alternation are ongoing. **Conclusions:** BKM120 monotherapy showed promising efficacy and mild toxicity profile in patients with pretreated advanced ESCC. BKM120 is worth evaluating in a further confirmatory study. Result of subgroup analyses with respect to gene alternation status will be presented. Clinical trial information: UMIN000011217.

4070 Poster Session (Board #62), Sat, 8:00 AM-11:30 AM

Comparison of efficacy and safety of first-line palliative chemotherapy with TX and XELOX regimens in patients with metastatic gastric adenocarcinoma: A randomized phase II trial. *First Author: Xiaodong Zhu, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Docetaxel has shown antitumor activity in the treatment of MGC as a single or combination chemotherapy. This study was designed to compare the clinical outcome of docetaxel based and platinum based doublet regimen as first-line treatment in MGC patients. **Methods:** In an open, randomized, single center phase II trial, 134 pts were randomly assigned and treated with either TX (capecitabine 1g/m2/twice daily/ 1-14 days and docetaxel 75mg/m2 in 1st day) or XELOX (capecitabine 1g/m2/twice daily/ 1-14 days and oxaliplatin 130 mg/m2 in 1st day) as first-line chemotherapy. The primary endpoint is finding potential predictive factors, secondary endpoint is ORR, PFS, OS and safety. After progression, patients were switched into the other group. **Results:** Now, the potential predictive factors are testing in genomics and proteomics. In 134 randomly assigned and treated pts (TX = 69; XELOX = 65). Most pts were male (87pts).Overall survival was longer with TX versus XELOX (13.1m vs. 9.6m, p = 0.173), but no statistical differences. Progression free survival was similar with TX versus XELOX (4.57m vs. 5.27m, p = 0.297). Overall response rate was equal with TX versus XELOX (50.8% vs. 47.6%, p = 0.72). G3-4 treatment-related AE occurred in 60.6% (TX) v 55.4% (XELOX) of patients. Frequent G3-4 toxicities for TX v XELOX were: neutropenia (60.6% v 15.4%), febrile granulocyte deficiency (17.4% v 1.5%), anemia (10.1% v 10.8%), thrombocytopenia (1.4% v 15.4%), and all grade peripheral neurotoxicity (11.6% v 38.5%).After first-line treatment failure, 35 patients in the TX group switched to XELOX, and 27 patients in the XELOX group switched to TX, and there is also no significant difference in survival time from the first-line treatment between the two groups (p = 0.129). **Conclusions:** Although TX led to more neutropenia, first-line palliative chemotherapy with docetaxel based doublet regimens provides a new choice and can gain almost the same response rate and survival time as frequently-used fluorouracil and platinum based regimen. And potential predictive factors will indicate who will get more benefit from taxanes or platinums. Clinical trial information: NCT01963702.

4071 Poster Session (Board #63), Sat, 8:00 AM-11:30 AM

Safety and clinical activity of durvalumab monotherapy in patients with hepatocellular carcinoma (HCC). *First Author: Zev A. Wainberg, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Durvalumab, an anti-PD-L1 mAb, has shown early and durable clinical activity with manageable safety in an ongoing Phase 1/2, multicenter, open-label study in pts with advanced solid tumors. Interim analyses from the HCC cohort in the dose-expansion part of this study are reported here. **Methods:** Patients with HCC (Child-Pugh class A) received durvalumab 10 mg/kg i.v. q2w for 12 months or until confirmed progressive disease, whichever occurred first. The primary objective was to evaluate the safety profile; secondary objective was to assess the antitumor activity (investigator-assessed RECIST v1.1). Clinical activity was evaluated for the total HCC population and by viral status. **Results:** As of Oct 24 2016, 40 HCC pts with median 23.9 (range 2.4–34.7) weeks follow-up received durvalumab. 93% had prior sorafenib. Treatment-related AEs occurred in 80.0% of pts, most commonly fatigue (27.5%), pruritus (25.0%) and elevated aspartate aminotransferase (AST) (22.5%). Grade 3–4 treatment-related AEs were reported in 20.0% of pts, most commonly elevated AST (7.5%) and elevated alanine aminotransferase (5.0%). 7 (17.5%) pts completed the initial 12-month treatment and 7 (17.5%) pts discontinued treatment because of an AE (none related to treatment). There were no deaths due to treatment-related AEs. Clinical activity is presented in the table. 4 pts achieved a PR; 2 were ongoing at data cut-off. **Conclusions:** Durvalumab had an acceptable safety profile and showed promising antitumor activity and OS in pts with HCC, particularly HCV+ pts. Clinical trial information: NCT01693562.

4072 Poster Session (Board #64), Sat, 8:00 AM-11:30 AM

PrE0204: A multi-institutional, single arm, two-stage phase II trial of nab-paclitaxel and gemcitabine for first-line treatment of patients with advanced or metastatic cholangiocarcinoma—A PrECOG LLC study. *First Author: Vaibhav Sahai, University of Michigan, Ann Arbor, MI*

Background: Pts with advanced or metastatic cholangiocarcinoma (CCA) have limited response to current chemotherapy regimens and poor overall survival (OS). Nab-Paclitaxel (nabPAC) can increase the intra-cellular concentration of gemcitabine (GEM) through depletion of its metabolizing enzyme, cytidine deaminase (CDA). We investigated the nabPAC+GEM combination in a ph II single arm trial in advanced or metastatic CCA pts with exploratory biomarker evaluation, including CDA, hENT1, SPARC and circulating tumor cells (CTCs). **Methods:** Key eligibility criteria: advanced or metastatic CCA with no prior systemic chemotherapy, age $>$ 18, ECOG PS 0-1 and Child-Pugh $<$ 8. Pts received nabPAC (125 mg/m2 IV) and GEM (1000 mg/m2 IV) days 1, 8 and 15 Q4 weeks until progression. Primary endpoint: progression-free survival (PFS) rate at 6 months. Secondary endpoints: safety, time to progression (TTP), objective response (ORR) and disease control rates (DCR), median PFS and OS, as well as correlation of change in CA 19-9 to clinical efficacy. The study required $>$ 43 of 67 evaluable patients alive and progression-free at 6 months to conclude the 6-month PFS rate is at least 70% against a null hypothesis of 55% based on historical data. **Results:** 73 eligible patients (41.1% male, 91.8% Caucasian, 45.2% ECOG PS 0) were enrolled across 22 sites with a median age of 62 (range 36-87) years and received a median of 6 (range 1-18) cycles. The primary endpoint of PFS rate at 6 months was 54.7% on intention to treat analysis. Response evaluation is underway and will be reported at the meeting. The median PFS and OS were 6.5 (95% CI, 5.1-7.7) and 10.3 (95% CI, 9.1-14.6) months, respectively. The safety profile of nabPAC +GEM was similar to that reported in ph III MPACT trial. The most common treatment-related G3/4 toxicities were neutropenia (24.3%), fatigue (13.5%) and anemia (12.2%). Five patients remain on the trial. Exploratory analyses are pending. **Conclusions:** The observed PFS rate at 6 months with nabPAC+GEM in CCA is insufficient to reject the null hypothesis of 55% PFS at 6 months, and appears to be as effective as the historical control. Clinical trial information: NCT02181634.

4073 Poster Session (Board #65), Sat, 8:00 AM-11:30 AM

Phase I/II study of durvalumab and tremelimumab in patients with unresectable hepatocellular carcinoma (HCC): Phase I safety and efficacy analyses. *First Author: Robin Kate Kelley, University of California, San Francisco, San Francisco, CA*

Background: Durvalumab and tremelimumab, investigational monoclonal antibodies against PD-L1 and CTLA-4 immune checkpoints, respectively, have shown efficacy in monotherapy and offer promise in combination for patients (pts) with HCC. This is a phase I/II, open-label, randomized study of durvalumab combined with tremelimumab in unresectable HCC. **Methods:** Phase I part of this study is a safety run-in cohort treated at the recommended phase II doses of the durvalumab/tremelimumab combination (20 and 1 mg/kg IV Q4W respectively for 4 doses followed by 20 mg/kg Q4W durvalumab alone) in pts with unresectable HCC with or without concomitant HBV or HCV infection who progress on, are intolerant to, or have refused sorafenib therapy. Secondary objectives include evaluation of antitumor activity. Here we present results of a preplanned analysis from the completed phase I part of the study. **Results:** As of 10 January 2017, 40 pts have been enrolled (11 HBV+, 9 HCV+, 20 uninfected). 30% had no prior systemic therapy; 93% were Child Pugh Class A. 24 (60%) had ≥1 treatment-related AE; 20% had ≥1 grade ≥3 related AE. Most common (≥15%) treatment-related AEs: fatigue (20%), increased ALT (18%), pruritus (18%), and increased AST (15%). Most common grade ≥3 related AE was asymptomatic increased AST (10%). 24 pts have discontinued treatment: 3 due to treatment-related AEs (grade 3 pneumonitis, grade 3 colitis/diarrhea, asymptomatic grade 4 elevated AST and ALT), 16 due to progressive disease, 4 due to death unrelated to treatment (cardiac arrest, variceal bleed, progressive disease, probable HCC rupture), and 1 other (pt entered hospice care). 40 pts were evaluable for response at ≥16 weeks follow-up. **Conclusions:** No unexpected safety signals with durvalumab and tremelimumab were seen in this unresectable HCC population. Clinical activity observed predominantly in uninfected pts though interpretation limited by small subsets. Enrollment to the phase II portion of the study is ongoing. Clinical trial information: NCT02519348.

n (%)	HBV+ (N = 11)	HCV+ (N = 9)	Uninfected (N = 20)	All (N = 40)

4074 Poster Session (Board #66), Sat, 8:00 AM-11:30 AM

Safety and activity of the pan-fibroblast growth factor receptor (FGFR) inhibitor erdafitinib in phase 1 study patients (Pts) with molecularly selected advanced cholangiocarcinoma (CCA). *First Author: Jean-Charles Soria, Drug Development Department (DITEP), Gustave Roussy, Villejuif, France*

Background: Erdafitinib (JNJ-42756493) is a potent, oral pan-FGFR tyrosine kinase inhibitor that demonstrated encouraging preliminary clinical activity and manageable adverse events (AEs) in its first-in-human phase 1 study in advanced solid tumors (NCT01703481). Here we report results from pts with CCA from this study. **Methods:** This 4-part study enrolled pts age ≥ 18 years (y) with advanced solid tumors. Dose escalation (part 1) followed a 3+3 design, with pts receiving ascending doses of erdafitinib continuously or intermittently (7 days on/7 days off). Subsequent parts required FGFR gene alterations in the tumor, including activating mutations and translocations or other FGFR-activating aberrations. Part 2 was a pharmacodynamics cohort. Parts 3 and 4 were dose-expansion cohorts for recommended phase 2 doses of 9 mg once daily (QD) and 10 mg intermittently, respectively. **Results:** Eleven pts with FGFR-aberrant CCA were treated at 9 mg QD (n = 1) or 10 mg intermittent (n = 10). Median age was 60 y; 7 of 11 pts were female (64%). 73% of pts had ECOG performance status 1. All had prior systemic therapy. Median treatment duration with erdafitinib was 5.3 months (mo). Systemic erdafitinib exposure, per C_{max} and AUC, in CCA pts was similar to other indications. The most common AEs were stomatitis (82%), hyperphosphatemia (64%), dry mouth (55%), dysgeusia (45%), dry skin (45%), and asthenia (45%), mostly grade 1/2 severity. No drug-related grade ≥3 AEs were reported in > 1 pt except grade 3 stomatitis (n = 2; 18%). The objective response rate, all confirmed partial responses (PRs) per RECIST 1.1, was 27.3% (3/11; 95% CI 6, 61); an additional 27.3% (3/11) had stable disease as their best response. Overall disease control rate was 55%. All 3 PRs were at the 10 mg intermittent dosage, and the median duration of response was 12.9 mo. With a median follow-up of 5.1 mo, median progression-free survival was 5.1 mo (95% CI 1.6, 16.4). As of the cutoff date, 2 pts continue on study treatment. **Conclusions:** Erdafitinib showed encouraging clinical activity and minimal toxicity in pts with advanced CCA and FGFR alterations. These results warrant further study. Clinical trial information: NCT01703481.

4075 Poster Session (Board #67), Sat, 8:00 AM-11:30 AM

A phase I study of DKN-01 (D), an anti-DKK1 monoclonal antibody, in combination with gemcitabine (G) and cisplatin (C) in patients (pts) for first-line therapy with advanced biliary tract cancer (BTC). *First Author: Jennifer Rachel Eads, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: DKK1 is a secreted modulator of Wnt signaling often expressed in tumors, including BTC. DKK1 expression in BTC is associated with advanced stage and shorter survival. Depletion of DKK1 has efficacy in BTC xenograft models, inhibits cell invasion, and decreases MMP9 and VEGF-C expression, known promoters of metastasis and angiogenesis. D is a humanized monoclonal antibody against DKK1. This study evaluated the safety and efficacy of D in combination with GC in pts with advanced BTC. **Methods:** In Part A, pts received D at either 150 or 300 mg (and 300 mg D in Part B expansion) with 1000 mg/m2 G and 25 mg/m2 C on days 1 and 8 of each 21-day cycle. Response assessed every 2 cycles using RECISTv1.1. **Results:** 27 pts were enrolled; 4 dosed at 150 mg and 23 dosed at 300 mg. Median age: 65; Female: 74%; White: 85%. Gallbladder cancer 37%, intrahepatic cholangiocarcinoma 59%. 3 pts had prior G: 2 pts with adjuvant G; 1 pt with 2 prior regimens. Median number of cycles with D: 8 (range 1, 17). Median duration on study 6.8 mos; 8 pts still on therapy. No dose limiting toxicities or D-related serious adverse events have been observed. 24 pts (89%) had grade 3/4 treatment emergent adverse events (TEAEs); events in ≥ 3 pts include: neutropenia (n = 19), leukopenia (n = 9), thrombocytopenia (n = 9), hyperbilirubinemia (n = 6), anemia (n = 5), AST/ALT elevation (n = 4), and ALP elevation, bacteremia, hypertension, and hyponatremia (n = 3 each). The MTD of D + GC was 300 mg. At the MTD; 7 pts had a confirmed partial response (PR), 14 pts had stable disease > 6 weeks, and 1 pt had progressive disease. Both overall and MTD median PFS were 9.4 mos (95% CI 4.6, NE); median overall survival and duration of response were not reached. **Conclusions:** The addition of D (300 mg) to GC demonstrated a preliminary PFS of 9.4 mos and disease control rate of 96% with a 32% PR rate in pts with BTC. D + GC is well tolerated with no new emerging safety trends. Clinical trial information: NCT02375880.

4076 Poster Session (Board #68), Sat, 8:00 AM-11:30 AM

Precision medicine for gallbladder cancer using somatic copy number amplifications (SCNA) and DNA repair pathway gene alterations. *First Author: Milind M. Javle, Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Gallbladder carcinoma (GBC) is commonly diagnosed at an advanced, unresectable disease stage and has a poor prognosis. Comprehensive genomic profiling (CGP) has a developing role in guiding systemic, precision anti-cancer therapy. **Methods:** We performed hybrid capture-based CGP on FFPE samples for 491 consecutive advanced GBCs. Mean coverage depth was >550X for up to 315 cancer-related genes plus 37 introns from 28 genes frequently rearranged in cancer. All 4 classes of genomic alterations (GA) were detected. Tumor mutational burden (TMB) was determined on up to 1.1 Mb of sequenced DNA. **Results:** Median age was 64 (range 25-88) and 69% (337/491) of patients were female. 96% (470), 2.9% (14), and 1.4% (7) of GBC patients had the diagnosis of adenocarcinoma, adenosquamous, or carcinoma not specified (NOS), respectively. Commonly altered genes were *TP53* (62%), *CDNK2A* (31%), *ARID1A* (18%), and *SMAD4* (15%), and most of the genetic aberrations (GA) were short variants. Potentially targetable SCNAs (including *ERBB* genes, *MET*, *FGFR*s, and the *CCND1-FGF3/4/19* 11q13 amplicon) were identified in 21% of cases (Table). Oncogenic *BRAF*, *ALK*, or *FGFR2/3* rearrangements were found in 7 cases (1.4%). Moreover, 7.8% of cases had *BRCA2* or *ATM* GA, and 0.8% had *INI1* loss suggesting benefit from PARP or EZH2 inhibitors, respectively. TMB was low; the 25th, 50th, and 75th percentiles were 2.5, 3.8 and 6.3 mutations/Mb, respectively. Less than 1% of cases had microsatellite instability. Radiological response to TKIs and immunotherapy was noted. **Conclusions:** In addition to the significant opportunity for anti-HER targeted therapies, other subsets of GBC cases harbored kinase GA (particularly SCNA), the 11q13 amplicon, or *BRCA2*/*ATM*/*INI1* mutations that are linked to therapeutic benefit. How the frequency of both driver SCNA and DNA repair alterations in GBC can be linked with inflammation awaits additional investigation.

Gene	SCNA cases (%)	Median copy number

4077 Poster Session (Board #69), Sat, 8:00 AM-11:30 AM

BBI608-503-103HCC: A phase Ib/II clinical study of napabucasin (BBI608) in combination with sorafenib or amcasertib (BBI503) in combination with sorafenib (Sor) in adult patients with hepatocellular carcinoma (HCC). *First Author: Bassel F. El-Rayes, Winship Cancer Institute, Atlanta, GA*

Background: Napabucasin, a first-in-class cancer stemness inhibitor in clinical development, suppresses cancer stemness by targeting STAT3-driven gene transcription. Amcasertib targets multiple serine threonine stemness kinases and inhibits Nanog and other cancer stemness pathways. Preclinically, potent and broad-spectrum anti-cancer activity was observed *in vitro* and *in vivo*, alone and in combination with sorafenib. **Methods:** A phase Ib/II open-label, multi-center study in adult patients with advanced HCC who have not received prior systemic chemotherapy was performed to determine the safety, tolerability, and recommended Phase II dose (RP2D) , according to the criteria for DLT and for dose-escalation of Napabucasin (Arm 1), administered at 160 mg BID (dose level I) and at 240 mg BID (dose level II) in combination with sorafenib and of Amcasertib (Arm 2), administered at 100 mg QD (dose level I) and at 200 mg QD (dose level II) in combination with sorafenib. **Results:** 20 pts were enrolled, 10 in Arm 1 and 10 in Arm 2. 12 patients were evaluable for DLT determination; 2 pts d/c prior to starting protocol treatment; 11 pts received evaluation by RECIST, 6 pts in Arm 1 and 5 pts in Arm 2. The safety profile was consistent with that of each agent as monotherapy and most common AEs were attributed to *(Sor)* and included rash, PPE, grade 1/2 diarrhea, nausea, abdominal cramps, and vomiting. No signs of drug-drug interactions were observed in pharmacokinetics. Among all patients who received RECIST evaluation, Disease Control Rate (DCR=CR+PR+SD) for Arm 1 was 100% (6/6pts) and 100% (5/5pts) for Arm 2. DCR in ITT Arm 1 population was 67% and 50% in Arm 2. Median OS is not yet reached. **Conclusions:** In this phase Ib study, RP2D were determined for napabucasin and amcasertib to be safely combined with sorafenib at full dose, showing encouraging anti-tumor activity in patients with HCC who have not received prior systemic chemotherapy. A randomized phase II is schedule to start. Clinical trial information: NCD02279719.

4078 Poster Session (Board #70), Sat, 8:00 AM-11:30 AM

Efficacy of regorafenib (REG) in patients with hepatocellular carcinoma (HCC) in the phase III RESORCE trial according to alpha-fetoprotein (AFP) and c-Met levels as predictors of poor prognosis. *First Author: Michael Teufel, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ*

Background: REG is a multikinase inhibitor which improved overall survival (OS; HR 0.63, 95% CI 0.50, 0.79; P<0.0001) and time to progression (TTP; HR 0.44, 95% CI 0.36, 0.55; P<0.0001) compared with placebo in patients with HCC who progressed during prior sorafenib treatment in the RESORCE trial. This exploratory analysis evaluated the impact of baseline AFP and c-Met on REG treatment benefit (OS and TTP) in the RESORCE trial. **Methods:** Circulating AFP and c-Met protein (shed ectodomain) levels were quantified by a Luminex assay (Myriad RBM) in plasma samples collected at baseline from patients enrolled in the RESORCE trial. Valid biomarker data were available from 497 (AFP) and 499 (c-Met) out of 573 patients. Patients were subgrouped according to the median protein concentration (high vs low), and the treatment effect HR and its 95% CI were evaluated using a Cox proportional hazards model. The predictive effect was modeledas a protein–treatment interaction effect and subjected to Akaike information criterion (AIC)-based selection to assess its association with OS and TTP. **Results:** Baseline characteristics of patients were balanced across protein subgroups. While increased levels of both AFP (HR 1.09, 95% CI 1.07, 1.12; P<0.001) and c-Met (HR 1.32, CI 95% 1.06, 1.63; P=0.011) were associated with a worse prognosis for OS, increased AFP levels were also associated with poor prognosis for TTP (HR 1.05, 95% CI 1.03, 1.07; P<0.001). REG treatment benefit for both OS and TTP was independent of AFP and c-Met protein expression (Table). The protein–treatment interaction effect was not statistically significant. **Conclusions:** The treatment benefit of REG in patients with HCC was independent of AFP and c-MET protein expression at baseline. So far, no single protein has been associated with REG clinical benefit. Clinical trial information: NCT01774344.

Protein, expression	OS HR (95% CI)	OS P-value	TTP HR (95% CI)	TTP P-value

4079 Poster Session (Board #71), Sat, 8:00 AM-11:30 AM

Predictive model for microvascular invasion of hepatocellular carcinoma among candidates for either hepatectomy or liver transplantation. *First Author: Hidetoshi Nitta, Centre Hépato-Biliaire, AP-HP, Hôpital Paul Brousse, Villejuif, France*

Background: Microvascular invasion (MVI) is the strongest prognostic factor following surgery of hepatocellular carcinoma (HCC). However, it is usually not available on the preoperative setting. A predictive model of MVI in patients scheduled for hepatic resection (HR) or liver transplantation (LT) would thus help guiding treatment strategy. The aim of this study was to develop a predictive model for MVI of HCC before either HR or LT. **Methods:** HCC patients who consecutively performed HR or LT from January 1994 to June 2016 at a single institution were subdivided into a training and validation cohort. Risk factors for MVI in the training cohort were used to develop a predictive model for MVI, to be validated in the validation cohort. The outcomes of the HR and LT patients with high or low MVI probability based on the model, were compared using propensity score matching (PSM). Cut-off values for continuous factors were determined based on ROC curve analysis. **Results:** A total of 910 patients (425 HR, 485 LT) were included in the training (n = 637) and validation (n = 273) cohorts. In the training cohort, multivariate analysis demonstrated that alpha-fetoprotein ≥100ng/ml ($p < 0.0001$), largest tumor size ≥40mm ($p = 0.0002$), non-boundary HCC type on contrast-enhanced CT ($p = 0.001$), neutrophils-to-lymphocytes ratio ≥3.2 ($p = 0.002$), aspartate aminotransferase ≥62U/l ($p = 0.02$) were independently associated with MVI. Combinations of these 5 factors varied the MVI probability from 15.5% to 91.1%. This predictive model achieved a good c-index of 0.76 in the validation cohort. In PSM (109 HR, 109 LT), there was no difference in survival between HR and LT patients among the high MVI probability (≥50%) patients, (5y-OS; 46.3% vs 42.2%, $p = 0.77$, 5y-RFS; 54.0% vs 28.8%, $p = 0.21$). Among the low probability (< 50%), survival was significantly decreased following HR compared with LT (5y-OS; 54.1% vs 78.8%, $p = 0.007$, 5y-RFS; 17.3% vs 86.1%, $p < 0.0001$). **Conclusions:** This model developed from preoperative data allows reliable prediction of MVI, and may thus help with preoperative decisions about the suitability of HR or LT in patients with HCC.

4080 Poster Session (Board #72), Sat, 8:00 AM-11:30 AM

Stereotactic body radiation therapy to generate comparable survival to surgery in treating hepatocellular carcinoma (HCC): Results of 756 patients. *First Author: Feng Ming Kong, Indiana University Department of Radiation Oncology, Indianapolis, IN*

Background: Stereotactic Body Radiation Therapy (SBRT) has emerged as a viable treatment option in patients with hepatocellular carcinoma (HCC). This study aimed to compare survival outcomes after SBRT with other front line local treatments for HCC. **Methods:** This is a retrospective analysis of patients identified through our cancer registry from 2000 to 2016. Patients treated with any local therapy alone were eligible: SBRT, surgery, conventional external beam radiation (CEBRT), and other local therapies including brachytherapy. Patients treated with combined therapies such as SBRT plus liver transplant were excluded. The primary endpoint was overall survival which was estimated from the time of diagnosis. Differences between the groups were compared using log-rank test. The data are presented as median (95%CI). **Results:** A total of 756 patients with a median follow-up of 45 months (mo) met the selection criteria: 116, 380, 43, and 217 patients received SBRT, surgery, CEBRT, and other local treatment, respectively. Median age was 61, 60, 61 and 60 years, respectively. The median overall survival/3 year overall survival rate were 49 (32-66) mo /53% (44-65%) for patients treated with SBRT, which were not significantly different from 75 (57-94) mo /63% (58-69%) of surgery (p = 0.27), non-significantly better than 22 (13-31) mo /41% (27-60%) of CEBRT (p = 0.13), significantly better than 15 (13-20) mo /26% (20-34%) of other local treatments ($p = 3\times10^{-7}$). After adjusting for significant prognostic factors including age, race, status of tobacco abuse, history of alcohol use, tumor size, histology grade and stage, the survival outcomes of SBRT remained to be insignificantly different from surgery (HR = 0.8, p = 0.2), have a trend of significant difference from CEBRT (HR = 1.4, p = 0.1) and remarkably superior to that of other local treatments (HR = 1.8, $p = 2\times10^{-4}$). **Conclusions:** This study suggests that SBRT is an excellent front line option for HCC, potentially comparable to surgical resection and associated with longer survival than other front line local treatments. Randomized studies are needed to validate these findings.

4081 Poster Session (Board #73), Sat, 8:00 AM-11:30 AM

A phase 2 trial of regorafenib as a single agent in patients with chemotherapy refractory advanced and metastatic biliary adenocarcinoma/cholangiocarcinoma. *First Author: Weijing Sun, University of Pittsburgh, Pittsburgh, PA*

Background: Biliary adenocarcinoma/cholangiocarcinoma is a rare but aggressive neoplasm. Most patients present with unresectable or metastatic disease with 5-year survival rate ~5%. No second-line regimen has demonstrated clinical benefit in this disease. Regorafenib is an oral multi-kinase inhibitor with potent antitumor activity. This single arm phase II study evaluates the efficacy and safety of regorafenib as a single agent in advanced or metastatic biliary carcinoma/cholangiocarcinoma pts who failed systemic chemotherapy. **Methods:** Patients with ECOG PS 0-1and adequate liver, kidney and bone marrow function were given regorafenib orally once daily, 21 days on and 7 days off in a 28-day cycle. The initial dose of 160 mg was given to the first 3 patients. After toxicity assessment, the dose was reduced to 120 mg for the subsequent pts. The primary endpoint is PFS with the null hypotheses of 2.0 months, and median PFS $\geq$3.5 months as evidence of the study drug activity ($\alpha = 0.10$, 80% power). Secondary objectives include OS, RR, and DCR. **Results:** Thirty-seven patients received at least one dose of regorafenib, of whom 28 were evaluable for efficacy. All had previous gemcitabine/cisplatin treatment. The mean age was 62.5 (34.5-82.8) with 17 (46%) females. PR was achieved in 3 (10.7%), SD in 18 (64.3%, with DCR of 75%), and PD in 7 (25%). For all 37 patients, median PFS was 3.55 months (95% CI = 2.1- 5.72) and mOS was 5.55 months (95% CI = 4.04 -NA) with survival rate of 42 % at 12 months, and 38% at 18 months. Medan PFS and OS of 30 patients who had $\geq$1 cycle were 3.91 months (95% CI = 3.55-9.79) and 13.4 months (95% CI = 5.06 - NA), respectively. The overall toxicity profile was as expected, with G3/4 AE's of 40.5%. The most common toxicities were HTN, hypophosphatemia, hand-foot skin reaction, and increased serum bilirubin. Dose modification was required in 11 (30.6%) patients. Tumor samples were collected in 80% of patients, with planned correlative studies underway. **Conclusions:** This study showed promising efficacy of regorafenib in chemotherapy refractory advanced/metastatic cholangiocarcinoma. Further studies to confirm the clinic efficacy are recommended. Clinical trial information: NCT02053376.

4082 Poster Session (Board #74), Sat, 8:00 AM-11:30 AM

Pharmacokinetic/pharmacodynamic (PK/PD) profile of AG-120 in patients with IDH1-mutant cholangiocarcinoma from a phase 1 study of advanced solid tumors. *First Author: Bin Fan, Agios Pharmaceuticals, Inc., Cambridge, MA*

Background: Somatic mutations in isocitrate dehydrogenase 1 (IDH1) produce the oncometabolite D-2-hydroxyglutarate (2-HG). AG-120 is a first-in-class selective inhibitor of mutant IDH1 (mIDH1) under evaluation in an ongoing phase 1 study in patients with mIDH1 advanced solid tumors, including cholangiocarcinoma (CC) (NCT02073994). Objectives for this abstract were to 1) characterize the PK profile of AG-120 and the relationship between AG-120 exposure and 2-HG suppression, and 2) evaluate the influence of intrinsic patient factors on AG-120 clearance, in patients with mIDH1 CC. **Methods:** AG-120 was administered orally once daily (QD) or twice daily (BID) in continuous 28-day cycles. As of Dec 5, 2016, 60 of 73 patients enrolled with mIDH1 CC had PK/PD samples available for analysis at 100 mg BID, 300 mg QD, 400 mg QD, 500 mg QD, 800 mg QD, and 1200 mg QD in dose escalation (n = 24) and 500 mg QD (n = 36) in dose expansion. Blood (n = 60) and fresh tumor biopsy samples (n = 14) were collected to assess AG-120 and 2-HG using qualified liquid chromatography-tandem mass spectrometry methods. **Results:** Following both single and multiple doses, AG-120 plasma exposure increased less than dose proportionally from 100 to 1200 mg. Mean terminal half-life was 38.4–85.8 h, supporting a QD dosing regimen. Following multiple doses, steady state was reached within 15 days, with approximately 2-fold accumulation in plasma AG-120 exposure. No patient-specific factors were identified as clinically significant covariates affecting AG-120 plasma clearance. After multiple doses, plasma 2-HG levels were reduced (up to 98.4% inhibition, achieving levels similar to those in healthy volunteers) and tumor biopsy 2-HG levels were also substantially reduced (by up to 99.9%) at all dose levels tested. The 500 mg QD dose resulted in the largest magnitude of 2-HG inhibition vs. other dose levels. **Conclusions:** AG-120 demonstrated a long half-life in patients with mIDH1 CC and robustly inhibited 2-HG in plasma and tumor samples. These PK/PD data, along with emerging safety and clinical activity data, support the selection of 500 mg QD for future clinical investigation. Clinical trial information: NCT02073994.

4083 Poster Session (Board #75), Sat, 8:00 AM-11:30 AM

A phase II study of sorafenib and yttrium-90 glass microspheres for advanced hepatocellular carcinoma, BCLC stage C. *First Author: Ahmed Omar Kaseb, GI Medical Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Combined use of sorafenib and local therapy for treating unresectable hepatocellular carcinoma (HCC) is not well established. Notably, most common cause of death in HCC is liver failure, therefore we tested the promise of controlling the local tumors even in the setting of advanced/metastatic disease to improve survival. Our study aimed to assess the efficacy and safety of combined use of sorafenib and yttrium-90 resin microspheres (Y90 RMS) in unresectable HCC defined as Barcelona Clinic Liver Cancer class C. **Methods:** Between October 2013 and August 2016 we enrolled 40 advanced stage HCC patients, 38 patients were treated with sorafenib followed (after 4 weeks) with Y90 RMS at MD Anderson Cancer Center. Survival analysis was done to evaluate median overall survival (OS) and progression-free survival (PFS). We used modified Response Evaluation Criteria in Solid Tumors (RECIST) to assess response to treatment and the Common Terminology Criteria for Adverse Events (CTCAE) v4.0 to evaluate the grading of treatment related toxicity. **Results:** The majority of our patients were males (74%), white (47%), 66% of patients had underlying liver cirrhosis, 26% had vascular invasion, and 26% had extrahepatic disease. The estimated median OS and 95% confidence interval (CI) in months was 18.46 (12.29 – NA) and the estimated PFS was 12.29 months (5.72 – 18.79). Stable disease (SD) was observed in 44.74% of patients, while 28.95% achieved partial response (PR). Grade III-IV adverse events included fatigue (n = 3), hyperbilirubinemia (n = 2), thrombocytopenia (n = 1), proteinuria (n = 1), hyponatremia (n = 1), elevated liver enzymes (n = 4), hypertension (n = 4), diarrhea (n = 1), nausea (n = 1) and vomiting (n = 2). **Conclusions:** This is the first prospective study to evaluate sorafenib followed by Y90 in HCC. Our study included patients with metastatic HCC and showed that combined use of sorafenib and Y90 was tolerable and was associated with longer OS and PFS compared to previous studies which evaluated sorafenib alone. However, future randomized phase III studies are warranted to assess sorafenib+/-Y90 in metastatc disease setting. Clinical trial information: NCT01900002.

4084 Poster Session (Board #76), Sat, 8:00 AM-11:30 AM

Effect of sorafenib (S) starting dose and dose intensity on survival in patients with hepatocellular carcinoma (HCC): Results from a Canadian multicenter HCC database. *First Author: Mohammed Abdullah Alghamdi, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: The SHARP trial showed that S improves survival in advanced HCC. Full dose (FD) S at 400mg bid can be difficult to tolerate, so some clinicians begin with a reduced dose (RD) & escalate as tolerated to maximum dose. The purpose of this study was to determine whether starting dose or dose intensity of S affects survival. **Methods:** All patients treated with S for HCC from 01/2008 to 06/2016 in British Columbia, Alberta, Ontario (Princess Margaret Cancer Centre & Sunnybrook Odette Cancer Centre), were included. Patient demographics, clinical, tumor characteristics, S starting dose & mean dose intensity were collected & analyzed. Patients were dichotomized into starting FD or RD of S. Mean dose intensity was categorized into $>$ 75%, 50-75% & $<$ 50%. Survival outcomes were assessed with Kaplan-Meier curves & compared with the log-rank test. A Cox-proportional hazard model was constructed with starting dose, dose intensity & relevant clinical & pathologic factors to assess their impact on survival. **Results:** We included 681 patients. Median age 64 years, 80% men, 37% East Asian, & most frequent causes of liver disease were hepatitis B (33%) & C (29%). ECOG performance status prior to starting S was 0 in 30% & 1 in 60%. Most patients were Childs-Pugh A (86%) at start of S. Overall median survival was 9.1 months (m). S was started at FD in 42% of patients & 31% had a dose intensity $>$ 75%. The median survival for starting FD & RD was 9.4 m & 8.9 m, respectively (p = 0.15). The median survival for a dose intensity $>$ 75% was 9.5 m, 50-75% was 12.9 m & $<$ 50% was 7.1 m (p = 0.005). In multivariate models that adjusted for demographic, stage, performance status, AFP, prior treatment, toxicity & liver function, starting dose (HR 1.1, 95%CI 0.86-1.3, p = 0.51) & dose intensity (50-75% HR 0.93, 95% CI 0.73-1.2; $<$ 50% HR 0.89, 95% CI 0.69-1.1, p = 0.65) were not predictors of survival. **Conclusions:** Based on our multi-center database, starting HCC patients on a RD of S may be a reasonable since it does not appear to compromise survival. Patients receiving a dose intensity of S at 50-75% appear to have a superior median survival, though this is not significant after controlling for baseline characteristics.

4085 Poster Session (Board #77), Sat, 8:00 AM-11:30 AM

A prospective analysis of germline alterations (GA) in biliary tract cancer (BTC). *First Author: Maeve Aine Lowery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The incidence of hereditary cancer predisposition syndromes in patients (pts) with BTC is unknown. Cholangiocarcinoma has been reported in pts with germline mutations in BAP1, BRCA1/2, and mismatch repair genes. These associations are poorly characterized to date and the majority of pts do not undergo clinical germline analysis (CGA). **Methods:** Pts with BTC were offered consent to CGA between 01/2016 and 01/2017 under an IRB approved protocol (NCT01775072). Using the MSK-IMPACT platform, 76 genes associated with hereditary cancer predisposition were analyzed for germline variants and matched tumor samples were analysed for somatic alterations in > 340 genes. Demographic and clinical data were collected. **Results:** 78 patients were accrued: Intrahepatic = 52, extrahepatic = 13, gallbladder = 13. Median age at diagnosis was 57 years (range 21-80), 45 (58%) had a positive family history of cancer in at least one 1st degree or two 2nd degree relatives. 7 patients had a personal history of cancer. A pathogenic or likely pathogenic GA was identified in 16 pts (20%). (See table). **Conclusions:** Prospective analysis of GAs in pts with BTC, unselected by family history or age, revealed potentially actionable findings in 20% of pts. CGA in pts with BTC may benefit patients and their families in view of screening and therapeutic implications.

4086 Poster Session (Board #78), Sat, 8:00 AM-11:30 AM

Tumor mutational burden (TMB) and co-existing actionable mutations in biliary tract cancers (BTC). *First Author: Apurva Jain, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutations in DNA repair pathway were identified in 13% of Biliary Tract Cancers (BTC) [*Cancer*2016;122:3838–3847]. High TMB tumors including melanoma, lung cancer and those with microsatellite instability (MSI-H) are associated with susceptibility to immune blockade using checkpoint inhibitors. TMB data in BTC is limited and its association with actionable somatic mutation (mut) profiles in BTC is unknown. **Methods:** Comprehensive genomic profiling (CGP) of 309 FFPE tissue blocks of BTC pts with a hybrid capture of all coding exons of 236 cancer-related genes and 47 introns of 19 genes rearranged in cancer was done using FoundationOne. Base substitutions, indels, gene fusion/rearrangements, TMB, and MSI status were assessed. TMB was calculated by counting mutations across a 1.25Mb region and classified into high (TMBH; ≥20 mut/Mb), intermediate (TMBI; 6 - 19mut/Mb) and low (TMBL; < 6mut/Mb). MSI high (MSIH) and Stable (MSS) status was assigned by a computational algorithm examining 114 intronic homopolymer loci. Patients with TMB ≥6 mut/Mb (N = 60) were included in the clinical correlative portion of this study. **Results:** Sixty patients with TMB ≥6 mut were identified out of 309 pts of which 9 (15%) were TMBH and 51 (85%) were TMBI. These included 3 (5%) MSIH and 18 (30 %) MSS. The median age was 59 years (range: 29-86), 35 (58%) were females, majority were intrahepatic cholangiocarcinoma (n = 31; 52%) and 28 (47%) presented with advanced disease at diagnosis. Twenty three (38%) pts had received radiation therapy, 28 (47%) surgery and 3 (5%) received immunotherapy. Most frequent co-existing mut seen was *TP53* (N = 35; 58%). *APC* mut was seen in 7 (12%) pts. DNA repair pathway muts (*MSH6, BRCA1, BRCA2, ATM, MLH1*, or *MSH2* genes) were identified in 78% of TMBH versus 16% in TMBI cases ($p < 0.0001$). Frequency of *PIK3CA* mut differed significantly between TMBH and TMBI (44% vs 10%, $p < 0.0001$). Pts with TMBI had a significantly better median OS (110 weeks) as compared to TMBH (43 weeks) (p = 0.003). **Conclusions:** DNA repair pathway and *PIK3CA* mut maybe associated with TMBH in BTC. A better understanding of TMB and associated actionable mutations in BTC may be of value for the management of BTC patients with targeted agents and immunotherapy.

4087 Poster Session (Board #79), Sat, 8:00 AM-11:30 AM

Phase Ib trial of tepotinib in Asian patients with advanced hepatocellular carcinoma (HCC): Final data including long-term outcomes. *First Author: Shukui Qin, Nanjing Bayi Hospital, Nanjing, China*

Background: The incidence of hepatocellular carcinoma (HCC), a leading cause of cancer death, is increasing with the increasing incidence of chronic liver disease. Sorafenib, the only approved systemic therapy for advanced HCC, provides modest improvement in overall survival. Preclinical studies suggest c-Met is a valid target in HCC, but non-selective TKIs with c-Met inhibitory activity have not shown efficacy in trials, possibly due to lack of c-Met inhibition. Tepotinib (MSC2156119J) is a highly selective c-Met inhibitor that has favorable safety and promising activity, particularly against c-Met+ solid tumors. We report the final results of a phase Ib trial of tepotinib in patients (pts) with advanced HCC. **Methods:** Pts were Asian adults with confirmed HCC of BCLC Stage C, Child-Pugh Class A liver function without encephalopathy, and ECOG PS 0–2. Pts received tepotinib 300, 500 (the RP2D) or 1,000 mg/day on a 21-day cycle. c-Met expression status was retrospectively determined by IHC. **Results:** 27 pts were enrolled (median age 57 [38-69]; male 23; ECOG PS 0/1 11/16); 7 received tepotinib 300 mg/day, 14 500 mg/day, and 6 1,000 mg/day (3 with dose reduction). No DLTs were observed. 22 pts experienced treatment-related treatment-emergent adverse events (TRTEAEs), most commonly diarrhea (n = 10), nausea (8), elevated AST (7), and elevated ALT (6). 9 pts had grade ≥3 TRTEAEs, including elevated AST (3) and elevated ALT (3). Best overall response (BOR) was partial response (PR) in 2 pts, one of whom received tepotinib 500 mg (response duration 16.1 months) and one 1,000 mg (4.4 months); both had c-Met+ tumors. A further 8 pts had a BOR of stable disease (SD), 1 pt non-complete response (CR)/non-progressive disease (PD), and 14 pts had PD (2 pts not evaluable). Five pts had progression free survival > 8 months. PK were as expected from previous studies. **Conclusions:** Tepotinib at doses of up to 1,000 mg/day was well tolerated by Asian pts with advanced HCC and a maximum tolerated dose was not reached. Antitumor activity was observed, particularly in pts with c-Met+ tumors. The ongoing phase II part of this study is comparing the efficacy and safety of first-line tepotinib and sorafenib in pts with c-Met+ HCC. Clinical trial information: NCT01988493.

4088 Poster Session (Board #80), Sat, 8:00 AM-11:30 AM

Lanreotide depot (LAN) for symptomatic control of carcinoid syndrome (CS) in neuroendocrine tumor (NET) patients previously responsive to octreotide (OCT): Subanalysis of patient-reported symptoms from the phase III elect study. *First Author: George A. Fisher, Stanford University, Stanford, CA*

Background: In ELECT, LAN significantly reduced the need for short-acting OCT rescue therapy for symptomatic control of CS in NET patients (pts) vs placebo (PBO) (primary result). Here we present flushing and diarrhea symptom data and biochemical response for pts with or without prior OCT use from ELECT. **Methods:** Adults with histopathologically-confirmed NET and history of stable CS (diarrhea and/or flushing) who were OCT-naive or responsive to OCT long-acting release (LAR) (≤30 mg q4W) or short-acting OCT (≤600 μg daily) were randomized to LAN 120 mg (SC q4W) or PBO for 16 wks. Pts administered SC OCT if needed and recorded daily frequency and severity of symptoms using Interactive Voice/Web Response System for 1 month pre-randomization and throughout the study. 24-hr urinary 5-hydroxindoleacetic acid (5HIAA) and plasma chromogranin A (CgA) were assessed at baseline and wk 12. **Results:** Of 115 pts randomized, 51 were OCT-naive and 64 received prior OCT. The least squares (LS) mean percentages of days with moderate/severe diarrhea and/or flushing were lower in both naive and prior OCT LAN pts vs naive and prior OCT PBO pts; LS mean difference (LAN-PBO) was significant in the naive group (Table). By week 12, 5HIAA and CgA levels dropped by ≥30% to normal in 35.3% and 15.8% of naive LAN pts and 28.6% and 4.5% of prior OCT LAN pts; 5HIAA and CgA reductions were seen in 15.4% and 21.4% of naive PBO pts and 5HIAA in 7.1% of prior OCT PBO pts. **Conclusions:** Pts showed improvement in CS symptoms of flushing and diarrhea and reduction in 5HIAA levels with LAN treatment, indicating efficacy of LAN regardless of prior OCT use. Transition from OCT to LAN was well tolerated among prior OCT pts in ELECT. Clinical trial information: NCT00774930.

Percentage of days with moderate/severe diarrhea and/or flushing (ANCOVA, ITT population).

	OCT-Naive			Prior OCT		
	LAN n = 26	PBO n = 25	LAN-PBO	LAN n = 33	PBO n = 31	LAN-PBO

4089 Poster Session (Board #81), Sat, 8:00 AM-11:30 AM

Final progression-free survival (PFS) analyses for lanreotide autogel/depot 120 mg in metastatic enteropancreatic neuroendocrine tumors (NETs): The CLARINET extension study. *First Author: Edward M. Wolin, Montefiore Einstein Cancer Center, Bronx, NY*

Background: In the CLARINET core study, lanreotide Autogel (LAN) 120 mg deep sc monthly significantly improved PFS vs PBO in metastatic grade-1/2 enteropancreatic NETs. An interim analysis of patients with stable disease (SD) in the core study continuing LAN in the open-label extension (OLE, of which safety was primary objective) showed continued antitumor effects. Here, we report final LAN PFS analyses for subgroups according to tumor origin and prior therapy. **Methods:** In the core study, patients with metastatic well/moderately differentiated non-functioning (N-F) enteropancreatic NETs, Ki-67 <10%, no prior somatostatin-analog treatment and no other prior medical therapies in the previous 6 months were randomized to LAN 120 mg (n=101) or PBO (n=103) for 96 weeks or until death/progressive disease (PD; RECIST 1.0). Patients with SD receiving LAN and any patient receiving PBO could enter a single-arm (LAN) OLE (NCT00842348). Main efficacy endpoint: PFS (time from core-study randomization to death/PD) for core-study intent-to-treat population from Kaplan–Meier survival analysis. Here, PFS was analyzed in subgroups of LAN–LAN patients. **Results:** OLE final population comprised 89 patients (LAN–LAN 42 [41 with SD]; PBO–LAN 47 [15 with SD]); 38% had pancreatic and 38% midgut NETs. During the OLE, 40% continuing LAN vs 47% switched to LAN had treatment-related adverse events. No new safety concerns were identified. Overall LAN median PFS from the LAN–LAN group was 38.5 months, and varied with tumor origin and prior therapy (Table). **Conclusions:** CLARINET OLE suggests sustained antitumor effects with LAN 120 mg in enteropancreatic NETs irrespective of tumor origin, and suggests benefits with LAN as early treatment. Clinical trial information: NCT00842348.

LAN PFS for patients with SD: overall and in pre-specified subgroups.

	Median PFS [95% CI](no. patients), months*
Overall	38.5 [30.9; 59.4] (101)
Tumor origin	
Midgut	61.5 [30.9; NC] (33)
Pancreas	29.7 [12.0; 38.5] (42)
Hindgut	55.0 [2.9; NC] (11)
Other/unknown	59.4 [32.8; 74.8] (15)
Previous therapy for N-F NET	
Yes	29.7 [6.0; 31.3] (16)
No	50.8 [32.4; 74.8] (85)

*Approximated (4 weeks/month). NC, not calculable

4090 Poster Session (Board #82), Sat, 8:00 AM-11:30 AM

Predictors of outcome in patients treated with peptide radio-labelled receptor target therapy (PRRT). *First Author: Dalvinder Mandair, Royal Free Hospital Neuroendocrine Tumour Unit, London, United Kingdom*

Background: The efficacy of peptide-radiolabelled receptor targeted therapy (PRRT) in patients with well differentiated neuroendocrine tumours has been demonstrated in Phase II and Phase III studies. The recently completed phase IV NETTER-01 demonstrated disease stabilisation or partial response in approximately 80% of patients. However, more studies are needed to identify predictors of PRRT response. We sought to investigate the clinicopathological characteristics in patients that had radiological progression or death within 12 months of completion of treatment with PRRT. **Methods:** We performed a retrospective analysis of all patients who had PRRT from 2011-2016. Patient with at least one year of follow-up data from the last treatment dose were included. Patients with evidence of radiological progression within one year of finishing treatment (Group 1) were compared to a similar group with disease stabilisation/response (Group 2)that were matched for age, grade, primary and distribution of metastases. The indication for PRRT was defined as either small volume progression (< 20%) or progression by RECIST. **Results:** 307 patients underwent PRRT with Lu-177 or Y-90 DOTATATE during this period. 66 patients in Group 1 were compared to 64 patients in Group 2. There was a significant difference in median overall survival, Group 1 = 21 months compared to Group 2 = 35 months, ($p < 0.002$). A significantly higher proportion of patients in group 1 had more than 50% liver volume ($p < 0.0001$). Mean CgA was significantly higher in Group 1, 1250 pg/ml vs 608 pg/ml in Group 2 ($p < 0.03$). 18 patients in Group 2 had small volume progression prior to treatment commencement compared to 6 in Group 1 ($p < 0.003$). **Conclusions:** Radiological progression within 12 months of completion of PRRT is associated with a worse outcome in terms of OS. Patients with greater liver involvement and highest CgA levels are more likely to progress within 12 months of treatment completion. Earlier treatment with PRRT in patients with radiological progression not meeting RECIST criteria may need to be conisdered. There may be a greater survival benefit if PRRT is given prior to the development of large volume disease.

4091 Poster Session (Board #83), Sat, 8:00 AM-11:30 AM

Blood measurements of neuroendocrine tumor (NET) transcripts and gene cluster analysis to predict efficacy of peptide radioreceptor therapy. *First Author: Lisa Bodei, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Peptide receptor radionuclide therapy (PRRT) capitalizes on somatostatin receptor (SSR) overexpression on NETs to deliver targeted isotope therapy. Objective prediction of efficacy remains to be established. Functional imaging of SSR expression (SRE) is used as a predictor of efficacy. Biomarkers e.g. circulating CgA, are ineffective. Circulating NET transcript analysis (NETest) integrated with tumor grade provides a *Predictive Quotient Index* (PQI) of PRRT. We validated the utility of this PRRT complementary diagnostic in a prospective, blinded study. **Methods:** ^{177}Lu-PRRT (29.1±2.2 GBq). NETs (n= 35); with progressive disease (66%). Baseline evaluations: Clinical status, Grade (Ki67), SRE, CgA (NeoLisa, ULN > 108ng/ml), and NETest (qRT-PCR - multianalyte algorithmic analyses, ULN > 14%). PQI: "omic" NETest gene expression (regulating metabolism and growth factor signaling) mathematically combined with Ki67 index. PQI has two prediction outputs: "responder" (R) vs "non-responder" (NR). Disease control was by RECIST criteria (R vs NR). All samples were blinded. Statistics: Cox proportional multiple regression, Kaplan-Meier survival, & McNemar-test. **Results:** At restaging, the overall response (disease control rate) was 77%; median PFS not reached (follow-up 4-13 months). Histology: GI: 5; GII: 21; GIII 1; and lung: TC: 2; AC: 5. SRE was Grade 3 (80%). Baseline CgA was 1556±1454ng/ml (89% elevated) and NETest was 60±21% (100% elevated) respectively. Predictive accuracies of SRE, clinical status, CgA levels (> 2ULN) and NETest ranged from 25-54% (not-significant). PQI was the only predictive marker by multivariate analysis (p= 0.002). The PQI diagnostic was 92% concordant with outcome and significantly more accurate than all other markers (McNemar: p< 0.002). Cox-proportional modeling confirmed PQI utility (OR: 9.1, p< 0.004). K-MS analysis identified significantly different mPFS between R (not reached) and NR (9.3 months; HR: 8.3, p< 0.0005). **Conclusions:** A pre-PRRT analysis of circulating NET genes, the predictive quotient index comprising "omic" analysis and grading, is validated to predict the efficacy of PRRT therapy in GEP and lung NETs.

4092 Poster Session (Board #84), Sat, 8:00 AM-11:30 AM

Pre-existing symptoms, resource utilization, and healthcare costs prior to diagnosis of neuroendocrine tumors: A SEER-Medicare database study. *First Author: Chan Shen, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The incidence and prevalence of neuroendocrine tumors (NETs) are continually increasing. While it is known that NET symptoms often predate diagnosis, the prevalence of these symptoms and the impacts on resource utilization and costs are largely unknown. **Methods:** We identified 12,052 elderly patients diagnosed with NET between 1/2003 and 12/2011 by ICD-0-3 codes from the Surveillance, Epidemiology and End Results (SEER)-Medicare database with continuous Medicare Parts A and B enrollment during the one year before NET diagnosis. We used propensity score matching to identify a group of comparable elderly patients from a non-cancer Medicare cohort. We captured patients' potentially relevant conditions (defined as > 1 indicative claim), resource utilization and costs from patients' medical claims during the year before diagnosis. We examined a) resource utilization in terms of number of outpatient visits, percentage of patients having any emergency room (ER) visits and hospitalizations, and b) health care costs including inpatient, outpatient and total costs. We used chi-square test for categorical variables and Mann-Whitney U test for continuous variables. **Results:** NET patients were more likely to have diagnoses of diarrhea (8% vs. 2%), abdominal pain (37% vs. 8%), irritable bowel syndrome (1.5% vs. 0.6%), hypertension (72% vs. 55%), heart failure (16% vs. 8%), and peripheral edema (7% vs. 4%) compared to the non-cancer control group. They also had much higher resource utilization including number of outpatient visits (mean: 27.25 vs. 18.45); and percentage with ER visits (64% vs. 36%), and hospitalizations (66% vs. 34%). Similarly, NET patients incurred significantly higher total (mean: $32924 vs. $10048), outpatient (mean: $8869 vs. 4580), and inpatient costs (mean: $24055 vs. $10048). All $p < 0.001$. **Conclusions:** To the best of our knowledge, this is the first population-based study to examine potentially relevant pre-existing symptoms, resource utilization and healthcare costs before NET diagnosis. NET patients were more likely to have certain conditions and incurred higher resource utilizations and costs in the year preceding diagnosis of NET.

4093 Poster Session (Board #85), Sat, 8:00 AM-11:30 AM

68Ga-DOTATATE PET/CT to predict response to peptide receptor radionuclide therapy (PRRT) in neuroendocrine tumours (NETs). *First Author: Rohini Sharma, Imperial College London, London, United Kingdom*

Background: PRRT represents a step change in NET management, significantly improving survival. However, objective response to PRRT, approximately 20%, is poor. There are no predictive biomarkers of response. Uptake on ^{68}Ga-DOTATATE PET/CT imaging is used to assess patient suitability for PRRT, highlighting the presence of somatostatin receptors (SSTR) to which PRRT selectively binds. We hypothesise that the density of SSTRs, as defined by a minimum SUV uptake, predicts for response to PRRT. **Methods:** 54 patients underwent PRRT. Modified PERCIST assessment was performed: up to 2 target lesions per organ were identified and volume of interest drawn. Maximum 5 targets were counted. Average SUV (SUVave) was calculated by dividing sum of SUVmax of target lesions by number of lesions. Response was determined by RECIST 1.1. Ki67 and SSTR2 expression were assessed on tumour samples and compared with SUVave. **Results:** Response to PRRT: partial response (PR) 26%, stable disease (SD) 40% progressive disease (PD) 12%. Response to PRRT predicted progression free survival (PFS) with patients experiencing PR having a PFS 2.5x that of those with SD, and almost 20x as long as PD. Using ROC curve analysis, SUVave of 21.6 predicted for tumour response with high sensitivity (0.74) and specificity (1.0), p = 0.15, 95% CI 0.71-3.96. No association between baseline SUVave and SSTR2 or Ki-67 was observed. SUVave $>$ 21.6 was an independent predictor of clinical outcome. **Conclusions:** Objective response to PRRT defines a subset of patients with markedly improved PFS. SUVave 21.6 defines a threshold below which patients have a poor response to PRRT. This threshold should be taken forward into prospective study.

4094 Poster Session (Board #86), Sat, 8:00 AM-11:30 AM

Theranostic trial of well differentiated neuroendocrine tumors (NETs) with somatostatin antagonists ^{68}Ga-OPS202 and ^{177}Lu-OPS201. *First Author: Diane Lauren Reidy, Weill Cornell Medical College, New York, NY*

Background: Radiolabeled somatostatin receptor 2 (sstr2) antagonists have shown higher tumor uptake and tumor-to-organ ratios than agonists in preclinical models. We performed a phase I study to evaluate the safety and radiation dosimetry of the sstr2 antagonists ^{68}Ga-OPS202 and ^{177}Lu-OPS201 (^{68}Ga/^{177}Lu-DOTA-JR11) in patients (pts) with metastatic well differentiated NETs (NCT02609737). Efficacy data after ^{177}Lu-OPS201were recorded. **Methods:** Pts with RECIST disease progression underwent a ^{68}Ga-OPS202 PET/CT to confirm in-vivo binding of the sstr2 antagonists and if positive, underwent treatment with 3 doses of ^{177}Lu-OPS201. The first dose of 50 mCi ^{177}Lu-OPS201was used to calculate tumor and normal organ radiation doses. Dosimetry was then calculated to administer ^{177}Lu-OPS201in divided doses for the 2nd and 3rdfractions, 8-10 weeks apart. **Results:** 19 pts enrolled (primary tumors: 1 lung, 7 small bowel, 8 pancreatic NETs, 1 gastric NET, 1 rectal NET, 1 kidney). Average age was 55 y (22-73 y), 52% female; mean number of prior treatments was 3. All pts received 1 therapeutic dose of ^{177}Lu-OPS201, 7 pts received 2 doses. All tumors were visualized by ^{68}Ga-OPS202 PET/CT. With the exception of the kidneys and bladder, no organ demonstrated uptake of ^{68}Ga-OPS202 above background. Tumor radiation doses ranged from 0.15 Gy/mCi to 0.48 Gy/mCi. Subacute hematologic toxicity after cycle 1 was mild-moderate (G3 2/19 leukopenia that reversed before cycle 2). 4/7 (57%) pts that received the second dose of ^{177}Lu-OPS201had G4 hematological toxicities, which occurred 4-6 weeks after administration. G 3/4 toxicities in the four pts have resolved to G2 or lower; none of these pts demonstrated fever, infection, bleeding, or renal toxicity. Substantial efficacy was observed: 1 patient achieved a CR (1/19, 5%), 32% PR (6/19), 47% SD (9/19) and 16% POD (3/19). Median PFS has not yet been reached. **Conclusions:** In this trial of heavily treated NETs, preliminary data are promising for the use of ^{68}Ga-OPS202/^{177}Lu-OPS201 as a theranostic combination for imaging and therapy. Additional studies are planned to determine an optimal therapeutic dose and schedule. Clinical trial information: NCT02609737.

4095 Poster Session (Board #87), Sat, 8:00 AM-11:30 AM

Effect of lanreotide depot (LAN) on 5-hydroxyindoleacetic acid (5HIAA) and chromogranin A (CgA) in gastroenteropancreatic neuroendocrine (GEP NET) tumors: Correlation with tumor response and progression-free survival (PFS) from the phase III CLARINET study. *First Author: Alexandria T. Phan, University of New Mexico Comprehensive Cancer Center, Albuquerque, NM*

Background: 5HIAA or CgA are biomarkers in some GEP NETs. We present posthoc analyses using prospectively collected urinary 5HIAA and serum CgA data from CLARINET. **Methods:** Adults with moderately or well differentiated, nonfunctioning (no symptoms of carcinoid syndrome), locally advanced or metastatic GEP NETs were randomized to LAN 120mg or placebo (PBO) every 4 weeks (wks) for 96 wks. Tumor response evaluated centrally (RECIST 1.0) and PFS were assessed by treatment. Biochemical response was defined as baseline $>$ upper limit of normal (ULN, 41.6μmol/d 5HIAA; 98.1μg/L CgA) and $\geq$50% decrease from baseline to $\leq$ULN value on study. CgA analyses excluded gastrinoma patients (pts). **Results:** 48% (82/171) (45LAN; 37PBO) and 66% (129/195) (65LAN, 64PBO) of pts had $>$ ULN baseline 5HIAA and CgA. In those pts with no radiologic progression, significantly greater reductions in 5HIAA (Table) and CgA were observed in LAN vs PBO pts at all assessments (all $P<$ 0.05). PFS was significantly prolonged in LAN 5HIAA responders vs nonresponders (median not reached vs 22.1 months, P= 0.0076) but was not significantly different in PBO 5HIAA responders vs nonresponders. There were no significant differences in PFS by CgA response (responders vs nonresponders) in either LAN or PBO pts. **Conclusions:** These data suggest that serotonin is secreted by nonfunctioning tumors, but does not reach the threshold required for clinical carcinoid symptoms. Monitoring 5HIAA and CgA may be useful during LAN treatment of nonfunctional GEP NETs. Clinical trial information: NCT00353496.

Median (IQR) 5HIAA levels and changes from baseline.

	No Tumor Progression (RECIST)	
	LAN	PBO
Baseline, n	35	17
Median (IQR)	86.3 (58.8, 217.4)	95.7 (64.0, 330.7)

4096 Poster Session (Board #88), Sat, 8:00 AM-11:30 AM

Use of antiresorptive therapy (ART) and skeletal-related events (SREs) in patients with bone metastases of neuroendocrine neoplasms (NEN). *First Author: Leonidas Apostolidis, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany*

Background: Antiresorptive therapy (ART) with bisphosphonates or denosumab is effective in preventing skeletal-related events (SREs) in patients with bone metastases (BM). In neuroendocrine neoplasms (NEN), BM are a negative prognostic factor, however tend to be asymptomatic and SREs are considered a rare event. The role of ART in preventing SREs in NEN has not been investigated so far. **Methods:** Retrospective analysis of all patients with bone metastases in the NEN database of the National Center for Tumor Diseases who presented at our center between 12/2012 and 01/2017. Overall survival (OS) from diagnosis of BM as well as time to SRE (TTSRE) were calculated. In patients experiencing an SRE within 1 month after diagnosis (i.e. before efficacy of ART could be assessed), TTSRE was defined as the time to a subsequent SRE. **Results:** In a total of 513 patients in the database, 108 patients with BM could be identified. Median OS was not reached in a median follow-up of 15.2 months. ART was applied to 42.6 % of patients. OS with or without ART did not differ significantly (p = 0.2538). 28.7 % of patients experienced at least 1 SRE, 20.4 % after more than 1 month. Median TTSRE was 63.8 months with ART and 127.0 months without ART (p = 0.1751). TTSRE was shortened in grade 3 vs. grade 1+2 NEN (172 months vs. not reached, HR 4.058, p = 0.0032), as well as in lytic vs. non-lytic metastases (24.5 vs. not reached, HR 7.319, p $<$ 0.0001), however not significantly different in oligometastatic vs. disseminated bone disease (not reached vs. 63,8 months, HR 1.415, p = 0.4287). Application of ART did not significantly change TTSRE in either of these subgroups. Significant toxicity attributable to ART was observed in 15.2 % of ART patients. **Conclusions:** SREs in NEN patients with BM were not uncommon, especially in patients with grade 3 NEN and osteolytic metastases. Application of ART did not significantly alter median OS or TTSRE, no subgroup with a benefit of ART could be identified. The use of ART in NEN should be questioned and evaluated prospectively.

4097 Poster Session (Board #89), Sat, 8:00 AM-11:30 AM

A phase 2 study of galunisertib (TGF-B R1 inhibitor) and sorafenib in patients with advanced hepatocellular carcinoma (HCC). *First Author: Robin Kate Kelley, University of California, San Francisco, San Francisco, CA*

Background: TGFβ signaling is associated with HCC progression. Inhibition of TGFβ R1 potentiates activity of sorafenib in in-vitro and in-vivo models. Here we report the clinical activity of galunisertib (G) plus sorafenib (S) in pts with incurable HCC and no prior systemic therapy. **Methods:** Eligibility criteria included incurable HCC with measurable disease per RECIST 1.1, no prior systemic therapy, Child Pugh A, ECOG PS ≤1.G was administered as 80 mg PO BID (lead-in Cohort 1) or 150 mg PO BID (lead-in Cohort 2 and expansion cohort), as intermittent dosing of 14 days on/off (28 days = 1 cycle). S was administered continuously as a 400 mg PO BID. Primary objective was to characterize time-to-progression (TTP) and biomarker changes in pts. Secondary objectives included evaluation of OS, PK, and toxicity (CTCAE v 4.0). **Results:** 47 pts were enrolled (Cohort 1 = 3, Cohort 2 and expansion cohort = 44). In the 150 mg BID cohort: Male = 88.6%; median age = 64 years; PS = 0/1, 81.8%/18.2%; etiology: hepatitis C = 34.1%, hepatitis B = 18.2%, alcohol = 20.5%, multiple = 13.6%; AFP≥200 μg/L = 50%; portal vein invasion = 34.1%. Incidence of AEs was similar between G dose levels. Overall in the 150mg BID cohort, treatment related AEs (> 15%) were hand and foot syndrome (61.4%), diarrhea (40.9%), pruritus (22.7%), anemia and weight loss (20.5%), fatigue (29.5%), alopecia (18.2%), myalgia (22.7%), decrease in platelet count and nausea (15.9%). Two pts on 150 mg BID discontinued treatment due to study drug related AEs (anemia and weight loss). PK of G at 150 mg BID (n = 12) when co-administered with S, was similar to that observed in the G monotherapy study. G was rapidly absorbed and had an elimination half-life of approximately 8h. Median TTP (RECIST) was 4.1 (2.8, 5.5) months. OS, with a high censor rate of 55% was not mature at the time of this data cutoff. Median OS was 17.9 (14.8, NE) months. **Conclusions:** The combination of G plus S demonstrated acceptable safety and a meaningful OS of 17.9 months in an advanced HCC population. TTP was similar to S monotherapy in contemporary clinical trials though interpretation is limited by single arm design. Clinical trial information: NCT01246986.

4098 Poster Session (Board #90), Sat, 8:00 AM-11:30 AM

Long-term outcomes with cytoreductive surgery and hyperthermic intraperitoneal chemotherapy in peritoneal carcinomatosis from appendiceal cancer: An 18-year experience. *First Author: Carlos A. Munoz-Zuluaga, Mercy Medical Center, Baltimore, MD*

Background: Cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS/HIPEC) have become standard of care for patients with peritoneal carcinomatosis (PC) from appendiceal cancer (AC). We reviewed our experience and outcomes. **Methods:** A retrospective review of 614 CRS/HIPEC procedures from 1998-2016 was performed. Patient characteristics, surgical variables, and postoperative outcomes of first CRS/HIPEC were analyzed. **Results:** Two hundred ninety patients with PC from AC underwent 334 CRS/HIPEC's. Median age at diagnosis and surgery was 52 (22-79) and 53 (23-81) years, respectively; 65% (187) were female. Prior surgical score was 0, 1, 2, and 3 in 20%, 38%, 37%, and 5%, respectively. Prior systemic chemotherapy was reported in 30% of patients. Median time from diagnosis to CRS/HIPEC was 4 months (0-182). Pre-operative tumor markers (CEA, CA-125, CA-19-9) were positive in 48% with one, two, and three positive markers in 21%, 15%, and 13% patients, respectively. Median Peritoneal Cancer Index was 29. Mitomycin-C was the HIPEC agent of choice. Mean operative time was 10 hours (R: 4-19) and median length of stay was 10 days (R: 4-93). Histology included 59% (171) peritoneal mucinous carcinomatosis (PMCA), 41% (119) disseminated peritoneal adenomucinosis (DPAM). Lymph nodes were positive in 47% PMCA. Complete cytoreduction rate was 87% (84% PMCA, 92% DPAM [p = 0.048]). Grade III-V complications occurred in 21%, with one 30-day mortality (0.3%). Overall, median progression-free survival (PFS) was 84 months with 5-year PFS of 56%. Median PFS was 43 months in PMCA and not reached in DPAM. Five year PFS was 40% PMCA and 82% DPAM (p < 0.001). Median overall survival (MOS) was 139 months with 61% 5-year OS. MOS was 53 months in PMCA and not reached in DPAM. Five year OS was 47% PMCA and 85% DPAM (p < 0.001). At 42-month median follow-up, 68% were alive (92 PMCA/103 DPAM) with 84% disease free (72 PMCA/92 DPAM), 28% died of disease (73 PMCA/7 DPAM). **Conclusions:** CRS/HIPEC is an effective treatment for patients with PC from AC providing meaningful long term survival in low and high grade tumors and should be considered the standard of care.

4099 Poster Session (Board #91), Sat, 8:00 AM-11:30 AM

TAS-118 (S-1 plus leucovorin) versus S-1 in gemcitabine-refractory advanced pancreatic cancer: A randomized, open-label, phase III trial (GRAPE trial). *First Author: Makoto Ueno, Division of Hepatobiliary and Pancreatic Medical Oncology, Kanagawa Cancer Center, Yokohama, Japan*

Background: Addition of oral leucovorin (LV) to S-1 significantly improved progression-free survival (PFS) in a previous randomized phase II trial in Japanese patients (pts) with gemcitabine (GEM)-refractory advanced pancreatic cancer (PC). TAS-118 is an oral drug containing S-1 and LV. This phase III trial conducted in Japan and Korea compared overall survival (OS) between GEM-refractory advanced PC pts treated with TAS-118 and S-1. **Methods:** GEM-refractory PC pts were randomized in a 1:1 ratio to receive TAS-118 (S-1; 40-60 mg and LV; 25 mg bid for 1w, q2w) or S-1 (S-1; 40-60 mg bid for 4w, q6w). The primary endpoint was OS. The secondary endpoints included PFS, overall response rate, disease control rate, duration of response, and safety. **Results:** Five hundred and eighty-six pts were eligible for efficacy assessment (TAS-118: n=296 and S-1: n=290). Baseline characteristics were well balanced between the treatment arms. TAS-118 did not result in a statistically significant improvement in OS compared with that achieved with S-1 (median OS, 7.6 months vs. 7.9 months; hazard ratio [HR], 0.98; 95% CI, 0.82 to 1.16; P=0.756). However, it significantly improved PFS compared to that achieved with S-1 (median PFS, 3.9 months vs. 2.8 months; HR, 0.80; 95% CI, 0.67 to 0.95; P=0.009). Pre-planned subgroup analysis of OS showed significant interactions between the treatment effects and pancreatic resection (P=0.025), and between the treatment effects and country (P=0.004). Grade 3/4 drug-related adverse events (≥5% incidences) in TAS-118 and S-1 arms included diarrhea (7.0% vs. 7.3%), anorexia (6.7% vs. 5.0%), stomatitis (6.7% vs. 0.7%), and anemia (3.3% vs. 5.0%). **Conclusions:** The primary endpoint was not met. Further, the interactions between the treatment effects and pancreatic resection, and between the treatment effects and country, might affect the results. Clinical trial information: 132172.

Subgroup		Number of pts (TAS-118 vs. S-1)	Median OS (months) TAS-118	S-1	HR (95% CI)	P value for interaction
Pancreatic resection	Yes	85 vs. 81	8.7	9.4	1.51 (1.07-2.14)	0.025
	No	211 vs. 209	7.3	7.4	0.85 (0.70-1.04)	
Country	Japan	235 vs. 231	8.0	7.9	0.85 (0.70-1.04)	0.004
	Korea	61 vs. 59	6.0	7.4	1.57 (1.07-2.30)	

4100 Poster Session (Board #92), Sat, 8:00 AM-11:30 AM

A randomized phase II trial comparing different schedules of nab-paclitaxel (nabP) combined with gemcitabine (GEM) as first line treatment for metastatic pancreatic adenocarcinoma (mPDAC). *First Author: Philippa Corrie, Cambridge Cancer Trials Centre, Cambridge, United Kingdom*

Background: NabP+GEM chemotherapy improves survival compared with GEM monotherapy as treatment for mPDAC. A PDAC mouse model suggested that *nab*P potentiates GEM activity by reducing cytidine deaminase levels and scheduling may be critical to optimise clinical benefit. **Methods:** Patients (pts) were randomised to receive standard concomitant (CON) nabP+GEM or sequential (SEQ) administration, with nabP given 24 hours before GEM. After 6 cycles, pts benefiting from treatment could continue the same regimen until disease progression. The primary endpoint was progression-free survival (PFS) by RECIST v1.1; secondary endpoints included safety, objective response rate (ORR), overall survival (OS) and quality of life (QoL). Serial blood and baseline tumour samples were collected for exploratory biomarkers. **Results:** Between March 2014 and 2016, 146 pts (71 SEQ, 75 CON) were recruited. Median age (range) was 66 (45-82) years; Karnofsky performance status was 70 (in 12% pts), 80 (27%), 90 (38%) or 100 (24%); 47% had pancreatic head primaries; 84% had liver metastases. Median no. cycles received was 4 SEQ, 3 CON; 51 pts (35%) received ≥6 cycles of treatment (42% SEQ, 28% CON). A 24+2hr interval was achieved in > 90% SEQ admin. Grade ≥3 adverse events experienced by ≥10% pts (SEQ, CON) were neutropaenia (54%, 30%; p = 0.003), febrile neutropaenia (12%, 12%), fatigue (22%, 15%), vomiting (7%, 11%) and anaemia (10%, 5%). G-CSF was administered at local investigator's discretion to 35 pts (23 SEQ, 12 CON; p = 0.015). To date, 112 pts have died. 6 month (m) PFS by SEQ and CON arms were 47% and 33%; median PFS were 5.8 and 4.0m; hazard ratio (HR) = 0.66, 95% CI = 0.46-0.95; 12m OS by SEQ and CON arms were 29% and 26%; median OS were 10.1 and 7.9m; HR = 0.88, 95% CI = 0.61-1.29. ORR was 50% SEQ and 33% CON (p = 0.065). Mean baseline QoL Global health status score was 60.6 SEQ and 63.4 CON. The mean change in QoL score from baseline at 24 weeks was -2.1 SEQ and -12.1 CON. **Conclusions:** Sequential delivery of nabP combined with GEM trended towards improving all clinically relevant efficacy end points: PFS, OS, and ORR. Translational correlates will be reported in due course. Clinical trial information: ISRCTN71070888.

4101 Poster Session (Board #93), Sat, 8:00 AM-11:30 AM

Potential role of circulating tumor DNA (ctDNA) in the early diagnosis and post-operative management of localised pancreatic cancer. *First Author: Belinda Lee, The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia*

Background: Pancreatic cancer remains a devastating disease, with the diagnosis typically being made late. ctDNA has shown promise as a screening test for various tumor types. The detection of ctDNA post curative intent surgery has been associated with a high risk of recurrence in multiple solid tumors. We explored the potential of ctDNA to improve pancreatic cancer outcomes. **Methods:** Data from separate US and Australian series were combined. Plasma samples were collected prior to surgery in both studies and post-operative samples were collected in Australia from cases undergoing curative intent surgery. Clinicians were blinded to ctDNA results and adjuvant therapy was at clinician discretion. Tissue samples from both series were analyzed at Johns Hopkins University. Next generation sequencing was used to search for somatic KRAS mutations in the primary tumors and in cell-free DNA in the plasma. Clinico-pathologic, treatment and outcome data were collected. **Results:** 119 pts had a ctDNA sample at diagnosis (median age 67 years, 56.3% male). Sixty six pts (55.5 %) had detectable ctDNA, including 3/7 (42.9%) with stage I disease, 54/99 (54.5%) with stage II disease, 4/8 (50%) with stage III disease and 5/5 (100%) with metastases. Specific codon 12 KRAS (G12D, G12V or G12R) mutations were identified in the tumor tissue of 12/16 (75%) patients who had a ctDNA sample collected post-surgery. At a median follow-up of 15.2 months, 7/12 (58.3%) pts had recurred, including 3/8 (37.5%) with no detectable ctDNA and 4/4 (100%) with detectable ctDNA post-surgery (HR 4.9, p = 0.04). Detectable ctDNA post-surgery was significantly associated with poor overall survival (HR 6.93, p = 0.006), with a median of 8 months for pts with detectable ctDNA. **Conclusions:** ctDNA shows promise as a pancreatic cancer screening test, being detectable in a high proportion of pts with early stage disease. The detection of ctDNA post operatively predicts a very high risk of recurrence. The clinical utility of ctDNA to guide adjuvant therapy decision making, and its potential as a real-time marker of treatment effect, are being explored in further studies. Clinical trial information: ACTRN12612000763842.

4102 Poster Session (Board #94), Sat, 8:00 AM-11:30 AM

Prospective assessment for pathogenic germline alterations (PGA) in pancreas cancer (PAC). *First Author: Emmet Jordan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer predisposition syndromes are identified in a subset of PAC. Identifying PGA has implications for therapy as well as for cancer predisposition in blood relatives. Germline testing (GT) in the US is currently performed in a small subset of PAC patients according to NCCN/other guidelines. At MSKCC, we have implemented an 'opt in' strategy to perform germline testing in all patients evaluated in PAC clinics at MSKCC. **Methods:** PAC pts consented prospectively for GT had samples analyzed for pathogenic or likely pathogenic variants using the MSK-IMPACT germline platform (NCT01775072). All pts first had somatic profiling of tumor samples for $>$ 340 genes by MSK-IMPACT. Clinicopathological features, time to progression on platinum (TTPP) and overall survival (OS) were collated. **Results:** N = 305 PAC pts consented for GT between 9/2015-11/2016.164/305 (54%) were male, 70/305 (23%) were Ashkenazi Jewish. 242 pts (79%) had a family hx of cancer. 67/305 (22%) had a GA identified, 45/67 (67%) were stage III/IV at dx. Median age at PAC dx for all GA carriers was 60 years (y) (range 29-81) compared to 66 y (18-69) without GA. Median age at dx was 54 y (32-68) for BRCA1 and 61 y (37-77) for BRCA2 GA. 3/9 and 3/20 pts with BRCA1/2 GA had a PAC dx $<$ 50 y. 2/63 pts (3%) with no family hx had a GA (CDKN2A, PMS2). N = 5/22 pts (23%) with a 1st degree relative (DR) with PAC had a GA. N = 13/45 pts (29%) had a GA with either a 1st or 2nd DR with PAC. 19/84 pts (23%) with $\geq$2 1stDR with cancer had a GA detected. For median OS and TTP on platinum therapy, see Table. Pts with BRCA1/2, ATM and those with coexisting GA tended to have a better median OS as well as longer TTP on platinum therapy (Table). **Conclusions:** GA's are significantly under identified in PAC using current practices with a high, frequency (22%) observed in this relatively unselected cohort. BRCA mutations are the most frequent GA noted. There are significant implications of these observations for therapy and for blood relatives.

4103 Poster Session (Board #95), Sat, 8:00 AM-11:30 AM

Chemotherapy with or without definitive radiation therapy in locally advanced pancreatic cancer. *First Author: Jim Zhong, Department of Radiation Oncology, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: The recently reported LAP07 randomized trial calls into question the role of radiation therapy (RT) in the modern treatment of locally advanced pancreatic cancer (LAPC). However, advances in chemotherapy and RT limit application of the LAP07 results to current clinical practice. Here we utilize the National Cancer Database (NCDB) to evaluate the effects of RT in patients receiving chemotherapy for LAPC. **Methods:** Using the NCDB, patients with AJCC clinical stage T2-T4, N0-1, M0 adenocarcinoma of the pancreas from 2004-2014 were analyzed. Only those that received chemotherapy and did not undergo surgery were included. Patients were stratified into chemotherapy only (CT) and chemoradiation (CRT) cohorts. Patients undergoing definitive RT, defined as at least 20 fractions (fxs) or $\geq$ 5 Gy per fraction (i.e. SBRT) were included in the CRT cohort. Propensity-score matching (PSM) and landmark analysis were used to address selection bias and lead-time bias, respectively. The primary endpoint was overall survival (OS). **Results:** 13,004 patients met inclusion criteria, of which 7,034 (54%) received CT and 5,970 (46%) received CRT. After PSM, 5,215 patients remained in each cohort. Median follow-up was 22.6 months. The CRT group had younger median age (65 vs. 67) and less treatment at academic centers (44 vs. 51%); performance status was similar between groups. The median fractionated RT dose was 50.4 Gy in 28 fxs and SBRT dose was 24 Gy in 3 fxs. The CRT cohort demonstrated better OS compared with CT alone, with median and 1-yr OS of 12 vs. 10 months, and 50% and 41%, respectively ($p < 0.001$). On multivariable analysis, CRT was associated with superior OS with a hazard ratio (HR) of 0.79 (95% confidence interval (CI): 0.76-0.83, $p < 0.001$) compared with CT alone. The SBRT subgroup demonstrated the best survival (HR 0.71 [95% CI: 0.64-0.80], $p < 0.001$). OS was superior for CRT after PSM and for all patient subsets. **Conclusions:** In unresected LAPC, the addition of definitive radiotherapy to chemotherapy is associated with superior OS when compared with chemotherapy alone. Survival was greatest when SBRT was used. Definitive radiotherapy should remain a standard option for LAPC but optimal selection criteria remain unclear.

4104 Poster Session (Board #96), Sat, 8:00 AM-11:30 AM

Biomarker prediction of efficacy to vandetanib plus gemcitabine in a phase II double blind multicenter randomized placebo-controlled trial in locally advanced or metastatic pancreatic carcinoma. *First Author: John P. Neoptolemos, University of Liverpool, Liverpool, United Kingdom*

Background: We investigated the potential of biomarkers to predict efficacy of vandetanib and gemcitabine in patients with locally advanced (N = 41) or metastatic (N = 101) pancreatic cancer in a phase II double-blind multicentre randomised placebo-controlled trial. **Methods:** All patients were 18y or above, (ECOG = 0-2), with at least 3 mths life expectancy had gemcitabine (1000mg/m^2 30min iv wkly for 7 wks, followed by a 1wk break, then cycles of wkly treatment for 3wks with a 1-wk break) and randomly assigned to 300mg/d vandetanib or placebo once daily until disease progression. The primary outcome was overall survival (OS) by intention to treat. A panel of potential biomarkers was tested to predict best survival with vandetanib and gemcitabine. **Results:** 142 patients were randomised, median FU = 24·9 mths with 131 deaths. The median (95% CI) OS in the 70 gemcitabine-placebo patients was 8·95 (6·55-11·7) mths and 8·83 (7·11-11·6) mths in the 72 gemcitabine-vandetanib patients (HR = 1·21, 95% CI = 0·85, 1·73; log rank X^2_{1df} = 1·1; P = 0·303). A CTCAE V.4.02 rash grade 2 or above occurred in 4 (6 %) of 70 placebo patients versus 14 (19%) of 72 vandetanib patients. The median OS for the 14 vandetanib patients and with rash was 11·92 (10·89 – NA) mths, 7·76 (4·34 – 11·5) mths for the 58 vandetanib patients and without rash and 8·95 (6·55 – 11·7) mths for the gemcitabine-placebo patients (log rank X^2_{2df} = 7·23; P = 0·03). We identified two biomarkers that could select patients for response to vandetanib (JN101, JN102). The biomarker combination was present in 26 patients with median OS of 12.1 (10.9, 16.0) mths versus 8.15 (6.67, 11.7) mths for 23 patients with the same biomarker profile in the placebo group (HR = 0.53 [0.29, 0.97], p = 0.0396). A logistic regression model showed that patients with JN102 were more likely to develop a rash (OR =0.81 [0.713, 0.925] p = 0.002). **Conclusions:** A two biomarker combination and a rash grade 2 or above may predict response to vandetanib and gemcitabine. This requires prospective evaluation. Clinical trial information: 96397434.

4105 Poster Session (Board #97), Sat, 8:00 AM-11:30 AM

A novel scoring system to predict survival in patients with advanced pancreatic adenocarcinoma: The Memorial Sloan Kettering Cancer Center (MSKCC) Prognostic Score (MPS). *First Author: Andrew Chung Yang, Brown University Hematology and Oncology-Rhode Island Hospital, Providence, RI*

Background: A major limitation of several common prognostic tools, e.g. the Eastern Cooperative Oncology Group (ECOG), Karnofsky, and Palliative Performance Scales, is a reliance on subjective clinical assessment. An objective tool, the Glasgow Prognostic Score (GPS) derived from C-reactive Protein (CRP) and albumin levels, has been validated in patients with operable and inoperable malignancies but has the disadvantage that CRP is not routinely measured in the United States. We examined if the Neutrophil-Lymphocyte Ratios (NLR) (Ahn, H.K., et al., *Neutrophil-Lymphocyte Ratio Predicts Survival in Terminal Cancer Patients.* J Palliat Med, 2016) could be substituted for CRP in the GPS to predict survival in patients with advanced pancreatic adenocarcinoma. **Methods:** A retrospective review chart identified patients at MSKCC with pathology-confirmed stage IV pancreatic adenocarcinoma diagnosed between 2011 to 2014. Pre-treatment absolute neutrophil count, absolute lymphocyte count, and albumin were extracted. The NLR for each patient was calculated and assigned NLR ≤ 4 a value of 0; NLRs > 4 a value of 1, serum albumin > 4 g/dl assigned a value of 0; and serum albumin < 4 g/dl assigned a value of 1. Combining NLR and albumin scores results in a composite MPS score of 0-2, similar to GPS. We evaluated the association of the MPS with overall survival. **Results:** N = 833 patients were identified with median survivals in the table below. A log-rank test showed statistically significant differences in survival between MPS groups ($p < 0.00005$). The MPS on univariate analysis had a HR of 1.36 (95% CI 1.23 – 1.50, $p < 0.0005$) associated with overall survival. **Conclusions:** The MPS, a composite of NLR and albumin, is an objective prognostic tool that divided this sample of patients into three clinically and statistically significant subgroups. Further interrogation will control for performance status, disease characteristics and therapy.

Cohort	Median OS (months)	Interquartile Range	Percent Alive (N)
MPS 0 (n = 213)	14.7	8.5-26.3	22.1 (47)
MPS 1 (n = 332)	10.3	4.5-21.9	17.2 (57)
MPS 2 (n = 288)	6.2	2.3-14.8	13.2 (38)
Overall (n = 833)	10.2	4.4-21.5	17.0 (142)

4106 Poster Session (Board #98), Sat, 8:00 AM-11:30 AM

A phase Ib/II study of cancer stemness inhibitor napabucasin (BBI-608) in combination with gemcitabine (gem) and nab-paclitaxel (nabPTX) in metastatic pancreatic adenocarcinoma (mPDAC) patients (pts). *First Author: Tanios S. Bekaii-Saab, Mayo Clinic Cancer Center, Phoenix, AZ*

Background: Cancer stem cells are fundamentally important for resistance to therapy, recurrence and metastasis. Napabucasin is a first-in-class cancer stemness inhibitor in development identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al, PNAS 112(6):1839, 2015). Preclinical studies suggest that napabucasin sensitizes heterogeneous cancer cells to chemotherapy and targeted agents. **Methods:** A phase Ib/II multi-center study in mPDAC pts was performed to confirm the RP2D, PK profile and evidence of anticancer activity of napabucasin in combination with nabPTX and Gem. Pts received napabucasin 240 mg BID with weekly nabPTX 125 mg/m^2 and gem 1000 mg/m^{2}for 3 out of every 4 weeks until disease progression (PD) or other discontinuation criterion. **Results:** Of 71 intent to treat (ITT) pts enrolled, 49 (69%) were treatment-naïve and 22 (31%) received neoadjuvant treatment. There were no significant PK interactions, dose-limiting or unexpected toxicities. Most common adverse events (AEs) included grade 1 diarrhea/cramping, nausea and fatigue with grade 3 AEs noted in 12 pts: fatigue (8), electrolyte imbalance (2), diarrhea (1), dehydration (1), nausea (1) and weight loss (1). Among pts who received RECIST evaluation (60), disease control (DCR; CR+PR+SD) was observed in 55 (92%), with 1 CR (2%) and 26 PR (43%) (31 - 78% regression). Of 11 pts with non-evaluable disease, treatment stopped due to compliance (4), consent withdrawal (3), clinical PD (1), toxicity (1), insurance (1) and death (1). Among 71 ITT pts, DCR was observed in 55 (77%), with 1 CR (1.4%) and 26 PR (37%). Maturing median progression free survival and overall survival (OS) in ITT pts is >7.1 and >10.4 m, respectively. **Conclusions:** This study showed that napabucasin can be combined with nabPTX and gem, with encouraging signs of efficacy in mPDAC now being confirmed in a phase 3 study. Clinical trial information: NCT02231723.

4107 Poster Session (Board #99), Sat, 8:00 AM-11:30 AM

Phase II trial of neoadjuvant S-1 and concurrent radiotherapy for borderline resectable pancreatic cancer: Interim results of JASPAC05. *First Author: Shinichiro Takahashi, Department of Hepato-Biliary Pancreatic Surgery, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Borderline resectable pancreatic cancer (BRPC) has a high probability of a positive surgical margin and poor prognosis because the tumor interacts with surrounding arteries or veins. Chemoradiotherapy (CRT) with S-1 has shown favorable activity in locally advanced pancreatic cancer. This study was designed to assess S-1 and concurrent radiotherapy in a neoadjuvant setting to determine whether it increases R0 resection rate for BRPC. **Methods:** This was a multicenter, single-arm phase II study. Patients with BRPC received S-1 (40 mg/m^2 BID) and concurrent radiotherapy (50.4 Gy in 28 fractions) before surgery if they fulfilled any of the following: (1) bilateral impingement of superior mesenteric vein or portal vein; (2) tumor contact with superior mesenteric artery $\leq$180°; or (3) tumor contact with common hepatic artery or celiac axis $\leq$180°. Primary endpoint was R0 resection rate in BRPC confirmed by central review. At least 40 patients were required, with one-sided $\alpha = 0.05$ and $\beta = 0.05$, with an expected and a threshold values for primary endpoint of 30% and 10%. **Results:** Fifty-two patients were eligible between December 2012 and May 2016. CRT was completed in 50 patients (96%) and was safe, with mostly grade 1 or 2 adverse events. Protocol treatment was withdrawn before surgery in 12 patients because of progressive disease diagnosed by computed tomography, and in one because of treatment refusal. Ten patients received exploratory laparotomy, or palliative/noncurative resection. In the rest of 29, R0 resection was conducted in 27, and R1 and RX in 1 patient each. This gave an R0 resection rate of 52% in all 52 eligible patients. In the 41 cases of BRPC confirmed by central review, R0 was confirmed in 26 (63%). Destruction of > 50% of tumor cells was confirmed pathologically in 10 (32%). Postoperative grade III/IV adverse events according to Clavien–Dindo classification were observed in 6 (15%). **Conclusions:** S-1 and concurrent radiotherapy were well tolerated and found to be effective in BRPC. A randomized controlled trial comparing neoadjuvant CRT and chemotherapy, including gemcitabine+nab-paclitaxel, for BRPC is under planning. Clinical trial information: NCT02459652.

4108 Poster Session (Board #100), Sat, 8:00 AM-11:30 AM

Efficacy of gemcitabine with erlotinib in rash-positive patients selected according to eligibility for FOLFIRINOX. *First Author: Michael Haas, Department of Internal Medicine III and Comprehensive Cancer Center, Klinikum Grosshadern, Ludwig-Maximilians University of Munich, Munich, Germany*

Background: The efficacy and safety of gemcitabine + erlotinib has not yet been defined prospectively in patients (pts) with metastatic pancreatic cancer (mPC) selected according to the inclusion criteria defined by Conroy et al. for FOLFIRINOX (e. g. ECOG 0-1, age < 75, bilirubin < 1.5xULN). **Methods:** In this German phase II trial, 150 pts with histologically confirmed mPC were recruited between July 2012 and July 2015 in 20 centers. If pts showed skin rash of any grade within 4 weeks after start of treatment with gemcitabine (1000 mg/m^2 weekly) and erlotinib (100 mg daily), this regimen was continued; rash-negative pts were switched to FOLFIRINOX. The primary study endpoint was the 1-year survival rate in rash-positive pts (hypothesis: $\geq$40%). **Results:** Ninety pts who were under treatment with gemcitabine + erlotinib for 4 weeks developed skin rash of any grade: the 1-year survival rate in those pts positive for skin rash was 40.0% (95%CI 29.8-50.9); median overall survival (OS) counted from day of first treatment was 10.1 months (mo) (95%CI 9.0-12.5), progression-free survival (PFS) 3.9 mo (95%CI 3.5-4.9), objective response rate (ORR) and disease control rate (DCR) were 21% and 64%, respectively. Median treatment duration with gemcitabine+erlotinib was 3.7 mo (Range 0.7-17.5). In rash-negative pts who were switched to FOLFIRINOX after 4 weeks of gemcitabine + erlotinib (n = 28) the 1-year survival rate was 46.4% (95%CI 27.5-66.1), median OS 10.6 mo (95%CI 6.6-13.6), median PFS 5.2 mo (95%CI 2.3-7.9) and the corresponding ORR and DCR rates were 29 and 54%, respectively. The rate of salvage therapy was 53% after gemcitabine+erlotinib, mostly consisting of 5-FU-based schemas (42 % 5-FU/folinic acid + irinotecan or oxaliplatin, 38% FOLFIRINOX) and 43% after FOLFIRINOX (all pts received gemcitabine, 67% in combination with nab-paclitaxel). In the Intention To Treat (ITT) population (n = 145) OS was 9.7 mon (95%CI 7.8-10.9). **Conclusions:** In rash-positive pts deemed fit for FOLFIRINOX first-line treatment with gemcitabine + erlotinib appears effective achieving a one-year-survival rate of 40%. Early switch to FOLFIRINOX was an effective strategy in rash-negative patients. Clinical trial information: NCT01729481.

4109 Poster Session (Board #101), Sat, 8:00 AM-11:30 AM

Nomogram for predicting overall survival (OS) in patients (pts) treated with *nab*-paclitaxel (*nab*-P) plus gemcitabine (Gem) or Gem alone for metastatic pancreatic cancer (MPC). *First Author: David Goldstein, Prince of Wales Hospital, University of New South Wales, Cancer Survivors Centre, Sydney, Australia*

Background: Prognostic nomograms have been developed in various cancers, including ovarian, breast, and gastrointestinal; however, there is limited information on nomograms in MPC. The large, phase 3 MPACT study of *nab*-P + Gem vs Gem alone for the treatment of MPC provides a robust database for the development of a nomogram to predict OS using baseline patient variables. **Methods:** A multivariable Cox model was created from MPACT data using factors that were significantly predictive of OS in univariable analysis or considered clinically important (stepwise selection to remain in model). From the Cox model, a nomogram was derived that assigned points equal to the weighted sum of relative significance of each variable. The nomogram was internally validated using bootstrapping, a concordance index (c-index), and calibration plots. **Results:** Data from all 861 pts were used. Seven of the 34 considered variables were retained in the multivariable analysis (Table; all factors significant at the $P < 0.01$ level, except for analgesic use [$P = 0.07$]). The resulting nomogram was able to distinguish low (n = 216), medium (n = 430), and high (n = 215) risk groups (c-index: 0.69; CI: 0.67-0.71) with median OS values of 12.9, 8.2, and 3.7 months, respectively. Calibration curves showed that the nomogram's predicted probabilities were mostly consistent with observed probabilities for 6-, 9-, and 12-month OS. **Conclusions:** Treatment arm, Karnofsky performance status (KPS), neutrophil-to-lymphocyte ratio (NLR), albumin level, sum of longest tumor diameters (SLD), and presence of liver metastasis were the key predictors of OS. This nomogram, which will be presented in visual format in the final presentation, may help physicians and pts make informed treatment decisions. Clinical trial information: NCT00844649.

Multivariable cox model for OS.

Variable[a]	HR	CI
Treatment arm	1.56	1.34-1.82
NLR	1.05	1.04-1.07
Albumin	0.94	0.92-0.95
KPS (per 10-unit increase)	0.97	0.96-0.98
SLD	1.02	1.01-1.03
Presence of liver metastasis	1.62	1.29-2.03
Analgesic use	1.16	0.99-1.36

[a] Results similar in a sensitivity analysis that excluded CA19-9 non-secretors

4110 Poster Session (Board #102), Sat, 8:00 AM-11:30 AM

Single agent HuMab-5B1 (MVT-5873), a monoclonal antibody targeting sLe[a], in patients with pancreatic cancer and other CA19-9 positive malignancies. *First Author: Eileen Mary O'Reilly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MVT-5873, a fully human IgG1 monoclonal antibody (mAb), targets sialyl Lewis A (sLe[a]), an epitope on CA19-9. CA19-9 is expressed in pancreatic (PDAC) and other GI cancers, plays a role in tumor adhesion and metastasis, and is a marker of an aggressive tumor phenotype. MVT-5873 is active as a single agent and with chemotherapy in murine xenografts. **Methods:** MVT-5873 was given IV every other week (Group 1) or weekly (Group 2). Eligible patients had progressive, locally-advanced or metastatic PDAC or other CA19-9+ malignancy and ECOG PS $\leq$1. Dose escalation followed a 3+3 design with a 10 patient expansion at MTD. Endpoints include safety, MTD, pharmacokinetics (PK) and efficacy. Exploratory endpoints include changes in serum CA19-9 levels. **Results:** As of 2-Feb 2017, data are available from N = 25 in Groups 1 (N = 9) and 2 (N = 16) at doses ranging from 1 to 3 mg/kg. Dose limiting toxicities of transient grade 3 elevations in AST, ALT, and total bilirubin were encountered at 3 mg/kg in both groups. Liver function laboratory abnormalities typically emerged and resolved within a week of dosing without significant clinical sequelae. Of toxicities deemed possibly related, most were low grade and included GI toxicity (abdominal pain/cramps/diarrhea/nausea) and infusion reactions. Infusion reactions were mitigated by using pre-medications and decreasing the infusion rate. Initial PK data demonstrate initial (20 hours) and terminal (211 hours) half-lives, comparable to other mAbs. Stable disease of $>$ 4 months was observed in 24% of patients. CA19-9 levels were measured pre- and post-dose with each treatment. Immediate reductions showed dose-dependent reductions of up to 97% from baseline at 3 mg/kg. Downward trends of CA19-9 with successive doses were seen, with 48% and 22% of patients exhibiting $\geq$50% and $\geq$90% reductions in CA19-9 levels, respectively. **Conclusions:** Single agent MVT-5873 appears safe and tolerable at biologically active doses. DLTs included reversible serologic liver toxicity. The safety profile, efficacy, and reductions in serum CA19-9 levels over time support further development of MVT-5873 in this indication both as a single agent and in combination. Clinical trial information: NCT02672917.

4111 Poster Session (Board #103), Sat, 8:00 AM-11:30 AM

Efficacy, safety, and immune activation with pegylated human IL-10 (AM0010) plus FOLFOX in metastatic pancreatic adenocarcinoma (PDAC). *First Author: J. Randolph Hecht, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Oxaliplatin or nal-irinotecan plus 5-FU are used as 2nd-line PDAC therapy (mOS 5-6 months (m)). PDAC also has been largely refractory to immune therapies which may depend on the expansion of activated, intratumoral, tumor specific cytotoxic CD8+ T cells that are low in most PDACs. AM0010 stimulates survival, expansion and cytotoxicity of intratumoral CD8+ T cells. Immune activation, durable stable disease and a 1yr survival of 22.5% was seen in salvage PDAC patients (pts) receiving AM0010 alone. Platins or 5-FU may activate immune responses to cancer and AM0010 has shown synergistic anti-tumor results with FOLFOX in preclinical models. In this phase 1b clinical study, the safety and efficacy of AM0010 +FOLFOX was studied in PDAC pts. **Methods:** PDAC pts progressing on a median of 1 prior therapy (range 1-3) were treated with AM0010 (5ug/kg SQ, qd) + FOLFOX (n = 21), an additional 4 pts with prior oxaliplatin and 5-FU were included in the safety population (n = 25). Tumor responses were assessed using irRC. Serum cytokines, activation of blood derived T cells and peripheral T cell clonality were analyzed. Pretreatment archival tissue samples were evaluated by IHC for tumor infiltration by CD8+ T cells. **Results:** On AM0010 + FOLFOX, G3/4 TrAEs included thrombocytopenia (52%), anemia (36%) and neutropenia (36%). A modified AM0010 dose schedule (5 days on 2 days off) avoided G3/4 thrombocytopenia. As of 01/31/2017, 2 patients remained on treatment for $>$ 1 year. 19 pts had objective tumor response assessment; 2 had irCR, 1 irPR, 11 irSD. ORR is 15.8%, DCR is 73.7%. With median follow-up of 11.0 m (range 5.8-16.3), mPFS was 3.5 m and mOS 10.0 m. Pts with more intra-tumoral CD8+ T cells had longer OS. AM0010 + FOLFOX increased serum Th1 cytokines and reduced mediators of chronic inflammation and TGFb. AM0010 induced de-novo oligoclonal expansion of T cell clones in patients with prolonged survival. **Conclusions:** AM0010 plus FOLFOX is well tolerated in patients with PDAC. The observed immune activation including clonal T cell expansion and prolonged objective tumor responses are encouraging in this advanced PDAC population. This regimen is currently being studied in a phase 3 trial. Clinical trial information: NCT02009449.

4113 Poster Session (Board #105), Sat, 8:00 AM-11:30 AM

FOLFIRINOX (F-NOX) followed by individualized radiation for borderline-resectable pancreatic cancer (BRPC): Toxicity, R0 resection, and interim survival data from a prospective phase II study. *First Author: Janet E. Murphy, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: F-NOX is increasingly utilized in BRPC as neoadjuvant therapy. However, prospective data remains limited; the largest series is a 22 patient (pt) cooperative group trial (Alliance A021101), in which 14 pts had R0 resection. In this study, we evaluate neoadjuvant F-NOX followed by individualized chemoradiation (CRT) for BRPC. **Methods:** Pts ECOG PS 0-1 with biopsy-proven BRPC defined by NCCN criteria were enrolled in a single institution, NCI-sponsored phase II study (NCT01591733). Pts received F-NOX for 8 cycles. If after chemotherapy the tumor was radiographically resectable, pts received short course CRT in 5 (protons 25 GyE) or 10 fractions (photons 30 Gy) with capecitabine 825 mg/m2 bid. If the tumor was still abutting vasculature, pts received CRT to 50.4 Gy with a vascular boost to 58.8 Gy. Primary endpoint was R0 resection rate. **Results:** 50 pts were enrolled from 8/2012 to 8/2016. Two pts were ineligible (lung metastasis, negative biopsy); 48 pts were evaluable. Median age was 62y (46-74). Median tumor size was 37 mm (21-56). Thirty-six pts (75%) had pancreatic head tumors. Median follow up was 18.2 months among 31 patients still alive. Of the evaluable pts, 40 (83%) completed therapy. Reasons for not completing therapy include pt withdrawal (3), physician decision (3), unacceptable toxicity (1) and progression (1). Grade 3 or greater toxicity occurred in 48% of pts, but no individual grade 3 toxicity exceeded 15%. Twenty-seven pts (56%) had short course CRT, while 13 pts (27%) had long course CRT. Twenty-nine pts were resected; R0 resection was achieved in 28/29 (96.5%). R0 resection rate among all evaluable pts was 58.3%. Median PFS among all evaluable pts was was 14.7 months; mOS was 37.7 months, with 1y OS 79.5% and 2y OS 59.3%. Among resected patients, mOS has not been reached. 1y PFS was 78.1% and 2y PFS 55.4%; 1y OS was 92.6% and 2y OS was 80.6%. **Conclusions:** Preoperative F-NOX followed by individualized chemoradiation in BRPC results in high R0 resection rates as well as prolonged mPFS and mOS in this large prospective cohort. Clinical trial information: NCT01591733.

4114 Poster Session (Board #106), Sat, 8:00 AM-11:30 AM

Adjuvant chemotherapy and outcome in patients (pts) with nodal (N-) and resection margin negative (R0) pancreatic adenocarcinoma (PC): A systematic review and meta-analysis. *First Author: Nicola Flaum, Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Adjuvant chemotherapy following PC resection improves overall survival (OS). It is uncertain whether benefit is influenced by nodal and resection status or other factors. **Methods:** A systematic review of electronic databases identified published phase 2/3 studies investigating use of adjuvant chemotherapy in pts with resected PC. Efficacy (disease-free survival [DFS], OS, 5 yr OS) was explored using meta-analysis. Subgroup analysis explored effects based on nodal/resection status. Meta-regression also explored influence of age, gender, performance status [PS] and proportion of pts with head of pancreas (HOP) tumors on benefit of adjuvant chemotherapy. **Results:** Ten studies comprising 3644 pts were included. Two prospective phase 2 studies; 8 phase 3 trials. Median age was 63 yrs (range 24-84), 46% male. In 2268 pts with PS reported; 42% were PS 0, 51% PS 1. Tumor location was reported in 719 pts; 82% had HOP tumors. Of 3524 pts with available data; 33% N- and 67% R0. Overall, in studies of experimental vs control, adjuvant therapy significantly improved DFS (HR 0.67, CI 0.48-0.93, P = 0.02), OS (HR 0.77, 95% CI 0.68-0.87, P $<$ 0.001) and odds of death risk at 5 yrs (OR 0.53, 95% CI 0.41-0.70, P $<$ 0.001). In studies comparing chemotherapy to surgery only, adjuvant therapy also significantly improved DFS (HR 0.57, 95% CI 0.49-0.76, P $<$ 0.001) and OS (HR 0.74, 95% CI 0.64-0.87, P $<$ 0.001). There was a numerical but non-significant greater effect of adjuvant therapy in N- vs N+ pts (HR 0.58 vs 0.71, P for difference = 0.29). There was no difference in effect between pts with R0 or R1 disease (HR 0.70 vs 0.69, P for difference = 0.95). There was greater OS benefit from adjuvant therapy in pts with PS 0 (P = 0.04) and significantly less benefit on 5 yr OS in pts with HOP tumors (P = 0.04). **Conclusions:** The relative benefit of adjuvant chemotherapy seems similar in N-/N+ and in R0/R1 pts. This will translate into greater absolute benefit in the N+ and R1 pts due to their greater absolute risk of recurrence/death. Adjuvant chemotherapy is recommended for all pts with resected PC, where clinically appropriate, and greater benefit was seen in pts with PS 0 and body/tail tumors.

4115 Poster Session (Board #107), Sat, 8:00 AM-11:30 AM

Defining DDR defectiveness in pancreatic cancer. *First Author: Stephan Dreyer, Wolfson Wohl Cancer Research Centre, Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom*

Background: Recent whole genome sequencing analysis of Pancreatic Cancer (PC) revealed that up to 24% of PC may harbor defects in DNA damage response (DDR). There is increasing evidence that DDR defective tumors preferentially respond to DNA damaging agents, representing novel therapeutic strategy for PC using a synthetic lethality approach. The aim of this study is to define and refine DDR defective phenotypes in PC using next-generation preclinical model systems. **Methods:** From a panel of 40 patient-derived cell lines (PDCL) and 64 patient-derived xenografts (PDX), generated and extensively characterized as part of the International Cancer Genome Initiative (ICGC), we identified DDR defective models using recently described putative biomarkers of DDR defectiveness. Cytotoxic viability assays were performed using a panel of DNA damaging agents and inhibitors of key molecules in DDR pathway, including Cisplatin, PARP inhibitors, ATR inhibitor (AZD6738); and ATM inhibitor (AZD0156). Appropriate subcutaneous PDX models were also generated to test the hypothesis using various therapeutic regimens. **Results:** DDR defective PDCLs were selected based on a combination of an unstable genome, and/or a high *BRCA* mutational signature, and/or deleterious mutations in *BRCA1/2*, *PALB2* or *ARID1A*. DDR defective PDCLs were significantly more sensitive to Cisplatin, PARP and ATR inhibitors. The ATR inhibitor AZD6738, and ATM inhibitor AZD0156 sensitized PDCLs with no putative biomarkers of DDR defectiveness to Cisplatin, demonstrating a 'fabricated' synthetic lethality. A *BRCA1* mutant PDX model responded exceptionally to Cisplatin and the PARP inhibitor Olaparib monotherapy. **Conclusions:** This study provides proof of concept data that DDR deficiency represents an attractive segment to target in PC using a variety of DNA damaging agents and novel agents targeting key molecules of the DDR pathway in PC. In addition, the DDR defective segment may be significantly larger than just germline *BRCA1/2* mutants, which is current clinical trial recruitment criteria. Robust molecular assays with clinical utility to define DDR defectiveness is urgently needed.

4116 Poster Session (Board #108), Sat, 8:00 AM-11:30 AM

Characterization of germline genomic alterations in familial pancreas cancer. *First Author: Jennifer Brooke Goldstein, The University of Texas MD Anderson Cancer Center, Medical Oncology Fellowship, Houston, TX*

Background: Family history of BRCA-related tumors may correlate with response to chemotherapy and overall survival in patients with pancreatic cancer (PC). We retrospectively compared family history of such cancers with clinical outcomes and underlying molecular aberrations. **Methods:** A retrospective chart review was conducted of 350 metastatic PC patients treated with first line FOLFIRINOX and Gem/Abraxane at MDACC from 1/2010 -1/2016. Family history was defined as 1st through 3rdgeneration relatives with breast, ovarian, or pancreas cancer. Germline DNA was collected and sequenced using a familial cancer panel using an Illumina 2500. Average coverage was 200X. Platypus calls were analyzed for germline mutations. We assessed mutations in BRCA1, BRCA2, PALB2, MMR genes, ATM, and PolE. **Results:** Average age was 61. 60% of patients were male. We sequenced blood and tissue samples where available. We found at lease one mutation in 47 of 129 patients tested. There were 56 mutations identified among the 47 patients. Of patients with 0-1,2, or 3 or more affected family members we found mutations in 44%, 47%, and 29%, respectively. Patients with 3+ family members affected tended to have mutations in BRCA1 or PolE. Among the subset of patients with possible deleterious mutations, there were trends towards improved survival in pts with BRCA or PALB aberrations (307d vs 271d, p = ns) but worse outcomes in those with MMR gene defects (181d vs 387d, p = .126). Table 1 indicates outcomes based on number of family members with cancer and their associated mutations. **Conclusions:** Approximately one third of all patients tested had at least one germline mutation in previously described familial pancreas cancer genes. Screening for inherited cancer susceptibility genes may have prognostic value.

Overall survival by number of affected family members and associated germline mutations.

# Affected Family Members	OS All Patients	95% CI	OS Sequenced Pts	95% CI	Mutations Found
3+	518	251 - 785	518 d	377 - 659	BRCA1 (14%); POLE (14%)
2	296	189 - 403	312 d	233 - 400	BRCA2 (10%), MMR (16%), POLE (10%), ATM (10%)
0-1	283	249- 317	267 d	213 - 320	BRCA1 (3%), BRCA2 (8%), PALB2 (6%), POLE (6%), MMR(12%), ATM (9%)

4117 Poster Session (Board #109), Sat, 8:00 AM-11:30 AM

Neoadjuvant FOLFIRINOX for patients with borderline resectable or locally advanced pancreatic cancer: Results of a decision analysis. *First Author: Jin Choi, Institute for Technology Assessment, Massachusetts General Hospital, Boston, MA*

Background: With the advent of more effective therapies for metastatic pancreatic ductal adenocarcinoma (PDAC), efforts to incorporate these agents, such as FOLFIRINOX, into the neoadjuvant setting are increasing. However, the efficacy and cost-effectiveness of using neoadjuvant FOLFIRINOX for patients with borderline resectable or locally advanced PDAC are unknown. We performed a decision analysis to assess the value of neoadjuvant FOLFIRINOX versus upfront surgery and adjuvant therapy. **Methods:** We developed a mathematical simulation model to evaluate the efficacy and cost-effectiveness of neoadjuvant FOLFIRINOX compared to upfront surgery and adjuvant therapy. We used published and institutional data as inputs to inform model development. Model outcomes included overall and disease-free survival, net benefits expressed as discounted quality-adjusted life-years (QALYs), costs in US dollars, and cost-effectiveness expressed as an incremental cost-effectiveness ratio. We used deterministic and probabilistic sensitivity analyses to explore the uncertainty of model assumptions. **Results:** Model estimated median overall survival (29 vs 23 months) and disease-free survival (14 vs 13 months) were better for neoadjuvant strategy compared with upfront surgery. Neoadjuvant strategy resulted in an additional 0.68 life-years gained, or 0.57 QALYs, at a cost of $59,000/QALY gained. Sensitivity analysis found that cancer recurrence rates affected model results the most. Our findings were otherwise robust with respect to changes in other model parameters, including chemotherapy toxicity, surgical complications and cancer mortality. Probabilistic sensitivity analyses showed that neoadjuvant strategy was cost-effective 80% of the time with a willingness-to-pay threshold of $100,000/QALY. **Conclusions:** Our model results demonstrate that neoadjuvant strategy is preferable to upfront surgery for patients with borderline resectable or locally advanced PDAC from both an efficacy and cost-effectiveness standpoint. Additional clinical data are needed to further define the long-term effectiveness of neoadjuvant FOLFIRINOX to confirm our results.

4118 Poster Session (Board #110), Sat, 8:00 AM-11:30 AM

Phase II study of autophagy inhibition with hydroxychloroquine (HCQ) and preoperative (preop) short course chemoradiation (SCRT) followed by early surgery for resectable ductal adenocarcinoma of the head of pancreas (PDAC). *First Author: Theodore S. Hong, NSABP/NRG Oncology, and Massachusetts General Hospital, Boston, MA*

Background: PDAC is highly dependent on autophagy, a metabolic process that renders cancer cells resistant to cytotoxic therapies. HCQ is an inhibitor of autophagy, and has preclinical activity in PDAC. We evaluate the efficacy of concurrent and adjuvant HCQ with preop SCRT and adjuvant chemotherapy in early, resectable PDAC. **Methods:** Pts with radiographically resectable, biopsy-proven PDAC of the head were enrolled from 12/2011-9/2016 on this IRB-approved, NCI-sponsored clinical trial (NCT01494155). Eligibility included no involvement of SMA or celiac artery on CT; adequate renal, hepatic and hematopoetic function; and ECOG PS 0/1. SCRT was 5 Gy x 5 with protons or 3 Gy x 10 with photons concurrent with Cape 825 mg/m2 BID wk 1 and 2 M-F. HCQ was started at 400 mg po BID 1 wk prior to radiation through SCRT until the day of surgery. Surgery was performed 1-3 wks after completion of SCRT. Pts were recommended to receive 6 mo of gemcitabine-based chemotherapy after surgery. Pts resumed HCQ after discharge from surgery and continued until progression. Follow-up was performed every 3 months with CT scanning every 6 mo. Sample size of 50 to evaluate an increase of 2-year PFS from 30% to 45%. **Results:** 50 pts were enrolled on study and all are evaluable for this analysis. Median age- 69 (range 54-86); pre-treatment CA19-9 median 69.5 U/mL ($<$ 1-10235), female- 24 pts (48%). Gr 3 toxicity was noted in 2 (4%) pts (nausea-1, hyperglycemia-1). All 50 pts completed SCRT. 46 pts underwent resection. Reasons for no resections: metastatic disease-2, toxicity-1, intercurrent illness- 1. 38 pts had R0 resection, 8 had R1 resection. 29 of 46 pts had positive nodes. 1 pt achieved pathologic complete response (CR), 2 pts had near CR . 11 pts remain on HCQ. Median follow up in 26 surviving pts is 18.3 months. mPFS is 11.7 mo, mOS 23.3 mo. OS-2 yr- 43.1%, PFS-2-yr 32.0%. **Conclusions:** HCQ with preop SCRT and adjuvant gemcitabine-based chemotherapy is well tolerated but did not meaningfully impact DFS. Further pathologic/correlative studies, particularly in outstanding pathologic responders and long term survivors are ongoing. Clinical trial information: NCT01494155.

4119 Poster Session (Board #111), Sat, 8:00 AM-11:30 AM

A phase I/II trial of TG01/GM-CSF and gemcitabine as adjuvant therapy for treating patients with resected RAS-mutant adenocarcinoma of the pancreas. *First Author: Daniel H. Palmer, Department of Molecular and Clinical Cancer Medicine, University of Liverpool and Clatterbridge Cancer Centre, Liverpool, United Kingdom*

Background: TG01 (a mixture of 7 RAS peptides) is an injectable antigen-specific cancer immunotherapy targeted to treat patients (Pts) with KRAS mutations, found in more than 85% of pancreatic adenocarcinomas. There is scope for improvement in adjuvant treatment of resected pancreatic cancer; with 1- and 2-year published overall survival (OS) rates ranging from 56-80% and 30-54% respectively. TG01 induces RAS mutant-specific T-cell responses which are enhanced by co-administration of GM-CSF. This study evaluates safety, immunological response and OS of TG01-immunotherapy with adjuvant gemcitabine chemotherapy. **Methods:** Pts were eligible after an R0 or R1 pancreatic adenocarcinoma resection. As soon as possible after surgery, TG01 (0.7 mg intradermal injection (id)) together with GM-CSF (0.03 mg id) was given on days 1, 3, 5, 8, 15, 22 and 2-weekly thereafter until the end of gemcitabine (starting within 12 weeks of surgery and given for 6 cycles). Thereafter TG01/GM-CFS were given 4-weekly up to 1 yr and 12-weekly up to 2 yrs. Immune response was assessed using antigen-specific (TG01) Delayed-Type Hypersensitivity (DTH) and T-cell proliferation. OS was assessed from surgery; ~8 weeks before first TG01 injection. **Results:** To date**,** 19 pts (68% R1) from 3 sites (Norway and UK**)** and have been followed for 2 yrs**.**Eight SARs in 5 pts have occurred; 4 related to gemcitabine (anemia, pulmonary infection and 2 fever); 3 related to TG01/GM-CSF (2 anaphylaxes and 1 hypersensitivity); and 1 possibly related to all products (dyspnea). The allergic reactions only occurred after several cycles of gemcitabine and resolved within 1-2 hrs. There was no treatment related deaths.16/19 (84%) pts had a positive DTH by week 11. Proliferation of mutant RAS specific T-cells is being analyzed. OS rate at 1 and 2 yrs were 89.5% (95% CI 75.7, 100.0) and 68.4 (95% CI 47.5, 89.3), respectively. Median OS was 33.1 months (95% CI 16.8, 40.1). **Conclusions:** TG01/GM-CSF generated early immune responses in 84% of patients with R0/R1 resected pancreatic cancer. The regimen was generally well tolerated although some late, manageable allergic reactions were seen. OS was encouraging in view of published reports. Clinical trial information: NCT02261714.

4120 Poster Session (Board #112), Sat, 8:00 AM-11:30 AM

Neutrophil count and efficacy of chemoradiation in patients with locally advanced unresectable pancreatic carcinoma: An ancillary study of in the LAP 07 trial. *First Author: Antoine Schernberg, Hôpital Tenon, Paris, France*

Background: Predictive biomarkers of Overall Survival (OS) and Progression Free Survival (PFS) in locally advanced pancreatic cancer (LAPC) pts are mandatory. Baseline leukocyte, neutrophil and monocyte counts in addition to lymphocyte ratio (NLR) may predict OS in LAPC pts. Efficacy of chemoradiation (CRT) depending on neutrophil count was retrospectively analyzed in the largest Phase III cohort of LAPC. **Methods:** The international multicenter randomized LAP07 phase III trial (NCT00634725) has recruited 442 LAPC pts. We have studied the predictive and prognostic value of systemic inflammation, as defined: *(i)* baseline neutrophilia (neutrophil count $>$ 7 G/L at first randomization) or *(ii)*increased absolute neutrophil count (IANC) after induction chemotherapy vs baseline. Univariate and multivariate Cox analysis evaluated the benefit of CRT for OS, PFS and Local Control (LC) in pts without systemic inflammation. **Results:** Patients with baseline neutrophilia (11%) had a worse OS (median 8.9 vs 13.3 months, p = 0.01). At 2nd randomization, 9% and 29% pts had baseline neutrophilia or IANC, respectively. Both neutrophilia (median OS 10.6 vs 16.1 months, p = 0.03) and IANC (median OS 14.6 vs 17.4 months, p = 0.02) predicted poor OS. Systemic inflammation predicted local resistance to CRT (p = 0.02, interaction = 0.015). After excluding pts with systemic inflammation, 1-year local control was 80% in CRT vs 54% in chemotherapy arms ($p < 0.001$). Pts without systemic inflammation in CRT arm had improved PFS vs chemotherapy arm (median 10.3 vs 8.3 months, p = 0.04). In multivariate analysis in this population, CRT increased PFS (HR = 0.66, 95%CI: 0.45 - 0.97, p = 0.03), after adjusting on age, tumor size, pain at enrollment, albumin, and CA 19.9 according to PROLAP nomogram parameters. **Conclusions:** In LAPC pts with tumor controlled after induction chemotherapy, systemic inflammation may help to better predict those who will benefit from CRT. This result may impact clinical management and the design of future clinical trials for LAPC. An external validation with a cohort from the ARCAD pancreas meta-analysis is under consideration. Clinical trial information: NCT00634725.

4122 Poster Session (Board #114), Sat, 8:00 AM-11:30 AM

Selective benefit of adjuvant chemoradiation in resectable pancreatic cancer. *First Author: Jesse P Wright, Division of Surgical Oncology, Department of Surgery, Vanderbilt University Medical Center, Nasvhille, TN*

Background: Although level 1 data supports the use of adjuvant chemotherapy (ACT) in resected pancreatic adenocarcinoma (PDAC), the role of adjuvant chemoradiation (ACRT) remains controversial. The objective of this study is to investigate the impact of adding ACRT to ACT on overall survival (OS), based on lymph node (LN) and margin status. **Methods:** Resected AJCC Stage I and II PDAC patients from 2004-2013 identified within the National Cancer Database were classified into groups based on treatment: surgery alone (SX), ACT alone, ACT+ACRT, and ACRT only. Kaplan-Meier analyses were performed to determine median OS. Multivariable (MV) Cox regression models with interactions of treatment with LN and margin status were constructed to examine the independent effects of ACT and ACT+ACRT in these subgroups. **Results:** Of 31,348 patients, 30% were treated with SX, 30% with ACT, 38% with ACT+ACRT, and 2% with ACRT alone. Median OS (mos.) for ACT (22.5, 95% CI 21.9-23.1) and ACT+ACRT (23.7, 23.3-24.2) were significantly longer than SX (14, 13.4-14.5) or ACRT (11.2, 9.8-12.9). MV analysis confirmed a significant OS benefit of both ACT and ACT+ACRT controlling for patient and tumor related factors. ACRT+ACT was associated with improved OS compared to ACT in patients with positive margins and/or LN. Those with negative margins and LN did not benefit from the additional use of ACRT (Table). **Conclusions:** This large hospital-based study demonstrates that ACT and ACRT are associated with improved OS when compared to SX. The addition of ACRT to ACT, however, was only beneficial in high-risk patients with positive margins and/or LN. ACT+ACRT in patients with both margin and LN negative disease may not be warranted. Future clinical trials should stratify patients based on LN and margin status in order to determine which patients are most likely to benefit from the use of ACRT.

MV cox proportional hazard model: HR and 95% CI.

	ACT	SX	ACRT	ACT+ACRT
LN -, MARGIN -	Ref	1.44 (1.33 – 1.55)	1.45 (1.10 – 1.91)	1.00 (0.93 – 1.08)

(*Significant survival benefit)

4123 Poster Session (Board #115), Sat, 8:00 AM-11:30 AM

Effect of inflammatory and nutritional (IN) status on induction chemotherapy (CT) followed by chemoradiotherapy (CRT) for locally advanced pancreatic cancer (LAPC): An exploratory subgroup analysis of JCOG1106. *First Author: Nobumasa Mizuno, Department of Gastroenterology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: JCOG1106 is a randomized selection phase 2 trial to evaluate the efficacy and safety of CRT (S-1 concurrent RT) with (Arm B) or without (Arm A) induction CT of gemcitabine (GEM) for LAPC. In the final analysis, we selected Arm A as a promising regimen due to a poorer 2-year overall survival (OS) of Arm B, in spite of a favorable 1-year OS with crossing of the survival curves around 1-year (Ioka, ESMO2016). Therefore, this study aimed to explore subgroups benefit more from either treatment. IN statuses defined by such as serum C-reactive protein (CRP) and serum albumin (Alb) are recognized as prognostic and predictive factors in patients (pts) with various cancers receiving CT or CRT. We hypothesized that IN status may modify the effect of induction CT. **Methods:** Subjects were all eligible pts who were enrolled in JCOG1106 (n = 51/49 in Arm A/B). Glasgow Prognostic Score (GPS) was classified by baseline CRP and Alb. Pts with a CRP $\leq$ 10 mg/L and Alb $\geq$ 35 g/L were allocated to GPS 0, with a CRP $>$ 10 mg/L or Alb $<$ 35 g/L to GPS 1, and with a CRP $>$ 10 mg/L and Alb $<$ 35 g/L to GPS 2. This exploratory subgroup analysis was performed by Cox regression analysis to investigate the impact of IN status at baseline on OS. Less than 0.1 of P-value for interaction was regarded as significant. **Results:** GPS, CRP and Alb showed significant treatment interactions in terms of OS. HRs of Arm B to Arm A were 1.35 (0.82–2.23) and 0.59 (0.24–1.50) in the GPS 0 (n = 44/34 in Arm A/B) and GPS 1/2 group (n = 7/15) (*P*-interaction = 0.06). HRs were 2.57 (1.36–4.86) and 0.70 (0.37–1.32) in the low CRP group ($\leq$ 1.35 mg/L, n = 25/25) and high CRP ($>$ 1.35 mg/L, n = 26/24) (*P*= 0.01). HRs were 1.62 (0.77–3.40), 2.70 (1.17–6.23) and 0.52 (0.24–1.13) in the 1st ($\leq$ 0.7 mg/L, n = 16/16), 2nd ($>$ 0.7, $\leq$ 3.0 mg/L, n = 20/16), and 3rd tertiary CRP group ($>$ 3.0 mg/L, n = 15/17) (*P*= 0.01). HRs were 2.29 (1.11–4.69) and 0.89 (0.51–1.54) in the high Alb group ($>$ 40 g/L, n = 23/17) and low Alb ($\leq$ 40 g/L, n = 28/32) (*P*= 0.04). Arm B showed better survival in subgroups of GPS 1/2, higher CRP or lower Alb compared to Arm A. **Conclusions:** Pts with poor IN status may have treatment benefit of induction CT followed by CRT for LAPC. Clinical trial information: UMIN000006811.

4124 Poster Session (Board #116), Sat, 8:00 AM-11:30 AM

Molecular profiling of advanced pancreatic cancer (PC) patients from a phase I/II study using circulating tumor DNA. *First Author: Daniel V.T. Catenacci, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: PC has a poor prognosis with a 5-year survival of 9%. Targeted therapies have yet to demonstrate improved outcomes in this disease. Circulating tumour DNA (ctDNA) may be used as a non-invasive method for the detection and quantification of genomic abnormalities. We performed a retrospective-prospective study to assess molecular alterations in the ctDNA of advanced PC patients. **Methods:** Plasma samples were banked from patients enrolled in the previously reported Phase Ib/II trial of gemcitabine with placebo or vismodegib (NCT01064622; Catenacci et al JCO 2015). Eligible patients had unresectable PC and no prior therapy for metastatic disease. Patient samples ($<$ 3ml) collected pre-treatment and at regular intervals and stored for ~6-8 years were analyzed using InVision (enhanced tagged-amplicon sequencing) for "hotspot" regions of 34 genes, including *KRAS* (exons 2 and 3), and select full gene coverage. **Results:** Of 113 patients enrolled in the trial, a cohort of 72 patients were included in this study. Baseline plasma ctDNA profiling detected any genomic event in 88% of patients (SNV/indels found at range of 0.07%-23% allele fraction (AF) with 20% detected at $<$ 0.5% AF). Patients had between 1-5 mutations (median, 2): *KRAS* mutations were detected in 80% of patients tested, of which 86% had concurrent *KRAS/TP53* mutation(s) and 16% with concurrent *KRAS/TP53/CDK2NA*. Of note, 2 cases presented with *IDH1* point mutations (R132C, R132H). An *ERBB2* amplification and a *FGFR2* amplification were detected in 2 individuals. An update on the analyses will include serial ctDNA testing during treatment and correlation with outcomes. **Conclusions:** ctDNA analysis of this cohort of banked PC plasma samples described the landscape of genomic aberrations at baseline and over time, including rare but potentially important actionable events including *ERBB2* and *FGFR2* amplifications and *IDH1* mutation. We demonstrate a sensitive method for re-analysing trial outcomes, despite limiting plasma volume and time lapse since samples were collected.

4125 Poster Session (Board #117), Sat, 8:00 AM-11:30 AM

Preliminary safety data from a randomized multicenter phase Ib/II study of neoadjuvant chemoradiation therapy (CRT) alone or in combination with pembrolizumab in patients with resectable or borderline resectable pancreatic cancer. *First Author: Matthew H. G. Katz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pancreatic cancer (PC) is a challenging target for immunotherapy.Tumor-infiltrating lymphocytes (TILs) do not reach the PC cells in significant numbers due to the presence of stroma and a suppressive microenvironment. Neoadjuvant chemoradiation (CRT) can increase the presence of TILs in the PC microenvironment. We hypothesized that combination of CRT and pembrolizumab can lead to further increase in TILs and their activation. **Methods:** Patients with resectable or borderline resectable PC have been randomized 2:1 to the investigational treatment (Arm A) to receive pembrolizumab 200mg IV every 3 weeks on days 1, 22, and 43 during concurrent CRT with capecitabine (825 mg/m2 orally twice daily, Monday-Friday, on days of radiation only) and radiation (50.4 Gy in 28 fractions over 28 days) or Arm B to receive only concurrent CRT with capecitabine. Restaging CT scan or MRI is performed at 4-6 weeks after completion of neoadjuvant treatment, and patients with resectable disease will undergo surgical resection. Here we report the preliminary safety data based on 22 enrolled patients. **Results:** As of February 3-2017,22 patients have been enrolled (14 Arm A and 8 Arm B). 50% of the patients had resectable disease (7 arm A; 4 arm B) and the other 50% had borderline resectable disease (7 Arm A; 4 arm B). Post-neoadjuvant therapy, 6 patients had unresectable disease (3 on each arm), and 14 patients underwent surgery (10 arm A and 4 arm B). There were 7 grade 3 treatment-related toxicities in Arm A (5 patients): 2 grade 3 diarrhea attributed to CRT; 4 grade 3 lymphopenias attributed to pembrolizumab, CRT or the combination; and one patient had elevated alkaline phosphatase probably related to the combination that met the definition of DLT and resolved after holding the treatment and receiving steroids. There was only one grade 3 toxicity on Arm B: lymphopenia attributed to CRT. No grade 4 toxicities have been reported on either arm. There were no major surgical complications reported within 30 days post-surgery. **Conclusions:** The combination of CRT and pembrolizuamb is safe based on the presented data. Clinical trial information: NCT02305186.

4126 Poster Session (Board #118), Sat, 8:00 AM-11:30 AM

Initiation and shift of antidiabetic therapy and pancreatic cancer. *First Author: Philippe Autier, University of Strathclyde Institute for Global Public Health at iPRI, Ecully, France*

Background: Concerns have been raised on the risk of pancreatic cancer associated with specific anti-diabetic therapies. We have examined the risk of pancreatic cancer among patients with diabetes prescribed with an oral anti-diabetic drug (OAD) or an incretin drug (DPP4i and GLP-1 RA) or insulin. **Methods:** The public health insurance databases of Belgium and of Lombardy Region, Italy include nearly 100% of the population living in these countries. We created within these databases two cohorts that included adult patients who were first prescribed an incretin drug or another noninsulin antidiabetic drug (NIAD) during 01/07/2008-31/12/2013 in Belgium and during 01/01/2008-31/12/2012 in Lombardy Region. The risk of pancreatic cancer after prescription of an anti-diabetic drug was evaluated using multivariate adjusted Cox models including time-dependent variables. Adjusted hazard ratios (aHRs) from Belgium and Italy were pooled using fixed effects meta-analyses. **Results:** Results in both cohorts were similar. Among those patients prescribed an OAD, 45% of pancreatic cancers occurred within the 6 months following first prescription, 20% in months 7 to 12 after first prescription and proportions decreased progressively during follow-up. The aHR of pancreatic cancer among subjects prescribed an incretin compared to an OAD was 2.14 [95% CI, 1.71 to 2.67]. The aHR decreased from 3.35 [CI, 2.32 to 4.84] in the first 3 months after first incretin prescription, 2.12 [CI, 1.22 to 3.66] in months 3 to 5.9, 1.95 [CI, 1.20 to 3.16] in months 6 to 11.9, to 1.69 [CI, 1.12 to 2.55] after 12 months. The risk of pancreatic cancer among subjects who were subsequently prescribed insulin was 6.89 [CI, 6.05 to 7.85]. The time from OAD prescription to a shift to incretins or to insulin was significantly lower in patients who were subsequently diagnosed with a pancreatic cancer. **Conclusions:** The increased risk of pancreatic cancer associated with anti-diabetic therapies could be the consequence of an occult pancreatic cancer that provokes diabetes (reverse causation bias). The search for an occult pancreatic cancer in subjects with newly diagnosed diabetes or patients shifting to more potent anti-diabetic therapy may lead to earlier detection of this cancer.

4127 Poster Session (Board #119), Sat, 8:00 AM-11:30 AM

Subgroup analysis by prior lines of metastatic therapy (mtx) in NAPOLI-1: A global, randomized phase 3 study of liposomal irinotecan (nal-IRI) ± 5-fluorouracil and leucovorin (5-FU/LV), vs. 5-FU/LV in patients (pts) with metastatic pancreatic ductal adenocarcinoma (mPDAC) who have progressed following gemcitabine-based therapy. *First Author: Teresa Mercade Macarulla, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: In the NAPOLI-1 study, nal-IRI+5-FU/LV significantly increased median OS vs. 5-FU/LV control (6.1 vs. 4.2 mo; unstratified HR = 0.67 [0.49–0.92]; p = .012). This is a subgroup analysis by prior lines of mtx. **Methods:** Study methodology has been published (Wang-Gillam; Lancet 2016). This exploratory subgroup analysis compares outcomes in pts with 0–1 vs. ≥2 prior mtx lines, based on primary survival analysis data (cut-off February 2014) of the ITT population. **Results:** OS, PFS and CA19-9 response rates in pts with 0–1 (65.8% of pts) or ≥2 (34.2%) prior mtx lines are shown (see Table). Median OS for nal-IRI+5-FU/LV improved vs. 5-FU/LV by 2.1 mo to 6.2 mo (HR = 0.66; p = .03) in pts with 0–1 prior mtx lines and by 1.1 mo to 5.4 mo (HR = 0.68; p = .18) in pts with ≥2 prior mtx lines. The safety profile was similar between subgroups with nal-IRI+5-FU/LV (≥grade 3 drug-related AEs: 43 [55%] with 0–1 and 20 [51%] with ≥2 prior mtx lines). **Conclusions:** This post-hoc subgroup analysis shows significant increases for nal-IRI+5-FU/LV over 5-FU/LV in OS, PFS and CA19-9 response in pts with 0–1 prior mtx lines. Median OS benefit was less prominent in later lines, but conclusions are restricted by limited pt numbers. Clinical trial information: NCT01494506.

	0–1 prior mtx lines		
	nal-IRI+5-FU/LV (n = 77 [65.8%])	5-FU/LV (n = 82 [68.9%])	Unstratified HR (95%CI); p-value
Median OS, mo (95%CI)	6.24 (4.70–8.97)	4.17 (3.35–5.82)	0.66 (0.45–0.96); p = .03
Median PFS, mo (95%CI)	2.89 (2.40–4.34)	1.46 (1.38–1.87)	0.51 (0.35–0.73); p < .001
CA19-9 response rates, n/N (%)	21/68 (30.9)	6/56 (10.7)	p < .01
	≥2 prior mtx lines		
	nal-IRI+5-FU/LV (n = 40 [34.2%])	5-FU/LV (n = 37 [31.1%])	
Median OS, mo (95%CI)	5.42 (4.44–9.30)	4.34 (2.63–6.37)	0.68 (0.38–1.20); p = .18
Median PFS, mo (95%CI)	4.01 (1.41–4.53)	1.56 (1.35–2.66)	0.65 (0.37–1.14); p = .13
CA19-9 response rates, n/N (%)	7/29 (24.1)	1/25 (4.0)	p = .06

4128 Poster Session (Board #120), Sat, 8:00 AM-11:30 AM

Genomic profiling of circulating tumor DNA (ctDNA) from patients (pts) with pancreatic ductal adenocarcinoma (PDA). *First Author: Nathan Bahary, University of Pittsburgh Medical Center Cancer Center Pavilion, Pittsburgh, PA*

Background: PDA is a lethal and increasingly common malignancy and tissue samples for genomic characterization may be limited. As PDA has a high and consistent frequency of *KRAS*, *p53* and *CDKN2A* mutations it serves as a robust indication to test the utility of ctDNA in accurately characterizing genomic alterations (GA). A prior study suggested significant differences between ctDNA and tissue base profiling but assays were not conducted on the same platform (PMID27833075). We undertook this study to see whether ctDNA could recapitulate the known genomic hallmarks of tumor based profiling. **Methods:** Hybrid-capture based genomic profiling of 62 genes (FoundationACT) was performed on ctDNA from 78 pts with advanced PDA with samples received in the course of clinical care. The fraction of ctDNA in the blood was estimated using the maximum somatic allele frequency (MSAF) for each sample. Frequencies of alterations in these common drivers were then compared to those seen in tumors of pts who underwent comprehensive genomic profiling (CGP) tissue testing performed on the same core platform, FoundationOne, and The Cancer Genome Atlas (TCGA). **Results:** Pt characteristics: Median age 65 (range, 47-88); Female (33) /Male (45). FoundationACT results show that 53/78 (68%) cases had MSAF >0 (56%-78%%, 95% CI). ≥1 GA was reported in 81% of the cases with evidence of ctDNA in the blood. The most common GA detected by FoundationACT (based on cases with evidence of ctDNA in blood) vs FoundationOne were in *KRAS* (59% vs 89%, p< 0.0001), *TP53* (69% vs.74%, p=0.19), and *CDKN2A* (14% vs.45%). Other detected clinically relevant GA detected by FoundationACT included: *BRCA1, ERBB2, NF1, PIK3CA*. **Conclusions:** This study demonstrates significant differences between the established driver oncogenic alterations for PDA, as assessed by ct DNA and tissue based genomic profiling which are unlikely to be explained by differences in assay, but rather novel cancer biology. At present use of ctDNA genomic profiling in PDA should not routinely replace tissue based genomic characterization.

GENE	F-ACT- Clinical cases (n=78) %	FACT-MSAF > 0 (n=53)%	F1(FoundationCORE) (n>2000) %	TCGA (n=146) %
TP53	47	69	74	70
KRAS	40	59	89	91
CDKN2A	10	14	45	46

4129 Poster Session (Board #121), Sat, 8:00 AM-11:30 AM

Characteristics and outcomes of resected pancreatic cystadenocarcinoma: 1,205 cases from the National Cancer Data Base. *First Author: Jiping Wang, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: Cystadenocarcinoma (CAC) of the pancreas is a rare pancreatic and therefore there is limited data on the characteristics, treatment and prognosis of this disease. **Methods:** Patients who underwent resection for CAC (n = 1,205) between 2003 and 2012 were identified from National Cancer Data Base. The clinicopathological characteristics and treatment outcomes were compared to patients with resected ductal adenocarcinoma (DAC) (n = 15,696). Cox-proportional hazard model was used to adjust for potential prognostic factors. A nomogram was constructed and validated to predict the outcomes of patients with CAC by using multiple variable Cox-proportional model and receiver operating characteristics curve methods. **Results:** Compared with resected DAC, patients with resected CAC are diagnosed at a younger age (58.7 vs. 61.2, p < 0.0001); female predominant (63.7% vs. 48.8%, p < 0.0001); more often Black (15.0% vs. 9.3%, p < 0.0001);had larger tumor (0-2, 2-4 and > 4cm:17.5%, 24.3%, 53.5% vs. 16.8%, 48.3% , 32.1%, respectively, p < 0.0001); have less total number of examined lymph nodes (10.6 vs. 14.5, p < 0.0001) and fewer positive lymph nodes(0.6 vs. 2.3, respectively). CAC patients were less likely to receive chemotherapy (28.8% vs. 62.5%, p < 0.0001) and radiation therapy (16.4% vs. 36.9%, p < 0.0001). CAC patients had significantly better overall survival than those with DAC (5 year survival: 55.6% vs. 17.3%, p < 0.0001). The survival advantage was primarily seen in patients with early stage disease (5 year survival: 70.9% vs. 36.9% in stage I patients, p < 0.0001, and 32.7% vs. 14.5% in stage II patients, p < 0.0001 respectively) and persisted after adjusting the known prognostic factors including age, AJCC staging, Charlson-Deyo score, type of surgery, chemotherapy, tumor size, and lymph node ratio (adjusted hazard ratio: 0.43, 95% confidence interval: 0.39-0.48, p < 0.0001). **Conclusions:** Patients with CAC had significantly better survival than those with pancreatic DAC even after controlling for known prognostic factors. The proposed nomogram could accurately predict patients' outcome and may be used as a tool for clinical decision making.

4130 Poster Session (Board #122), Sat, 8:00 AM-11:30 AM

***BRCA1/2* reversion mutations in pancreatobiliary cancer identified from patient biopsies.** *First Author: Laurie M. Gay, Foudation Medicine, Inc., Cambridge, MA*

Background: Germline genomic alterations (GA) in *BRCA1* or *BRCA2* (*BRCA*) are associated with increased risk of pancreatic cancer. Tumors with *BRCA* GA may be more sensitive to platinum (Pt) therapies or PARP inhibitors (PARPi). However, secondary reversion mutations (revGA) that may restore *BRCA* function and underlie reduced sensitivity to Pt compounds or PARPi can arise. **Methods:** DNA extracted from FFPE tumor tissue obtained during routine clinical care for 7077 patients with predominantly relapsed, refractory or metastatic pancreatobiliary carcinoma was analyzed using comprehensive genomic profiling (CGP) for all classes of GA: base substitutions, indels, rearrangements, and copy number changes. RevGA were any GA that could restore the reading frame if in cis with a nonsense or frameshift (fs) GA. Tumor tissue only was used to predict germline (g*BRCA*) or somatic status by an algorithm with a call rate of 85% and > 95% accuracy. **Results:** 417/7077 (5.9% ± 0.5%) tumors had ≥1 deleterious *BRCA* GA; 205 (2.9% ± 0.4%) had a predicted g*BRCA* GA. Significantly fewer women had deleterious *BRCA* GA (182/417; 43.6%)(p = 0.02); g*BRCA* GA frequency did not differ significantly (96/205; 46.8%)(p = NS). Overall, 49.1% of patients were women. 12 samples harbored potential revGA: pancreatic ductal adenocarcinoma (ACa) (7) or acinar cell carcinoma (Ca) (2), gallbladder ACa (2), and pancreatobiliary Ca NOS (1). 10/12 samples with revGA were metastases. Potential revGA were of 3 types: overlapping indel (7), compensatory fs (4), and missense (2). One case harbored 2 indels, both with potential to excise a fs GA. Apparent g*BRCA* were present in 7 cases, only somatic *BRCA* GA in 3 cases, and g*BRCA*/somatic status was ambiguous in 2 cases. For 2 patients, testing of multiple samples reveals the acquisition of revGA over time. KRAS mutation frequencies were similar for all samples (57.1%), *BRCA*-mutated samples (58.8%) and revGA-positive samples (58.3%). Clinical histories for patients with revGA will be presented. **Conclusions:** CGP of 7077 pancreatobiliary carcinomas reveals 5.9% had ≥1 deleterious *BRCA* GA, nearly 50% of which were g*BRCA*. Although rare, revGA can be acquired over time and potentially compensatory missense, fs and indel mutations were observed.

TPS4131 Poster Session (Board #123a), Sat, 8:00 AM-11:30 AM

CheckMate 577: A randomized, double-blind, phase 3 study of adjuvant nivolumab (nivo) or placebo in pts with resected esophageal (E) or gastroesophageal junction (GEJ) cancer. *First Author: Ronan Joseph Kelly, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Expression of the PD-1 ligands PD-L1 and PD-L2 has been reported in ≈ 40% of pts with E/GEJ cancer and is associated with a poor prognosis. In a phase 3 trial, the PD-1 inhibitor nivo demonstrated an OS benefit vs placebo (HR, 0.63; $P < 0.0001$), resulting in a 37% reduction in the risk of death and double the OS rate at 12 mo (27% vs 11%) in pts with advanced gastric (G)/GEJ cancer refractory to ≥ 2 lines of chemotherapy (Kang YK, et al. *J Clin Oncol.* 2017;35 (suppl 4S) [abstract 2]). In this study, nivo was well tolerated, with a safety profile comparable with that of the placebo arm. These results indicate that nivo could be a new standard of care (SOC) for pts with heavily pretreated advanced G/GEJ cancer and provide a strong rationale to explore nivo in earlier lines of treatment for G/E/GEJ cancer. Currently, no effective adjuvant SOC is available after chemoradiotherapy (CRT) followed by resection for pts with E/GEJ cancer. This multinational, double-blind, phase 3 trial will evaluate nivo as an adjuvant therapy for pts with resected E/GEJ cancer (CheckMate 577; NCT02743494). **Methods:** In this study, an estimated 760 pts aged ≥ 18 years with stage II/III E/GEJ cancer are randomized to receive nivo or placebo. Prior to randomization, pts must have completed preoperative CRT followed by surgery and been diagnosed with residual pathologic disease after being surgically rendered free of disease with negative margins following complete resection. Pts with stage 4 resectable disease, cervical esophageal cancer, or those who have not received concurrent CRT prior to surgery are not eligible for study enrollment. Primary endpoints are OS and disease-free survival. Other key endpoints include the OS rate at 1, 2, and 3 years and safety. Clinical trial information: NCT02743494.

TPS4132 Poster Session (Board #123b), Sat, 8:00 AM-11:30 AM

CheckMate 649: A randomized, multicenter, open-label, phase 3 study of nivolumab (nivo) + ipilimumab (ipi) or nivo + chemotherapy (CTX) vs CTX alone in pts with previously untreated advanced (adv) gastric (G) or gastroesophageal junction (GEJ) cancer. *First Author: Markus H. Moehler, University Medical Center Mainz, Mainz, Germany*

Background: Pts with adv G/GEJ cancer have an OS of ≈ 1 y, indicating an unmet medical need for new first-line treatments (Tx). Expression of the PD-1 ligands PD-L1/PD-L2 is observed in up to 40% of pts with G/GEJ cancer and is associated with poor prognosis. In a phase 3 study of the PD-1 inhibitor nivo vs placebo in pts with adv CTX-refractory (CTX-R; ≥ 2 lines) G/GEJ cancer, nivo reduced the risk of death by 37% (HR, 0.63; $P < 0.0001$) and increased the OS rate at 12 mo (27% vs 11%; Kang YK, et al. *J Clin Oncol.* 2017;35 (suppl 4S) [abstract 2]). In a phase 1/2 study in pts with CTX-R G/GEJ/esophageal cancer (79% ≥ 2 prior Tx lines), nivo 1 mg/kg + ipi 3 mg/kg had a manageable safety profile and resulted in 26% ORR (44% ORR in pts with PD-L1$^+$ tumors), a median OS of 6.9 mo, and a 34% OS rate at 12 mo (Janjigian Y, et al. ASCO, 2016 [abstract 4010]). In the phase 1 CheckMate 012 trial, nivo + CTX had clinical activity and manageable safety in pts with NSCLC (Rizvi NA, et al. *J Clin Oncol.* 2016;34:2969-2979). These positive results support investigation of nivo, nivo + ipi, and nivo + CTX in earlier lines of Tx for G/GEJ cancer. The open-label, phase 3 CheckMate 649 trial will evaluate nivo + ipi and nivo + CTX vs CTX alone as first-line Tx for pts with adv G/GEJ cancer (NCT02872116). **Methods:** 1266 pts aged ≥ 18 y with untreated, inoperable adv/metastatic G/GEJ cancer (histologically confirmed adenocarcinoma) regardless of PD-L1 status will be randomized to receive either nivo + ipi, nivo + CTX (capecitabine/oxaliplatin [XELOX] or fluorouracil/leucovorin/oxaliplatin [FOLFOX]), or investigator choice of XELOX or FOLFOX. Tumor tissue for determination of PD-L1 status (Dako assay) must be provided from ≤ 6 mo before study Tx. No prior systemic Tx, including HER2 inhibitors, are allowed. Pts with known HER2$^+$ status, suspected autoimmune disease, grade > 1 peripheral neuropathy, or active infection are excluded. Primary endpoint is OS in pts with PD-L1$^+$ (≥ 1%) tumors. Other endpoints include OS in all pts; PFS and time to symptom deterioration in all pts and in pts with PD-L1$^+$ tumors; and safety. Clinical trial information: NCT02872116.

TPS4133 Poster Session (Board #124a), Sat, 8:00 AM-11:30 AM

Perioperative trastuzumab and pertuzumab in combination with FLOT versus FLOT alone for HER2 positive resectable esophagogastric adenocarcinoma: Petrarca—A phase II trial of the German AIO. *First Author: Ralf Hofheinz, University Medical Center Mannheim, Mannheim, Germany*

Background: Neoadjuvant or perioperative chemotherapy has become a standard of care for locally advanced, resectable gastric cancer and adenocarcinoma of the GEJ. However, patient's outcome is still unsatisfactory and 5-year survival, even in prospective trials, has been below 40%. Targeting HER2 with Trastuzumab and Pertuzumab prolonged survival in patients with HER2-positive advanced breast cancer as did Trastuzumab in patients with HER2-positive advanced gastric cancer. This provides a rationale for the evaluation of anti-HER2 treatment for resectable patients. **Methods:** This is a prospective, multicenter, randomized, investigator initiated phase II trial. Patients with HER2-positive locally advanced adenocarcinoma of the stomach and GEJ (i.e. ≥cT2 any N or any T N-positive) with exclusion of distant metastases are enrolled. HER2 status is centrally assessed. Patients are randomized 1:1 to 4 pre-operative 2-week cycles (8 weeks) of FLOT (Docetaxel 50 mg/m²; Oxaliplatin 85 mg/m²; Leucovorin 200 mg/m²; 5-FU 2600 mg/m²) followed by surgery and 4 additional cycles of FLOT (arm A); or the same therapy in combination with Trastuzumab 8/6 mg/kg and Pertuzumab 840 mg every 3 weeks pre- and postop, followed by a total of 9 additional cycles of Trastuzumab/Pertuzumab monotherapy (arm B). Primary endpoint of the phase II part (n = 100) of the trial is to show numerical improvement of the rate of pathological complete remission to approx. 25% with antibodies compared to approx. 16% with FLOT alone as assessed by a centralized pathology. Main secondary endpoints are safety and tolerability. Once results from phase II become available, study transition into phase III will be evaluated based on de facto results and current medical standards. Recruitment has already started; by February 2017 a total of 19 patients have been randomized. EudraCT: 2014-002695-86 Clinical trial information: NCT02581462.

TPS4134 Poster Session (Board #124b), Sat, 8:00 AM-11:30 AM

Phase III trial to evaluate the efficacy of neoadjuvant chemotherapy with S-1 plus oxaliplatin followed by D2 gastrectomy with adjuvant S-1 in locally advanced gastric cancer: Japan Clinical Oncology Group study JCOG1509 (NAGISA trial). *First Author: Masanori Tokunaga, Division of Gastric Surgery, Shizuoka Cancer Center, Nagaizumi, Japan*

Background: In Japan, while post-operative adjuvant chemotherapy with S-1 or capecitabine plus oxaliplatin is standard care for pStage II/III gastric cancer after curative resection with D2 lymph node dissection, the clinical outcomes of pStage III patients are not satisfactory. In Europe, neoadjuvant chemotherapy (NAC) followed by gastrectomy is standard. The Japan Clinical Oncology Group (JCOG) has conducted several phase II trials of NAC, and deemed NAC as one of the most promising treatment strategies for gastric cancer with lymph node metastasis (Stage III). However, no established criteria exists for diagnosis of lymph node metastasis. JCOG1302A which was a cross-sectional study evaluating the accuracy of preoperative staging by imaging, showed that cT3-4N1-3M0 (positive lymph node was defined as that with a long axis diameter ≥ 10 mm or short axis diameter ≥ 8 mm) included just 6.5% overdiagnosed pStage I patients and accounted for 52.6% of all pStage III patients. **Methods:** JCOG1509 (UMIN000024065) is designed as a randomized phase III study to confirm the survival superiority of addition of NAC to standard treatment for patients with cT3-4N1-3M0 gastric cancer. In the standard arm, a gastrectomy with D2 lymphadenectomy is performed followed by adjuvant chemotherapy with oral S-1 for 1 year. In the experimental arm, combination of an infusion of oxaliplatin (130 mg/m^2/day, day 1) and oral S-1 (80 mg/m^2/day, days 1–14) is repeated every 3 weeks for 3 courses before gastrectomy, followed by surgery and adjuvant chemotherapy with S-1 for 1 year. The primary endpoint is overall survival. The planned sample size is 470 in total with a 1-sided alpha of 5%, a power of 80%, expecting a 10% increase in the 5-year OS (60% vs 70%). Patients will be enrolled from 58 Japanese institutions over 3.5 years. The study was activated in September 2016 and, as of January 2017, 18 patients were enrolled for the study. Clinical trial information: UMIN000024065.

TPS4135 Poster Session (Board #125a), Sat, 8:00 AM-11:30 AM

Impact of early FDG-PET directed intervention on preoperative therapy for locally advanced gastric cancer: A Cooperative Group random assignment phase II study (Alliance A021302) Impac. *First Author: Manish A. Shah, New York-Presbyterian Hospital, New York, NY*

Background: Gastric cancer is a prevalent and morbid illness for which new treatment strategies are needed. Peri-operative therapy is a standard approach that is associated with only a 15% improvement in overall survival. Early FDG-PET scanning, performed prior to cycle 2, can distinguish patients (pts) responding to chemotherapy from those who are not. FDG-PET non-responding pts have poorer survival. This study addresses the question of salvage therapy in pts who are PET non-responders. Specifically, does salvage chemotherapy with docetaxel /irinotecan improve pt survival in FDG-PET-nonresponding pts with locally advanced gastric cancer. **Methods:** This is a multicenter, cooperative group, NCI supported, randomized phase II study of salvage chemotherapy + surgery versus surgery and post-operative chemoradiotherapy in pts who are FDG-PET non-responders (defined as a decrease in SUV_{max} of the primary tumor of less than 35%). A total of 176 pts with locally advanced, resectable gastric cancer who were FDG-PET non-responders to cycle 1 of platinum/capecitabine based chemotherapy will be randomized in a 1:1 manner to receive either (Arm A) surgery followed by fluoropyrimidine-sensitized radiotherapy (4500 cGy), or (Arm B) salvage chemotherapy with docetaxel / irinotecan (DI) for 2 cycles followed by standard resection and 3 cycles DI post-operatively. DI is administered as D 30 mg/m2, I 50 mg/m2 given on D1, D8 of a 21 day cycle. 416 pts will be screened to yield 162 non-responders (81 FDG-PET non-responders per treatment group). With expected 120 events, the study will have 80% power to detect a hazard ratio of 0.625 for improved survival at the one-sided significant level of 0.15. Pts will be required to provide tissue at the time of resection, as well as whole blood prior to resection for correlative studies associated with platinum sensitivity, FDG avidity, and prognostic markers. This study is available through all cooperative groups (SWOG, ACRIN/ECOG, Alliance, and NRG) and the National Clinical Trials Network. Enrollment began in November 2015. Support: U10CA180821, U10CA180882; Clinical Trial Information: NCT02485834.

TPS4136 Poster Session (Board #125b), Sat, 8:00 AM-11:30 AM

Integrate II: A randomised phase 3 double-blind placebo-controlled study of regorafenib in refractory advanced gastro-oesophageal cancer (AGOC)—An international study organized by the Australasian Gastrointestinal Trials Group (AGITG). *First Author: Katrin Marie Sjoquist, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, Australia*

Background: AGOC has a poor prognosis with no established standard treatment following failure of chemotherapy (CT). Regorafenib (BAY 73-4506)(REG) is an oral multi-kinase inhibitor targeting kinases involved in angiogenesis (VEGFR1-3, TIE-2), tumor microenvironment (PDGFR-β, FGFR), and oncogenesis (RAF, RET and KIT). INTEGRATE (phase 2) demonstrated REG was highly effective in prolonging PFS across a range of AGOC pts, with a positive OS trend. Regional differences were found in magnitude of effect, but REG was effective in all regions/subgroups. The phase 3 INTEGRATE II will explore whether REG is effective in prolonging survival in patients overall, and in the Asian sub-population. **Methods:** International (Australia/New Zealand (NHMRC CTC); Canada (CCTG), Korea, Japan, Taiwan, USA (ACCRU)) randomised phase III, double-blind, placebo-controlled trial with 2:1 (REG:placebo)(PBO) randomisation and stratification by: Location of tumour, Geographic region, prior VEGF inhibitors. Eligible patients (histologically confirmed AGOC), with evaluable metastatic or locally advanced disease refractory to, or relapsed following second line CT, will receive best supportive care plus 160mg REG or matched placebo orally on days 1-21 of each 28 day cycle until disease progression or prohibitive adverse events. Primary endpoint is OS. Secondary endpoints: PFS, response rate, quality of life, safety, identification of prognostic/predictive biomarkers for study endpoints, and REG PK across geographical regions. 350 patients (50% from Asia) randomized in a 2:1 ratio will provide 90% power to detect a hazard ratio (HR) for OS of 0.67 with a 2-sided α of 0.05 assuming PBO median survival is 4.5 mos. The sample size accommodates 2 interim analyses undertaken at 1/3 and 2/3 of required events. As of January 2017, 12 of 28 planned ANZ sites are open, with 4 patients enrolled. Regulatory approval has been received for 12 Canadian sites, and 12 Korean sites. Korean recruitment is expected to commence in February 2017. Regulatory submissions are pending in Taiwan, Japan, and the USA. Clinical trial information: NCT02773524.

TPS4137 Poster Session (Board #126a), Sat, 8:00 AM-11:30 AM

FRACTION (Fast Real-time Assessment of Combination Therapies in Immuno-Oncology)-gastric cancer (GC): A randomized, open-label, adaptive, phase 2 study of nivolumab in combination with other immuno-oncology (IO) agents in patients with advanced GC. *First Author: Praveen Aanur, Bristol-Myers Squibb, Princeton, NJ*

Background: Nivolumab, a fully human IgG4 mAb that targets programmed death-1, alone and in combination with ipilimumab, a fully human IgG1 mAb that targets cytotoxic T-lymphocyte antigen 4, has demonstrated encouraging clinical activity in patients with advanced GC. These data support the rationale that nivolumab in combination with other IO agents or targeted therapies may improve treatment outcomes in patients with advanced GC. Given the rapid development of novel IO agents, traditional studies cannot efficiently evaluate all possible IO-IO and IO-targeted therapy combinations. FRACTION is an innovative clinical trial program with a rolling, adaptive platform design that allows for the addition of new combination regimens, as well as withdrawal of ineffective regimens. Here we describe the study concept, key design components, and the first IO treatment combinations of FRACTION-GC, a phase 2, randomized, open-label, adaptive study in advanced GC (NCT02935634). **Methods:** Patients with advanced GC or gastroesophageal junction (GEJ) cancer will be enrolled based on prior IO treatment and randomized to receive nivolumab plus BMS-986016 (fully human IgG4 mAb that targets lymphocyte activation gene 3) or nivolumab plus ipilimumab. Enrollment is continuous and may offer patients consecutive treatment options based on their treatment exposure and response. The primary endpoints are objective response rate, duration of response, and progression-free survival rate at 24 weeks. The secondary endpoint is safety. Comprehensive biomarker analyses will also be performed. New treatment combinations will be added over time to explore their potential benefits and to provide a continuous flow of treatment options for patients whose cancer progresses on existing treatments. In this way, FRACTION-GC is envisioned to accelerate the development of the next generation of IO combinations for patients with metastatic GC and GEJ cancer. Clinical trial information: NCT02935634.

TPS4138 Poster Session (Board #126b), Sat, 8:00 AM-11:30 AM

A prospective, randomized, double-blinded, placebo-controlled, phase III study to evaluate the efficacy and safety of apatinib plus best supportive care (BSC) compared to placebo plus BSC in patients with advanced or metastatic gastric cancer: The ANGEL study. *First Author: Yoon-Koo Kang, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Apatinib is an orally administered, highly selective tyrosine kinase inhibitor of VEGFR-2 that has been studied in many clinical trials, primarily in China, treating various solid tumors. Based on the results of the Chinese Phase 3 study, apatinib was approved in China for the treatment of advanced gastric cancer (GC), but apatinib has yet to be evaluated in a randomized placebo-controlled study in the rest of the world. ANGEL is a multinational, placebo controlled, Phase 3 study investigating the efficacy and safety of apatinib in advanced GC patients in North America, Europe, and Asia Pacific. **Methods:** Main eligibility criteria include patients with advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction for whom at least 2 prior lines of standard chemotherapy had failed, ECOG performance status ≤ 1, and disease progression < 6 months after last chemotherapy treatment. Approximately 459 patients will be randomized in a 2:1 ratio to receive continuous 28-day cycles of apatinib 700 mg or a matched placebo daily with best supportive care until disease progression, intolerable toxicity or withdrawal of consent. Stratification factors include geographic region (Asia vs. North America/Europe), disease measurability, prior ramucirumab treatment, and treatment therapy line (3^{rd} or 4^{th}). Primary endpoint is overall survival (OS) in the intent-to-treat population, and secondary endpoints are progression free survival (PFS), objective response rate (ORR), disease control rate (DCR), quality of life, and safety. The primary analysis of OS will be conducted in intention-to-treat population using a stratified log-rank test at the two-sided alpha = 0.05 level of significance. If the primary analysis of OS is statistically significant, then PFS and ORR will be analyzed. All other secondary efficacy endpoints will be analyzed using two-sided tests at the alpha = 0.05 level of significance. Enrollment opened Feb 2017. Clinical trial information: NCT03042611.

TPS4139 Poster Session (Board #127a), Sat, 8:00 AM-11:30 AM

A phase 3 randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of GS-5745 combined with mFOLFOX6 as first-line treatment in patients with advanced gastric or gastroesophageal junction adenocarcinoma. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: GS-5745 is a monoclonal antibody that inhibits matrix metalloproteinase 9 (MMP9), an extracellular enzyme involved in matrix remodeling, tumor growth, and metastasis. Inhibiting MMP9 blocks paracrine signaling and metastasis and alters the tumor immune microenvironment. GS-5745 (800 mg q 2 weeks) with mFOLFOX6 was examined in a Phase 1b study in 40 patients with gastric and GEJ adenocarcinoma (GS-US-296-0101), and demonstrated encouraging activity without added toxicity (10% CR, median PFS 10.7 mo (Shah et al ASCO GI 2017, a108)). Decreased free MMP9 suggested inhibition of MMP9 enzymatic activity by GS-5745. These data support the hypothesis that GS-5745 treatment inhibits MMP9 activity and that the inhibition may lead to improved clinical outcomes. **Methods:** This phase 3, randomized, double-blind, multicenter study investigates the efficacy and safety of GS-5745 combined with mFOLFOX6 in subjects with untreated gastric and GEJ adenocarcinoma. Total of 430 eligible subjects with advanced gastric and GEJ cancer will be randomized in a 1:1 manner to mFOLFOX6 plus GS-5745 or mFOLFOX6 plus placebo. Stratification factors include ECOG status (0 v 1), geographic region (Latin America v All other countries), and primary tumor site (gastric v GEJ). CT or MRI scans will be performed every 8 weeks to evaluate response to treatment. mFOLFOX6 will be administered on Days 1 and 15 of each 28-day treatment cycle for a total of 6 cycles followed thereafter by leucovorin (LV) and 5-fluorouracil (5-FU) dosing on Days 1 and 15 of each 28-day treatment cycle until disease progression. GS-5745/placebo 800 mg will be infused on Days 1 and Day 15 of each 28 day cycle until disease progression. Primary endpoint is OS, and secondary endpoints include PFS, ORR (RECIST 1.1), and safety. The study is designed to have an 85% power to detect clinically meaningful improvement in overall survival at the one-sided significance level of 0.025. The association of exploratory biomarkers with study drug response will also be evaluated. Enrollment opened Oct. 2015. Clinical trial information: NCT02545504.

TPS4140 Poster Session (Board #127b), Sat, 8:00 AM-11:30 AM

The "RENAISSANCE" Trial: Effect of chemotherapy alone vs. chemotherapy followed by surgical resection on survival and quality of life in patients with limited-metastatic adenocarcinoma of the stomach or esophagogastric junction—A phase III trial of the German AIO/CAO-V/CAOGI. *First Author: Daniel Wilhelm Mueller, Institute of Clinical Cancer Research (IKF) at Krankenhaus Nordwest, UCT-University Cancer Center, Frankfurt, Germany*

Background: Recent data indicates that surgical resection may bring a benefit for select patients with metastatic gastric / esophagogastric junction cancer. However, no data obtained in randomized trials is available up to now. The current RENAISSANCE trial investigates this long-lasting question about the role of surgical intervention in limited-metastatic gastric / esophagogastric junction cancer. **Methods:** This is a prospective, multicenter, randomized, investigator initiated phase III trial. In this study, previously untreated patients with limited metastatic stage (retroperitoneal lymph node metastases only or a maximum of one incurable organ site that is potentially resectable or locally controllable with or without retroperitoneal lymph nodes) will receive 4 cycles of FLOT (docetaxel 50 mg/m^2; oxaliplatin 85 mg/m^2; leucovorin 200 mg/m^2; 5-FU 2,600 mg/m^2), and if Her2+ with trastuzumab. Patients without disease progression after 4 cycles are randomized 1:1 to receive additional chemotherapy cycles or surgical resection of primary and metastases followed by subsequent chemotherapy. 271 patients are to be allocated to the trial, of which at least 176 patients will be randomized. The primary endpoint is overall survival; main secondary endpoints are quality of life parameters as assessed by EORTC-QLQ-C30 questionnaire, progression free survival and surgical morbidity and mortality. Recruitment has already started; currently (Feb 2017) 21 patients have been enrolled. EudraCT: 2014-002665-30. Clinical trial information: NCT02578368.

TPS4141 Poster Session (Board #128a), Sat, 8:00 AM-11:30 AM

A phase II, open-label, randomized study to evaluate the efficacy and safety of GS-5745 combined with nivolumab versus nivolumab alone in subjects with unresectable or recurrent gastric or gastroesophageal junction adenocarcinoma. *First Author: Manish A. Shah, Weill Cornell Medical College, New York-Presbyterian Hospital, New York, NY*

Background: GS-5745 is a monoclonal antibody that inhibits matrix metalloproteinase 9 (MMP9), an extracellular enzyme involved in matrix remodeling, tumor growth, and metastasis. Inhibiting MMP9 is expected to block paracrine signaling and metastasis and to alter the immune microenvironment within the tumor. Results from the ATTRACTION-2 Phase III trial showed the PD-1 inhibitor nivolumab significantly improved overall survival (OS), progression-free survival (PFS), and overall response rate (ORR) in patients with heavily pre-treated advanced gastric or gastroesophageal junction cancer. Preclinical studies indicate that selective inhibition of MMP9 can inhibit immune-suppressive myeloid cell polarization, regulatory T cell generation, desmoplasia, and the destruction of ligands for CXCR3 (a critical chemokine receptor that enables effector T cell trafficking). In combination with a checkpoint inhibitor, CD8+, CD4+ and CD44+ cytotoxic T cells are significantly increased in a checkpoint-refractory model, suggesting that MMP9 inhibition could relieve immune suppression. **Methods:** This phase 2, open-label, randomized study investigates the efficacy and safety of GS-5745 combined with nivolumab versus nivolumab alone in patients with unresectable or recurrent gastric or gastroesophageal adenocarcinoma. 120 patients will be randomized to either GS-5745 800mg IV + nivolumab 3mg/kg IV, or nivolumab alone. Treatment will be administered every 2 weeks and stratified by PD-L1 status. CT will be performed every 8 weeks to evaluate response. The primary endpoint of the study is ORR; secondary endpoints include PFS, OS, and occurrence of adverse events. Key inclusion criteria: metastatic or inoperable adenocarcinoma of the stomach or GEJ which has progressed after $\geq$1 prior systemic therapy, ECOG performance status $\leq$1, RECISTv1.1 measureable disease, archival tissue adequate for PD-L1 evaluation. Exploratory biomarkers correlated with study drug response will also be evaluated. Enrollment opened September 2016. Clinical trial information: NCT02864381.

TPS4142 Poster Session (Board #128b), Sat, 8:00 AM-11:30 AM

ClarIDHy: A phase 3, multicenter, randomized, double-blind study of AG-120 vs placebo in patients with an advanced cholangiocarcinoma with an IDH1 mutation. *First Author: Maeve Aine Lowery, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: Advanced cholangiocarcinoma (CC) is a life-threatening disease for which there are limited therapeutic options. Mutations in isocitrate dehydrogenase 1 (mIDH1) occur in up to 25% of intrahepatic CC cases. mIDH1 lead to epigenetic and genetic changes that promote oncogenesis via production of the oncometabolite, D-2-hydroxyglutarate (2-HG). AG-120 is a first-in-class oral inhibitor of the mIDH1 enzyme, and is being tested in a phase 1 study that enrolled 73 patients (pts) with mIDH1 CC who had received a median of 2 prior therapies (range 1–5). AG-120 has demonstrated a favorable safety profile and clinical activity in this study. Among the 72 efficacy evaluable pts ($\geq$1 post-baseline response assessment or discontinued prematurely), 6% (n = 4) had a confirmed partial response and 56% (n = 40) had stable disease. Progression-free survival (PFS) rate at 6 months was 40% as of Dec 16, 2016. The 500 mg once daily (QD) dose of AG-120 was selected for the ongoing phase 3 study in mIDH1 CC described here. **Methods:** ClarIDHy is a global, phase 3, multicenter, double-blind study randomizing 186 pts with mIDH1 CC in a 2:1 ratio to AG-120 (500 mg QD) or matched placebo (NCT02989857). Key eligibility criteria: nonresectable or metastatic CC; documented mIDH1 based on central laboratory testing; ECOG 0–1; measurable disease (RECIST v1.1); documented disease progression following $\leq$2 prior systemic therapies in the advanced setting, including at least 1 gemcitabine- or 5-fluorouracil-containing regimen; and no prior mIDH inhibitor therapy. Crossover from the placebo arm to the AG-120 arm will be permitted. The primary endpoint is PFS as assessed by an independent review. Secondary endpoints include safety, tolerability, overall response rate, overall survival, pharmacokinetic and pharmacodynamic analyses on plasma, and quality of life as assessed by the EORTC QLQ-C30, EORTC QLQ-BIL21, and EQ-5D-5L instruments. An independent data monitoring committee will monitor the data throughout the study. The ClarIDHy study is currently activated at participating sites in the US and will be activated in centers throughout Europe and in South Korea. Clinical trial information: NCT02989857.

TPS4143 Poster Session (Board #129a), Sat, 8:00 AM-11:30 AM

Phase 3, randomized study of pembrolizumab (pembro) vs best supportive care (BSC) for second-line advanced hepatocellular carcinoma (HCC): KEYNOTE-240. *First Author: Richard S. Finn, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: The tyrosine kinase inhibitor sorafenib is the standard of care for first-line HCC; currently, there is no clear standard of care after disease progression on sorafenib or for patients (pts) with intolerance to sorafenib. Because most HCC is driven by inflammation, there is a strong rationale to evaluate immunotherapy in pts with this type of cancer. The randomized, double-blind, placebo-controlled phase 3 KEYNOTE-240 study (ClinicalTrials.gov, NCT02702401) was designed to compare the efficacy and safety of the anti–PD-1 antibody pembro + BSC vs placebo + BSC in pts with previously treated advanced HCC. **Methods:** Eligibility criteria include age ≥ 18 years, histologically or cytologically confirmed diagnosis of HCC, documented progression after stopping treatment with sorafenib or intolerance to sorafenib, disease not amenable to a curative treatmentapproach (eg, transplantation, surgery, or ablation), measurable disease confirmed by central imaging vendor review per RECIST v1.1, Child-Pugh liver score A, ECOG performance status 0-1, and predicted life expectancy > 3 months. Pts will be randomly assigned 2:1 to receive pembro 200 mg IV Q3W + BSC or placebo Q3W + BSC for up to 35 cycles (~2 years) or until disease progression, unacceptable toxicity, or investigator decision. Randomization will be stratified by geographic region, presence of macrovascular invasion, and α-fetoprotein level. BSC will be provided by the investigator per local treatment practices. Response will be assessed every 6 weeks per RECIST v1.1 by central imaging vendor review. Adverse events (AEs) will be assessed throughout treatment and for 30 days thereafter (90 days for serious AEs) and graded per NCI CTCAE v4.0. Primary objectives are comparison of progression-free survival per RECIST v1.1 by central imaging vendor review and overall survival between treatment arms. Secondary objectives are comparison of objective response rate, duration of response, disease control rate, and time to progression per RECIST v1.1 by central imaging vendor review; and evaluation of safety and tolerability. Planned enrollment in KEYNOTE-240 is 408 pts across 26 countries. Clinical trial information: NCT02702401.

TPS4144 Poster Session (Board #129b), Sat, 8:00 AM-11:30 AM

A randomized phase III trial comparing adjuvant chemotherapy with S-1 vs. surgery alone in patients with resectable biliary tract cancer (JCOG1202: ASCOT). *First Author: Masafumi Ikeda, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: No standard adjuvant treatment has been established for patients with curatively resected biliary tract cancer (BTC). S-1, which is one of the oral fluoropyrimidine derivatives, showed promising efficacy with a mild toxicity profiles in patients with advanced BTC, and the survival benefit of adjuvant S-1 therapy has been demonstrated in patients with resected gastric cancer and pancreatic cancer. The aim of this open-label, multicenter, randomized phase III trial is to assess whether adjuvant S-1 would prolong the overall survival in patients with resected BTC. **Methods:** The main eligibility criteria are as follows: 1) curatively resected carcinoma of the extrahepatic bile duct, gallbladder or ampulla of Vater (T2-4, N0, M0 or T1-4, N1, M0), or carcinoma of the intrahepatic bile duct (T1-4, N0-1, M0) (7^{th} UICC classification), 2) histologically confirmed adeno (squamous) carcinoma, 3) R0 or R1 residual disease, 4) age 20 to 80 years, 5) ECOG performance status 0 or 1, 6) no prior chemotherapy or radiotherapy, 7) adequate organ functions, 8) written informed consent. Patients are randomly assigned to the surgery alone arm (arm A) or the adjuvant S-1 arm (arm B) by the minimization method for balancing institution, primary site of cancer and lymph node metastasis between the arms. Patients in arm A do not receive any anti-cancer treatment, while patients in arm B receive 4 cycles of oral S-1 chemotherapy at the dose of 40 mg/m^2 twice daily for 4 weeks followed by 2 weeks of rest. The primary endpoint is overall survival, while the secondary endpoints are relapse-free survival, incidence of (serious) adverse events, and proportion of treatment completion. We assumed a 3-year survival in arm A of 47% and a 10% increase in the 3-year survival in arm B. The sample size was calculated as a total of 350, with a one-side alpha of 5% and power of 70%; planned accrual period is 4 years, and follow-up period, 3 years. Primary analysis will be conducted at 3 years and updated analysis will be conducted at 5 years after closing of accrual. As of Jan 31, 2016, a total of 285 patients have already been enrolled in this trial from Sep 2013. Clinical trial information: UMIN000011688.

TPS4145 Poster Session (Board #130a), Sat, 8:00 AM-11:30 AM

Phase 2, open-label, multicenter study of the efficacy and safety of INCB054828 in patients (pts) with advanced, metastatic, or surgically unresectable cholangiocarcinoma (CCA) with inadequate response to prior therapy. *First Author: Mitesh J. Borad, Mayo Clinic, Scottsdale, AZ*

Background: Dysregulation of fibroblast growth factor receptor (FGFR) signaling by *FGFR* translocations and activating mutations is implicated in many cancers, including CCA. *FGFR2* translocation, the most common *FGFR*alteration, occurs in ~13% of pts with intrahepatic CCA. INCB054828 is a novel, orally available, selective inhibitor of FGFR1, FGFR2, and FGFR3 tyrosine kinase activity (AACR 2015; Abstract 771). **Methods:** This phase 2, open-label trial will evaluate INCB054828 monotherapy in pts with advanced/metastatic or unresectable CCA (NCT02924376). Pts will be prescreened locally or centrally for *FGF/FGFR* status prior to enrollment (Table): *FGFR2* translocation (Cohort A); other *FGF/FGFR* alteration (Cohort B); no *FGF/FGFR* alteration (Cohort C; negative control for effects of *FGF/FGFR* alteration on objective response rate [ORR]). Eligibility criteria include: age ≥18 years; ECOG performance status ≤2; adequate liver and renal function; life expectancy ≥12 wks; disease progression after ≥1 prior systemic therapy; no prior use of selective FGFR inhibitors. Pts will self-administer INCB054828 orally at a starting dose of 13.5 mg QD on a 21-day cycle (2 wks on; 1 wk off); treatment will continue until disease progression or unacceptable toxicity. The primary endpoint will be ORR (complete or partial response, independent radiologic review committee, RECIST v1.1) in pts with *FGFR2* translocation (Cohort A). Secondary endpoints include ORR in pts positive or negative for any *FGF/FGFR*alteration and duration of response, PFS, OS, and safety (all cohorts). The study has currently enrolled 2 pts (recruitment ongoing; estimated primary completion, April 2018). Clinical trial information: NCT02924376.

Study design.

Prescreen	• *FGFR2* translocation → cohort A (n=60) • Other *FGF/FGFR* alteration → cohort B (n=20) • No *FGF/FGFR* alteration → cohort C (n=20)
Screen, enroll and initiate INCB054828	• Oral QD dosing • 21-day cycle (2 wks on; 1 wk off)
Assessments start after cycle 2	• Stable disease/partial or complete response → continue treatment (restaging after cycle 4) • Disease progression → discontinue treatment; safety and survival follow-up

TPS4146 Poster Session (Board #130b), Sat, 8:00 AM-11:30 AM

A multicohort phase II study of durvalumab plus tremelimumab for the treatment of patients (PTS) with advanced neuroendocrine neoplasms (NENs) of gastroenteropancreatic (GEP) or lung origin (the DUNE trial-GETNE1601-). *First Author: Ignacio Matos Garcia, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: NENs include a heterogeneous group of tumors with different behavior. Despite immunomodulators such as interferon are approved for the management of grade 1-2 NENs, the low mutation tumor load and PD-1/PDL-1 expression have limited the development of immune check-point inhibitors in this setting. The rational for immunotherapy in high grade NENs is stronger compared with low grade NENs based on the results observed in small cell lung cancer. However, the combination of an antiPDL-1 and antiCTLA-4 could increase the probability of success regardless of tumor growth rate, mutational tumor load or PDL-1 expression in low grade NENs. **Methods:** This prospective, multi-center, open label, phase II study (EudraCT:2016-002858-20) will evaluate the efficacy and safety of durvalumab plus tremelimumab in 126 pts within four different cohorts, including well-moderately differentiated lung NENs (Cohort 1), grade 1-2 gastrointestinal NENs (Cohort 2), grade 1-2 pancreatic NENs (Cohort 3) and grade 3 GEP NENs (Cohort 4). To optimize the efficacy of immunotherapy in low grade NENs, pts included in the trial must have progressed to all standard approved therapy in each setting, including somatostatin analogues, targeted agents and chemotherapy for lung and GEP grade 1-2 NENs up to 4 prior lines. For pts included in cohort 4, progression to standard platinum-based chemotherapy is mandatory. All pts will receive durvalumab 1500 mg every 28 days for 12 months, and tremelimumab 75 mg Q4W up to 4 doses/cycles. Retreatment is allowed after disease progression in the follow-up period. The primary endpoint of the study for cohorts 1-3 is disease control rate at 9 months including the percentage of pts achieving complete response, partial response, or stable disease according to RECIST v1.1; Median overall survival will be the primary endpoint for cohort 4. Primary endpoints will be assessed by investigators and confirmed by central radiological review. Secondary endpoints include median progression-free survival, safety and tolerability and a wide panel of biomarkers in blood samples and tumor tissue. Clinical trial information: 2016-002858-20.

TPS4147 Poster Session (Board #131a), Sat, 8:00 AM-11:30 AM

Randomized phase II study of 2nd-line FOLFIRI versus modified FOLFIRI with PARP inhibitor ABT-888 (veliparib) (NSC-737664) in metastatic pancreatic cancer (mPC): SWOG S1513. *First Author: E. Gabriela Chiorean, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: PC is characterized by multiple DNA repair defects, including in *BRCA1/2*, and other homologous recombination (HR) genes such as *FANC*, *ATM, ATR* (Waddell N, Nature 2015). Folinic acid/5-fluorouracil/irinotecan (FOLFIRI) is a 2nd line therapy option in mPC, but overall survival (OS) averages only 6 mos (Yoo C, Br J Cancer 2009). It is known that PARP facilitates repair from topoisomerase 1-associated DNA damage, and that preclinically PARP inhibitors (PARPi) increase DNA breaks from camptothecins, resulting in synergistic antitumor effects (Smith LM, Clin Cancer Res 2005, Davidson D, Invest New Drugs 2013). PARPi are active in mPC harboring *BRCA1/2* mutations. Given the preclinical synergism between ABT-888 with irinotecan, and the safety and preliminary efficacy noted in a phase I trial (Berlin J, J Clin Oncol 2014; abstr 2574), we designed a randomized phase II study of mFOLFIRI /ABT-888 vs FOLFIRI alone for 2nd line mPC patients (pts). Blood and tumor samples are collected at baseline to retrospectively analyze biomarkers related to DNA repair capacity, including the HRD assay and BROCA-HR, a targeted multi-gene sequencing to detect alterations within the Fanconi Anemia-BRCA (HR), non-homologous end joining (NHEJ), and DNA mismatch repair pathways, and correlate with efficacy. **Methods:** Phase II study in 143 pts randomized (1:1) to mFOLFIRI/ABT-888 or FOLFIRI. For optimal PARP inhibition, ABT-888 is dosed Days (D) 1-7 and mFOLFIRI (no 5-FU bolus) D3-5 in 14D-cycles. In the control arm, FOLFIRI is dosed D1-3 in 14D-cycles. Primary endpoint: compare OS between treatment arms; secondary endpoints: safety, progression-free survival, response rates; translational: correlate germline/somatic *BRCA1/2* mutations, and other DNA repair biomarkers with efficacy in each arm. Standard eligibility criteria apply. Assuming that the addition of ABT-888 will increase OS from 6 to 9 mos, 128 eligible pts (143 pts total) are required, based on a one-sided type 1 error of 10%, and 80% power. Kaplan-Meier methodology will be used to estimate median OS for each treatment arm. This study is open to accrual (NCT02890355). Clinical trial information: NCT02890355.

TPS4148 Poster Session (Board #131b), Sat, 8:00 AM-11:30 AM

CanStem111P trial: A phase III study of napabucasin (BBI-608) plus nab-paclitaxel (nab-PTX) with gemcitabine (gem) in adult patients with metastatic pancreatic adenocarcinoma (mPDAC). *First Author: Tanios S. Bekaii-Saab, Mayo Clinic Cancer Center, Phoenix, AZ*

Background: Cancer stem cells are considered to be fundamentally important for resistance to therapy, recurrence and metastasis. Napabucasin is a first-in-class cancer stemness inhibitor identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al, PNAS 112(6):1839, 2015). Preclinical studies suggest that napabucasin sensitizes heterogeneous cancer cells to chemotherapeutic agents, including nab-PTX and gem. Encouraging anticancer activity in mPDAC was observed in a phase Ib (El-Rayes et al, ASCO 2016) study of 37 pts, reporting 93% (28/30) disease control rate (DCR) and 50% (15/30) overall response rate (ORR), with 1 complete and 14 partial responses and prolonged disease control ($>$ 24 wks) in 57% (17/30) of pts who have had a RECIST evaluation. On the basis of these data, a phase III trial is being conducted in North America, Europe, Australia and Asia. **Methods:** This study (ClinicalTrials.gov NCT02993731) will assess the efficacy of napabucasin+nab-PTX+gem *vs* nab-PTX+gem in pts with mPDAC (n = 1132). Pts must have been diagnosed with mPDAC $<$ 6 weeks prior to randomization and not have received treatment for metastatic disease. Pts are randomized in a 1:1 ratio to receive napabucasin 240 mg PO twice daily continuously plus nab-PTX +gem IV weekly for 3 out every 4 weeks, or nab-PTX+gem IV weekly for 3 out every 4 weeks. Pts will be stratified by geography, performance status and presence of liver metastases. Treatment will continue until disease progression, death, intolerability or patient/investigator decision to stop. Primary endpoint is overall survival (OS) in the general study population (HR 0.80 for OS improvement from 8.5 to 10.63 months); secondary endpoints include progression free survival (PFS), OS and PFS in the biomarker positive sub-population, ORR and DCR, safety and quality of life. In addition, blood and tumor archival tissue will be assessed for pharmacokinetic and biomarker analyses. Global enrollment is underway. Clinical trial information: NCT02993731.

TPS4149 Poster Session (Board #132a), Sat, 8:00 AM-11:30 AM

The CCTG PA.7 trial: A randomized phase II study of gemcitabine and nab-paclitaxel vs. gemcitabine, nab-paclitaxel, durvalumab, and tremelimumab as 1st line therapy in metastatic pancreatic ductal adenocarcinoma (PDAC). *First Author: Daniel John Renouf, BC Cancer Agency, Vancouver, BC, Canada*

Background: Gemcitabine (GEM) and Nab-Paclitaxel (Nab-P) has become a standard 1st line therapy for advanced PDAC based on the MPACT Trial. Durvalumab (D) is a human monoclonal antibody (mAb) that inhibits binding of programmed cell death ligand 1 (PD-L1) to its receptor (PD-1). Tremelimumab (T) is a mAb directed against the cytotoxic T-lymphocyte-associated protein 4 (CTLA-4). Monotherapy with immune checkpoint inhibitors has thus far demonstrated limited activity in PDAC. This may be partly related to the activity of cancer associated fibroblasts (CAF) in promoting an immunosuppressive tumoural microenvironment in PDAC. GEM and Nab-P treatment may deplete stroma and CAFs, release neo-antigens and increase the immunogenicity of PDAC. This study is designed to evaluate whether the addition of PD-L1 and CTLA-4 inhibition to GEM/Nab-P increases treatment efficacy. **Methods:** This randomized phase II study (ClinicalTrials.gov NCT02879318) will assess the efficacy and safety of GEM/Nab-P vs. GEM/Nab-P/D/T in patients (pts) with metastatic PDAC (n = 190). Good performance status pts (ECOG $<$ 2) with untreated metastatic PDAC will be eligible. Prior adjuvant therapy is allowed provided recurrence is $>$ 6 months post-completion. There is a safety lead in of 10 pts receiving GEM/Nab-P/D/T. Assuming no safety concerns the study will go on to randomize pts in a 2:1 ratio to receive GEM (1000mg/m^2 D1, 8, 15)/Nab-P (125mg/m^2 D1, 8, 15) with/without D (1500 mg) D1 q 28 days and T (75 mg) D1 for first 4 cycles. Treatment will continue until disease progression, death, intolerable toxicity, or patient/investigator decision to stop. Primary endpoint is overall survival; secondary endpoints include progression free survival, safety, overall response rate and quality of life. Analysis will be according to randomized group stratified by ECOG PS and receipt of prior adjuvant chemotherapy. Blood, plasma, and archival tissue will be collected and assessed for potential prognostic and predictive biomarkers. As of February 1 2017, 11 pts have been enrolled and the initial safety analysis is ongoing. Clinical trial information: NCT02879318.

TPS4150 Poster Session (Board #132b), Sat, 8:00 AM-11:30 AM

A phase II study of abemaciclib as a monotherapy and in combination with other agents in patients with previously treated metastatic pancreatic ductal adenocarcinoma (PDAC). *First Author: E. Gabriela Chiorean, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: PDAC is a lethal tumor with unusual resistance to cytotoxic and targeted therapies, and pathogenesis frequently associated with hyperactive CDK 4&6 signaling. Pre-clinical models have demonstrated anti-proliferative activity with CDK 4&6 inhibitors alone, however, synergistic effects have been observed when combined with a PI3K/mTOR or TGF- βR1 inhibitor. Abemaciclib is a selective inhibitor of CDK 4&6 with an acceptable safety profile in clinical studies.This study will evaluate the safety and efficacy of abemaciclib alone or in combination with LY3023414, a PI3K/mTOR dual inhibitor, or galunisertib, a TGF-βR1 inhibitor, versus standard of care (SOC) in pateints (pts) with metastatic PDAC. **Methods:** Design: Study JPCJ is an adaptive, open-label, randomized, Phase 2 study in pts with previously treated metastatic PDAC. Pts will be stratified based on number of prior systemic therapies (1 or 2), and in Stage 1 (25 pts/arm) will be randomized in a 1:1:1:1 ratio to 4 treatment arms: abemaciclib; abemaciclib+LY3023414; abemaciclib + galunisertib; SOC treatment gemcitabine or capecitabine. Investigational arms demonstrating evidence of disease control rate (DCR) comparable to or better than the SOC will advance to Stage 2 (additional 50 pts/arm). Eligibility: Pts must have metastatic PDAC with disease progression following 1 or 2 prior lines of therapy, measurable disease, ECOG PS $\leq$1, no prior treatment with any CDK 4&6, TGF-β, or PI3K and/or mTOR inhibitors, no severe cardiac disorders, and must not have insulin-dependent diabetes. Objectives: The primary endpoint is to evaluate the DCR (Stage 1) and progression-free survival (PFS [Stage 2]). Secondary objectives include response rate, overall survival, safety, pharmacokinetics, biomarkers related to the CDK 4&6 pathway, and quality of life. Statistics: Assuming a hazard ratio of 0.65 in PFS (median PFS of 2.3 months in abemaciclib containing arms vs. 1.5 months in the SOC arm), the study has approximately 76% power to detect superiority of the abemaciclib-containing arm using a 2-sided log-rank test at 0.10 significance level. Accrual began on 01/12/2017. Clinical trial information: NCT02981342.

TPS4151 Poster Session (Board #133a), Sat, 8:00 AM-11:30 AM

Alliance for clinical trials in oncology trial A021501: Preoperative extended chemotherapy vs. chemotherapy plus hypofractionated radiation therapy for borderline resectable adenocarcinoma of the head of the pancreas. *First Author: Matthew H. G. Katz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Borderline resectable pancreatic cancers infiltrate into adjacent vascular structures to an extent that makes an R0 resection unlikely when pancreatectomy is performed *de novo*. In a pilot study, Alliance for Clinical Trials in Oncology Trial A021101, the median survival of patients who received chemotherapy and radiation prior to anticipated pancreatectomy was 22 months, and an R0 resection was achieved in 64% of operations. However, the individual contributions of preoperative chemotherapy and radiation therapy are poorly defined.This study, Alliance for Clinical Oncology Trial A021501, will help define a standard preoperative treatment regimen for borderline resectable pancreatic cancer and position the superior arm for further evaluation in future phase III trials. **Methods:** In this recently activated randomized phase II trial, 134 patients with a biopsy-confirmed pancreatic ductal adenocarcinoma that meets centrally-reviewed radiographic criteria for borderline resectable disease are randomized to receive either 8 cycles of modified FOLFIRINOX (oxaliplatin 85 mg/m^2, irinotecan 180 mg/m^2, leucovorin 400 mg/m^2 and infusional 5-fluorouracil 2400 mg/m^2 for 4 cycles) or to 7 cycles of modified FOLFIRINOX followed by stereotactic body radiation therapy (33-40 Gy in 5 fractions). Patients without evidence of disease progression following preoperative therapy undergo pancreatectomy and subsequently receive 4 cycles of postoperative modified FOLFOX6 (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2 and infusional 5-fluorouracil 2400 mg/m^2 for 4 cycles). The primary endpoint is the 18-month overall survival rate of patients enrolled into each of the two treatment arms. An interim analysis of the R0 resection rate within each arm will be conducted to assess treatment futility after accrual of 30 patients. Secondary endpoints include rates of margin-negative resection and event-free survival. The trial is activated nationwide and eligible to be opened for accrual at any National Clinical Trials Network cooperative group member site. Clinical trial information: NCT02839343.

TPS4152 Poster Session (Board #133b), Sat, 8:00 AM-11:30 AM

SWOG S1505: A randomized phase II study of perioperative mFOLFIRINOX vs. gemcitabine/nab-paclitaxel as therapy for resectable pancreatic adenocarcinoma. *First Author: Davendra Sohal, Cleveland Clinic, Cleveland, OH*

Background: Clinical outcomes after curative therapy for resectable pancreatic ductal adenocarcinoma (PDA) remain suboptimal. Series show that 70-85% of patients die of systemic recurrence. Improved overall survival (OS) in the metastatic setting with the use of multi-agent chemotherapy regimens (FOLFIRINOX, gemcitabine/nab-paclitaxel) holds the promise of progress in the curative setting as well. However, aggressive systemic therapy is usually not feasible after major pancreatic surgery. Therefore, early control of systemic disease by increased preoperative chemotherapy may improve outcomes. Furthermore, the perioperative platform facilitates early identification of patients with chemotherapy-resistant tumors and allows prospective biomarker studies in the future. **Methods:** This is a randomized phase II study intended to choose the most promising perioperative regimen to test in a larger trial. Eligibility requirements include adult patients with an ECOG PS of 0 or 1, a confirmed histopathologic diagnosis of PDA, and resectable disease as confirmed by central radiology review: no involvement of the celiac, common hepatic, or superior mesenteric arteries (and, if present, variants); no involvement, or $< 180°$ interface between tumor and vessel wall, of the portal or superior mesenteric veins; patent portal vein/splenic vein confluence; no metastases. Treatment includes 12 weeks [either 6 doses of mFOLFIRINOX (5-fluorouracil, irinotecan, oxaliplatin – without bolus 5-FU and leucovorin), or 9 doses of gemcitabine/nab-paclitaxel, on standard schedules] of preoperative chemotherapy, followed by surgical resection and 12 weeks of identical postoperative chemotherapy. Primary outcome is 2-year OS, using a "pick the winner" design with minimum two-year OS of 40% assuming a 58% alternative hypothesis, 88% power, and a 1-sided α of 0.05, providing 90% probability of selecting the better regimen with a total sample size of 118 patients. Correlative studies are planned. The study opened through the National Clinical Trials Network (NCT02562716), and is supported by NIH/NCI/NCTN grants CA180888, CA180819, CA180821, CA180833. Clinical trial information: NCT02562716.

TPS4153 Poster Session (Board #134a), Sat, 8:00 AM-11:30 AM

A phase III, double-blind, randomized clinical trial comparing S-1 in combination with DC vaccine loaded with WT1 peptides (TLP0-001) or placebo for the patients with advanced pancreatic cancer refractory to standard chemotherapy. *First Author: Masahiro Katsuda, Second Department of Surgery, Wakayama Medical University, Wakayama, Japan*

Background: The development of new potent therapeutic is strongly called for treating pancreatic cancer. Dendritic cells (DCs) are a type of antigen-presenting cells that play an important role in adaptive immune system, and this property has prompted their recent application to therapeutic cancer vaccines. DCs loaded with tumor antigen ex vivo and administered as a cellular vaccine have been found to induce therapeutic anti-tumor immunity. Wilms' tumor gene WT1 is expressed in various kinds of cancers including pancreatic cancer. In pilot clinical trials of DC vaccination loaded with WT1 peptides for patients with advanced pancreatic cancer, induction of anti-tumor WT1 specific immune responses and tumor regressions have been observed (Kimura et al, Pancreas, 2012 / Kobayashi et al, Cancer Immunol Immunother, 2014 / Mayanagi et al Cancer Sci, 2015). TLP0-001 is activated Dendritic cells loaded with epitope peptides derived from WT-1. **Methods:** This is an investigator initiated, phaseIII, multicenter, double-blind, randomized trial of TLP0-001+S-1 versus placebo+S-1 for the patients with locally advanced or metastatic pancreatic cancer refractory to standard chemotherapy. Patients are allocated to either DC vaccine (TLP0-001) + S-1 group or placebo + S-1 in 1:1 ratio by dynamic allocation method. The primary endpoint is overall survival. Sample size is estimated presuming the effects will be observed from the time point of 50% cumulative survival rate. Assuming a type I error alpha (two-sided) level of 5% and a power of 80% or more for hazard ratio 0.644, sample size necessary is estimated as 174 patients. When the first 6 patients are administerd TLP0-001, the independent Data Monitoring Commitee checks safety data to assess continuation of the study. Enrollment begins in March 2017.

TPS4154 Poster Session (Board #134b), Sat, 8:00 AM-11:30 AM

Phase II study of GM-CSF secreting allogeneic pancreatic cancer vaccine (GVAX) with PD-1 blockade antibody and stereotactic body radiation therapy (SBRT) for locally advanced pancreas cancer (LAPC). *First Author: Valerie Lee, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Optimal treatment strategy beyond systemic chemotherapy for LAPC remains undefined. SBRT improves local control, but distant metastasis free survival (DMFS) is only 7.7 months. Checkpoint inhibitors are poor monotherapies in pancreas cancer, but may be primed by SBRT via absocopal effect and GVAX, which induces novel lymphoid infiltrates and increased effector T-cells in tumor microenvironment. **Methods:** This is a single-arm, single-institution, open-label study for pts with LAPC. Eligibility: surgically unresectable LAPC, predominant adenocarcinoma at diagnosis, with ECOG 0-1, who remain metastases free after 4-8 cycles of FOLFIRINOX or gemcitabine/abraxane based-chemotherapy. Exclusion: those off chemotherapy $>$ 49 days prior to study treatment, prior immunotherapy, active immunosuppressive use, autoimmune disease, HIV, HBV, or HCV infection, and non-oncology vaccines within 28 days of study treatment. Pts receive cyclophosphamide (200mg/m2 IV) and pembrolizumab (200mg IV) on day 1, followed by GVAX (six intradermal injections) on day 2 every three weeks for two cycles, with cycle 2 initiating concurrently with five days of SBRT. If non-metastatic, pts undergo surgical resection, nano-knife, or EUS guided biopsy (if non-surgical). Pts receive two further cycles of chemotherapy, and if remain free of metastases, receive q3 week cyclophosphamide, pembrolizumab, and GVAX for six cycles, then are monitored for two years. The primary endpoint is DMFS. Secondary endpoints include overall survival, surgical resectability, pathologic response, quality of life, and toxicity. Exploratory objectives of peripheral antigen specific t-cell responses, and changes in immune parameters of tumor microenvironment. 11 of 54 pts have been enrolled since July 2016. Clinical trial information: NCT02648282.

4500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Comprehensive molecular characterization and analysis of muscle-invasive urothelial carcinomas. *First Author: Seth P. Lerner, Baylor College of Medicine, Houston, TX*

Background: We reported the integrated molecular analysis of 131 tumors in 2014 (Nature 507:315, 2014) and now report on the entire cohort of 412 tumors from the TCGA project in chemotherapy-naïve, muscle-invasive urothelial bladder cancer. **Methods:** Following strict clinical and pathologic quality control, tumors were analyzed for DNA copy number variants, somatic mutations (WES), DNA methylation, mRNA, non-coding RNA (lncRNA and miRNA) and (phospho-) protein expression, gene fusions, viral integration, pathway perturbation, clinical correlates, outcomes, and histopathology. **Results:** There was a high overall somatic mutation rate (8.2/Mb), as previously reported. There were 58 significantly mutated genes (SMGs) (MutSig_2CV), increased from 32 in the original report. We identified 5 mutation signatures including APOBEC-a and b, ERCC2, C > T_CpG, and a single ultra-mutated sample with a functional POLE mutation. APOBEC mutagenesis explained 70% of the mutation burden and was associated with survival (p = 0.0013). High mutation burden and neoantigen load were also associated with improved outcome (p = 0.00014 and 0.00078). The previously identified four mRNA subtypes were predicted on the larger set and also identified a novel poor-survival 'neuronal' subtype that nevertheless lacked small cell or neuroendocrine histology. Clustering converged for mRNA, lncRNA and miRNA expression, and for inferred activity of gene sets associated with regulator expression. We identified subsets with differential epithelial-mesenchymal transition scores, carcinoma-in-situ scores, and survival, with implications for distinct therapeutic potential. **Conclusions:** This integrated analysis of 412 TCGA patient samples validates and extends observations from the first 131 patients and significantly increases our power to detect additional low-frequency aberrations. The results provide unique insights into mechanisms of bladder cancer development, and identify novel subsets of MIBC that may benefit from differential treatment approaches.

4501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Planned survival analysis from KEYNOTE-045: Phase 3, open-label study of pembrolizumab (pembro) versus paclitaxel, docetaxel, or vinflunine in recurrent, advanced urothelial cancer (UC). *First Author: Dean F. Bajorin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Second-line chemotherapies (chemo) for advanced UC have limited clinical benefit (OS, 7-9 mo). Data from the open-label, phase 3 KEYNOTE-045 study (NCT02256436) showed significantly longer OS with pembro v chemo (median, 10.3 v 7.4 mo; hazard ratio [HR], 0.73; P = 0.002) in recurrent, advanced UC. Data from a planned survival analysis are presented. **Methods:** Pts had histologically or cytologically confirmed UC, progression after platinum, ECOG PS 0-2, measurable disease (RECIST v 1.1), and ≤2 lines of systemic therapy. Pts were randomly assigned 1:1 to pembro 200 mg Q3W or investigator's choice of paclitaxel 175 mg/m^2 Q3W, docetaxel 75 mg/m^2 Q3W, or vinflunine 320 mg/m^2 Q3W. Primary efficacy end points were OS and PFS (RECIST v1.1, blinded central review). ORR (RECIST v1.1, blinded central review) was a secondary end point. **Results:** 542 pts were enrolled (pembro, 270; chemo, 272). Baseline characteristics were generally similar between arms. As of Jan 18, 2017, median follow-up was 18.5 mo (range, 14.2-26.5). Median OS was significantly longer with pembro v chemo (10.3 v 7.4 mo; HR, 0.70; P < 0.001), and significance was maintained regardless of PD-L1 expression as measured by combined positive score (HR: CPS < 1%, 0.84; CPS ≥1%, 0.59; CPS < 10%, 0.76; CPS ≥10%, 0.57). OS benefit with pembro v chemo was seen regardless of age, ECOG PS, prior therapy, liver metastases, histology, and choice of chemo. The 18-mo OS rate (95% CI) was 36.1% (30.1%-42.0%) with pembro v 20.5% (15.2%-25.8%) with chemo (KM estimate). PFS was not different between arms. ORR was higher with pembro v chemo (21.1% v 11.0%), and median (range) duration of response was longer (not reached [1.6+-20.7+ mo] v 4.4 mo [1.4+-20.3]). 69% (pembro) v 36% (chemo) of responses lasted ≥12 mo. Fewer pts experienced a treatment-related AE with pembro v chemo (any grade, 61.3% v 90.2%; grade ≥3, 16.5% v 49.8%). **Conclusions:** The OS benefit and superior safety profile of pembro over chemo are maintained with longer follow-up. Combined, these results support the potential of pembro as a new standard of care for patients with UC who previously received platinum. Clinical trial information: NCT02256436.

4502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Biomarker findings and mature clinical results from KEYNOTE-052: First-line pembrolizumab (pembro) in cisplatin-ineligible advanced urothelial cancer (UC). *First Author: Peter H. O'Donnell, The University of Chicago Medical Center, Chicago, IL*

Background: Comorbidities and renal impairment preclude many with advanced UC from receiving chemotherapy. Initial results from the phase 2 KEYNOTE-052 (NCT02335424) trial suggested first-line pembro is active and safe in cisplatin-ineligible advanced UC. We present updated efficacy and safety data (all pts have ≥6 mo follow-up) and evaluate biomarkers correlated with outcomes. **Methods:** Eligibility criteria included cisplatin-ineligible (ECOG PS 2, CrCl ≥30- < 60 mL/min, grade ≥2 neuropathy/hearing loss, NYHA Class 3 heart failure), advanced UC, and no prior systemic chemotherapy. Pts received pembro 200 mg IV Q3W. Imaging was performed at wk 9, then Q6W for the first year, and Q12W thereafter. Primary end point was confirmed ORR (RECIST v1.1, independent review). Efficacy and safety were assessed in the 370 pts with ≥1 pembro dose. The associations of an 18-gene expression profile (GEP) and IHC PD-L1 combined positive score (CPS) with ORR were evaluated. **Results:** As of the Dec 19, 2016, data cutoff, ORR was 29% (95% CI, 24-34): 25 (7%) and 81 (22%) pts achieved complete and partial responses. Another 69 pts (19%) had stable disease as best response, for a clinical benefit rate of 47%. Median time to response was 2 mo (range, 1-5). At a median follow-up of 8 mo (range, 0.1-20) across all pts, median duration of response was not reached (range, 1+-18+ mo). 74% of responses were ongoing. Any-grade and grade ≥3 drug-related AEs occurred in 239 (65%) and 68 (18%) pts. Immune-mediated AEs occurred in 76 (21%) pts. Evidence supporting a positive association with response was seen in the first 100 pts for both biomarkers (GEP, n = 72, P = 0.007, ROC AUC 0.69; CPS, n = 96, P = 0.111, ROC AUC 0.58); biomarker data for all pts will be presented. ORR in the 110 pts with CPS ≥10% was 47% (95% CI, 38-57). **Conclusions:** Results confirm that pembro elicits clinically meaningful, durable responses in cisplatin-ineligible advanced UC. Consistent with PD-1 pathway biology, biomarkers (GEP and CPS) showed the expected trends of positive association with response to pembro. Pembro was well tolerated across cisplatin-ineligible pts, including elderly and pts with poor performance status. Clinical trial information: NCT02335424.

4503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Epacadostat plus pembrolizumab in patients with advanced urothelial carcinoma: Preliminary phase I/II results of ECHO-202/KEYNOTE-037. *First Author: David C. Smith, University of Michigan, Ann Arbor, MI*

Background: Pembrolizumab (P), a PD-1 inhibitor, is active and well tolerated in platinum-treated, advanced urothelial carcinoma (UC). Epacadostat (E) potently and selectively inhibits indoleamine 2,3-dioxygenase 1 (IDO1), a tryptophan-catabolizing enzyme that suppresses T-cell–mediated immune surveillance. IDO1 overexpression is associated with tumor progression and shortened patient (pt) survival. ECHO-202/KEYNOTE-037 is an open-label, phase I/II study of E + P in pts with advanced tumors. We report phase I/II efficacy and safety outcomes for the UC cohort at an October 29, 2016 data cutoff. **Methods:** Adult pts with advanced UC, prior platinum therapy (adjuvant or advanced disease setting) or alternative therapy (if platinum was not appropriate), and no prior checkpoint inhibitor therapy were eligible to participate. In phase I, pts received E (25, 50, 100, or 300 mg PO BID) + P (2 mg/kg or 200 mg IV Q3W); MTD was not exceeded. E (100 mg BID) + P (200 mg Q3W) dosing was selected for phase II. Response was assessed in RECIST 1.1–evaluable pts. Safety was assessed in pts receiving ≥1 E + P dose. **Results:** A total of 40 pts (phase I, n = 5; phase II, n = 35) were evaluated. Median age was 67 years, 75% were men, 88% were white, 100% had prior platinum therapy, and 75% had 0–1 prior line of therapy for advanced disease. Preliminary ORR (CR+PR) and DCR (CR+PR+SD) for all efficacy-evaluable pts were 35% (13/37; all PR) and 57% (21/37; 13 PR, 8 SD), respectively; for pts with 0–1 prior line of therapy for advanced disease, ORR and DCR were 37% (10/27) and 63% (17/27). At data cutoff, 12/13 responses were ongoing (range, 1+ to 652+ days). PFS and biomarker analyses are ongoing. The most common TRAEs (≥10% of 40 pts) were fatigue (28%), rash (18%), and increased amylase (10%; asymptomatic). Grade ≥3 TRAEs occurred in 20% of pts (rash was the only grade ≥3 TRAE to occur in > 1 pt [n = 3]). Three pts discontinued due to TRAEs (grade 3 rash [n = 1]; grade 3 COPD exacerbation [n = 1], grade 2 diarrhea [n = 1]). **Conclusions:** E + P was generally well tolerated and associated with increased response compared with previously reported PD-1 inhibitor monotherapy in pts with advanced UC. A phase III UC study is planned. Clinical trial information: NCT02178722.

4504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

First-line avelumab + axitinib therapy in patients (pts) with advanced renal cell carcinoma (aRCC): Results from a phase Ib trial. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: Combining an immune checkpoint inhibitor with a targeted antiangiogenic agent may leverage complementary mechanisms of action for treatment of aRCC. Avelumab is a fully human anti–PD-L1 IgG1 antibody with clinical activity in various tumor types; axitinib, a VEGF receptor inhibitor, is approved for second-line treatment of aRCC. JAVELIN Renal 100 (NCT02493751) is a phase Ib study evaluating safety and clinical activity of avelumab + axitinib in treatment-naïve pts with aRCC; updated results are reported here. **Methods:** Eligible pts had confirmed clear-cell aRCC, ≥1 measurable lesion, fresh or archival tumor specimen, ECOG PS ≤1, and no prior systemic therapy. Pts received avelumab 10 mg/kg IV Q2W + axitinib 5 mg orally BID until progression, unacceptable toxicity, or withdrawal. Endpoints included safety (NCI CTCAE v4.03) and objective response (RECIST v1.1). **Results:** As of Dec 30, 2016, 55 pts (median age 60.0 yrs [range 42.0–76.0]; 76.4% male; 34.5% ECOG PS = 1) were enrolled. 54 pts were treated with avelumab for a median of 24.1 wks (range 2.0–62.0); 55 pts were treated with axitinib for a median of 25.3 wks (range 3.0-61.0). 51 pts (92.7%) had an avelumab-related adverse event (AE) with the therapy combination, the most common (≥30% any grade) were fatigue and diarrhea (30.9% each). 10 pts (18.2%) had a max grade 3 and 1 pt (1.8%) had a max grade 4 avelumab-related AE. 52 pts (94.5%) had an axitinib-related AE with the therapy combination; the most common (≥30% any grade) were diarrhea (52.7%), hypertension (45.5%), dysphonia (43.6%), and fatigue (43.6%). 24 pts (43.6%) had a max grade 3 and 5 pts (9.1%) had a max grade 4 axitinib-related AE. 2 deaths occurred in the study during the reporting period: 1 due to progression and 1 related to both treatments (myocarditis). An AE led to discontinuation of avelumab in 5 pts (9.1%) and axitinib in 4 pts (7.3%). Confirmed ORR was 54.5% (95% CI 40.6–68.0) based on 2 CR and 28 PR. Unconfirmed ORR was 60.0% (95% CI 45.9–73.0). **Conclusions:** The safety profile of the combination of avelumab + axitinib appears manageable and consistent with those agents administered as monotherapy, and early encouraging antitumor activity was observed. Follow-up is ongoing. Clinical trial information: NCT02493751.

4505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

IMmotion150: A phase II trial in untreated metastatic renal cell carcinoma (mRCC) patients (pts) of atezolizumab (atezo) and bevacizumab (bev) vs and following atezo or sunitinib (sun). *First Author: Michael B. Atkins, Georgetown University Hospital, Lombardi Comprehensive Cancer Center, Washington, DC*

Background: While inhibiting VEGF improves outcomes in mRCC pts, most develop resistance, often within a year. Here, we report results from a Ph II study of atezo (anti–PD-L1) and bev (anti-VEGF) vs and following atezo or sun (TKI) in mRCC pts. **Methods:** Pts with untreated mRCC were enrolled in the hypothesis generating IMmotion150 study (NCT01984242) and randomized to atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w, atezo alone or sun 50 mg PO QD 4 wk on/2 wk off. After progression on atezo or sun, crossover to atezo + bev was allowed. PD-L1 status was scored on tumor-infiltrating immune cells (IC, SP142 IHC assay). The primary analysis was modified prior to final analysis to reflect the coprimary endpoints of IRF-assessed PFS (RECIST v1.1) in ITT pts and pts with PD-L1 expression on ≥ 1% of IC (PD-L1+). **Results:** 54% of pts were PD-L1+. In PD-L1+ pts 1L treatment resulted in a PFS hazard ratio (HR) of 0.64 for atezo + bev vs sun (table). After 1L treatment, 78% of sun and 60% of atezo pts who progressed subsequently received atezo + bev and achieved ORRs of 28% and 24%, respectively (table). Safety was comparable to the known individual profiles of atezo and bev. Additional clinical, safety and biomarker data will be presented. **Conclusions:** Atezo + bev resulted in encouraging antitumor activity in 1L pts with PD-L1+ mRCC. Preliminary activity in the 2L setting was demonstrated in pts who crossed over to atezo + bev, regardless of prior therapy. 1L atezo + bev vs sun is being evaluated in the ongoing Ph III study IMmotion151 (NCT02420821). Clinical trial information: NCT01984242.

A phase I/II study to assess the safety and efficacy of pazopanib (PAZ) and pembrolizumab (PEM) in patients (pts) with advanced renal cell carcinoma (aRCC). *First Author: Simon Chowdhury, Sarah Cannon Research Institute, London, United Kingdom*

Background: PAZ is indicated for the treatment of aRCC. The combination of an antiangiogenic agent and immunotherapy may improve anti-tumor activity. We report preliminary safety and efficacy results of the phase I part of the study. **Methods:** Twenty pts were originally enrolled in cohorts A and B assessing PAZ 800 mg and 600 mg, respectively, both with 2mg/kg (Q2W and then Q3W) PEM to determine the maximum tolerated dose. Due to dose limiting liver toxicity, cohort C was opened to assess if the sequential schedule of 9 weeks PAZ run-in followed by PAZ+PEM would improve safety. Strict safety criteria for initiating PAZ+PEM were set. The data from this ongoing study are presented given the limited information available on the combination of TKI + PD-1 inhibitors in RCC. **Results:** Overall, 35 pts were treated; 5 out of 15 pts in cohort C received PAZ+PEM at the data cut-off. Three dose-limiting toxicities (DLT) occurred in cohort C in pts receiving PAZ+PEM; updated DLTs in all cohorts are reported in Table. G3/4 AEs were observed in 90% of pts in cohorts A and B and in 80% of pts in cohort C receiving PAZ+PEM. No G3/4 ALT/AST elevation was reported in cohort C PAZ+PEM while they were observed in 70% and 60% in cohorts A and B, respectively. Best overall response (CR+PR) was reported in 6, 2 and 1 pts receiving PAZ+PEM in cohorts A, B and C, respectively. **Conclusions:** Results from cohorts A and B showed significant hepatotoxicity. The sequential schedule PAZ → PAZ+PEM has shown reduced hepatotoxicity and preliminary signs of efficacy but overall limited tolerability. PAZ+PEM is not suitable to test in a larger cohort. Clinical trial information: 2013-003785-14.

Randomized phase III trial of adjuvant pazopanib versus placebo after nephrectomy in patients with locally advanced renal cell carcinoma (RCC) (PROTECT). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: PROTECT (NCT01235962) evaluated the efficacy and safety of pazopanib (PAZ) versus placebo in patients (pts) with locally advanced renal cell carcinoma (RCC) post nephrectomy. **Methods:** 1538 pts with resected pT2 (high grade), pT3 or greater clear cell RCC were randomly assigned to PAZ or placebo for 1 year. The starting dose (800 mg) following treatment of 403 pts was lowered to 600 mg to improve tolerability and primary endpoint was changed to disease-free survival (DFS) with PAZ 600 (N = 1135). Primary analysis was performed after 350 DFS events in intent-to-treat (ITT) PAZ 600, and DFS follow-up analysis was performed after an additional 12 months. Secondary endpoints included DFS with ITT PAZ 800 and ITT ALL, and safety. **Results:** Disease characteristics were similar between arms. The primary analysis results of DFS ITT 600 were not significant [HR: 0.862; 95% CI, 0.699, 1.063; p = 0.165] (Table). The secondary endpoint of DFS in ITT PAZ 800 and ITT ALL yielded 31% and 20% risk reduction, respectively. Updated DFS analysis in ITT 600 showed a higher HR with longer follow up. Increased ALT and AST were the most common adverse events leading to treatment discontinuation in the PAZ 600 (ALT 16% and AST 5%) and PAZ 800 (ALT 18% and AST 7%) groups. **Conclusions:** The study did not meet the primary DFS endpoint in ITT 600; however, a 31% decrease in the risk of recurrence was observed in ITT 800. The safety profiles in the 600 mg and 800 mg groups were similar and consistent with PAZ prior experience. Clinical trial information: NCT01235962.

4508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III trial of adjuvant sunitinib in patients with high-risk renal cell carcinoma (RCC): Validation of the 16-gene Recurrence Score in stage III patients. *First Author: Bernard J. Escudier, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Adjuvant therapy with sunitinib (SU) compared with placebo (PBO) prolonged disease-free survival (DFS) in 615 patients (pts) with high-risk RCC (hazard ratio [HR] 0.76; *P*= 0.03) in the S-TRAC trial. The 16-gene Recurrence Score (RS) was developed and validated to predict risk of recurrence of RCC after nephrectomy in 2 cohorts of stage I–III pts (Rini et al., *Lancet Oncol* 2015;16:676-85). We present further validation of RS results in high-risk stage III pts from S-TRAC. **Methods:** The study was prospectively designed with prespecified genes, algorithm, endpoints, analytical methods, and analysis plan using primary RCC tissues from 212 evaluable pts with informed consent. Gene expression was quantitated by RT-PCR; primary analysis focused on stage III (n = 193 pts). Time to recurrence (TTR) and DFS were analyzed using Cox proportional hazard regression. **Results:** Baseline characteristics were similar in SU and PBO arms and in pts with and without gene expression data; effect of SU was numerically similar to that in the entire trial (DFS HR 0.78, 95% CI 0.48–1.24; *P*= 0.29). RS predicted TTR and DFS in both treatment arms with the strongest results observed in PBO arm where high RS group had significantly higher risk (Table). Interaction of RS with treatment was not significant (TTR *P*= 0.192; DFS *P*= 0.219); however, the number of events was relatively low. **Conclusions:** The prognostic value of the 16-gene assay was confirmed in S-TRAC. RS is now validated with consistent results in 2 separate studies (level IB evidence). RS results may help identify patients at high risk who could derive higher absolute benefit from adjuvant treatment. The predictive value of RS to select patients for adjuvant SU requires further investigation in independent adjuvant trials.

DNA damage repair and response (DDR) gene alterations (alt) and response to PD1/PDL1 blockade in platinum-treated metastatic urothelial carcinoma (mUC). *First Author: MinYuen Teo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Somatic DDR alts are associated with increased mutation load (ML) and improved clinical outcomes for platinum-treated mUC (Teo et al, CCR 2017). We examined the relationship between DDR alts and response to PD1/PDL1 blockade. **Methods:** mUC pts enrolled to phase 2 trials of atezolizumab or nivolumab who had targeted exon sequencing of 410 genes (MSK-IMPACT) were identified. Pts were dichotomized based on presence of alts in a panel of 34 DDR genes. Analyses were performed based on: (1) any DDR alts and (2) deleterious DDR alts (frameshift, splice site, nonsense or Hotspot point mutations). Study endpoint was overall response (OR) per RECIST. ML was defined as total number of nonsynonymous mutations by MSK-IMPACT. Fisher exact, Wilcoxon rank sum, and stratified logistic regression were used. **Results:** Fifty two pts were identified (atezo: n=18, nivo: n=34). Median age was 67 years (range: 32 – 84) and majority (44) was male. Median platinum-free interval was 10.2 months (range: 0.3 – 150.4). DDR and deleterious DDR were seen in 25 (48.1%) and 14 (26.9%) pts (including 2 MSI and 1 POLE). OR rate was 46.2%. Responses were associated with DDR alts but not with age, gender, treatment, platinum-free interval or ML (table). In univariate logistic regression model, DDR status was associated with OR (p<.001) while a trend was observed with ML as a continuous variable (p=.051). While DDR alts were associated with higher ML (all: p=.001, deleterious: p=.004), the effect of DDR alts on OR remained significant regardless of ML (>median: p=.027; ≤median: p=.023), indicating that the effect of DDR was independent of ML. **Conclusions:** DDR alts appeared to be associated with OR to PD1/PDL1 blockade and should be integrated into future validation efforts along with other potential predictors of response.

4510 Clinical Science Symposium, Fri, 2:45 PM-4:15 PM

Cancer predisposing germline mutations in patients (pts) with urothelial cancer (UC) of the renal pelvis (R-P), ureter (U) and bladder (B). *First Author: Maria Isabel Carlo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Urothelial cancers (UC) are suspected to have a substantial hereditary component, but other than highly penetrant genes such as those in mismatch-repair pathway (e.g. *MSH2*) typically associated with R-P/U primaries, heritable gene mutations have not been systematically studied. We sought to investigate the prevalence of known cancer pre-disposing germline mutations in pts with UC originating from all sites within the urinary tract. **Methods:** Pts with R-P, U and B primaries, unselected for suspicion of inherited cancer syndrome, were prospectively enrolled from medical oncology and urology clinics to a germline sequencing protocol from June 2016 to January 2017. Germline gene analysis was performed in a CLIA-certified lab using a next generation sequencing (NGS) platform (MSK-IMPACT) that analyzes tumor-normal DNA pairs. The germline gene panel consisted of 76 genes associated with hereditary cancer predisposition. **Results:** As of January 24, 2017, 101 pts have NGS results available, with median age 63 (31-87), 76% male, 24% female. Primary sites were B (67%), R-P/U (31%), or both (3%). 73% had organ-confined disease and 27% had metastases. 8% had early onset (≤45 yrs at diagnosis), 10% had a family history of UC, 25% had documented non-UC cancers. 25 pathogenic or likely pathogenic (P-LP) mutations were identified in 22 patients. P-LP mutations were present in 29% of pts with R-P/U primaries and 18% of pts with B primaries. 12 DNA damage response gene alterations were found (4 *CHEK2*, 3 *BRCA1*, 2 *BRCA2*, 1 *ATM*, 1 *BRIP1*, 1 *NBN*) and 8 in Lynch syndrome associated genes (5 *MSH2*, 2 *MSH6*, 1 *MLH1*). Other mutations include 2 *APC*, 1 *TP53*, and 1 *FH*. Notably 3 pts had 2 alterations each (*MSH6*/*APC*, *BRCA2*/*APC*, *BRCA1*/*CHEK2*). 9/22 pts with P-LP mutations did not meet American College of Medical Genetics criteria for genetic screening. **Conclusions:** 22% of UC pts had a germline mutation in a cancer-associated gene. There was an unexpectedly high frequency of pts with DNA-repair pathway mutations. Active accrual is ongoing to define the full spectrum of alterations. These results have profound implications for genetic counseling and screening and further studies are warranted.

4511 Clinical Science Symposium, Fri, 2:45 PM-4:15 PM

Mismatch repair (MMR) detection in urothelial carcinoma (UC) and correlation with immune checkpoint blockade (ICB) response. *First Author: Gopa Iyer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: High mutation burden correlates with response to ICB in UC. Loss of function alterations or epigenetic silencing of MMR genes results in MMR deficient (MMR-D) UC, leading to a microsatellite instability (MSI) mutation signature. We used a CLIA-certified pipeline (MSISensor) to interrogate Next Generation sequencing (NGS) data from UC tumors to identify MMR-D patients (pts). We correlated MMR-D with mutation load and response to ICB. **Methods:** 447 tumors from 424 UC pts underwent prospective NGS using the MSK-IMPACT exon capture assay and genomic interrogation of microsatellite (MS) sites using MSIsensor, which assesses the number/length of MS within the targeted regions of tumor-normal sample pairs. Loci are considered unstable (somatic) if k-mer distributions are significantly different between tumor and matched normal using a standard multiple testing correction of $\chi 2$ p-values. The fraction of unstable sites is reported as an MSIsensor score. MSI high tumors have scores >10 while <3 are denoted MS stable. Scores from 3-10 were categorized as MS intermediate. **Results:** Thirteen pts (3%) had an MSI score >10 and a median mutation count of 52 (36.5-73.5) vs 8 (5-13) in 410 non-MMR-D pts (p<0.01). Ten pts (71%) had upper tract UC. Of 9 pts with germline sequencing performed, 8 (89%) had heritable loss of function mutations in MMR proteins (Lynch syndrome, LS). One pt had a somatic MSH2 mutation. Fifteen pts had MS scores from 3-10: 3 had LS, one a BRCA1 germline alteration, and 9 did not have germline testing available. Two pts with MSI scores <3 had extremely high mutation loads (213 and 414) and both had POLE mutations. Five pts received ICB therapy for metastatic and all achieved near-complete or complete responses. No MMR-D pt has died at 27 months follow-up vs 125 non-MMR-D pts (p=0.014). **Conclusions:** The MSI Sensor assay can discriminate MSI high from MMR proficient UC. While rare, MMR-D UC is characterized by a high mutation load, strong association with Lynch syndrome, and durable responses to ICB, similar to data in colon cancer. An MMR-D signature should trigger genetic testing for Lynch syndrome. ICB should be considered early in the treatment course of patients with MMR-D metastatic UC.

4512 Clinical Science Symposium, Fri, 2:45 PM-4:15 PM

Subclonal mutational heterogeneity and survival in cisplatin-resistant muscle-invasive bladder cancer. *First Author: David Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: Biomarkers of survival and resistance in chemotherapy-resistant muscle-invasive bladder cancer (MIBC) are not well-characterized, but may inform management in this setting. **Methods:** Matched pre- and post-neoadjuvant cisplatin-based chemotherapy (NAC) tumor samples were obtained from 30 MIBC patients with gross residual disease (≥ pT2) at cystectomy, followed by whole exome sequencing of these "trios" (pre- and post-NAC tumor with matched germline samples). Phylogenetic analysis of matched tumor samples was performed to identify subclones, their associated mutations, and the corresponding enrichment in post-treatment tumors. Intratumoral heterogeneity was assessed by the proportion of mutations that were subclonal; the number of inferred subclones; and associated with overall survival using a Cox Proportional Hazards model. **Results:** Increased proportion of subclonal mutations in post-treatment tumors was associated with worse overall survival (HRR 1.86 [95% CI 1.12-3.06], p = 0.02), whereas pre-treatment proportion of subclonal mutations was only borderline statistically significant (HRR 1.48 [95% CI 0.99-2.20], p = 0.052). The total number of inferred tumor subclones in pre- or post-treatment tumor (or both) was associated with overall survival (HRR 1.60 [95% CI 1.05-2.43], p = 0.03), interpreted as a 60% increase in death rate per additional inferred subclone. While no single gene was statistically significantly enriched for new alterations in the post-chemotherapy resistant samples, we observed new post-treatment amplifications in cell-cycle genes (*E2F3*, *c-JUN*), biallelic events in cell-cycle regulators (*FBXW7*), and amplification of immune checkpoint genes (*PDL1/2*). **Conclusions:** These results suggest that intratumoral heterogeneity (particularly post-therapy) predicts survival in a chemotherapy-resistant cohort. Further, alterations in cell cycle regulation may contribute to the mechanism of chemotherapy resistance. Finally, we observe evidence of immune checkpoint gene amplification post-treatment, suggesting that testing immune checkpoint blockade during NAC or, in high risk patients, following NAC may be warranted.

4513 Poster Discussion Session; Displayed in Poster Session (Board #191), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Phase II study of alternate sunitinib schedule in patients with metastatic renal cell carinoma. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sunitinib is an antiangiogenic agent indicated for the treatment of metastatic renal cell carcinoma (mRCC). Sunitinib is given in a 4 week on, 2 week off (4/2) schedule. Significant toxicities are observed in patients in the 3rd and 4th weeks of therapy. We hypothesized that a 2 week on, 1 week off (2/1) schedule would provide improved toxicity without compromising efficacy. **Methods:** A multicenter, single arm study was performed, with patients initiating sunitinib 50mg on a 2/1 schedule. Schedule and dose alterations were performed if grade > 3 toxicities were observed. The primary objective was to determine the percentage of patients who experienced grade > 3 fatigue, diarrhea, or HFS. The sample size of 60 patients was selected to ensure the upper bound of a 95% confidence would fall below standard schedule rate of 25%-30% if sample rate was 10%-15%, respectively. Secondary outcomes included response rate (RR), progression free survival (PFS) and dose reductions. **Results:** Between August 2014 and April 2016, 60 patients were enrolled, and 59 treated. Patients had a median age of 65.5 years (ranging from 45-92). 24% of patients (14/59) had grade 3 or higher fatigue, diarrhea, or HFS (95% CI: 13.6%, 36.6%). This is similar to the average of the 4 week on, 2 week off schedule of 25%-30%, and the lower bound of the confidence interval is in the center of our target rate of 10%-15%. Among events at least possibly related to study drug, patients were most likely to experience the expected events of diarrhea (75% with 5 grade 3 events), fatigue (71% with 6 grade 3 events), and HFS (54% with 3 grade 3 events). 22 (37%) patients responded (25.0%, 50.9%). Among patients with secondary endpoint data available, median PFS was 19.3 months (95% CI: 8.2, NR) and 33/56 (59%) of patients underwent dose reduction. **Conclusions:** Sunitinib administered in a 2/1 schedule in this study did not result in a lower rate of grade 3 or higher fatigue, diarrhea or HFS when compared to historical data from trials employing a 4/2 schedule. However, efficacy data showed robust response rate and a prolonged PFS, suggestive of long-term tolerability in patients receiving sunitinib on a 2/1 schedule. Evaluation of toxicity kinetics and patient quality of life is ongoing. Clinical trial information: NCT02060370.

4514 Poster Discussion Session; Displayed in Poster Session (Board #192), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Phase II study of individualized sunitinib (SUN) as first-line therapy for metastatic renal cell cancer. *First Author: Georg A. Bjarnason, Sunnybrook Research Institute, Toronto, ON, Canada*

Background: Higher SUN exposure is associated with better outcomes. Patients (pts) with minimum toxicity on the standard schedule do worse than pts needing dosing changes for toxicity. **Methods:** It was hypothesized that toxicity-driven dose/schedule individualization would improve the primary endpoint (PFS) from 8.5 (EFFECT trial) to 14 months (mo), with 99 pts required to detect this with 90% power and 2-sided alpha = 0.05. In a prospective phase II study (eligibility as EFFECT) pts start on 50 mg/day (d) for 28 d with treatment (Rx) breaks reduced to 7 d. If grade-2 toxicity develops before d 28, pts stay on a 50 mg on the next cycle with the number of d on Rx individualized aiming for ≤ grade-2 toxicity. Dose is reduced to 37.5 mg and then 25 mg if pts do not tolerate a 50 mg or 37.5 mg dose respectively for at least 7 d. Pts with minimum toxicity on d 28 are escalated to 62.5 mg and then 75 mg. **Results:** 117 pts were enrolled in 12 centers. Nine non-evaluable pts came off early due to toxicity (5), non-compliance (2) and global deterioration (2). Of 108 pts evaluable for response (IMDC favorable 31.5%, intermediate 58.3%, poor 10.2%. Bone mets 19%, Nephrect 83%), 10 are still on Rx. Dose was escalated in 20 pts (18.5%) to 62.5 mg (12 pts) and then to 75 mg (8 pts). In 49 pts (45.4%) eligible for dose reduction by standard criteria, a 50 mg dose was maintained but for 7 - 24 d, while 7 pts (6.5%) stayed on a 28 d schedule. Dose was reduced to 37.5 mg in 22 pts (20.4% vs. 36 - 63% in 4 large SUN trials) and to 25 mg in 10 pts (9.3% vs. 27 - 43% in 4 trials). Rx was stopped due to toxicity in 10/117 pts (9.3% vs. 15 - 19% in 4 trials). See table for response (ORR, 108 pts) and survival (117 pts) data vs. EFFECT (146 pts). The median followup is 15.5 mo (0.6 -37.9) for PFS and 24.5 mo (4.4 - 47.7) for OS. **Conclusions:** The null hypothesis of the PFS being 8.5 mo can be rejected with a p < 0.001. Individualized dosing is safe and feasible in a multicenter setting and associated with improved dose intensity and one of the best ORR, PFS and OS reported for a TKI. Clinical trial information: NCT01499121.

	Current study	EFFECT 4/2 arm
CR%	2.8 (n = 3)	0
PR%	47.2 (n = 51)	32
CR + PR%	50.0 (n = 54)	32
SD%	40.7 (n = 44)	43
CR+PR+SD%	90.7 (n = 98)	75
PD%	9.2 (n = 10)	25
PFS (mo), (95% CI)	11.9 (9.3-16.5)	8.5 (6.9-11.1)
OS (mo) (95% CI)	35.9 (27.4- not reached)	23.1 (17.4-25.4)

Epacadostat plus pembrolizumab in patients with advanced RCC: Preliminary phase I/II results from ECHO-202/KEYNOTE-037. *First Author: Primo Lara, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Epacadostat (E) is a potent oral inhibitor of indoleamine 2,3-dioxygenase 1 (IDO1), a tryptophan-catabolizing enzyme that induces immune tolerance by T-cell suppression. Preclinical and clinical data suggest that epacadostat has antitumor activity when combined with checkpoint inhibitors, including the PD-1 inhibitor pembrolizumab (P). ECHO-202/KEYNOTE-037 is an ongoing open-label, phase 1/2 (P1/2) study evaluating E + P in multiple tumor types. We report preliminary P1/2 efficacy and safety data for the advanced renal cell carcinoma (RCC) cohort as of a 29OCT2016 data cutoff. **Methods:** Eligible patients (pts) had advanced clear-cell RCC, prior antiangiogenic therapy (tx), and no prior checkpoint inhibitor tx. In P1 dose escalation (3+3+3), pts received E (25, 50, 100, or 300 mg PO BID) + P (2 mg/kg or 200 mg IV Q3W); MTD was not exceeded. E (100 mg BID) + P (200 mg Q3W) dosing was selected for P2 cohort expansion. Response was assessed in RECIST 1.1 evaluable pts. Safety/tolerability was assessed in pts receiving ≥1 E + P dose. **Results:** 33 pts (P1, n = 11; P2, n = 22) were enrolled (median age, 63 years; 70% men; 97% white; MSKCC criteria of favorable, intermediate, and poor in 6%, 64%, and 12% of pts, respectively). Of 30 efficacy-evaluable pts, 63% (n = 19) had 0–1 prior tx and 37% (n = 11) had ≥2 prior tx for advanced disease. ORR (CR+PR) and DCR (CR+PR+SD) for pts with 0–1 prior tx was 47% (9/19; 1 CR, 8 PR) and 58% (11/19; 1 CR, 8 PR, 2 SD), respectively; for pts with ≥2 prior tx, ORR and DCR were 0% and 36% (4/11; all SD). At data cutoff, 9/9 responses were ongoing (range, 1+ to 372+ days). PFS and biomarker analyses are ongoing. TRAEs occurring in ≥10% of the 33 pts included fatigue and rash (36% each); and arthralgia, diarrhea, pruritus, and pyrexia (12% each). Grade ≥3 TRAEs occurred in 15% of pts (none in > 1 pt). Two pts discontinued due to TRAEs (grade 3 autoimmune hepatitis, n = 1; grade 3 aseptic meningitis/headache/nausea/vomiting/anxiety, n = 1). **Conclusions:** E + P was generally well tolerated and associated with encouraging response outcomes in advanced RCC pts with 0–1 prior line of tx. E + P represents a novel immunotherapeutic strategy. A phase 3 RCC study is planned. Clinical trial information: NCT02178722.

Phase II study of pazopanib in patients with von Hippel-Lindau disease. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Von Hippel-Lindau disease (VHL) is an autosomal dominant inherited disorder. Affected individuals develop vascular neoplastic lesions in multiple sites including eye, brain, pancreas, adrenal and kidney. Standards of care include surveillance imaging and surgical intervention. We hypothesized that treatment of VHL related lesions with an antiangiogenic agent would result in shrinkage of all lesion types. We chose the multikinase inhibitor pazopanib to test this hypothesis. **Methods:** After obtaining IRB approval, patients with clinical features or genetic confirmation of VHL disease and with measurable lesions were treated with pazopanib 800mg PO daily for two 12-week cycles. Efficacy was determined by RECIST after two cycles. Patients had the option to continue therapy if considered in patient's best interest. Continuous monitoring for any lesion progression and drug discontinuation due to toxicity during the whole period of the treatment was planned. **Results:** Patients were enrolled (N=32) and treated (N=31) between 1/2012 and 6/2016. Median age was 37 (range 19-67). 23 patients had genomically confirmed VHL disease; four had family and personal history but had not undergone genetic testing, and five patients had clinical features of VHL disease and negative genetic testing. A median of two cycles (range 1-12) of therapy was administered. Of 31 evaluable patients, 13 (42%) showed a response, 18 patients had stable disease and no patients had PD as best response. Responses were seen in renal (2 CR and 29 PR/59 total), pancreatic (9 PR/17 total) and CNS 2 PR/49 total) target lesions. The most common side effect was diarrhea (grades 1 and 2) experienced in 14 patients. Twelve patients dose reduced to 600 mg and 6 to 400 mg pazopanib PO daily. Eight patients discontinued therapy due to adverse events of whom 4 experienced transaminitis. One patient experienced a grade V CNS hemorrhage. **Conclusions:** This is the largest prospective VHL disease specific therapeutic study performed to date. Pazopanib resulted in significant and sustained disease control for the majority of VHL patients enrolled on the study, with an acceptable safety profile. This agent may be considered as an alternative to surgical intervention in patients with VHL disease. Clinical trial information: NCT01436227.

Comprehensive genomic profiling (CGP) of advanced papillary renal cell carcinoma (PRCC) to reveal distinctions from TCGA dataset. *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Biologic characterization of PRCC by TCGA reveals alterations in *MET* in type 1 disease, and *CDKN2A*silencing, *SETD2* mutations and *TFE3* fusions in type 2 disease. A limitation of TCGA data is that of 161 pts analyzed, 73% and 3% had M0 and M1 disease, respectively. We present the gene alterations (GA) identified in pts with advanced PRCC.**Methods:** FFPE tissue was obtained from 169 patients with PRCC. Diagnosis and PRCC subtyping was centrally confirmed by 2 board-certified pathologists. DNA was extracted and comprehensive genomic profiling (CGP) was performed (median coverage, 648X) in a CLIA-certified central laboratory. **Results:** Of 169 pts with advanced PRCC, 39 (23%) were type 1, 108 (64%) were type 2 and 22 (13%) were unclassified. 66 samples (39%) were from a metastatic site biopsy, and 103 were from the kidney (61%). An average of 2.4 GA/tumor were detected. In type 1 pts, commonly altered genes were *MET* (33%: 8 activating mutations, 5 amplifications), *TERT* (30%), *CDKN2A/B* (13%), and *EGFR* (8%). In type 2 pts, commonly altered genes were *CDKN2A/B* (18%), *TERT* (18%), *NF2* (13%) and *FH* (13%); *MET*GAs (5 mutations, 3 amplifications) were observed in 7.4% of type 2 pts. *MET* GA was significantly associated with type 1 PRCC (p = 0.0002) and *NF2* GA and alterations in SWI/SNF complex genes were both significantly associated with type2 PRCC (p = 0.02 and p = 0.007, respectively). Overall, frequent alterations were found in genes involved in SWI/SNF complexes (25%), chromatin modification (23%) and cell cycle regulation (22%). RAS/RAF pathway (9%) and PI3K/mTOR pathway (8%). Notable differences with TCGA include higher frequencies of *MET* and *NF2* GAs, association of GAs in the SWI/SNF with type 2 PRCC, and frequent *CDKN2A/B* alteration in both type 1 and type 2 disease. *MET* alteration was lower in metastases vs primary (type 1: 15% vs 38%; type 2: 4% vs 10%). **Conclusions:** In a cohort of PRCC patients slightly larger than the TCGA experience, key differences in CRGA frequency were observed. These likely underscore the marked difference in stage distribution between datasets. Results of this study may inform trials of relevant targeted therapy in metastatic PRCC.

Multiregion sequencing of penile cancer to reveal distinct patterns of heterogeneous actionable mutations. *First Author: Simon Rodney, University College London, London, United Kingdom*

Background: Penile cancer is a rare but mutilating disease. Due to its rarity few studies have investigated the molecular oncogenic changes. There is a huge need to improve the poor outcome of metastatic disease by advancing the standard practice of platinum based therapies. Treatment based on actionable mutations and the potential of immunotherapies may improve clinical outcomes. We present the first analysis of intra-tumour heterogeneity within penile cancer. **Methods:** Tissue samples, greater than 80% purity, were collected from four spatially distinct tumor regions together with matched normal and metastatic tissue. Deep whole exome sequencing was performed on the resulting 48 samples from eight patients. Mutations were called by using Mutect2 and annotated with Annovar. Copy number changes were estimated using Sequenza and phylogenetic trees created using pyclone. **Results:** A mean of 650 single nucleotide variants and insertion/deletion events were discovered per tumor sample. Extensive intra-tumor heterogeneity was found with a wide range of different predicted subclonal architectures. Two distinct patterns were noted: either the acquisition of mutations by the lymph node metastasis was an early event with a lower mutational load, or it was a later event with a high mutational load. In the two instances where patients were negative for human papillomavirus infection, the lymph node metastasis evolved at a later date. However in 5/6 cases of HPV infection, an early subclone developed which potentially led to the lymph node metastasis. Driver mutations in *p53*, *cMET* or *FAT1* were found to be truncal early events in 80% of cases. Actionable mutations in *PIK3CA* and *EGFR* were found to be subclonal in two further samples. **Conclusions:** There is extensive intra- and inter-tumour heterogeneity within penile cancer. The main truncal drivers in penile cancer are *cMET*, *FAT1* and *p53*. Samples infected with human papillomavirus appeared to have a distinct signature in terms of both copy number changes and clonal architecture. Actionable mutations *PIK3CA* and *EGFR* were found to be subclonal in origin. This may have profound effects on the clinical utility of targetable treatments such as tyrosine kinase inhibitors.

Infusional gemcitabine + docetaxel/melphalan/carboplatin (GemDMC) ± bevacizumab (BEV) as an effective high-dose chemotherapy (HDC) regimen for refractory of poor-risk relapsed germ-cell tumors (GCT). *First Author: Yago Nieto, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tandem HDC with carbo/etoposide (CE) is curative for a portion of relapsed GCT pts. However, outcomes of refractory or high-risk relapsed pts remain poor. We tested a new HDC regimen of GemDMC, based on DNA damage repair inhibition. We combined BEV with HDC given their potential synergy and the high vascularity of GCT metastases. **Methods:** Eligibility: Intermediate (int)/high-risk (Beyer Model), creatinine ≤1.8 mg/dL and adequate organ function. HDC included BEV (5 mg/kg) preceding GemDMC (HDC #1) and ifosfamide/CE (ICE) (HDC #2). Following accrual of 42 pts, we amended the trial omitting BEV. The trial was powered to distinguish a target 50% 2-yr RFS from an expected 25% in this population. **Results:** We enrolled 69 male pts in cohorts 1 (BEV, N=42) and 2 (no BEV, N=27) (Table). Pts were heavily pretreated and most had refractory tumors. Main AE: mucositis and renal (4 HDC-related deaths in cohort 1, 1 in cohort 2). Tumor markers normalized in 90% pts with active tumors at HDC. After HDC, 19 pts were in CR and 28 in PRm- (of these, 22 had residual lesions resected with no viable tumor found in 20/22, 2 xRT, 4 monitored). Median f/u = 39 (2-105) mo. The 2-yr RFS rates in cohorts 1 and 2 = 52% and 78%, respectively. Their respective 2-yr OS rates = 55% and 81%. **Conclusions:** Sequential HDC with GemDMC–ICE shows encouraging outcomes in heavily pretreated and refractory GCT, exceeding the anticipated results. Addition of BEV increases toxicity but not tumor control. Clinical trial information: NCT00936936.

Phase II trial of pembrolizumab in patients (pts) with incurable platinum refractory germ cell tumors (GCT). *First Author: Nabil Adra, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Despite remarkable results with salvage standard-dose (SDCT) or high-dose chemotherapy (HDCT), about 15% of pts with relapsed GCT are incurable. Immune therapy with Pembrolizumab is a novel approach for salvage in pts with metastatic GCT. **Methods:** Single arm phase 2 trial investigating pembrolizumab 200mg IV Q3weeks until disease progression in pts with relapsed GCT and no curable options. Pts age≥18 with metastatic GCT who progressed after first line cisplatin-based chemotherapy and after at least 1 salvage regimen (HDCT or SDCT) were eligible. Centrally assessed PD-L1 on tumor infiltrating immune cells using PD-L1 (22C3) assay was scored as 0, 1, 2, 3 along with PD-L1 expression score (H-score) incorporating intensity of staining. Pts were eligible irrespective of PD-L1 expression status. The primary endpoint was overall response rate using immune-related response criteria. Simon's 2-stage design required response in ≥ 1/12 pts to proceed to stage 2 enrolling 8 more pts for a total of 20. **Results:** 12 male pts were enrolled. Median age 38 (range, 27-55). All pts had non-seminoma. Primary tumor site was testis in 11 pts and mediastinum in 1. Median AFP 615 (range, 1-32,760) and hCG 4 (range, 0.6-37,096). 5 pts had late relapse (> 2years). Median number of previous chemotherapy regimens was 3 (range, 1-6). 6 pts received prior HDCT. 2 pts had positive PD-L1 staining (H-score 90 and 170). Median number of deliverable pembrolizumab doses was 2 (range, 1-8). There were 5 grade 3 adverse events, with 3 events possibly related to study treatment (chest pain, hyperglycemia, abdominal pain). No partial or complete responses were observed. 2 pts achieved stable disease for 12 and 9 weeks respectively; 10 pts had progression of disease as their best response. The 2 pts with stable disease had continued rising AFP level despite radiographic stability; both had negative PD-L1 staining. **Conclusions:** This is the first reported trial evaluating immune checkpoint inhibitors in GCT. Although 2 pts had stable disease, each had rising tumor markers suggesting continued treatment resistance. Pembrolizumab is well tolerated but does not appear to have clinically meaningful single-agent activity in refractory GCT. Clinical trial information: NCT02499952.

FDG PET scan (PET) positive residual lesions after chemotherapy (chemo) for metastatic seminoma: Results of an International Global Germ Cell Cancer Group (G3) registry. *First Author: Richard Cathomas, Kantonsspital, Chur, Switzerland*

Background: Residual disease is a frequent finding after chemo for metastatic seminoma. Watchful waiting is recommended for residual lesions < 3 cm or lesions ≥3 cm with negative PET. Data on the optimal management of PET positive residual lesions is lacking. **Methods:** A retrospective analysis within the G3 Group identified 91 patients (pts) from 9 countries with metastatic seminoma and residual PET positive lesions after chemo. Pts with elevated AFP (> 2xULN) or non-seminomatous components at diagnosis were excluded. We analyzed the post PET management chosen and its impact on relapse and survival. **Results:** Median follow-up was 29 (IQR 10 – 64) months. Median age at diagnosis was 41 (range 19 – 69) years. The primary tumor was gonadal in 68 pts (76%), retroperitoneal in 12 pts (13%) and mediastinal in 10 pts (11%). Prior to chemo the median size of the largest metastasis was 10 (range 1.4 – 23) cm, 67 pts (74%) had elevated LDH and 51 pts (57%) elevated HCG. Median diameter of the largest residual mass was 4.8 (range 1.1 – 14) cm mainly located in the retroperitoneum (77%), pelvis (15%), mediastinum (16%) or lung (4%). Median time from last day of chemo to PET was 7 (IQR 4 – 10) weeks. Post PET management was repeated imaging in 46 pts (51%), resection in 32 pts (35%), biopsy in 9 pts (10%) and radiotherapy in 4 pts (4%). Histology of the resected specimen was necrosis only in 25 (78%) and vital seminoma in 7 cases (22%). No biopsy revealed vital seminoma. Relapses occurred after a median of 3.7 (IQR 2.5 – 4.9) months in 16 pts (18%): 2/9 (22%) after biopsy, 12/46 (26%) on repeated imaging and 2/32 (6%) after resection (one necrosis, one < 10% vital seminoma). Site of relapse was the area of residual disease in 14 pts (88%) and additional distant relapse (one bone, one lung) in 2 pts (12%). All relapsed pts received successful salvage chemo apart from one who died from treatment and two pts who are alive with ongoing treatment. **Conclusions:** PET positive post chemo residual lesions in seminoma pts are false positive in about 75%. Relapses in PET positive pts occur early and can be salvaged with chemo. Further analysis is needed to identify risk factors for relapse.

Association of on-treatment plasma HGF levels with overall survival (OS) in patients (pts) with advanced renal cell carcinoma (RCC) treated with interferon alpha (INF) +/- bevacizumab (BEV): Results from CALGB 90206 (Alliance). *First Author: Daniel J. George, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Elevated baseline HGF levels were associated with shorter OS in pts treated with BEV+INF. We evaluated on-treatment HGF levels to describe treatment-related changes and associations with outcome. **Methods:** We analyzed baseline EDTA plasma samples from 310 pts (148 INF; 162 BEV+INF) using an optimized multiplex ELISA platform for HGF at baseline and after 4-weeks (wks) on treatment. Primary endpoint of this analysis was OS. The Kaplan-Meier estimated the OS distribution and the proportional hazards model tested the prognostic importance of change at 4-wks from baseline in HGF levels in predicting OS, adjusting for treatment arm, bone metastases and stratification variables. **Results:** The median baseline HGF level in 310 pts was 161.4 pg/ml. Elevated HGF at 4-wks (>median) was associated with a worse OS (median OS = 14 vs 27 months; adjusted hazard ratio (HR)= 1.75, p< 0.0001). Only 9/155 pts (5.8%) with baseline HGF levels ≤ median developed elevated HGF (>median) at 4-wks; 66/155 pts (43%) with baseline HGF levels >median lowered HGF (<median) at 4-wks from baseline. Compared to pts with persistently elevated HGF levels, a decline in HGF levels at 4-wks (< median) was associated with improved OS (19 vs 13 months, adjusted HR=1.41, p=0.043). **Conclusions:** In RCC pts with low baseline HGF levels (< median), levels remain consistently low and are associated with improved OS. Conversely, in pts with high baseline HGF levels results are split; some patients continue to have high levels on treatment and are associated with a worse OS, suggesting that, HGF predicts for therapeutic benefit and represents a potential mechanism of resistance. Support: U10CA180821, U10CA180882. Clinical trial information: NCT00072046.

4523 Poster Discussion Session; Displayed in Poster Session (Board #201), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Integrated biomarker analysis for 412 renal cell cancer (RCC) patients (pts) treated on the phase 3 COMPARZ trial: Correlating common mutation events in *PBRM1* and *BAP1* with angiogenesis expression signatures and outcomes on tyrosine kinase inhibitor (TKI) therapy. *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In RCC biology mutations in *PBRM1* and *BAP1*are largely non-overlapping and collectively affect >50% of pts. How and through which mechanism they influence disease kinetics is poorly understood. Sunitinib and pazopanib inhibit angiogenesis, a key driver in RCC. We analyzed mutation status and gene expression signatures in a large cohort of pts receiving first-line sunitinib or pazopanib on the COMPARZ trial. **Methods:** RNA and DNA were extracted from archival tissue. *PBRM1* and *BAP1*mutation status was determined via a custom exon-targeted platform. Transcriptome analysis was done using Affymetrix GeneChip HTA 2.0. We computed a 43 gene angiogenesis expression score with previously reported dynamic response to VEGF-directed therapy in xenograft models (Masiero, Cancer Cell 2013). DNA and RNA findings were correlated with clinical outcomes using parametric and non-parametric tests. **Results:** 412 pts contributed tumor RNA, 377 pts DNA; 362 pts both. PBRM1 and BAP1 were mutated (MT) in 44% and 15% of pts, respectively. Presence of *PBRM1*mutations correlated with superior PFS (p=0.008) and OS (p=0.004) on log-rank test, and PBRM1 mutation rate was higher in pts with objective response than those with progression (Fisher's Exact, p=0.012). In contrast, pts with MT BAP1 had inferior OS compared to those whose were wild type (WT) (log-rank, p=0.012). Across all 412 pts angiogenesis score associated favorably with outcome on uni and multivariate analyses (Cox proportional hazard regression, OS p<0.001 and PFS p<0.005); scores were higher in 123 pts with objective response than 81 pts with progression as best response (Mann-Whitney, p=0.009). Angiogenesis scores were higher in PBRM1 MT vs WT patients (Mann-Whitney, p<0.001), but lower in BAP1 MT vs WT patients (p<0.001). **Conclusions:** PBRM1 and BAP1 mutations appear to have opposite effects in advanced RCC. Loss of PBRM1 enhances the pro-angiogenic microenvironment of RCC with favorable effects on response to TKI; BAP1 loss associates with decreased angiogenic signaling and adverse outcome to TKI. Clinical trial information: NCT00720941.

Discovery and prevalence of cancer-susceptibility germline mutations (Mts) in patients (Pts) with advanced renal cell carcinoma (aRCC). *First Author: Maria Isabel Carlo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: About 5% of RCC is thought to be familial, but recent studies suggest this may be an underestimate (Int. J. Cancer;100:476). We studied the prevalence of germline cancer-susceptibility mts in pts with aRCC. **Methods:** Pts with aRCC (stage III or IV), unselected for suspicion of an inherited cancer syndrome, were offered germline testing for 76 cancer-associated genes between 10/2015 and 12/2016. Germline sequencing was done as part of MSK-IMPACT, a matched tumor-normal next-generation sequencing platform. **Results:** 203/213 pts accepted testing (median age 55, range 13-55) of whom 73% had clear cell RCC (ccRCC), 92% had metastases, 20% were early onset (≤46 yrs at diagnosis), 9% had a family history of RCC, 6% multifocal RCC at diagnosis, and 15% ≥2 primary malignancies. Pathogenic/likely pathogenic mts were found in 35 pts (17%): 12 (6%) with mts in genes associated with familial RCC; 10 (5%) mts in high/moderate penetrance genes not linked to RCC (Table).13 (6%) had mts in genes of low/uncertain penetrance or for autosomal recessive disease. Mts were present in 15% of ccRCC and 19% of non-ccRCC. Mts were not more common in pts with early onset, family history, multifocal RCC, or ≥2 malignancies ($p>0.1$ for each by Fisher's exact test). Notably, 4/12 pts with mts in familial RCC genes did not meet the American College of Medical Genetics (ACMG) criteria for testing (1 each *VHL*, *BAP1*, *SDHA*, *FH*). Prevalence of *CHEK2* mts was compared to population databases (ExAC); *CHEK2* conferred a relative risk of 10.9 ($p< 0.002$; CI=3.9-24.7) for RCC. **Conclusions:** 17% of aRCC pts had a germline mutation in a cancer-associated gene of which 33% of the high penetrance RCC germline mts were not identified using standard clinical criteria, providing rationale for broad testing. Once the increased risk is confirmed, *CHEK2* should be included in RCC genetic testing.

Selected Genes	Frequency (%)	# of ccRCC cases	# of nccRCC cases	Age at Dx
CHEK2	6 (3.0)	5**	2**	(52-69)
FH	5 (2.5)	0	5	(25-53)
BAP1	3 (1.5)	3*	2*	(44-64)
MET	1 (0.5)	0	1	67
SDHA/SDHB	2 (1.0)	1	1	35-55
VHL	1 (0.5)	1	0	57
MSH6	1 (0.5)	1	0	60
BRCA2	1 (0.5)	1	0	60
PALB2	1 (0.5)	0	1	28
RAD51C	1 (0.5)	1	0	57

*2 pts with *BAP1* had both ccRCC and nccRCC; **1 pt with *CHEK2* had both ccRCC and nccRCC

4525 Poster Session (Board #203), Sun, 8:00 AM-11:30 AM

Updated efficacy and tolerability of durvalumab in locally advanced or metastatic urothelial carcinoma (UC). *First Author: Noah M. Hahn, Johns Hopkins University Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Anti-PD-L1 immunotherapy shows promising clinical activity in UC. We report a planned update of the safety and efficacy of durvalumab in patients (pts) with locally advanced/metastatic UC from a multicenter, phase 1/2 open-label study. **Methods:** Pts received durvalumab 10 mg/kg every 2 weeks (Q2W) up to 12 months (mo) or until unacceptable toxicity, progression, or starting another anticancer therapy. Primary endpoints were safety and confirmed objective response rate (ORR) by blinded independent central review (RECIST v1.1). Duration of response (DoR), progression-free survival (PFS) and overall survival (OS) were key secondary endpoints. Tumor PD-L1 expression was assessed by Ventana SP263 assay (PD-L1 high = ≥25% PD-L1 expression on tumor or immune cells). **Results:** As of Oct 24, 2016 (data cutoff [DCO]), 191 pts had received treatment. Median follow-up was 5.78 mo (range, 0.4–25.9). All pts had Stage 4 disease and 99.5% had prior anticancer therapy (95.3% post-platinum). As of DCO, ORR was 17.8% (34/191), including 7 CRs, with responses observed regardless of PD-L1 status (Table). Responses occurred early (median time to response, 1.41 mo) and were durable (median DoR not reached [NR]). Median PFS and OS were 1.5 mo (95% CI, 1.4, 1.9) and 18.2 mo (95% CI, 8.1, not estimable [NE]), respectively; the 1-year OS rate was 55.0% (95% CI, 43.9%, 64.7%). Grade 3/4 treatment-related AEs occurred in 6.8% of pts; grade 3/4 immune-mediated (im)AEs occurred in 4 pts; 2 pts discontinued due to imAEs (acute kidney injury and autoimmune hepatitis). **Conclusions:** Durvalumab 10 mg/kg Q2W shows favorable clinical activity and an excellent safety profile in locally advanced/metastatic UC pts. Table. Antitumor activity in UC pts, including second-line or greater (≥2L) post-platinum pts Clinical trial information: NCT01693562.

All UC	Total N = 191	PD-L1 high n = 98	PD-L1 low/negative n = 79	PD-L1 unknown n = 14
Confirmed ORR, % (95% CI)	17.8 (12.7, 24.0)	27.6 (19.0, 37.5)	5.1 (1.4, 12.5)	21.4 (4.7, 50.8)
CR, %	3.7	4.1	2.5	7.1

Health-related quality of life as a marker of treatment benefit with nivolumab in platinum-refractory patients with metastatic or unresectable urothelial carcinoma from CheckMate 275. *First Author: Andrea Necchi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: CheckMate 275 (NCT02387996), a phase II, single-arm study of nivolumab (3 mg/kg every 2 weeks) treatment in platinum-refractory patients (pts) with metastatic urothelial carcinoma, showed an objective response rate of 19.6% (95% CI, 15.0%–24.9%) with manageable toxicity. The objective of this analysis was to examine the impact of nivolumab on health-related quality of life (HRQoL) in the study. **Methods:** HRQoL was measured using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30) and three-level EQ-5D (EQ-5D-3L) and visual analog scale (VAS). Questionnaires were completed at baseline and every 8 weeks thereafter for the first 48 weeks. The analysis cohort included pts with scores recorded at baseline and ≥1 postbaseline assessments while on treatment. Data were analyzed using mixed models, adjusting for baseline score. **Results:** Of the 270 patients treated with nivolumab, 168 (62%) had an assessment at baseline and ≥1 postbaseline assessment and were included in HRQoL analyses. Completion rates at baseline were 97% for both questionnaires. Statistically significant ($P< 0.05$) improvements in mean scores for the EORTC QLQ-C30 subscales measuring role, emotional, and social functioning; global health status/quality of life; nausea/vomiting; pain; dyspnea; insomnia; appetite loss; constipation; and diarrhea were observed at ≥1 time points. With the exception of cognitive functioning, no significant worsening in subscale scores was observed in the EORTC QLQ-C30. Statistically significant and clinically meaningful improvement (based on a minimally important difference of 7) in EQ-5D VAS was noted between weeks 17 and 41. EQ-5D-3L utility index scores based on the UK tariff remained stable during treatment. **Conclusions:** Results of CheckMate 275 indicate that pts with metastatic or unresectable urothelial carcinoma whose disease progressed or recurred after treatment with a platinum agent exhibited stable, or in some cases statistically significantly improved, HRQoL while being treated with nivolumab, as measured by EORTC QLQ-C30 and EQ-5D-3L. Clinical trial information: NCT02387996.

4527 Poster Session (Board #205), Sun, 8:00 AM-11:30 AM

Phase I/II trial of cetuximab with 5-fluorouracil and mitomycin C concurrent with radiotherapy in patients with muscle invasive bladder cancer. *First Author: Syed A. Hussain, University of Liverpool, Clatterbridge Cancer Centre NHS Foundation Trust, Wirral, United Kingdom*

Background: This phase I/II trial assessed the safety, feasibility and efficacy of cetuximab (Cet) in combination with 5-fluorouracil (5FU) and mitomycin C (MMC) with concurrent radiotherapy (RT) for the treatment of muscle invasive bladder cancer (MIBC). BC2001 trial has previously reported significant improvement in locoregional control in patients (pts) with MIBC who were randomised to synchronous chemo-RT compared to RT alone (James, Hussain, Hall et al NEJM 2012). Results for phase I have been reported previously. This abstract reports the combined results of phases I/II. **Methods:** From September 2012 to October 2016, 33 pts were recruited (7 pts to phase I from 2 UK centres and 26 patients to phase II from 5 UK centres). Pts received loading dose of Cet 400 mg/m^2 followed by weekly Cet 250 mg/m^2 for 7 weeks, continuous infusion 5FU 500mg/m^2/day during fractions 1-5 and 16-20 of RT and MMC 12mg/m^{2}on day 1 in combination with radical RT 64 Gy in 32 fractions. Neoadjuvant chemotherapy was mandatory in phase I but optional in phase II. Primary outcomes in phase I were feasibility and toxicity. Primary outcome in phase II was 3 month pathological complete response (CR) rate, secondary outcomes included toxicity, progression free survival (PFS) and overall survival (OS). **Results:** Median age of pts was 70 (range 46.9-85.6). Treatment completion rates in phase I were RT 100%, 5FU 100 %, MMC 100%, Cet 96%. Of the 28 analysable pts, phase II primary outcome data was available for 25 pts at the time of analysis with a 3 month pathological CR rate of 88%. 5 local progressions and 4 deaths were reported. 12 pts suffered at least one SAE. Grade 4 toxicities observed were dyspnoea, atrial fibrillation, interstitial pneumonitis, sepsis, thromboembolism, neutropenia and palpitations. The commonest grade 3 toxicities were skin rash, diarrhoea, low platelet count, low white blood cell count, fever and haematuria. The most common grade 1 and 2 toxicities were diarrhoea and skin rash. Data on PFS and OS will be presented. **Conclusions:** It was feasible and safe to add cetuximab to full dose chemo-RT with 5FU/MMC. The CR rate is encouraging and further randomised studies with this combination are warranted. Clinical trial information: ISRCTN80733590.

4528 Poster Session (Board #206), Sun, 8:00 AM-11:30 AM

Updated efficacy and safety of avelumab in metastatic urothelial carcinoma (mUC): Pooled analysis from 2 cohorts of the phase 1b Javelin solid tumor study. *First Author: Andrea B. Apolo, Genitourinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Avelumab, a fully human anti–PD-L1 IgG1 antibody, has shown promising efficacy and safety in 2 cohorts of patients (pts) with mUC. We now report updated data from a pooled analysis of these pts with mUC from JAVELIN Solid Tumor (NCT01772004) and further characterize the clinical activity of avelumab in this disease. **Methods:** Pts with mUC progressed after platinum-based therapy or cisplatin ineligible received avelumab 10 mg/kg 1-hour IV Q2W. Tumors were assessed every 6 weeks by independent review (RECIST v1.1). Endpoints included objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety (NCI CTCAE v4.0), and tumor PD-L1 expression. **Results:** As of Jun 9, 2016, 249 pts had received avelumab for a median of 12 weeks (range 2-92) and were followed up for a minimum of 6 weeks. Primary tumor site was upper tract (renal pelvis/ureter) in 23.3% and lower tract (bladder/urethra) in 76.7%. 242 pts (97.2%) had progressed on prior platinum therapy and 7 pts (2.8%) were platinum naive. In 161 post-platinum pts with ≥6 months of follow-up, confirmed ORR was 17.4% (95% CI 11.9-24.1; complete response in 6.2%) with a disease control rate of 39.8%. Response was ongoing in 23/28 responders at data cut (82.1%; median DOR not reached), and the 24-week durable response rate was 92.3% (95% CI 72.6-98.0). Responses occurred across PD-L1 expression levels tested (≥5% and < 5% tumor cell–staining [25.4% and 13.2%]). In all post-platinum pts (n = 242), median PFS was 6.6 weeks (95% CI 6.1-11.6), median OS was 7.4 months (95% CI 5.7-10.3) and 6-month OS rate was 54.9 (95% CI 47.7-61.7). Treatment-related adverse events (TRAE) of any grade occurred in 166/249 pts (66.7%); most common (≥10%) were infusion-related reaction (22.9%, all grade ≤2) and fatigue (16.1%). 21 pts (8.4%) had a grade ≥3 TRAE (fatigue [1.6%] and asthenia [0.8%] in > 1 pt). 34 pts (13.7%) had an immune-related AE (grade ≥3 in 2.4%). There was 1 treatment-related death (pneumonitis). **Conclusions:** Avelumab was well tolerated and showed durable responses in heavily pretreated pts with mUC, irrespective of tumor PD-L1 expression status. Clinical trial information: NCT01772004.

4529 Poster Session (Board #207), Sun, 8:00 AM-11:30 AM

Molecular profiling of small cell bladder cancer (SCBC) to reveal gene expression determinants of an aggressive phenotype. *First Author: Vadim S. Koshkin, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: SCBC is rare and its underlying biology poorly understood. Molecular profiling can shed light on the biology and identify treatment targets and biomarkers. **Methods:** A retrospective review of 63 patients (pts) with biopsy-confirmed SCBC at Cleveland Clinic (1994-2015) was performed. Percentage of small cell component (SC%) was defined by independent pathology review. DLL3 and PD-L1 protein expression were measured by IHC in 53 pts. Gene expression analysis was done in 38 primary SCBC tumor samples, 1 metastatic sample, and 5 normal bladder tissue samples (44 total) from the same cohort using HTG EdgeSeq OBP Assay with probes for 2568 genes. Analysis was performed via the RNAseq workflow (Partek Genomics Suite). **Results:** Among 63 identified pts, median age was 71 (39-90), 83% were men, median SC% was 100% (range 5-100%), median follow-up was 16.6 months and estimated median overall survival (OS) was 22.8 months. Unsupervised hierarchical clustering of gene expression patterns from 44 samples produced 4 distinct clusters. Pts with tumors in cluster 1 (that also included normal samples) did not have metastasis at diagnosis or distant recurrence, both of which were over-represented in the other 3 clusters. Kaplan-Meier analysis revealed a trend towards longer OS in cluster 1 patients (log rank p = 0.065). Higher gene expression of PRC1, NCAM1 (CD56) and DLL3 correlated with higher SC%, as did lower gene expression of ERBB2, PD-L1 and HPGD (p < 0.01). PD-L1 protein expression (≥1% cells) was noted in 30% of pts but did not correlate with outcome, SC%, DLL3 protein expression, or PD-L1 gene expression. DLL3 protein expression (≥1% cells) was noted in 68% of pts and DLL3 > 10% correlated with decreased OS (p = .03). Higher DLL3 protein expression correlated with DLL3 gene expression (Spearman r = 0.70, p < .01) and with SC% (r = .33, p = .01). **Conclusions:** This is the first study to reveal distinct gene expression patterns that define aggressive behavior, metastatic potential and outcomes in SCBC. The prognostic value of differential gene expression networks and the presence of underlying genomic and epigenetic alterations is the subject of ongoing prospective validation in a larger cohort.

4530 Poster Session (Board #208), Sun, 8:00 AM-11:30 AM

Health-related quality of life (HRQoL) of pembrolizumab (pembro) vs chemotherapy (chemo) for previously treated advanced urothelial cancer (UC) in KEYNOTE-045. *First Author: Ronald De Wit, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: In KEYNOTE-045 (NCT02256436) (N = 542), pembro 200 mg Q3W significantly improved OS over investigator's choice of paclitaxel, docetaxel, or vinflunine as second-line therapy for advanced UC following platinum-based chemo (HR 0.73; $P = 0.0022$). Fewer treatment-related AEs were reported with pembro. We present results of the prespecified HRQoL analysis of KEYNOTE-045. **Methods:** The EORTC QLQ-C30 HRQoL instrument was administered electronically at cycles 1–4, then every 2 cycles for up to 1 y and 30 d after discontinuation. The key HRQoL end points were 1) change from baseline to wk 15 and 2) time to deterioration (TTD) (defined as ≥10-point decrease from baseline) in the QLQ-C30 global health status/QoL score. HRQoL was assessed in patients (pts) who received ≥1 dose of assigned study treatment and completed ≥1 HRQoL instrument (N = 520). Score change from baseline was compared using a constrained longitudinal data analysis model. TTD was compared using a stratified log-rank test and Cox proportional hazards model. **Results:** Baseline global health status/QoL scores were similar between arms. HRQoL compliance at wk 15 was 88% for both arms. From baseline to wk 15, scores were stable for pembro (n = 266) (least squares [LS] mean +0.75 [95% CI −2.34 to +3.83]) but worsened for chemo (n = 254) (LS mean −8.30 [95% CI −11.76 to −4.83]); the difference in LS means between arms was 9.05 (95% CI 4.61-13.48; nominal 2-sided $P < 0.001$). At wk 15, pts without PD had improved scores with pembro but worsened scores with chemo (LS mean +5.97 vs −4.31), while pts with PD had less worsening with pembro (LS mean −3.54 vs −13.95). TTD was prolonged with pembro (HR 0.70; 95% CI 0.55-0.90; nominal 1-sided $P = 0.002$; median 3.5 mo vs 2.2 mo). Rates of improvement (defined as ≥10-point increase from baseline) at wk 15 were 31.2% with pembro and 22.0% with chemo; rates of deterioration were 28.9% and 40.6%, respectively. **Conclusions:** Pembro was associated with substantially better HRQoL for a longer duration than investigator-choice chemo in pts with previously treated advanced UC. Along with superior OS, these data support pembro as a new standard-of-care in this population. Clinical trial information: NCT02256436.

4531 Poster Session (Board #209), Sun, 8:00 AM-11:30 AM

Immune response results from vesigenurtacel-l (HS-410) in combination with BCG from a randomized phase 2 trial in patients with non-muscle invasive bladder cancer (NMIBC). *First Author: Gary D. Steinberg, Section of Urology, Department of Surgery, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: Vesigenurtacel-L (HS-410) is a vaccine comprised of an allogeneic cell line, selected for high expression from a series of bladder tumor antigens, and transfected with gp96-Ig. Cell-secreted gp96-Ig delivers these cell-derived antigens to a recipient's own antigen presenting cells, activating CD8+ cytotoxic T cells. Here we present the secondary immune outcomes from a randomized Phase 2 trial with HS-410 in combination with BCG in NMIBC. Trial ID NCT02010203. **Methods:** 78 patients with intermediate- (n = 5) or high-risk (n = 73) NMIBC who are either BCG-naïve or recurrent, with or without carcinoma in situ (CIS), were enrolled 1:1:1 to one of two doses of HS-410 (either 10^6 or 10^7cells/dose) or placebo in combination with 6 weeks of induction BCG, followed by 6 more weeks of HS-410 in the induction phase. Maintenance treatment consisted of 3-weekly treatments at the following timepoints: 3 mo., 6 mo., 12 mo. Concurrently, 16 patients (1 int. risk, 15 high-risk) were enrolled in an open-label monotherapy HS-410 arm for patients who did not receive BCG. The primary endpoint was 1-year RFS. Secondary immune evaluations include ELISPOT, tumor IHC, tumor antigen profiling, flow cytometry, urine cytokine analysis, and T cell receptor sequencing. **Results:** HS-410 treatment was well tolerated; AE profiles were similar across the treatment arms. HS-410 antigen expression showed prominent overlap with patient tumors. IFNγ ELISPOT assay demonstrated a high baseline response to HS-410; responses to overlapping peptide pools of HS-410 derived antigens defined immune responders (doubling of IFNγ-secreting cells). IHC demonstrated that ~60% of NMIBC patient tumor biopsies were TIL negative at baseline (n = 84), but that only ~15% of tumor biopsies were TIL negative post treatment (n = 40). Thus, TIL status may be used to define a responder and non-responder population to HS-410. **Conclusions:** Vesigenurtacel-L is well-tolerated, and immunologic responses consistent with vaccine mechanism of action may correlate with efficacy and suggest future biomarkers. Vesigenurtacel-L warrants further investigation as a potential treatment for NMIBC. Clinical trial information: NCT02010203.

4532 Poster Session (Board #210), Sun, 8:00 AM-11:30 AM

Atezolizumab (atezo) in platinum-treated locally advanced or metastatic urothelial carcinoma (mUC): Safety analysis from an expanded access study. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Boston, MA*

Background: A majority of mUC pts progress on standard platinum-based chemo regimens. Atezo (anti–PD-L1) was approved in the US for mUC in the post-platinum setting. Here we report the preliminary safety results from an expanded access program conducted to grant access to atezo, prior to commercial availability, to a broader range of mUC pts than are typically eligible for Phase I-III studies. **Methods:** From Nov 2015-Aug 2016, this study (NCT02589717) enrolled mUC pts who progressed during or following platinum. Atezo was given 1200 mg IV q3w, and pts could be treated post RECIST v1.1 PD until lack of clinical benefit (per investigator). Safety and clinical activity were key endpoints. PD-L1 expression on immune cells (IC) was assessed with the VENTANA SP142 IHC assay on the first 73 pts prior to protocol amendment omitting this requirement. This study was ended early following FDA approval of atezo. **Results:** 218 pts were enrolled at 36 sites in the US, with 214 treated pts comprising the safety/efficacy population (Table). Median treatment duration was 9 wks (range 3-26), corresponding to a median of 3 doses of atezo (range 1-8). Overall, 89% of pts had an AE. Treatment-related AEs (TRAEs) occurred in 46% (any Gr) and 7% (Gr3-4) of pts; 2 treatment-related Gr 5 AEs were seen (ileus; acute respiratory failure). TRAEs ≥ 5% were fatigue, decreased appetite and anemia. TRAEs leading to dose interruption or discontinuation occurred in 11% and 6% of pts, respectively. Investigator-assessed RECIST v1.1 ORR was 15% (95% CI: 9, 23), and disease control rate (ORR + SD) was 49% (95% CI: 40, 59). Additional clinical data will be reported. **Conclusions:** In this expanded access study, atezo was administered to > 200 mUC pts. Overall, atezo was safe and tolerable, supporting its use in a wider platinum-based population. Clinical trial information: NCT02589717.

Comparison of somatic mutation profiles from cell free DNA (cfDNA) versus tissue in metastatic urothelial carcinoma (mUC). *First Author: Michael L. Cheng, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Next-generation sequencing (NGS) of cfDNA is an emerging non-invasive strategy to define tumor mutation profiles that counters spatial and temporal limitations of sequencing single tissue specimens. We examined the feasibility of NGS of cfDNA in mUC and compared mutation profiles from cfDNA to results of tissue NGS previously performed in the clinical setting. **Methods:** Plasma cfDNA was collected in mUC pts and analyzed using a capture-based NGS assay (MSK-IMPACT) targeting 341-468 genes. NGS profiles from cfDNA and archival tumor tissue (using the same assay) were analyzed in parallel with an established bioinformatics pipeline to identify somatic variants. **Results:** In 26 pts, NGS analysis of cfDNA detected ≥1 somatic mutations (range 1-21) in 69% (18/26). For 15 pts, NGS data was available from archival tissue (11 primary tumors, 3 metastases, and matched primary/metastatic tissue in 1 case). The interval between cfDNA and tissue collection ranged from 35 days to > 4 yrs. 73% (11/15) of pts received intervening treatment, including 47% (7/15) with chemotherapy, 67% (10/15) with immunotherapy, and 40% (6/15) with both. In 40% (6/15), cfDNA harbored alterations not found in archival tumor tissue. In 73% (11/15), some mutations within archival tissue were not detected in cfDNA, including hotspot HER2 S310F and FGFR3 S249C mutations. Tumor and cfDNA mutation profiles were identical in 20% (3/15), with the tumor/cfDNA interval in this group ranging from 35 days to < 1.5 yrs. Somatic alterations including hotspot ERCC2 P463A and PIK3CA E545K mutations were detected in cfDNA from 3 pts where archival tumor tissue NGS failed. Thus, cfDNA identified new mutations in 50% (9/18) of pts for whom cfDNA identified somatic mutations and tissue NGS was previously attempted. **Conclusions:** NGS of cfDNA from mUC pts is feasible and successfully detected actionable alterations when archival tumor sequencing failed. The differences between tumor and cfDNA mutation profiles in many pts may reflect tumor evolution or intratumor heterogeneity. Mutation profiles in mUC may be incompletely assessed with NGS of archival tissue, and further investigation of plasma cfDNA for genomic profiling is warranted.

4534 Poster Session (Board #212), Sun, 8:00 AM-11:30 AM

Circulating tumor (ct)-DNA alterations in urothelial/bladder cancer (UC/BC): Updates on a dynamic genomic landscape. *First Author: Petros Grivas, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: Cell-free ctDNA may be potentially actionable, may have prognostic/predictive role and evolve after therapy. We updated our analysis of our retrospective study to shed light on UC/BC biology. **Methods:** Patients (pts) with UC/BC with ctDNA analysis for potentially actionable alterations using Guardant360 were identified. A 70-gene ctDNA next generation sequencing panel from a CLIA-licensed, CAP-accredited laboratory (Guardant Health, Inc.) offers complete exon sequencing for 29 cancer genes, critical exons in 39 genes and amplifications (16 genes), fusions (6 genes) and indels (3 genes) harvested from 10 mL of peripheral blood. Descriptive statistics were used. **Results:** There were 246 pts with 276 samples. At least 1 alteration was detected in 249 (90%) samples. Median age at time of ctDNA collection was 67 years (39-85), 78% men, median number of alterations per sample was 3.5 (1-35) most pts had MIBC. In MIBC pts, the most common alterations at the 1st ctDNA sample were in *TP53* (52%), *PI3KCA* (18%) *ARID1A* (17%), *FGFR2* (15%), *MET* & *NF1* (14%), EGFR (13%), BRAF (12%), FGFR3 (11%), RAF1 (10%), BRCA1 & CCNE1 (9%). In MIBC pts, the most common genes with increased copy number were *RAF1* & *CCNE1* (8%), *ERBB2* & *PI3KCA* (7%), *EGFR, BRAF, FGFR1, MYC* (each 5%), *MET* (4%), *KRAS* (3%). Most common altered pathways included TP53 signaling (56%), RAS/RAF/MEK/ERK (51%), RTK (48%), cell cycle (38%), FGFR family (34%), DNA damage response (25%), PI3KCA/AKT/mTOR (23%) and chromatin remodeling (17%). Interestingly, FGFR3 and RAS alterations were mutually exclusive in most cases, but each may co-occur with *TP53*alterations. 54 serial ctDNA samples from 24 pts (18 pts with 2 samples; 6 pts with 3 samples) revealed persistent, lost and new gene alterations. **Conclusions:** ctDNA was detected in 90% of pts and alterations were similar to those previously seen in UC tumor tissue. Tumor heterogeneity, interim therapy, genomic instability and clonal evolution can explain differences in serial samples. Correlation assessment with prior therapies and outcomes is being pursued to inform trial designs. Prospective validation, assessment of ctDNA concordance with tumor tissue DNA, and evaluation of clinical utility is warranted.

4535 Poster Session (Board #213), Sun, 8:00 AM-11:30 AM

Spectrum of tumor mutational load (TML) in genitourinary cancers (GU CA). *First Author: Muhammad Azam Hussain, Penn State College of Medicine, Hershey, PA*

Background: Immunotherapy (IO) is now standard of care for bladder and kidney cancer (CA) and is investigational in other GU CA such as prostate and germ cell CA. Tumor mutational load (TML) has correlated with response to IO in several tumor types. Herein, we explore TML across different histological subtypes in GU CA. In addition, we also assess the correlation between TML and PD-L1 status. **Methods:** 544 GU specimens were identified: bladder, 145; kidney, 164; prostate, 221; penile, 2; testicular, 12. TML was calculated using somatic non-synonymous missense mutations from a 592-gene panel (Illumina NextSeq). A high TML was > 17 mutations/MB. PD-L1 (SP142) was done depending tumor availability. **Results:** High TML was more prevalent in bladder CA (14.5%, 21/145) compared to other GU CA. Urothelial carcinomas had a noticeably high TML while squamous histology had a pronounced PD-L1 expression (Figure 1). A comparison of TML-high (n=15) versus TML-low (n=76) urothelial bladder CA showed the following differences (Figure 2). TML was rare in kidney CA (1.8%, 1/57); PD-L1 was high in sarcomatoid (33.3%, 5/15), CDC/RMC (28.6%, 2/7). Prostate adenocarcinoma had few TML-high (2.3%, 5/219) or PD-L1 expressing tumors (1.4%, 3/208). Tumors of penile or testicular origin lacked high TML and PD-L1 expression. No correlation was found between a high TML and PD-L1 expression. **Conclusions:** TML varied considerably amongst GU CA. As in other CA, TML-high scores did not predict PD-L1 expression and vice versa. Comprehension of the underlying biology may assist in determining which CA may respond better to IO.

Table 1: TML, PD-L1 in bladder CA subtypes.

Histology	TML	PD-L1
Adenocarcinoma	0% (0/11)	0% (0/11)
Neuroendocrine/Small Cell	0% (0/2)	0% (0/2)
Squamous Cell	12.5% (1/8)	37.5% (3/8)
Urothelial	16.5% (15/91)	20.5% (18/88)
Urothelial + Squamous	6.7% (1/15)	46.7% (7/15)
Not Otherwise Specified	22.2% (4/18)	27.8% (5/18)

Table 2: Gene mutation frequency in bladder CA.

Biomarker	Mutated Rate in TML-High Cohort	Mutated Rate in TML-Low Cohort	p-value
ARID1A*	22.2% (2/9)	0.0% (0/35)	0.004
ATM	13.3% (2/15)	2.6% (2/76)	0.065
BRCA2	20.0% (3/15)	1.3% (1/76)	0.001
PIK3CA	26.7% (4/15)	9.2% (7/76)	0.058
TSC1	13.3% (2/15)	1.3% (1/75)	0.018

* Lower # of interpretable *ARID1A*.

4536 Poster Session (Board #214), Sun, 8:00 AM-11:30 AM

Randomized study of intravesical chemotherapy using pirarubicin in patients with non-muscle-invasive bladder cancer in Japan: Comparing one immediate postoperative intravesical chemotherapy with short-term adjuvant intravesical chemotherapy after TURBT: Subanalysis in patients with intermediate risk. *First Author: Yoshio Naya, Meiji University of Integrative Medicine, Nantan, Japan*

Background: The objective is to evaluate the efficacy defining of 2-year tumor recurrence free rate of intravesical chemotherapy using pirarubicin (THP) for patients with intermediate risk. **Methods:** Between October 2010 and January 2015, 206 patients were enrolled in this study and finally 113 were randomized to one immediate postoperative intravesical instillation of THP 30mg (Group A), or additional intravesical instillation of THP 30mg weekly for 8 weeks after single postoperative instillation (Group B). The recurrent risk was stratified using EAU guidelines on non-muscle-invasive urothelial carcinoma of the bladder, the 2009 update. Of 113, 100 with intermediate risk were analyzed in this study. The patients were examined by cystoscopy and urine cytology every 3 months after trans urethral resection to determine bladder tumor recurrence. The primary endpoint was 2 year-recurrence-free survival rates. A statistical analysis was performed by SAS (SAS Institute Inc., Cary, USA). **Results:** The 2-year recurrence free survival rates were 66.2% in Group A and 86.1% in Group B, respectively (log rank test, p = 0.0043). In patients with recurrence score between 5 and 9, the 2-year recurrence free survival was 92.3% in Group B and 22.2% in Group A (log rank test, p = 0.0013). Cox regression analysis revealed that only additional instillation of THP was significant independent factor for recurrence free rate in patients with intermediate risk. There was no patient with progression during this period. Frequent adverse effects were frequent urination and micturition pain without severe adverse effect (Grade 3 or more). Limitation of this study is a failure to enroll sufficient number for statistical analysis. **Conclusions:** Additional instillation of THP 30mg weekly for 8 weeks reduced the risk of tumor recurrence without severe toxicity in NMIBC patients with intermediate recurrent risk.

4537 Poster Session (Board #215), Sun, 8:00 AM-11:30 AM

Intra-patient heterogeneity in urothelial cancer (UC) circulating tumor cells (CTC) and PDL1 expression to identify biomarkers of response and new therapeutic targets: A pilot study. *First Author: Waddah Arafat, University of Wisconsin, Madison, WI*

Background: Recent use of immune checkpoint inhibitors (CI) has improved overall survival (OS) in a subset of patients (pts) with metastatic UC. Intra-patient tumoral heterogeneity and epithelial-to-mesenchymal transition has been hypothesized as a driver of treatment resistance to both chemotherapy and CI in UC. There is a critical need to evaluate heterogeneity in UC for biomarkers of treatment response and new therapeutic targets. Trop2 is hypothesized to play a role in UC progression and is the target of a new antibody-drug conjugate, IMMU-132 that is being tested in UC trials. We report the phenotypic comparison of PDL1 expression among CTC sub-populations in UC pts. **Methods:** Peripheral blood samples were collected from pts with UC treated at Cleveland Clinic and U. of Wisconsin. Immunomagnetic capture and CTC enumeration using both EpCAM and Trop2 from matched blood samples was performed in the VERSA platform. Protein expression for PDL1 in these CTC populations was quantified. Longitudinal analysis of UC pts treated with chemotherapy or CI is ongoing. **Results:** CTC were captured using EpCAM and Trop2 in all 10 pts in our initial cohort. The frequency of Trop2 CTC was higher than EpCAM CTC with a mean of 248 Trop2 CTC (range 2-1885) compared to 76 EpCAM CTC (range 1-632). PDL1 expression was more frequent in Trop2 CTC than EpCAM CTC. In two pts progressing on Atezolizumab, Trop2 CTC had a higher frequency of PDL1 expression compared to EpCAM CTC (85% vs 2% in pt 1 and 2% vs 0% in pt 2). In pts followed longitudinally, Trop2 CTC dropped from 1885 to 1 in a pt with response to Atezolizumab and PDL1+ CTC declined from 4 to 0. After 1 cycle of Carbo/Gem in another pt, EpCAM CTC declined from 46 to 3 while Trop2 CTC from 116 to 47. **Conclusions:** This is the first report of CTC heterogeneity in pts with UC identifying high frequency of Trop2 CTCs with variable expression of PDL1 across different pts. Early results from longitudinal analysis suggest CTC as potential predictive / pharmacodynamic biomarkers of treatment response. Prospective data validation in larger cohort is ongoing, while IMMU-132 clinical trials in UC may provide context for future validation.

4538 Poster Session (Board #216), Sun, 8:00 AM-11:30 AM

Survival outcomes in elderly patients with muscle invasive bladder cancer: An analysis of the National Cancer Database. *First Author: Benjamin Walker Fischer-Valuck, Washington University School of Medicine in St. Louis, Department of Radiation Oncology, St. Louis, MO*

Background: Many elderly patients are precluded from radical cystectomy (RC) due to existing comorbidities or morbidities associated with RC. Chemoradiation therapy (CRT) is an alternative treatment in this population, but remains widely under-utilized with many receiving chemotherapy (CT) or radiation therapy (RT) alone. This population-based analysis sought to determine if CMT has similar overall survival (OS) to RC, and if CRT is associated with improved OS compared to monotherapy in these patients. **Methods:** We queried the National Cancer Database (NCDB) for all newly diagnosed MIBC (cT2-T4a N0 M0) cases in patients aged 80 years or older from 2004 to 2013. All included patients underwent TURBT followed by RC, RT alone, CT alone, CRT, or no further treatment. Only patients with radiation doses ($>=$ 50Gy) were included as receiving RT. Kaplan-Meier, log-rank, and multivariate Cox proportional hazards regression was performed with OS as the primary outcome. **Results:** 10,055 patients aged $>=$ 80 years were identified. 1,588 underwent RC, 839 received RT, 1,013 received CT, 1,035 had CRT, and 5580 had no further treatment. Mean age was 85.1 years (range, 80-90). 82.1% of patients had Stage II disease. Mean follow-up was 27.6 months (range, 0-137.8). Mean survival of the entire cohort was 28.0 months (95% CI, 27.2-28.8). Mean survival was 43.8 months (95% CI, 41.2-46.3) for patients with RC and 40.8 months (95% CI, 38.2-43.3) for CRT (P = 0.85). Mean survival was 29.1 months (95% CI, 26.8-31.4) and 30.7 months (95% CI, 28.2-33.2) for RT alone vs. CT alone, respectively ($P < 0.0001$ for both RC and CRT comparisons). 5-year OS for CT alone, RT alone, CRT, and RC was 15.7%, 15.1%, 24.0% and 29.6%, respectively. Multivariate analysis adjusting for age, year of diagnosis, gender, race, treatment location, treatment facility, insurance status, Charlson/Deyo Score, grade, and stage demonstrated an OS benefit in favor of CRT (HR 0.70; 95% CI, 0.63-0.77; $P < 0.0001$) and RC (HR 0.69; 95% CI, 0.63-0.76; $P < 0.0001$). **Conclusions:** For elderly patients with MIBC, both RC and CRT were associated with improved OS compared to CT or RT alone. CRT has similar OS compared to RC, and could be considered standard treatment in this population.

4539 Poster Session (Board #217), Sun, 8:00 AM-11:30 AM

Effectiveness of the Moreau strain of Bacillus Calmette-Guerin (BCG) for nonmuscle invasive bladder cancer. *First Author: Daher Cezar Chade, São Paulo Cancer Institute, University of Sao Paulo, São Paulo, Brazil*

Background: Intravesical instillation therapy of Bacillus Calmette-Guerin (BCG) for intermediate and high-risk non-muscle invasive bladder cancer (NMIBC) after complete transurethral resection has been widely shown to be more effective than any other adjuvant treatment. However, there are several different BCG strains not appropriately evaluated in clinical setting, but in current use. BCG Moreau is by far the most utilized strain in Brazil and has been recently introduced to the European market to cover the issue of BCG shortage, but there is insufficient data regarding its oncologic efficacy. **Methods:** We retrospectively analyzed 336 consecutive patients, who received adjuvant intravesical instillation therapy with BCG Moreau for intermediate- and high-risk NMIBC between January 2005 and February 2015 at a single institution. The end points of this study were time to first recurrence and progression to muscle-invasive disease. **Results:** Median age was 62 years (interquartile range 54-76, mean 64.3 years). In addition to induction BCG therapy, 228 (67.9%) patients received maintenance BCG. However, 35 (15.4%) patients interrupted maintenance BCG due to toxicity. Overall, after at least a complete induction BCG therapy, 87 (25.9%) patients presented with disease recurrence and 33 (9.8%) patients had disease progression. When analyzing on patients who received BCG maintenance in addition to induction therapy, 31 (13.6%) patients had disease recurrence and 10 (4.4%) had disease progression. The 5-year recurrence-free survival and progression-free survival rate was 69.8% (95% CI 52.8-77.2) and 86.2% (95% CI 69.9-93.2), respectively. **Conclusions:** BCG Moreau has shown to be safe and effective as adjuvant intravesical treatment in intermediate and high-risk NMIBC patients. Since results are comparable to other strains, wider use of BCG Moreau may be encouraged and prospective clinical trials stimulated for higher level of evidence.

4540 Poster Session (Board #218), Sun, 8:00 AM-11:30 AM

Safety and efficacy of docetaxel + b-701, a selective inhibitor of FGFR3, in subjects with advanced or metastatic urothelial carcinoma. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients w/ locally advanced or metastatic urothelial carcinoma (UCC) have a poor prognosis. Prior to atezolizumab's approval, there were no approved treatments (txs) for pts who progressed after chemotherapy. Even w/ immune checkpoint inhibitors, most pts require additional txs. FGFR3 is frequently overexpressed in UCC and 15-20% of pts w/ advanced disease have tumors w/ FGFR3 gene mutations or fusions. B-701 (formerly R3Mab) is a fully human monoclonal antibody against FGFR3 that blocks activation of the wildtype and genetically activated receptor. NCT02401542 is a phase (ph) 1b/2 study designed to evaluate the safety and efficacy of B-701 plus docetaxel (D) in advanced UCC pts. **Methods:** The study has a lead-in (n=20 pts) and a randomized ph (n=201). Eligible pts: Stage IV UCC, relapsed/refractory to 1 or 2 prior chemotherapy regimens not including taxanes with ECOG 0-1. Txs: B-701 at 25 mg/kg q3w (+ loading dose on C1D8) and D at 75 mg/m^2 q3w. Efficacy assessed by RECIST 1.1. Primary obj: PFS and safety. Secondary obj: overall response rate (ORR); duration of response (DOR); disease control rate (DCR); overall survival (OS). Exploratory obj: association of FGFR3 status w/ efficacy and AEs. **Results:** As of 20 Jan 2017, 19 pts enrolled to lead-in ph w/median age 66 yrs, ECOG 1 58%, Hgb $<$10 gm/dL 5%, liver mets 26% and $\geq$ 2 prior regimens 63%. 17 evaluable for PFS/ORR. 5 pts w/ FGFR3 mut or TACC3-fus. Gr $\geq$3 AEs occurring in $\geq$2 pts: decreased neutrophils (26.3%), neutropenia (10.5%), decreased WBCs (10.5%). 2 pts had D dose reductions and 1 pt discontinued tx due to AE (disseminated intravascular coagulation). **Conclusions:** Preliminary results show that B-701 combines safely and effectively with D in UCC, with the combination being well tolerated and showing promising ORR and PFS in pts w/ FGFR3 mut/fus. The protocol has been amended to add Cohorts 2 (B-701+D) and 3 (B-701) (n=20 pts/cohort) for pts w/ FGFR3 mut/fus+ tumors only. Clinical trial information: NCT02401542.

	All (N=17)	FGFR3 mut/fus (N=5)
Best Response	1CR;2PRs	1CR;1PR
DOR	NR	NR
PFS (wks)	13.0+ (95% CI: 6-47.6+)	NR
Median OS (wks)	28.7 (95% CI:13.4 -37.6+)	NR

4541 Poster Session (Board #219), Sun, 8:00 AM-11:30 AM

Neoadjuvant chemotherapy followed by concomitant chemoradiation with gemcitabine in muscle invasive bladder cancer. *First Author: Abdul Mateen, Department of Radiotherapy and Oncology, MINAR Cancer Hospital, Multan, Pakistan*

Background: Urinary bladder cancer is one of the most prevelent genitourinay cancer in Pakistan. It is especially common in population that consumes smokeless tobacco. Advanced stage at diagnosis is usual presentaion due to illiteracy, poverty and lack of primary health facilities. The study was aimed to optimize treatment of muscle invasive bladder cancer in poor resource country. **Methods:** A total of 65 patients were enrolled for the study. All patients had muscle invasive disease on transurethral resection. Patients were to in stage range from T2-3, N0 and M0 to be selected. The patients were planned for gemcitabine and cisplatinum (GC) every three weeks in a dose of 1000 mg/m^2 and 40 mg/m^2 on D1 and D8 of each cycle respectively. Ultrasonography was performed to assess for any bladder mass at this point. The patients with no visible tumor were planned for whole bladder external radiotherapy (ERT) along with weekly gemcitabine 100 mg/m^2. A total of 63 Gray (Gy) was planned with 1.8 Gy per fraction and five fractions a week. Gemcitabine was given on 1st day of every week during whole course of ERT. Treatment interruptions were allowed depending upon chemotherapy and ERT related toxicity. Primary end point was to assess disease free survival (DFS) while overall survival was also assessed as a secondary end point. **Results:** 54 patients (83%) were available for assessment to treatment and to assess DFS and OS. Rest of the patients 11/65 (17%) were excluded from the analysis due to inability to complete the treatment. Five patients (8%) showed disease recurrence during treatment and were switched to other treatment. 11 patients (20%) showed bowel, 15 patients (28%) showed bladder and 8 patients (15%) showed hematological related grade 1-2 toxicity. Four year DFS and OS were 43% and 52% respectively. Mean and median DFS (year) were 3.16$\pm$0.36 (95% confidence interval [CI] 2.91 to 3.42) and 2.68$\pm$0.54 (95% CI 2.41 to 2.93) respectively. Mean and median OS (year) were 3.95$\pm$0.43 (95% CI 3.67 to 4.21) and 3.55$\pm$0.31 (95% CI 3.37 to 3.76) respectively. **Conclusions:** Neoadjuvant chemotherapy with GC followed by concomitant CRT using gemcitabine is an excellent choice for bladder preservation in poor resource countries.

4542 Poster Session (Board #220), Sun, 8:00 AM-11:30 AM

Cabazitaxel in patients with locally advanced or metastatic transitional cell carcinoma who developed disease progression within 12 months of platinum based chemotherapy: Results of a phase II trial—CAB-B1. *First Author: Anjali Zarkar, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*

Background: There is a paucity of chemotherapy options for the treatment of patients who have relapsed following platinum based chemotherapy (CT). Cabazitaxel is a new taxane that showed in-vivo antiproliferative activity on resistant cell lines. **Methods:** CAB-B1 was a single centre phase II randomised controlled trial of Cabazitaxel (CAB; 25mg/m^2 q3 week for 6 cycles) versus best supportive care (BSC) in patients (pts) with histologically proven transitional cell carcinoma (TCC), locally advanced or metastatic, who had received platinum based treatment and recurred within 12 months of the last cycle of CT. Primary outcome was overall response rate (ORR) using RESIST. Secondary outcomes were Progression Free Survival (PFS), Overall Survival (OS), Quality of Life assessment, safety and tolerability. A total of 96 pts required to detect differences in ORR from 5% to 30%; 80% power; 5% alpha level; 10% dropouts. Stopping rules, using Simon's two stage optimal design to assess the individual effectiveness of CAB, required at least 1 ORR from 10 pts on CAB during 1st stage (i.e. total of 20 pts randomised) and 4 from 29 CAB pts in 2nd stage (assuming lower ORR limit of 0.05, target ORR of 0.20, 80% power, 5% alpha level). The trial was supported by grant from Sanofi. **Results:** Between January 2013 and October 2016, 20 pts were randomised (10 on each arm). 75% males; median age 68 years; 65% had recurred within 6 months of previous CT. BSC included paclitaxel CT for 9 pts and radiotherapy for 1 pt. 8 pts completed 6 cycles of CT (3 on CAB; 5 on BSC). 6 pts on each arm were evaluated for response after having 2/3 cycles; 2 pts had an ORR on CAB and 1 pt on BSC. 14 pts have died of disease (8 on CAB; 6 on BSC).Median OS was 5.6 months (95% confidence interval (CI) 0.7-15.2) for CAB pts and 8.2 months (95% CI 1.0-8.8) for BSC pts. Median PFS was 4.4 months (95% CI 0.7-9.4) for CAB pts and 4.1 months (95% CI 1.0-6.8) for BSC pts. **Conclusions:** It has been hard to recruit these poorly patients within a single centre, but CAB-B1 successfully reached the efficacy target for the 1st stage, showing that there could be a role for CAB in these pts. Clinical trial information: NCT01668459.

4543 Poster Session (Board #221), Sun, 8:00 AM-11:30 AM

Predictors of urinary diversion choice in patients with bladder cancer in integrated care settings. *First Author: Marilyn L. Kwan, Division of Research, Kaiser Permanente Northern California, Oakland, CA*

Background: Annually over 10,000 people with bladder cancer in the US have cystectomy surgery with urinary diversion (UD). While ileal conduit (IC) is most common, neobladder (NB) and continent pouch (CP) are options to retain urinary continence. Few studies in community settings have examined patient and clinician factors associated with UD choice. **Methods:** Eligible patients were age $\geq$21 with a cystectomy and UD for bladder cancer from 1/2010 to 6/2015 in 3 West coast Kaiser Permanente regions. Data were obtained from the EHR and chart review.We useda mixed effects logistic regression model with surgeon as a random effect, and region as a fixed effect, to identify patient factors associated with UD choice (IC vs NB/CP). We also examined whether surgeon factors were associated with UD choice above and beyond patient factors. **Results:** Among 1063 patients, 80% had an IC. IC patients were older (mean age 72 vs. 62), more likely female (24% vs. 16%), more likely diagnosed with AJCC stage III/IV (41% vs. 28%), and had higher Charlson comorbidity score (median 4 vs. 3) than NB/CP patients. Surgeons accounted for a sizable portion of the variability in UD choice (ICC = .26). The model with patient factors showed good fit (AUC = .93, Hosmer-Lemeshow test p = .22). Including surgeon factors (annual cystectomy volume, specialty training, clinical tenure) did not improve model fit (p = .32). Female sex, eGFR $<$ 45, 4+ comorbidities, and stage III/IV tumors were associated with higher odds of receiving an IC vs. NB/CP (Table). **Conclusions:** Patient factors predict much of the variability in UD choice. The high ICC indicates that surgeons also contribute to this process, but surgeon factors we examined were not uniquely associated with IC. Future studies should explore more nuanced surgeon factors, such as how UD choice is shaped by personal beliefs about UD and likely outcomes.

Patient factors that predict IC vs NB/CP in bladder cancer patients.

4544 Poster Session (Board #222), Sun, 8:00 AM-11:30 AM

Activity of RX-3117, an oral antimetabolite nucleoside, in subjects with metastatic bladder cancer resistant to gemcitabine: Preliminary results of a phase Ia/IIb study. *First Author: Jun Gong, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: RX-3117 is an oral small molecule antimetabolite, cyclopentyl pyrimidyl nucleoside that is activated by uridine cytidine kinase 2. RX-3117 has shown efficacy in xenograft models of gemcitabine resistant pancreatic, bladder and colorectal cancer. Preliminary data from an analysis of a phase 1b/2a clinical study of RX3117 in metastatic bladder cancer is described. **Methods:** This phase 1b/2a study (NCT02030067) was designed to evaluate safety, tolerability and efficacy following treatment with 700 mg administered orally once-daily for 5 consecutive days with 2 days off per week for 3 weeks with 1 week off in each 4 week cycle in a 2-stage design. Eligible subjects (aged $\geq$ 18 years) were those with relapsed/refractory metastatic bladder cancer with any number of prior therapies. Prior therapy with platinum-based chemotherapy was required. The primary endpoint was to assess the efficacy and safety of RX-3117 in metastatic bladder cancer, with secondary aims of evaluating PFS and CBR. **Results:** With 9 subjects enrolled, median age was 66 years, ECOG PS was 0-1. All subjects had received gemcitabine/cisplatin in the perioperative or metastatic setting, and 4 subjects had received 3 or more prior therapies. The most frequent related adverse events were anemia, mild-moderate fatigue, vomiting and diarrhea. No dose limiting toxicities were observed. PFS and CBR will be presented at the meeting, as 5 subjects continue to receive therapy at the time of this submission. One subject continues on treatment at 139 days with persistent stable disease. Molecular profiling of his bladder tumor showed alterations in *ARID1A*, *FBXW7*, *FGFR3*, *NF1*, and *TERT*. The patient previously responded to an FGFR3 inhibitor but progressed after 9 months, with ctDNA assessments showing incurrence of *TP53* alteration. Clinical benefit with RX-3117 was achieved in spite of incurrence of this alteration. **Conclusions:** RX-3117 demonstrated an excellent safety profile, and prolonged stable disease was seen in 1 subject who failed prior cisplatin/gemcitabine and FGFR3 inhibition. Activity persisted despite development a putative resistance alteration detected by ctDNA. Clinical trial information: NCT02030067.

4545 Poster Session (Board #223), Sun, 8:00 AM-11:30 AM

The clinical role of purified protein derivative skin test reaction in patients with non-muscle invasive bladder cancer treated with bacillus-Calmette Guerin. *First Author: Eiji Kikuchi, Department of Urology, Keio University School of Medicine, Tokyo, Japan*

Background: We investigated the association between purified protein derivative (PPD) skin test reaction prior to BCG therapy and clinical outcomes, both oncological outcomes and occurrence of side effects, in BCG-naïve non-muscle invasive bladder cancer (NMIBC) patients. **Methods:** A total of 288 NMIBC patients who received PPD skin test prior to BCG therapy were included. The PPD skin test reaction was categorized into three groups: positive, slightly positive, and negative. The presence of an induration was positive. If an induration was absent, an erythema 10 mm or more and less than 10 mm corresponds to slightly positive and negative, respectively. **Results:** Sixty-six (22.9%), 149 (51.7%), and 73 (25.3%) patients had positive, slightly positive, and negative PPD skin test results, respectively. The 5-year recurrence-free survival rate of patients with a positive PPD skin test was 89.4$\pm$4.1%, which was significantly higher than that of patients with slightly positive (65.5$\pm$4.2%, $p = 0.001$) and negative (56.4$\pm$6.6%, $p < 0.001$) results. Multivariate Cox regression analysis demonstrated that a positive PPD skin test was independently associated with tumor recurrence (Hazard ratio of 0.213, $p < 0.001$) but not with stage progression. The occurrence rate of major side effects in patients with a positive BCG skin test (33.3%) was significantly higher than that in patients with slightly positive (26.8%) and negative PPD skin tests (13.7%). The incidence rate of fever persisting beyond 2 days or fever of $\geq$38°C in patients with a positive PPD skin test (18.2%) was significantly higher than that in patients with slightly positive (8.7%) and negative PPD skin tests (4.1%). **Conclusions:** NMIBC patients with a positive PPD skin test and who were treated with BCG therapy had a significantly lower tumor recurrence rate and higher incidence of major side effects such as fever persisting beyond 2 days or fever of $\geq$38°C. Our findings suggest that PPD skin test prior to BCG therapy can predict clinical outcomes following BCG therapy and provide useful information regarding who would experience a strong therapeutic effect for BCG therapy and BCG-related major side effects.

4546 Poster Session (Board #224), Sun, 8:00 AM-11:30 AM

Oncological outcomes of intravesical gemcitabine and docetaxel for select patients with high grade recurrent NMIBC. *First Author: Niv Milbar, The James Buchanan Brady Urological Institute, Johns Hopkins Medical Institutions, Baltimore, MD*

Background: Bacillus Calmette-Guerin (BCG) unresponsive patients with Non-Muscle Invasive Bladder Cancer (NMIBC) who prefer bladder preservation over Radical Cystectomy (RC) or are poor surgical candidates may be offered intravesical therapies. 2nd line intravesical Gemcitabine (GEM) combined with Docetaxel (DOCE) has been offered at Johns Hopkins Hospital (JHH). Our objective was to evaluate JHH experience with GEM/DOCE, and specifically to address appropriate endpoints for 2nd-line therapies in NMIBC. **Methods:** 33 patients who received full induction courses of GEM/DOCE since 2011, per the protocol adapted from Michael O'Donnell at U. Iowa, were identified in the IRB-approved JHH NMIBC database. Multivariable logistic regression determined factors associated with LG and HG recurrence. Cox proportional hazard models evaluated risk factors for disease free survival (DFS) and HG recurrence-free survival (HG-RFS). **Results:** Median DFS was 6.5 months with 42% 1-year and 24% 2-year DFS. Median HG-RFS was 17.1 months with 56% 1-year and 42% 2- year HG-RFS. Median HG-RFS among patients who initiated GEM/DOCE with HG pathology was 15.7 months, with 51% 1-year HG-RFS and 34% 2-year HG-RFS. Within initial HG-NMIBC presentation, 46% (13/28) had HG recurrence. 80% (4/5) of patients with initial LgTa had LG recurrence and 20% (1/5) had HG recurrence. There were no significant predictors for HG-RFS or DFS. There were 5 LG recurrences, and 16 HG recurrences, with 6 progressions among these. 7 patients underwent RC at a median of 14.9 months. **Conclusions:** GEM/DOCE is a well-tolerated alternative to immediate RC for highly selected patients with HG-NMIBC. As anticipated, including LG recurrence as an endpoint made GEM/DOCE appear less efficacious. However, since standard of care for LG recurrence is further intravesical therapy and recurrence does not result in worse cancer outcomes, it may not be an appropriate endpoint. Future studies of 2nd line therapies for NMIBC should identify endpoints based on clinically meaningful outcomes of interest.

4547 Poster Session (Board #225), Sun, 8:00 AM-11:30 AM

ATM/RB1 mutations to predict shorter overall survival (OS) in bladder cancer. *First Author: Monika Joshi, Penn State Milton S. Hershey Medical Center, Hershey, PA*

Background: DNA repair defect plays an important role in tumorigenesis, progression and treatment outcomes of urothelial cancer. Somatic mutations of ATM/RB1 genes are frequently found in urothelial cancer and have been associated with a better response to cisplatin-based neoadjuvant chemotherapy. However, their prognostic value overall in urothelial cancer have not been determined. **Methods:** Exome sequencing data of 130 urothelial bladder cancer patients (pts) from The Cancer Genome Atlas (TCGA) dataset were analyzed as a discovery cohort to determine the prognostic value of ATM and RB1 mutations. Results from discovery dataset were further validated by an independent cohort of 79 advanced urothelial cancer pts who received comprehensive genomic sequencing for urothelial cancer with FoundationOne. OS was measured from time of initial diagnosis and Cox proportional hazard regression analysis was performed to calculate the hazard ratio (HR) and 95% confidence interval (CI). **Results:** In the discovery dataset, somatic mutations of ATM/RB1 genes were present in 24% of pts and were associated with significantly shorter OS [all stages: adjusted HR = 2.67, 95% CI, 1.45–4.92, P = 0.002; stage II-III only: adjHR = 2.76, 95% CI, 1.23–6.20, P = 0.014]. There was high mutation load in pts carrying ATM/RB1 mutations (median mutation count: 196 versus 160, P = 0.09). In the validation (stage IV) dataset, ATM/RB1 mutations were present in 31.7% of pts and tended to associate with shorter OS (adjHR = 1.97, 95% CI, 0.89–4.40, P = 0.094) and higher mutation load (median mutation load: 8.1 versus 7.2 per Mb, P = 0.136), although statistical significance was not reached. **Conclusions:** These results suggest that ATM/RB1 mutations may be considered as a poor prognostic biomarker in unselected urothelial cancer pts and may correlate with higher mutational load. Further studies are required to determine patient characteristics that can further stratify prognosis based on ATM/RB1 mutation status, and evaluate the potential predictive role of ATM/RB1 mutation status in response to immunotherapy.

4548 Poster Session (Board #226), Sun, 8:00 AM-11:30 AM

Myeloid derived suppressor cells (MDSC) and inflammatory biomarkers in metastatic urothelial carcinoma (mUC). *First Author: Moshe Chaim Ornstein, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: MDSC are potent immunosuppressive cells with prognostic implications in many solid tumors. We previously reported significant correlations between MDSC and clinicopathologic features in localized UC. We hypothesized that different MDSC populations may correlate with inflammatory biomarkers and clinicopathologic features in mUC. **Methods:** Peripheral blood samples were collected from 46 mUC pts. MDSCs were measured in fresh unfractionated whole blood (WB) and in peripheral blood mononuclear cells (PBMC). MDSCs were identified by flow cytometry in WB and defined as LinloCD33+/HLADR- [(T)otal MDSC]. MDSC subsets were defined as (G)ranulocytic (CD15+CD14-), (M)onocytic (CD15-CD14+), (I)mmature (CD15-CD14-), or CD11b+. MDSC populations were presented as % of live nucleated blood cells and as absolute numbers from WB. Spearman correlations (r) and Wilcoxon rank sum test were used to assess correlations between MDSC populations & clinicopathologic factors. **Results:** Of 46 pts:78% men, median age at diagnosis 69 (31-83), 33% never smokers, 76% pure UC, 76% bladder primary, 28% prior intravesical therapy, 35% prior neoadjuvant chemotherapy, 56% prior cystectomy, 83% overweight/obese. G-MDSC was the predominant subset in WB (43%) and PBMC (39%), although M-MDSC were almost equally predominant in PBMC (35%). There was a correlation between the WB and PBMC values of T-, I-, and M- MDSC ($p \leq 0.05$). Higher % WB I-MDSC correlated with lower blood neutrophil/lymphocyte ratio (NLR) ($p = 0.009$), while higher WB G-MDSC and %PBMC G-MDSC were associated with higher NLR ($p = 0.03$ and $p = 0.02$, respectively). Higher I-MDSC / G-MDSC ratio was associated with lower NLR ($r = -0.35$, $p = .02$) and with various clinicopathologic parameters. **Conclusions:** HigherI-MDSC / G-MDSC ratio correlates inversely with NLR, which is considered an inflammatory biomarker and had prognostic value in other studies. The mechanism of MDSC interaction with inflammatory response in mUC pts merits evaluation and is being investigated in a larger cohort of UC pts on chemotherapy or immunotherapy (with longer follow up).

4549 Poster Session (Board #227), Sun, 8:00 AM-11:30 AM

Incidence of secondary malignancies (SM) in patients (pts) with germ cell tumors (GCT) who received high-dose chemotherapy (HDCT): A retrospective study from the European Society for Blood and Marrow Transplantation (EBMT) database. *First Author: Simona Secondino, Medical Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy*

Background: Little is still known about the incidence of SM in young adult pts with GCT after HDCT, owing to the rarity of the disease, and the need for registries with long term follow-up (FUP) data. In Europe, the EBMT may provide a suitable platform for such retrospective analyses. **Methods:** Criteria for patient selection included diagnosis of GCT, adult male gender, ≥2yr of FUP after the administration of HDCT. Summary statistics were used to describe pt characteristics and outcomes. χ^2 tests were used to compare groups according to the length of FUP. Kaplan-Meier estimates were used to estimate overall survival (OS). Univariable Cox regression analyses examined clinical factors potentially associated with OS. Survival times were calculated from the HDCT administration date. To estimate the probability of developing SM, the cumulative incidence of SM was calculated for all pts. **Results:** From 1981 to 2014, 9,153 autografts, accounting for 5,100 pts, have been registered. Of them, 1,855 had ≥2yr of FUP. Among the latter, a total of 56 cases of SM were identified (3.0%). 28 (50%) had solid SM, 22 (39.3%) hematologic (hem) SM (5 had uncoded SM). Median age at first HDCT was 34 years (IQR: 30-42), median age at development of SM was 42 (37-51). 26 pts (46.4%) received single HDCT cycle, 22 (39.3%) multiple HDCT cycles (8 unknown). 31 pts had ≥5 yr FUP, 25 pts 2-5 yr FUP. The median latency of SM was 3.3yrs (IQR: 1.8-6.1) for hem SM and 5.6yrs (IQR: 1.2-10.8) for solid SM. Median FUP was 6.4yrs. Univariably, the type of SM (solid vs. hem) was significantly associated with OS. Hem vs solid SM: HR: 2.17 (95%CI: 1.19-4.97, $p = 0.020$). Median OS of pts who developed solid SM was 13.3yrs compared to 4.1yrs of those with hem SM. The retrospective nature of the data is the major limitation. **Conclusions:** In the largest European database of SM in GCT pts, we observed different trends for SM development according to the SM type. This information may be important for FUP guidelines of these pts. Dataset implementation is ongoing and we will compare the SM incidence from EBMT database with SM rates in the general EU population.

4550 Poster Session (Board #228), Sun, 8:00 AM-11:30 AM

Life expectancy 20 years after cisplatin-based treatment for testicular cancer (TC). *First Author: Sjoukje Lubberts, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Four decades have passed since the introduction of cisplatin-based chemotherapy for metastatic TC, providing the opportunity to evaluate very long-term survival. Although 80-90% of the patients are cured, the effect of treatment on residual life span is unknown. Aim of the study was to investigate life expectancy after TC treatment: from prolonging survival after cancer diagnosis, focus shifts to regaining a normal residual life span. **Methods:** Patients with metastatic TC treated with cisplatin-based chemotherapy > 20 years ago (1977 - 1996) at the University Medical Center Groningen were included. Survival status and cause of death were obtained from medical records, Netherlands Cancer Registry and general practitioners. Events were defined as death due to any cause (overall mortality) and death due to TC or TC treatment complications (TC specific mortality). Standardized mortality ratios (SMR) were calculated as ratio between observed and expected deaths, derived from the age-matched nationwide male population (Dutch Central Office of Statistics). SMRs were calculated for overall mortality, non TC specific mortality (censoring death from TC or treatment-related complications), mortality from cardiovascular disease (censoring death from other causes than cardiovascular disease (ICD-10 I0-I99)) and mortality from secondary malignancies (censoring death from other causes than secondary malignancies (ICD-10 C0-C99 excluding C62: TC)). **Results:** We included 321 metastatic TC patients with a median age of 28 years (range 16 - 64) at start of chemotherapy. After a median follow-up of 25 years (range 0 - 38) 106 patients died (33%). SMR for overall mortality was 4.0 (95% CI 3.6 - 4.4) and for non TC specific mortality 1.5 (95% CI 1.1 - 1.9). SMR for secondary malignancies was 1.7 (95% CI 1.0 - 2.2) and for cardiovascular diseases 1.5 (95% CI 0.7 - 2.2). Median age at death was 5-10 years lower in TC patients than expected. **Conclusions:** Twenty years after cisplatin-based chemotherapy, TC patients have a 50% increased risk of dying from non TC causes compared to the general population. These findings suggest that cisplatin-based treatment for TC comes at the expense of about 7.5 life years and induces early aging.

4551 Poster Session (Board #229), Sun, 8:00 AM-11:30 AM

Thromboembolic events after high-intensity training during cisplatin-based chemotherapy for testicular cancer. *First Author: Lene Thorsen, Oslo University Hospital, Oslo, Norway*

Background: Physical activity (PA) is believed to reduce acute side-effects as deconditioning, fatigue and nausea during chemotherapy and enhance post-treatment physical and psychosocial recovery. The national multicenter randomized TAST-trial (clinicaltrial.gov: NCT02577172) aimed to determine the effect of high-intensity training (HIT) during chemotherapy for testicular cancer (TC) on acute and post-treatment physical- and psychosocial outcomes. **Methods:** Patients aged 18 – 60 years with newly diagnosed metastatic TC, planned for 3 or 4 cisplatin-based chemotherapy cycles in combination with etoposide (EP) or etoposide plus bleomycin (BEP), were randomized to HIT during 9 or 12 weeks of chemotherapy or to one lifestyle counseling session (LCS) during first cycle. The HIT included two supervised endurance interval sessions per week, of which 10-15 minutes per session at 85 – 95 % of peak heart rate. The intensity, duration and number of the intervals were predetermined, but adjusted in accordance to the patients' daily condition. Thromboembolic (TE) complications were registered consecutively. **Results:** Among the first 9 patients randomized to HIT, 33% (3 patients aged 22, 30 and 44 years) developed severe TE complications; 2 cases of pulmonary embolism (respectively at day 9 and 7 of BEP cycle 2) and 1 myocardial infarction (at day 7 of BEP cycle 3). Common for these patients were non-seminoma TC, clinical stage IIA, good prognosis group and no known risk factors for TE events. TE complications were not observed among the 10 patients randomized to the LCS. **Conclusions:** Since TC patients within good prognosis group are expected to have about 5 % risk of TE complications during or shortly after cisplatin-based chemotherapy, we cannot exclude that the HIT may have contributed to the unexpected high number of TE events. Until possible mechanisms explaining our observations have been explored, we discourage high-intensity endurance training during cisplatin-based chemotherapy for TC. These observations led to closure of the TAST-trial after inclusion of 19 of 94 planned patients. Clinical trial information: NCT02577172.

4552 Poster Session (Board #230), Sun, 8:00 AM-11:30 AM

Phase II-study of sequential high-dose-chemotherapy with paclitaxel, ifosfamide, carboplatin, etoposide(P-ICE) in patients with relapsed or refractory germ cell tumors (GCT). *First Author: Thomas Kegel, University of Halle, Halle, Germany*

Background: High-dose chemotherapy (HD-CTx) is an active option for salvage chemotherapy in patients (pts) with refractory or relapsed GCT. All previous trials with HD-CTx used one or two cycles of high dose chemotherapy (CTx) including 2 or a maximum of 3 drugs. Another potentially more active option is the application of four sequential HD-CTx cycles (Schmoll et al, JCO 2003). **Methods:** We conducted a phase II trial of 1(-2) cycle(s) induction CTx with standard dose P-ICE (Paclitaxel 135mg/m² d1, Ifosfamide 1500mg/m² d1-3, Carboplatin 150mg/m² d1-3, Etoposide 150mg/m² d1-3), followed by 4 sequential cycles of HD-P-ICE (Paclitaxel 200mg/m² d1, Ifosfamide 3300mg/m² d1-3, Carboplatin 330mg/m² d1-3, Etoposide 330mg/m² d1-3). Eligibility criteria: relapse or progression under one or more induction CTx, ECOG PS (0-1), Creatinine-clearance > 30ml/min, adaequate liver function, measurable tumor or at least marker-elevation. **Results:** 37 pts entered the trial and 33 are evaluable (4 pts never received HD-CTx due to lack of stem cells (3) or medical reasons (1)). Prior CTx:1 (N = 26), 2 (N = 4), 3 (N = 3); primary extragonadal: 6; seminoma/ non-seminoma 5/28; ECOG-PS: 0 (19), 1 (14). Response rate: CR/NED 17 (51.5%), CR/NED/PR-/SD- with marker normalization 21 (63.6%), PD 12 (36.4%). DFS of CR/NED: median 59 (8-105) months; RFS of all favourable responders 60 (8-105) months, PFS total 46 (2-105) months. OS for all pts. 51 (6-105) months, OS Favourable Responders: 65 (23 – 105), Non-favourable Responders: 11 (6-27) months,. Toxicity was tolerable without treatment related death, with mainly grade 4 bone-marrow toxicity and grade 2 mucositis and/or diarrhea. **Conclusions:** Sequential HD-CTx with one cycle of SD-P-ICE and four cycles HD-CTx is feasible with acceptable toxicity and favourable efficacy. Sequential HD-CTx using the four most active drugs might be a potentially option for this pts-population due to good tolerability, applicability and interesting long-term outcome. Comparison of the standard approach with 1 to 3 sequential high dose cycles of Carboplatin/ Etoposide is ongoing (TIGER-Trial). Clinical trial information: EUDRA-CT: 2006-006004-11.

4553 Poster Session (Board #231), Sun, 8:00 AM-11:30 AM

Long-term causes of relative excess mortality after diagnosis of testicular germ cell tumor. *First Author: Oivind Kvammen, Helse Midt-Norge, Trondheim, Norway*

Background: Despite today's excellent cure rates among testicular germ cell tumor (TGCT) patients, reduced long-term relative survival (RS) is an increasing concern. We recently reported a continuing decline in RS among TGCT patients diagnosed in Norway, even beyond 30 years of follow-up. Late effects of treatment is the main culprit. Although several reports describe increased mortality from second cancer (SC), cardiovascular disease (CVD), and other causes (OC) among TGCT survivors, data beyond 20 years of follow-up are scarce. The study aim was to analyze long-term relative risks (RR) and causes of death (CD) among TGCT patients diagnosed in Norway, 1953-2014. **Methods:** Data sources were the Cancer Registry of Norway and the Norwegian Cause of Death Registry. All men diagnosed with TGCT in Norway during 1953-2014 were included, except spermatocytic seminomas. End of follow-up was December 31st, 2014. Patients were classified by CD, histology, disease extent and age at diagnosis, as well as by decade of diagnosis and follow-up time. Standardized mortality ratios (SMR), compared with the general Norwegian male population, were computed. **Results:** At end of follow-up, 2359 of 9390 patients were deceased. CD was obtained for 2320 patients; 37.6 % TGCT, 24.5 % SC, 19.1 % CVD and 18.8 % OC. SMR for all SC were significant particularly after 20 years of follow-up (1.8 – 3.1), with similar findings in localized disease at diagnosis. SMR were most consistently elevated beyond 20-30 years for SC of the pancreas, large intestine and bladder. By contrast, SMR for CVD were significant among patients diagnosed 2000-14, both before and after one year of follow-up (2.6). There were no significant SMR for CVD beyond 20 years of follow-up. Several OC SMR were elevated, such as for digestive and genitourinary diseases beyond 20-30 years (2.2 – 5.1). **Conclusions:** TGCT patients have increased RR of SC and OC death even beyond 20-30 years of follow-up, while the increased RR of CVD death is mostly confined to the first decade. CVD deaths in patients diagnosed 2000-14 are a particular concern. Continuing optimization of TGCT treatment and follow-up schemes is required, including further research on toxicity mechanisms.

4554 Poster Session (Board #232), Sun, 8:00 AM-11:30 AM

Individualization of high dose carboplatin based on therapeutic drug monitoring (TDM) for the treatment of testicular germ cell tumors (TICE protocol): Results of a multicenter phase II study. *First Author: Fabienne Thomas, Institut Claudius Regaud, IUCT-Oncopole, CRCT, Inserm, Toulouse, France*

Background: We conducted a national phase II multicenter trial that aimed at evaluating the efficacy and tolerance of Paclitaxel plus Ifosfamide followed by high-dose carboplatin plus etoposide treatment (TICE) in previously treated germ cell tumors. The particularity of our study (in comparison with the standard protocol [Motzer RJ, et al. J Clin Oncol 2000 Mar; 18(6): 1173-1180.]) is that the carboplatin dose was individualized for each patient according to therapeutic drug monitoring (TDM) in order to reach the target AUC of 24 mg.min/ml over 3 days. **Methods:** In total, 89 patients were evaluable for pharmacokinetic study. Blood samples were taken on day 1 to determine the carboplatin clearance using a Bayesian approach (NONMEM 7.2) and to adjust the dose on day 3 to reach the target AUC of 24 mg.min/ml over 3 days. On days 2 and 3, samples were taken for retrospective assessment of the actual AUC and the intra- and inter-cycle clearance variability. Secondly, a population pharmacokinetic analysis was also performed on 59 patients using NONMEM to develop a covariate equation for carboplatin clearance prediction adapted for future patients treated with the TICE protocol. The performance of this new equation was then prospectively evaluated on the other 30 patients along with different methods of carboplatin clearance prediction. **Results:** TDM allowed us to control the carboplatin exposure with a mean actual AUC of 24.5 mg.min/ml (22.2 and 28.0 for 5th and 95thpercentile respectively) per cycle. We observed a modest but significant decrease of carboplatin clearance over cycles (median value of change of -11.8% from cycle 1 to cycle 3, maximum value of -36%). The new covariate equation allows unbiased and more accurate prediction of carboplatin clearance in the prospective validation cohort compared to other equations. **Conclusions:** Carboplatin TDM allowed the target AUC to be accurately reached and thereby avoid over- or under-exposure. We propose a new equation to predict carboplatin clearance more adapted to these particular patients (young males) that could be used as an alternative if the TDM cannot be organized. Clinical trial information: 2008-005068-14.

4555 Poster Session (Board #233), Sun, 8:00 AM-11:30 AM

Histologic determinants of long-term overall survival in patients (pts) with germ cell tumors (GCT). *First Author: Samuel Funt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: GCT display totipotential differentiation ranging from pluripotent embryonal carcinoma to extraembryonic (choriocarcinoma, yolk sac) to somatic cell types (teratoma [T]). We hypothesized that long-term survival after platinum-based chemotherapy (PC) is dependent upon histology. **Methods:** Advanced GCT pts who received PC from 4/1975 to 5/1996 and had a pre-PC primary tumor specimen available were included. Each pre-PC cell type was reviewed and confirmed. Residual tumor size post-PC was recorded when available. Differences in cumulative incidence (CUI) of death due to disease (DOD) between histologic cell types and other baseline characteristics were evaluated using a competing risks approach and the Fine & Gray test. **Results:** Pre-PC primary tumor specimens (96% testis, 3% mediastinum) were available from 231 pts. Median age was 29 years (y) and median followup 17 y (range 0.3-35 y). 41 pts had pure seminoma; of the remaining 190 with nonseminomatous GCT (NSGCT), 81 had an element of T (n=29 mature T, n=42 immature T, n=10 both). At PC start, 60% of pts were IGCCCG good risk, 26% intermediate, and 13% poor with no difference for NSGCT based on presence vs. absence of T (p=0.53). Of 72 deaths, 50 were DOD, 20 from other causes, and 2 from unknown causes. The 5, 10, and 15 y CUI of death from any cause was 20%, 23%, and 26%, respectively. CUI of DOD at 5, 10 and 15 y was 18%, 20%, 22%, respectively. CUI of DOD at 2, 5, 10 and 15 y by histologic group is provided in the Table. Presence of T was associated with greater CUI of DOD vs. NSGCT without T (p=0.04) and mature T with a greater CUI of DOD vs. immature T (p=0.03). NSGCT pts with T were also more likely to have residual retroperitoneal disease >1cm after PC vs. those without T (50 vs. 4.2%; p=0.01). **Conclusions:** With long-term followup, the presence of an element of T, particularly mature T, in mixed NSGCT was associated with a higher risk of DOD than tumors without T, which have the same risk of DOD as pure seminoma. These data suggest that the presence of T in the primary tumor may be an important clinical predictor of long-term outcome in men with GCT.

Cumulative incidence (%) of DOD by histology.

	2 y	5 y	10 y	15 y
NSGCT with T	17	25	29	31
NSGCT without T	12	15	17	17
Seminoma	10	15	15	18

4556 Poster Session (Board #234), Sun, 8:00 AM-11:30 AM

Genomic comparison of matched primary and metastatic germ cell tumors (GCT). *First Author: Francois Audenet, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor genomic analysis may be useful in patients with GCT as a means of identifying potentially actionable genomic alterations or mutations such as *TP53* that confer resistance to chemotherapy. As GCTs often exhibit significant morphologic heterogeneity, we evaluated the level of concordance between genomic alterations in matched primary and metastatic GCT samples. **Methods:** GCT patients enrolled on an institutional prospective sequencing protocol with available primary and metastatic tumor tissue were eligible. Each tumor was subjected to MSK-IMPACT, an exon capture sequencing assay, which detects copy number alterations (CNAs) and mutations in 410 cancer-related genes. For each primary-metastasis pair, concordance and clonality was assessed using the FACETS algorithm. **Results:** Matched primary-metastasis tumor pairs were available for 36 patients (78% nonseminoma, 22% seminoma, median age 33.5 years). All patients received chemotherapy, with 25 (69%) receiving treatment prior to analysis of the metastatic samples. The frequency of genetic alterations was low with a median of 3 mutations (1-7), 7 amplifications (1-26) and 1 deletion (1-9) detected per sample, with no significant difference in mutational/CNA burden between primaries and metastases. Of 109 unique mutations across patients, only 44 (40%) were concordant between the primary and matched metastasis, including 5 of 9 hotspot mutations. For CNAs, 184 (81%) of 226 were concordant. Only 24 of 109 (22%) mutations were clonal (defined as predicted to be present in all cancer cells) in either the primary or metastatic matched samples; of these, only 4 were clonal in both the primary and metastatic samples, including 2 hotspots. However, 4 of 5 alterations in *TP53/MDM2* were shared by both the primary and metastasis pairs. In a separate exploratory cohort, 4 *TP53* mutations were identified in 3 primary tumors and 1 metastasis, and all 4 mutations were also detected by cell-free DNA profiling. **Conclusions:** Genomic concordance, particularly for mutations, is poor between primary and metastatic GCT samples. Cell-free DNA analysis may help overcome this limitation by identifying alterations in progressive tumors without need for a new biopsy.

4557 Poster Session (Board #235), Sun, 8:00 AM-11:30 AM

Efficacy of epirubicin-paclitaxel (EPI-TAX) prior to high-dose chemotherapy (HDCT) in germ cell tumors (GCTs): A 17-year experience. *First Author: Jean-Pierre Lotz, Medical Oncology Department, Hospital Tenon (AP-HP), Paris, France*

Background: GCTs patients (pts) relapsing after conventional-dose salvage chemotherapy (CDCT) are candidates to receive HDCT with hematopoietic stem cell (SC) support. We have previously reported (Ann Oncol 2014; 25: 1775-82) that non-refractory pts can benefit from HDCT. We here analyzed the efficacy of the induction regimen EPI-TAX. **Methods:** All male GCTs pts treated by EPI-TAX between 1998 and 2015 were identified from clinical records at Tenon Hospital. Primary aim was response rate after EPI-TAX. Secondary aims were efficacy of SC harvest, Beyer score, toxicities and overall survival (OS) after HDCT. Kaplan-Meier methods were used for analysis. **Results:** Of the 170 pts treated (EPI 100 mg/m2, TAX 250 mg/m2, days 1-15), 142 (83.5%) had received $>$ 2 previous lines of CDCT. 79 (46.5%) had disease progression at the time of treatment and 44 were absolutely refractory to cisplatin. The other pts were in remission (65) or had stable disease (SD, 26). Most of pts (75.3%) had Beyer score $>$ 1. Following EPI-TAX, favorable responses were achieved in 140 pts (82.4%,CI95% 79.8-85.0; 21 complete responses, 68 partial responses and 51 SD). EPI-TAX was able to control disease in 56 (70.9%, CI95% 61.0-80.8) out of 79 pts who were in progression. Beyer score after EPI-TAX resulted 0 in 70.6% of pts. Successful harvested of SC was achieved in 146 (85.8%, CI95% 80.5-91.1) pts. EPI-TAX was well tolerated with peripheral neuropathy as the main non-hematopoietic toxicity. Treatment discontinuation was needed in 3 (1.8%) pts and 2 (1.2%) related deaths were observed. Following EPI-TAX, 155 (91.2%) pts received HDCT. HDCT was given in consolidation, once progressive disease was controlled by EPI-TAX or for progressive pts. With a median follow-up of 31 months (0.5-223) the 2- and 10-years OS for the subgroup consolidation were 78.2% (95%CI 69.1-87.4) and 66.9% (95%CI 55.4-78.6). Disease control by EPI-TAX resulted in 55.8% (95%CI 42.4-69.2) and 38.2% (95%CI 24.9-51.4) 2- and 10-y OS compared to 14.6% (95%CI 0-33.2, logrank p = 0.006) 2-y OS for progressive pts. **Conclusions:** EPI-TAX is effective to collect SC and to control disease of pts who were in progression after CDCT allowing them to receive HDCT.

4558 Poster Session (Board #236), Sun, 8:00 AM-11:30 AM

High-dose chemotherapy (HDCT) plus peripheral-blood stem-cell transplant (PBSCT) for patients (pts) with relapsed germ-cell tumors (GCT) and active brain metastases (mets). *First Author: Maitri Kalra, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: The optimal management of progressive brain mets in pts with GCT remains unsettled. Treatment options include chemotherapy, stereotactic or whole brain radiation (XRT), surgery, or a combination thereof. Global germ cell cancer group analysis suggested multimodality therapy improves survival probabilities in pts with brain mets at relapse (JCO.2016;1;34(4): 345-51). We report our experience on managing 25 consecutive pts with relapsed GCT and progressive brain mets undergoing HDCT with PBSCT at Indiana University from 2006-2016. **Methods:** All pts received HDCT consisting of carboplatin 700 mg/m2 days 1-3 and etoposide 750 mg/m2 i.v. days 1-3 followed by PBSCT on day 5 for upto 2 cycles. Pts were treated with craniotomy, XRT, chemotherapy alone, or a combination of modalities. Patient and disease characteristics, management of brain mets, and outcomes were measured. Platelet transfusions were given to maintain platelet counts $>$ 30,000 and goal of $>$ 50,000 in those with signs of hemorrhage. **Results:** Patient characteristics and outcomes are summarized in Table 1. Median age was 27.7 years (range, 16-48). All pts had progressive brain mets at time of starting HDCT. AFP ranged 1.6 to 1130, hCG 0.5 to 25601. At median follow-up of 24.8 months (range 2.5 to 118.5 months), 11 pts (44%) were alive with NED, 2 pts were alive with relapsed disease, and 12 pts died of disease progression. 17/18 patients developed progressive CNS mets despite radiation and/or craniotomy and of those, 8 are alive with NED. Toxicity was as previously published with this regimen (N Engl J Med 2007;357:340-8). **Conclusions:** Patients with relapsed GCT with progressing brain mets, including those with prior locoregional therapy, are curable with HDCT.

Characteristic (N)	Alive with NED (11)	Dead of disease (12)	Alive with relapsed disease (2)
CNS as primary presentation (7)	4 (36.37%)	3 (25%)	-
Predominant histology of craniotomy specimen (13)			
Embryonal carcinoma (5)	4	1	-
Yolk Sac (6)	3	3	-
Teratoma (1)	1	0	-
Negative for malignancy (1)	1	-	-
Craniotomy and XRT before HDCT (10)	6	4	-
Craniotomy alone before HDCT (2)	2	-	-
XRT alone before HDCT (6)	1	4	1
HDCT alone (7)	2	4	1

4559 Poster Session (Board #237), Sun, 8:00 AM-11:30 AM

Applying radiomics to predict pathology of post chemotherapy retroperitoneal nodal masses in germ cell tumors (GCT). *First Author: Jeremy Howard Lewin, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: After chemotherapy, $>$ 50% of patients (pts) with metastatic testicular GCT who undergo retroperitoneal lymph node dissection (RPNLD) for residual masses are found to have fibrosis (F) alone on pathological examination. To minimize overtreatment, better prediction algorithms are needed to identify pts with F who can avoid RPLND. Radiomics uses image processing techniques to extract quantitative textures/features from tumor regions of interest (ROI) to train a classifier that predicts pathological findings. We hypothesized that radiomics may identify pts with a high predicted likelihood of F who may avoid RPLND. **Methods:** Pts with GCT who had an RPLND for nodal masses $>$ 1cm after first line platinum chemotherapy were included. Preoperative contrast enhanced axial CT images of retroperitoneal ROI were manually contoured. 153 radiomics features trained a radial basis function support vector machine classifier to discriminate between viable GCT /Mature Teratoma (T) vs F. Nested ten-fold cross-validation protocol was employed to determine classifier accuracy. Clinical variables and restricted size criteria were used to optimize the classifier. **Results:** A total of 82 pts with 102 ROI were analyzed (GCT: 21; T: 41; F: 40). The discriminative accuracy of radiomics to identify GCT/T vs F was 72%($\pm$2.2)(AUC: 0.74 ($\pm$0.028); positive predictive value: 67% (48-92%); negative predictive value: 74% (62-84%)(p = 0.001)). No major predictive differences were identified when data was restricted by varying maximal axial diameters (AUC range: 0.58($\pm$0.05) - 0.74($\pm$0.03)). Prediction algorithm using clinical variables alone identified an AUC of 0.71 ($\pm$0.15). When these variables were added to the radiomic signature, the best performing classifier was identified when axial tumors were limited to diameter $<$ 2cm (accuracy: 88.2 ($\pm$4.4); AUC: 0.80 ($\pm$0.05)(p = 0.02)). **Conclusions:** A predictive radiomics algorithm had an overall discriminative accuracy of 72% that improved to 88% when combined with clinical details. Further independent validation is required to assess whether radiomics, in conjunction with standard clinical predictors, may allow pts with a high predicted likelihood of F to avoid RPLND.

4560 Poster Session (Board #238), Sun, 8:00 AM-11:30 AM

Intermediate prognosis in metastatic germ cell tumors (IPGCT): Outcome and prognostic factors. *First Author: Christoph Alexander Seidel, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The IGCCCG classification published in 1997 is based on data from the 1970-80s. Approximately 25% of metastatic GCT patients belong to the intermediate prognosis category, that was associated with a 5-year overall survival (OS) rate of 79%. However, more recent data suggest significant changes. We have thus performed an international registry of IPGCT patients to analyze current treatment, outcome, and potential prognostic factors. **Methods:** Data of IPGCT patients, diagnosed between 1979-2012, were retrospectively collected from 14 centers. Treatment and outcome before and after implementation of IGCCCG were analyzed. For patients diagnosed since 1997 prognostic factors were investigated by uni- and multivariate analysis to test whether current patients or subgroups may require less intensive treatment. **Results:** This registry includes 637 patients: group 1 diagnosed prior 1997 (n = 237), and group 2 since 1997 (n = 400). Mean follow-up duration was 128.4 months (IQR: 168.9). Patients in group 1 and 2 received first-line treatment with BEP (median 4 cycles; range 1 - 6) in 98% and 97%, respectively. Response to chemotherapy (CR and marker negative PR) was similar: 91% group 1; 94% group 2; (p = 0.233), but survival curves were significantly superior in group 2 associated with a 5-year OS rate of 87% (group 2) and 81% (group 1), respectively (p = 0.011; 95%CI 294-317). Recurrence rates were higher in group 1 (36% versus 24%; p = 0.001). Patients treated with 3 cycles BEP (n = 58) in both groups had a similar outcome concerning OS compared to patients treated with 4 cycles (n = 489) (p = 0.415). Uni- and multivariate analysis revealed LDH levels $<$ 2.0 UNL prior chemotherapy (p = 0.018; HR 0.35) and an adequate tumor marker decline at days 18-21 (half-life) of first cycle (p = 0.025; HR 2.58) as independent prognosticators, both associated with 5-year OS rates of 94%, respectively. **Conclusions:** Outcome of intermediate patients seems improved after implementation of the IGCCCG classification and less intensive regimes may also be sufficient. Here, patients treated with 3xBEP had a non-inferior outcome. A baseline LDH $<$ 2.0 UNL and an adequate tumor marker decline after first treatment cycle can be used for further stratification.

4561 Poster Session (Board #239), Sun, 8:00 AM-11:30 AM

Safety and usefulness of patient-centered shared survivorship care after chemotherapy for testicular cancer. *First Author: Hink Boer, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Testicular cancer (TC) survivors are at risk to develop early cardiovascular morbidity. Close collaboration between oncologists and primary care physicians (PCPs) is mandatory for optimal cardiovascular risk management. We designed a simple shared survivorship care program in which TC patients regularly visit their PCP instead of their oncologist. The primary aim of this study was to test safety and feasibility of shared-care follow-up after chemotherapy for metastatic TC. **Methods:** TC patients with complete remission after chemotherapy and age $\geq$18 years were eligible. Participants received a personalized survivorship care plan with scheduled visits to the oncologist and PCP, which was available both on paper and as a mobile application. During PCP visits, signals indicating cancer recurrence, cardiovascular risk and psychosocial issues were assessed. Safety boundaries were defined for the occurrence of failed response to signals indicating cancer recurrence. Patient data were monitored real-time to check if the shared-care follow-up was carried out within these boundaries. Secondary outcomes were satisfaction among TC patients and PCPs, measured with an evaluation questionnaire, and anxiety levels, measured with the Hospital Anxiety and Depression Scale. **Results:** 64% of eligible TC patients and 99% of the approached PCPs were willing to participate; 162 patients were enrolled in the shared-care program and 241 primary care visits took place. No failures occurred in the detection of relapsed TC. Therefore, the safety boundary was crossed, indicating that shared-care follow-up is a safe alternative to hospital-only follow-up. Four primary care visits were deemed as failed visits because of logistic issues.Anxiety levels did not increase during shared-care follow-up (3.6 *vs* 3.3 (p = 0.38). Patients were satisfied with the knowledge of PCPs and appreciated this regular contact. 78% of the PCPs would like to extend their role in shared-care follow-up. **Conclusions:** This easy to use shared survivorship care program is safe and feasible in the follow-up of TC patients. Communication within this patient-centered follow-up program may be further supported with e-health tools. Clinical trial information: NCT01783145.

4562 Poster Session (Board #240), Sun, 8:00 AM-11:30 AM

A phase I study of cabozantinib plus nivolumab (CaboNivo) and cabonivo plus ipilimumab (CaboNivoIpi) in patients (pts) with refractory metastatic (m) urothelial carcinoma (UC) and other genitourinary (GU) tumors. *First Author: Andrea B. Apolo, Genitourinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: We report the safety and clinical activity of the combination of CaboNivo and CaboNivoIpi in pts with mUC and other mGU tumors (NCT02496208). **Methods:** In this phase I trial 30 pts were treated in 4 dose levels (DL) for part 1 (CaboNivo) and 18 pts were treated in 3 DL for part 2 (CaboNivoIpi). Pts received Cabo PO daily and Nivo IV (part 1) with Ipi 1mg/kg x 4 doses q3wks (part 2). A mUC and a renal cell carcinoma (RCC) expansion cohort of CaboNivo has initiated enrollment. Tumors were assessed for overall response rate (ORR) q8wks (RECIST 1.1). Adverse events (AEs) were graded (G) by NCI-CTCAE v4.0. **Results:** From 7/22/15 to 12/31/2016, 48pts (CaboNivo N = 30; CaboNivoIpi N = 18) (mUC N = 19; bladder urachal N = 4; bladder squamous cell carcinoma (bSCC) N = 2; germ cell tumor (GCT) N = 4; castrate-resistant prostate cancer (CRPC) N = 9; RCC N = 2, sarcomatoid RCC N = 2, Sertoli cell N = 1, and trophoblastic tumor N = 1 were treated. Median age was 58 (range 35-77), 41 (85%) were male. Common treatment-related G1/2 AEs for CaboNivo: ALT increase (67%), fatigue (63%), diarrhea (60%), hypothyroidism (57%); CaboNivoIpi: fatigue (72%), diarrhea (61%), anorexia (61%); Grade 3 AEs for CaboNivo: hypertension (23%), neutropenia (17%), hypophosphatemia (13%), lipase increase (10%), fatigue (7%), aseptic meningitis (3%); CaboNivoIpi: hypophosphatemia (19%), hypertension (19%), fatigue (13%), hyponatremia (13%), nausea (13%), lipase increase (11%), colitis (6%); G4 CaboNivo: lipase increase (7%) thrombocytopenia (3%); CaboNivoIpi lipase increase (6%) There were no G5 toxicities, no DLTs. 43 pts were evaluable for response: ORR was 30% 13/43 [3 CR (2 mUC, 1 bSCC); 10 PRs (4 mUC, 2 penile, 1 sarcomatoid RCC, 1 urachal, 1 CRPC, 1 bSCC)]. ORR for CaboNivo 39% (mUC 44%); CaboNivoIpi 18% (mUC 29%). 11/13 (85%) of responses were ongoing at cutoff. **Conclusions:** CaboNivo and CaboNivoIpi combinations were well tolerated with no DLTs and have durable efficacy in mGU tumors particularly mUC. Rare tumors such as bSCC, urachal, and penile cancers demonstrated response to the combination. Larger cohorts of mUC and rare GU tumors are ongoing. Clinical trial information: NCT02496208.

4563 Poster Session (Board #241), Sun, 8:00 AM-11:30 AM

Efficacy and safety of nivolumab in patients with metastatic renal cell carcinoma (mRCC) and brain metastases: Preliminary results from the GETUG-AFU 26 (Nivoren) study. *First Author: Bernard J. Escudier, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Nivolumab (N) has been shown active in patients (pts) with mRCC after failure of 1 or 2 TKIs. Efficacy and safety of N in pts with brain metastases (BM) from RCC is still unknown. The aim of this study is to report preliminary data of the Nivoren study in pts with BM. **Methods:** GETUG-AFU 26 (Nivoren) is a prospective phase 2 study assessing safety and efficacy of N in a broader mRCC patient population than those recruited in the pivotal phase 3, including pts with BM (previously treated or not, but not requiring steroids), with previous mTOR inhibitor, with PS 2 as well as in previously highly pretreated pts. N was given every 2 weeks at 3mg/kg, until disease progression or unacceptable toxicity. Treatment was allowed beyond progression in case of clinical benefit. All pts had brain CT scan or MRI at baseline. **Results:** Up to December 2016 , 588 pts have been enrolled including 55 pts with BM (35 (67%) ,6 (12%) and 11 (21%) with 1, 2 or $>$ 2 BM, respectively. Of those 55 pts, 10 pts (23%) were PS 2 and 25 (58%) PS 1, and 16 patients (29%) had received more that 2 lines of therapy. No previous treatment for BM was performed in 67% (n = 37), while 9% had previous brain surgery (n = 5 ;) or brain radiation (n = 17 (31%). 2/55 pts never received N. Median duration of therapy in BM pts was 2.4 months (varying from 0 to 9) with a 3-months PFS of 60% (IC95% = 45 – 73). Median OS is not reached at the time of this analysis. Among 44 pts with assessment of response on BM, 10 (23%) had objective response while 21 (48%) had local progressive disease. Neurologic deterioration requiring steroids was observed in 15 pts (32%) . Updated data will be presented at the meeting. **Conclusions:** This is the first large study to report preliminary safety and efficacy of N in RCC pts with BM. Safety of N in this pt population appears to be acceptable, although some pts do require steroids because of brain progressive disease. Objective response in the brain was observed in 23% of pts. Further follow up is required to determine the real benefit of N in this group of mRCC pts. Clinical trial information: NCT03013335.

4564 Poster Session (Board #242), Sun, 8:00 AM-11:30 AM

Pazopanib exposure-response assessment as adjuvant therapy for patients with localized or locally advanced renal cell carcinoma (RCC) following nephrectomy. *First Author: Cora N. Sternberg, San Camillo Forlanini Hospital, Rome, Italy*

Background: PROTECT was a Phase 3 randomized placebo-controlled study to evaluate pazopanib efficacy and safety as adjuvant RCC treatment. The starting dose was 800 mg daily, which was reduced to 600 mg in an attempt to improve tolerability. Pazopanib trough concentrations (Ctrough) were collected from 358 patients at the 600-mg starting dose at two timepoints (Week 3/ 5 and Week 16/20). This analysis characterized the relationship between Ctrough and efficacy and safety endpoints. **Methods:** The relationship between pazopanib Ctrough and disease-free survival (DFS) was explored by Cox regression analysis. DFS of pazopanib Ctrough quartiles was explored using Kaplan-Meier plots. Exposure-safety relationship was explored via summaries of all grade adverse events (AEs), grade 3/4 (G3/4) AEs, and AE-related treatment discontinuation by Ctrough quartiles. **Results:** The geometric mean (geo-CV%) of Ctrough at 600-mg dose was 31.4 (57%) μg/mL and 25.3 (70%) μg/mL for Week 3/5 and Week 16/20, respectively. At Week 16/20, Ctrough values overlapped among patients receiving 400-, 600-, and 800-mg doses. Cox regression analysis showed pazopanib Ctrough at Week 3/5 as a significant covariate for DFS after adjusting for TNM staging and Fuhrman Nuclear grading (HR: 0.58, 95% CI, 0.42, 0.82; p = 0.002). Longer DFS was observed in higher Week 3/5 Ctrough quartiles (median DFS by quartile—Q1: 41.89 months, Q2-Q4: median DFS not reached). Incidence of all-grade AEs, as well as G3/4 hypertension, increased as Ctrough increased. Treatment discontinuation due to hypertension among pazopanib-treated subjects was low (3.1% vs < 1% in the placebo group). Ctrough was not correlated to G3/4 ALT increase. Incidence of other G3/4 AEs plateaued at higher Ctrough. No relationship was observed between Ctrough and treatment discontinuation due to AEs. **Conclusions:** Pazopanib Ctrough levels in PROTECT were consistent with levels associated with efficacy in the advanced setting. Higher pazopanib Ctrough correlated with longer DFS. Higher pazopanib exposure did not increase the incidence of G3/4 AEs, with the exception of hypertension, which was adequately controlled and managed. Clinical trial information: NCT01235962.

4565 Poster Session (Board #243), Sun, 8:00 AM-11:30 AM

Microvessel density as a prognostic marker in high-risk renal cell carcinoma. *First Author: Sarah A. Weiss, Yale School of Medicine, New Haven, CT*

Background: Increased vascularity is a hallmark of renal cell carcinomas (RCC), particularly clear cell RCC. The vascular endothelial growth factor (VEGF) pathway, implicated in tumor angiogenesis, is dysregulated in RCC. The phase 3 trial ECOG-ACRIN E2805 enrolled 1,943 patients (pts) with resected high-risk RCC (pT1b high grade to pT4 any grade or N any). Pts were randomized to adjuvant sunitinib, sorafenib, or placebo. Our aim was to determine the prognostic and predictive role of microvessel density (MVD), VEGF receptors, and ligands in nephrectomy specimens. **Methods:** We obtainedpre-treatment primary RCC tissue from 822 pts and built tissue microarrays using 3 cores from each sample. Using quantitative immunofluorescence we measured tumor MVD (area of CD34-expressing cells) and intensity of the VEGF/VEGF-R family (VEGF-R1, R2, R3 and VEGF-A, B, C, D) in tumor cells. We tested for association with disease-free survival (DFS) and overall survival (OS) by the stratified log-rank test. Associations with treatment arm and clinicopathologic variables were determined. **Results:** High MVD (above the median) was associated with prolonged OS for the entire cohort (p = 0.021, HR 0.63) and for pts treated in the placebo group (p = 0.014). The association between high MVD and OS was weaker in patients treated with sunitinib or sorafenib (p = 0.060). High VEGFD expression overall was associated with shorter OS (p = 0.027) but not for placebo (p = 0.16). Yet high MVD was not associated with improved DFS (p = 1.00). High MVD correlated with above-median age (> 56) (p = 0.032), Fuhrman grade I/II (p < 0.001), clear cell histology (p < 0.001), and absence of necrosis (p < 0.001) but not with gender, sarcomatoid features, lymphovascular invasion, or tumor size. In multivariable analysis, MVD remained independently associated with improved OS for the entire cohort (p = 0.013). **Conclusions:** High MVD in nephrectomy specimens of high-risk RCC pts is associated with improved OS, regardless of treatment arm. MVD is thus an independent prognostic, rather than predictive, biomarker. Further studies should assess whether incorporating MVD into clinical models will predict outcome in resected high-risk RCC pts and if MVD can be used for pt selection for adjuvant therapy.

4566 Poster Session (Board #244), Sun, 8:00 AM-11:30 AM

Everolimus (EVE) exposure as a predictor of toxicity (Tox) in renal cell cancer (RCC) patients (Pts) in the adjuvant setting: Results of a pharmacokinetic analysis for SWOG S0931 (EVEREST), a phase III study (NCT01120249). *First Author: Timothy W. Synold, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: S0931 is assessing recurrence-free survival in RCC pts randomized to receive EVE versus placebo for one year following nephrectomy. To date, there has been a higher than expected dropout rate due to bothersome tox. Previous reports have shown an association between EVE trough levels and both tox and disease response in RCC pts. Therefore, we have assessed EVE trough levels to evaluate the relationship between measured exposure and probability of tox. This analysis has been approved by the DSMC. **Methods:** Patients received 10 mg daily EVE or placebo for nine 6-week cycles. Pre-dose whole blood samples collected pre-cycle 2 and pre-cycle 3 were analyzed for EVE. Pts with pre-cycle 2 and/or pre-cycle 3 EVE results were used in the analysis. When both trough levels were available, results were averaged. Pts were segregated into quartiles (Q) based on EVE levels and logistic regression was used to model the following adverse event outcomes using EVE trough as a predictor; any grade 3+ tox, grade 2+ triglycerides, grade 2+ hyperglycemia, grade 2+ oral mucositis, grade 2+ rash, and premature stopping of EVE. Hazard and odds ratios were adjusted for age, BMI and performance status. **Results:** This study reached its accrual goal and closed on 9/15/2016 with 1545 (775 EVE) randomized patients. A total of 386 pts are included in this preliminary analysis. Median EVE trough was 12.8 ng/mL (range 3.1, 75.6) per 10 mg dose. Event rates for tox were: any grade 3+ tox = 46%, grade 2+ triglycerides = 33%, grade 2+ hyperglycemia = 15%, grade 2+ oral mucositis = 34%, grade 2+ rash = 15%, and premature stopping of EVE = 40%. The risk of grade 2+ triglycerides was increased in Q2 and Q3 vs Q1 (OR = 2.95; p = 0.001 and OR = 3.48; p < 0.001). The risk of grade 2+ rash was increased in Q2 and Q4 vs Q1 (OR = 2.95; p = 0.02 and OR = 3.20; p = 0.01). There was also a trend towards an increased risk of any grade 3+ tox in Q3 vs Q1 (OR = 1.72; p = 0.07). **Conclusions:** This analysis has identified significant associations between EVE exposure and the probability of tox. EVE analysis is ongoing and the final results will be presented. Clinical trial information: NCT01120249.

4567 Poster Session (Board #245), Sun, 8:00 AM-11:30 AM

Efficacy and safety of pegylated human IL-10 (AM0010) in combination with an anti-PD-1 in renal cell cancer. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: IL-10 has anti-inflammatory activity and stimulates the cytotoxicity and proliferation of CD8+ T cells at higher concentrations. IL-10 receptors and PD1 are expressed on activated CD8 T cells, providing a rationale for combining AM0010 and an anti-PD1. The efficacy and safety profile for AM0010 alone was established in poor to intermediate risk RCC pts treated in 3rdLOT. Objective responses were observed in 4 of 15 pts with RCC. In the dose escalation of AM0010 plus pembrolizumab, 4 of 8 patients had an objective response. The mPFS was 16.7 months and the mOS has not been reached, median follow up (mFU) is 19.3 mo. **Methods:** In this Phase 1b, 29 pts. with metastatic RCC were enrolled until Nov. 18 2016 on AM0010 (10 ug/kg daily SC) and nivolumab (3mg/kg, q2wk IV). 2 had favorable, 20 had intermediate and 4 had poor IMDC risk (3 were not available). Pts. had a median of 1 prior therapy (range 1-3). All pts. had received a VEGFR-TKI. Tumor responses were assessed with irRC. Immune responses were evaluated by serum cytokines, activation of blood derived T cells and peripheral T cell clonality. **Results:** AM0010 plus nivolumab was well tolerated. TrAEs were reversible. There were no autoimmune colitis, pneumonitis, or endocrine disorders. 14 patients had at least 1 G3/4 TrAE, including anemia (9), thrombocytopenia (5), hypertriglyceridaemia (4). 2 pts had a reversible cytokine release syndrome with splenomegaly and increased immune mediated red blood cell phagocytosis most likely precipitated by T-cell activation, as both pts had tumor responses. As of Jan 31 2017, partial responses (PR) were observed in 8 of 26 evaluable pts (31%). An additional 13 of 26 pts had stable disease (41%), 7 pts had tumor reductions of more than 30%. The mPFS and mOS has not been reached with a mFU of 5.2 mo. (range 0.3-10.3). AM0010 + anti-PD1 increased Th1 cytokines in the serum while decreasing TGFb, an expansion of proliferating PD1+ Lag3+ activated CD8 T cells and de-novo oligoclonal expansion of T cell clones in the blood. **Conclusions:** AM0010 in combination with nivolumab is well-tolerated in RCC pts. The efficacy and the observed CD8 T cell activation is promising and encourages the continued study of AM0010 in combination with nivolumab. Clinical trial information: NCT02009449.

4568 Poster Session (Board #246), Sun, 8:00 AM-11:30 AM

Prognostic role of circulating tumor cells-CTCs in metastatic renal cell carcinoma. *First Author: Umberto Basso, Medical Oncology Unit, Department of Clinical and Experimental Oncology, Istituto Oncologico Veneto IOV - IRCCS, Padova, Italy*

Background: CTCs can be isolated in peripheral blood of cancer pts and have demonstrated to have prognostic role in several metastatic tumors such as breast, colorectal and prostate cancer. Few data are available for Renal Cell Carcinoma-RCC. **Methods:** We designed a multicenter prospective observational trial aiming to assess the association between CTC counts and PFS of RCC pts treated with an antiangiogenic tyrosine-kinase inhibitors as a first-line regimen for metastatic disease. OS and response rate were secondary objectives. Both basal and sequential counts were enumerated by Cellsearch system at 4 time points: day 0 of treatment, +1 mo, +3 mo, at progression or 12 mo in the absence of progression. Ethics Committee approval was obtained. **Results:** Among 246 pts, 195 are eligible for the present analysis, 71.4% males, median age 69 yrs (range, 27 to 91), 81% with previous partial/total nephrectomy. Treatment was sunitinib (77.5%), pazopanib (21%) or sorafenib (1.5%). According to Heng criteria there were 24.6% good, 62.6% intermediate and 24.6% poor prognosis pts. After a median follow-up of 31.5 mo, median PFS is 13.6 mo (23% censored), 49.2% of pts are still alive. Investigator-assessed best response was 3.8% complete, 37.3% partial response, 33% stable, 25.9% progression. At baseline 91 pts had 1 or more CTCs, median 2, range 1 to 263. Pts with at least 1 CTC had a significantly shorter PFS compared to negative pts (8.8 vs 16.6 mo, p = 0.03), HR = 1.41 (95%CI 1.02-1.9). Thirty pts had $>=3$ CTCs, with a median PFS of 5.8 vs 15 mo in the remaining pts (p = 0.002), HR = 1.99 (CI 1.28-3.03). Percentage of pts with $>=3$ CTCs increased from 6.6% of good, 18.4% intermediate and 38.9% poor Heng score pts (p = 0.042). Pts with $>=3$ CTCs had a shorter estimated OS of 13.8 mo vs 52.8 mo (p = 0.003), HR = 1.99 (CI 1,17-3.2). Correlation between CTC positivity and response rate was not significant. **Conclusions:** In this robust multicenter prospective cohort of first-line metastatic RCC pts, the presence of 3 or more CTCs predicts a significantly shorter PFS and OS. Further analyses are ongoing on apoptotic markers of CTCs and concomitant counts of endothelial cells collected in the same cohort.

4569 Poster Session (Board #247), Sun, 8:00 AM-11:30 AM

Inter and intra-tumor heterogeneity of PD-L1 and MET expression in metastatic renal cell carcinoma (mRCC). *First Author: Lisa Derosa, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Villejuif, France*

Background: Although inhibition of PD-1/PD-L1 and MET receptors have clinical efficacy in mRCC, their expression is not a predictive biomarker. Heterogeneity between the sites of disease might be one explanation. The aim of our study was to evaluate PD-L1 and MET expression in primary and metastases (brain (BM)/pancreas (PM)) RCC lesions and their correlation with clinicopathologic characteristics. **Methods:** RCC specimen from different institutions were collected. Clinicopathologic characteristics were assessed by revision of samples. PD-L1 and MET expression in tumor cells (TC) and immune cells (IC) ($>$ 1%) were assessed by immunohistochemistry. **Results:** 180resected RCC specimen were successful collected (42 primary tumors and 138 metastases (87 BM/51 PM)). Overall, 22%, 51% and 23% of patients had at least one specimen expressing PD-L1 TC, IC and MET, respectively. In primary tumours, the proportion was 12%, 50% and 0%, respectively. In metastasis, the proportion of PD-L1 TC was 22% (23% in BM vs 19% in PM, p = 0.631), PD-L1 IC was 48% (47% in BM vs 49% in PM, p = 0.821) and MET was 24% (35% in BM vs 2% in PM, $p < 0.001$). Comparing paired samples (primary tumour and metastasis) there was discordances of PD-L1 in TC or IC and of MET expression in 30%, 27% and 24% of samples, respectively. These two first disagreements seem varied over time. The discordance in PD-L1 TC or IC and MET between primary tumor and PM (BM) was 15% (40%), 33% (22%) and 0% (67%), respectively. Some correlations were observed between MET and PD-L1 and clinicopathologic characteristics. **Conclusions:** In this largest analysis, evaluating heterogeneity between primary tumor and metastases (brain/pancreatic lesions) in mRCC, PD-L1 and MET expression suggests that the assessment as predictive biomarkers may require analysis of metastatic lesions.

		Metastases				
Biomarker expression	**Primary RCC**	**All**	**PM**	**BM**	**P value**	**All specimens**
All patients (N = 180)						
PD-L1 TC	12%	22%	19%	23%	< 0.631	22%
PD-L1 IC	50%	48%	49%	47%	< 0.821	51%
MET	0%	24%	2%	35%	< 0.001	23%

4570 Poster Session (Board #248), Sun, 8:00 AM-11:30 AM

Clinical outcomes by nephrectomy status in METEOR, a randomized phase 3 trial of cabozantinib (cabo) vs everolimus (eve) in patients (pts) with advanced renal cell carcinoma (RCC). *First Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Most pts with advanced RCC undergo nephrectomy (Nx) as curative or palliative therapy. In a retrospective analysis of pts treated with targeted therapy, pts who were older and had more comorbidities and higher tumor grade were less likely to have had Nx. Pts without Nx had shorter overall survival (OS) than pts with Nx (Hanna, J Clin Oncol 2016). Here we report outcomes for cabo vs eve in pts with advanced RCC with or without prior Nx in the phase 3 METEOR trial (NCT01865747). **Methods:** 658 pts with clear cell RCC and $\geq$1 prior VEGFR TKI were randomized 1:1 to receive cabo at 60 mg qd or eve at 10 mg qd. Stratification was by MSKCC risk group and number of prior VEGFR TKIs. Endpoints included progression-free survival (PFS), OS, and objective response rate (ORR). **Results:** 85% of enrolled pts had prior Nx of which 7% were partial; 15% had no prior nephrectomy (NoNx). Baseline characteristics, including Karnofsky performance status (KPS), MSKCC risk group, time from diagnosis to randomization, and median sum of diameters (SoD) for tumor target lesions, were less favorable for the NoNx subgroup (Table). Improved PFS and OS with cabo vs eve were observed regardless of Nx status. For the Nx subgroup, the hazard ratio (HR) was 0.51 (95% CI 0.41-0.64) for PFS and 0.66 (95% CI 0.52-0.84) for OS; for the NoNx subgroup, the HR was 0.51 (95% CI 0.30-0.86) for PFS and 0.75 (95% CI 0.44-1.27) for OS. Median OS was longer in the Nx subgroup for both treatment arms (Table). ORR per independent radiology committee (IRC) for cabo vs eve was 17% vs 4% for Nx and 21% vs 2% for NoNx. Grade 3 or 4 adverse events for both subgroups were generally consistent with the safety profiles of cabo and eve in the overall population. **Conclusions:** Cabo improved PFS, ORR, and OS compared with eve in pts with advanced RCC irrespective of nephrectomy status. Clinical trial information: NCT01865747.

	Prior Nephrectomy		No Nephrectomy	
	Cabo (N=283)	**Eve (N=279)**	**Cabo (N=47)**	**Eve (N=49)**
KPS <80, %	8	6	13	12

4571 Poster Session (Board #249), Sun, 8:00 AM-11:30 AM

Integrative analysis of sarcomatoid clear-cell renal cell carcinomas reveals an immune subgroup. *First Author: Gabriel G. Malouf, Pitié-Salpêtrière Hospital, Paris, France*

Background: Integrative analysis of clear-cell renal cell carcinomas (ccRCC) has revealed four transcriptomic subgroups associated with distinct patients outcomes. Integrative analysis of sarcomatoid ccRCC which represent the most agressive forms of ccRCC remains unknown. **Methods:** We performed integrative analysis of sarcomatoid (n = 28) and Fuhrman grade IV ccRCC (n = 9) using whole-exome sequencing (n = 37), RNA-sequencing (n = 32), and DNA methylation profiling by Infinium 450K arrays (n = 31). Correlation with clinico-pathlogical tumor features and patients outcomes were performed. **Results:** The most frequent somatic mutations in sarcomatoid ccRCC were *VHL* (71%), *PBRM1* (50%), *SETD2* (21%), *BAP1* (11%), and *TP53* (11%). Hierarchical unsupervised clustering of gene expression revealed two transcriptomic subgroups C1 and C2 which do not differ in term of clinical features, presence of sarcomatoid dedifferentiation and patients outcomes. Furthermore, these clusters do not differ according to their genomic features (*VHL, PBRM1* and *SETD2* mutations) or their mutational loads. Strikingly, C1 cluster was highly enriched for genes related to T cell receptor signaling pathway ($p = 2.6x10^{-6}$) and adapative immunity ($p = 8.5x10^{-5}$); in addition, the C1 « immune » subgroup was characterized by up-regulation of genes related to cell cycle. Conversely, C2 cluster revealed down-regulation of metabolic pathways ($p = 7.\ 5x10^{-5}$). At the epigenetic level, methylome clustering revealed two distinct epi-clusters, epi-C1 (n = 10) and epi-C2 (n = 21); patients with tumors belonging to C2 epi-cluster displayed 9p loss and harbored inferior progression-free survival as compared to those in C1 epi-cluster (11 months versus NR ; P = 0.02); of note, this was independent of clinico-pathological tumor features and transcriptomic classification. **Conclusions:** Our data suggest that genetic and epigenetic landscapes of sarcomatoid ccRCC might not differ from grade IV ccRCC. In addition, we discovered an immune sarcomatoid ccRCC cluster. This finding provides a rationale for use of immune checkpoint inhibitors in sarcomatoid ccRCC.

4572 Poster Session (Board #250), Sun, 8:00 AM-11:30 AM

Long-term response and time to response to pazopanib (PAZ) and sunitinib (SUN) in metastatic renal cell carcinoma (mRCC): COMPARZ subanalysis. *First Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: COMPARZ (NCT00720941) was a phase 3, randomized, controlled, open-label trial that demonstrated comparable efficacy of first-line PAZ and SUN, but favorable safety and quality of life profiles for PAZ in 1110 patients with mRCC (NEJM 2013;369:722). The objectives of this study were to identify patients from COMPARZ who exhibited a long-term response (LTR) to PAZ and SUN, determine time to response, and describe the clinical characteristics of patients who achieved LTR. **Methods:** Patients in the intention-to-treat population of COMPARZ were analyzed for differences in LTR (≥10 months [mos]) as measured by responder rate with either complete response or partial response (CR/PR) and PFS rate, and time to response. We also compared the clinical characteristics between long-term and shorter-term responders within and between each treatment arm. **Results:** The overall percentage of long-term responders with CR/PR (PAZ = 14%, SUN = 13%) and PFS (PAZ = 31.4%, SUN = 33.6%) in the PAZ and SUN groups were similar. This similarity was observed regardless of the cut-off for long-term duration of response. However, a shorter time to achieve CR/PR was observed in the overall population with PAZ (11.9 weeks [95% CI, 11.3–12.1] vs 17.4 weeks; [95% CI, 12.7–18.0]). Analysis conducted to identify baseline clinical characteristics that may be related to LTR will be reported. **Conclusions:** These exploratory subanalyses in long-term responders support the overall efficacy results with PAZ and SUN, which were reported in the COMPARZ trial. However, the results here demonstrate that the time to response was shorter with PAZ versus SUN. Clinical trial information: NCT00720941.

4573 Poster Session (Board #251), Sun, 8:00 AM-11:30 AM

Differential expression of c-Met between primary and metastatic sites in clear-cell renal cell carcinoma (ccRCC) and its association with PD-L1 expression. *First Author: Aly-Khan A. Lalani, Dana-Farber Cancer Institute, Boston, MA*

Background: Preclinical models show that c-Met promotes survival of renal cancer cells through the regulation of programmed death-ligand 1 (PD-L1). The relationship between c-Met and PD-L1 in human ccRCC is not well characterized. We compared c-Met expression between primary and metastatic sites in ccRCC tissues and evaluated the association with PD-L1 expression. **Methods:** Pairedprimary and metastatic samples from 45 ccRCC patients were included. Areas with predominant and highest Fuhrman nuclear grade (FNG) were selected. c-Met expression was evaluated by IHC using an anti-Met monoclonal antibody (MET4 Ab, VARI) and calculated by a combined score (CS, 0-300) as: intensity of c-Met staining (0-3) x % of positive cells (0-100). PD-L1 expression was previously assessed by IHC (PMID: 26014095). c-Met expression (average c-Met CS) between paired primary and metastatic samples were compared using Wilcoxon signed-rank test. Associations of c-Met expression with PD-L1 expression (+/-) and other clinical features were assessed with Wilcoxon rank-sum tests. **Results:** Our cohort included 45 primary ccRCCs and 54 corresponding metastases. c-Met expression was higher in metastatic sites compared to primary (c-Met CS: 55 vs. 28, p=0.0003) and was numerically-greater in PD-L1+ vs. PD-L1- tumors. Higher c-Met expression was associated with higher FNG and T-stage in both primary and metastatic sites (Table). **Conclusions:** Higher c-Met expression in metastases compared to paired primary tumors in our cohort of ccRCC suggests that testing for biomarkers of response to c-Met inhibitors should be conducted in metastases. Although the observation of higher c-Met expression in PD-L1+ tumors requires further investigation, it supports exploring these targets in combination trials.

Effects of pazopanib (PAZ) and sunitinib (SUN) dose modification on safety and efficacy in patients with metastatic renal cell carcinoma (mRCC) from COMPARZ. *First Author: Georg A. Bjarnason, Sunnybrook Research Institute, Toronto, ON, Canada*

Background: COMPARZ was a randomized, controlled, open-label, phase 3 trial that demonstrated comparable efficacy of first-line PAZ and SUN, but favorable safety and quality of life profiles for PAZ in patients (pts) with mRCC (NEJM 2013;369:722). We evaluated the relationship between dosing, safety, and efficacy in PAZ- and SUN-treated pts who did or did not undergo dose reduction or interruption resulting from adverse events (AEs) and other reasons. **Methods:** The AEs and median progression-free survival (mPFS) of PAZ and SUN were evaluated for pts with no, any, 1, and ≥2 dose reductions or dose interruptions lasting ≥7 days. **Results:** Similar percentages of pts in the PAZ and SUN groups had a dose interruption (44% vs 49%, respectively) or reduction (44% and 51%, respectively). The incidence of AEs in pts from the PAZ and SUN groups with dose modifications was higher compared to those with no dose modifications. Longer mPFS was observed in pts with dose modification (Table). Pts treated with PAZ or SUN with no dose reductions had mPFS of 7.3 months (mos) and 5.5 mos, respectively, whereas pts with any dose reduction had mPFS of 12.5 mos and 13.8 mos, respectively. Similarly, pts treated with PAZ or SUN with no dose interruptions lasting ≥7 days had mPFS of 8.2 mos and 5.6 mos, respectively, whereas those with any dose interruption lasting ≥7 days had mPFS of 12.6 mos and 13.8 mos, respectively. Pts with 2 or more dose interruptions or reductions had mPFS > 16 mos with both SUN and PAZ. **Conclusions:** Consistent with previous data for SUN, the current analyses showed longer mPFS with PAZ and SUN when dose modification is required to manage toxicity, suggesting that pts are not disadvantaged by such dose reductions or interruptions. Pts not requiring dose modification may have sub-optimal therapeutic drug exposure. Clinical trial information: NCT00720941.

4575 Poster Session (Board #253), Sun, 8:00 AM-11:30 AM

A phase I clinical trial of CM082 (X-82) in combination with everolimus for treatment of metastatic renal cell carcinoma. *First Author: Xinan Sheng, Peking University Cancer Hospital and Institute, Beijing, China*

Background: CM082 is an oral multikinase inhibitor targeting VEGFR, PDGFR and CSF1R with a shorter half-life and limited tissue accumulation, designed to lower toxicity and enable combination with other therapies. This is a phase I study to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of CM082 in combination with everolimus in patients with metastatic renal cell carcinoma. **Methods:** A 3+3 dose escalation design with expansion cohort was utilized to determine the dose-limiting toxicities (DLT) and the maximum tolerated dose (MTD) of CM082 plus everolimus at 5 mg PO daily for patients with metastatic clear cell renal cell carcinoma. Eligibility include PS 0-1, age ≥18 y, measurable disease, adequate organ function. **Results:** 22 patients (M/F: 16/6; median age: 55 y [range 32-69]; 21/22 pts [95.5%] had received prior anti-VEGF treatment (tx); 2/22 pts [9.1%] had also received prior mTOR-targeted tx) were treated at 3 dose levels of CM082 (100 mg [n = 4]; 150 mg [n = 3]; 200 mg [n = 15]) in combination with everolimus 5 mg. One patient in cohort 1 was not evaluable for DLT due to consent withdrawal. DLT were observed in one patient: G4 thrombocytopenia at 200 mg. CM082 200 mg plus everolimus 5 mg did not exceed MTD, but was chosen as the optimal biological dose regimen. Median duration of tx was 24 wk (range 1-57, 7/22 [32%] pts ongoing. The most common tx-related adverse events (AEs), all grades, were proteinuria 96% (G3, 5%); leukopenia 77% (G3, 9%); neutropenia 59%, hypercholesterolemia 64%, anemia 50% (G3, 9%), hypertension 46% (G3, 14%), raised aspartate aminotransferase 41%, fatigue 45%, diarrhea 32%, hypertriglyceridemia 32% (G3, 5%) and thrombocytopenia 20% (G4, 5%). At 200mg, partial response (PR) was observed in 5/14 (36%) patients, durable stable disease (SD) (≥24 week) or PR were achieved in 10/14 (71%) patients. Median PFS was 170 days (5.7 months) at this cohort. **Conclusions:** CM082 200mg in combination with everolimus 5 mg appeared to be well tolerated when administered to pretreated patients with advanced RCC in this Ph1 study. The preliminary efficacy warrant further evaluationand and the follow-up Ph 2/3 study is underway. Clinical trial information: NCT02577458.

4576 Poster Session (Board #254), Sun, 8:00 AM-11:30 AM

The association of tumor infiltrating CD8$^+$ and Foxp3$^+$ cells with overall response rate (ORR) in metastatic renal cell carcinoma (mRCC) patients treated with high-dose aldesleukin (HD IL-2). *First Author: Jean-Christophe Pignon, Brigham and Women's Hospital, Boston, MA*

Background: In the prospective, biomarker validation HD IL-2 "Select" study, durable remissions and prolonged survival were seen in both proposed "good" and "poor-risk" patients, based on clear-cell histology sub-classification and carbonic anhydrase-9 (CA-9) IHC staining. Given the toxicity and limited efficacy of HD IL-2, efforts to improve its therapeutic index are warranted. Since the high-affinity receptor of IL2 is expressed on both T regulatory cells and activated effector T lymphocytes, we explored the association between HD IL-2 response and tumor infiltration of CD8$^+$ T and FoxP3$^+$cells. **Methods:** Archival tumor tissue was collected for pathologic analysis on 120 mRCC patients enrolled in the HD IL-2 "Select" trial. Density of tumor infiltrating CD8$^+$ T cells and Foxp3$^+$ cells (cell/mm^2) were evaluated in the invasive margin (IM) and the tumor center (TC) by IHC and automated image analysis using Aperio algorithms. The association between ORR and immune cell density was assessed using Fisher exact test. **Results:** Tumor specimens of 89 patients were available for analysis. 24 pts experienced response (R, including 2 CR and 22 PR) and 65 pts did not respond (NR, including 11 SD and 54 PD). Baseline patient characteristics were similar between R and NR groups. A very high density of CD8$^+$ cells in the IM, or a high density of Foxp3$^+$ cells in the TC were significantly associated with ORR. A stronger association with ORR was found for patients having both high density of CD8$^+$ cells in the IM and Foxp3$^+$ cells in the TC. **Conclusions:** In this prospective, biomarker validation study, response to HD IL-2 was associated with a high density of CD8$^+$ cells in the invasive margin, and a high density of Foxp3$^+$cells in the tumor center. Independent validation is ongoing. To improve the predictive value of Foxp3, characterization of Foxp3 expressing cells (Tregs vs activated effector T cells) in highly infiltrated tumors is underway.

Marker	Percentile Cutoff (cells/mm2)	R %	NR %	Total n	p-value
CD8 IM	≥ 75th (759)	41	18	77	0.039
Foxp3 TC	≥ 25th (3.7)	95	67	89	0.004
	≥ 50th (8.1)	75	41	89	0.005
CD8 IM + Foxp3 TC	≥ 75th and ≥ 25th	41	9	77	0.002

4577 Poster Session (Board #255), Sun, 8:00 AM-11:30 AM

Safety and efficacy of nivolumab for metastatic renal cell carcinoma (mRCC): Real world data from an Italian expanded access program (EAP). *First Author: Ugo De Giorgi, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: Nivolumab showed a survival benefit in a randomised phase III trial in pre-treated mRCC. The EAP provided the opportunity to treat patients (pts) in real world clinical practice before market availability of the drug clinical practice. The aim of this analysis was to evaluate the safety and activity of nivolumab in a real world setting. **Methods:** Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for mRCC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events using CTCAE v.4.0. **Results:** Totally, 389 pts were enrolled in the EAP across 95 Italian sites, median age was 65 years (range, 34-85) with 70 (18%) aged ≥ 75 yrs. Pts had a clear-cell RCC in 92% of cases, bone metastases in 50% and brain metastases in 8%, and received more than one previous line in 79% of cases. At the time of this analysis, median number of doses received was 10 (1-31) and 82 (21%) pts were treated beyond progression. Among 389 pts, 18 pts (5%) discontinued treatment due to AE. The best overall response rate was 17% including one complete and 66 partial responses, whereas 121 (31%) had stable disease. With a median follow-up of 7 months (range, 1 to 16), 6-month and 9-month survival rates were 83% and 77%, respectively. Response and survival rates were comparable among pts regardless age, presence of brain or bone metastases and number of prior therapies. **Conclusions:** This EAP represents the most extensive reported real-world experience with nivolumab in pre-treated RCC pts. These first data seem to confirm efficacy and safety data of the pivotal trial in a real world setting. Results in patient populations poorly (elderly or bone metastases) or not represented at all (brain metastases) in the pivotal trial encourage the use of nivolumab in these subgroups of RCC pts.

4578 Poster Session (Board #256), Sun, 8:00 AM-11:30 AM

Outcomes based on age in the phase 3 METEOR trial of cabozantinib (cabo) vs everolimus (eve) in patients with advanced renal cell carcinoma (RCC). *First Author: Frede Donskov, Aarhus University Hospital, Aarhus, Denmark*

Background: The incidence of RCC increases with age with the highest incidence at ~75 years of age (Znaor, Eur Urol 2015). The Phase 3 METEOR trial (NCT01865747) showed a significant improvement in progression-free survival (PFS; HR 0.58, 95% CI 0.45–0.74; P < 0.0001), overall survival (OS; HR 0.66, 95% CI 0.53–0.83, P = 0.0003), and objective response rate (ORR; 17% vs 3%; P < 0.0001) for cabo compared with eve in patients with advanced RCC previously treated with VEGFR TKIs (Choueiri, NEJM 2015, Lancet Oncol 2016). Here we present outcomes by 3 categories of age for the METEOR trial. **Methods:** 658 patients were randomized 1:1 to cabo (60 mg qd) or eve (10 mg qd). Stratification factors were MSKCC risk group and number of prior VEGFR TKIs. Endpoints included PFS, OS, and ORR. Subgroup analyses by age (< 65, 65 to 74, and ≥75 years) are presented. **Results:** At baseline, 60% of patients were < 65 years old, 31% were 65 to 74 years old, and 10% were ≥75 years old. Subgroups by age generally had similar baseline characteristics in both arms. The HRs for PFS favored cabo for all age groups (HR 0.53, 95% CI 0.41–0.68 for < 65 years old; 0.53, 95% CI 0.37–0.77 for 65 to 74 years old; and 0.38, 95% CI 0.18–0.79 for ≥75 years old). ORR per independent radiology committee for cabo vs eve was 15% vs 5% for < 65 years old, 21% vs 2% for 65 to 74 years old, and 19% vs 0% for ≥75 years old. HRs for OS also favored cabo (HR 0.72, 95% CI 0.54–0.95 for < 65 years old; 0.66, 95% CI 0.44–0.99 for 65 to 74 years old; and 0.57, 95% CI 0.28–1.14 for ≥75 years old). Median OS for cabo vs eve was 21.4 mo vs 17.1 mo for < 65 years old, not reached vs 18.0 mo for 65 to 74 years old, and 18.4 mo vs 14.0 mo for ≥75 years old. Older patients more frequently had dose reductions (60% with cabo and 22% with eve for < 65 years old vs 85% with cabo and 36% with eve for ≥75 years old). Grade 3 or 4 adverse events were generally consistent with the safety profiles in the overall population although some events such as fatigue and hypertension occurred at a higher rate in older patients. **Conclusions:** Treatment with cabo improved PFS, ORR, and OS compared with eve in patients with advanced RCC irrespective of age. Adverse events in older patients were more frequently managed with dose reductions. Clinical trial information: NCT01865747.

4579 Poster Session (Board #257), Sun, 8:00 AM-11:30 AM

Development and clinical validation of circulating tumor cell (CTC) biomarkers in clear cell renal cell carcinoma (ccRCC) for the OMNIVORE clinical trial. *First Author: Waddah Arafat, University of Wisconsin, Madison, WI*

Background: New therapeutic strategies and biomarkers of treatment resistance are needed for metastatic ccRCC patients (pts) progressing on Nivolumab (Nivo). The upcoming OMNIVORE phase II clinical trial will evaluate whether adding Ipilumimab improves rPFS for pts with SD or PD on Nivo alone. We report development and clinical validation of predictive CTC biomarkers that will be evaluated in the OMNIVORE trial. **Methods:** We tested blood samples from ccRCC pts collected on biomarker trials at Dana Farber and U. of Wisconsin. Carbonic Anhydrase (CA) IX was used to capture CTCs in the VERSA platform to compare protein and gene expression signatures of resistance to Nivo. HLA and PD-L1 expression on CTC was quantified with independent confirmation with multicolor flow cytometry (FC). **Results:** We identified CTCs in 26/27 pts using RCC-specific CA IX antibody. Staining with CAXII and PAX8 confirmed CTC were of renal origin. The range of captured CK+/CAXII+/CD45- CTCs was 3-279 (median 15) from 18 pts. Multicolor FC found 8/9 pts with triple positive events for renal specific markers CAIX/CAXII/PAX8 [0-14.9%, median 0.32]. PDL1 and HLA staining was validated in cell line and pts samples with high reproducibility. PDL1 was expressed in < 10% of CTCs while HLA expression had high intra- and interpatient heterogeneity. Three pts had CTCs positive for both HLA and PDL1 that correlated with a high frequency of CTCs that were positive for 3 RCC markers (1.3, 5.1 and 14.9% of events) for an R^2 value of 0.92 ($p < 0.0001$). In 3 pts with ongoing response to Nivo (9-13 moths) triple positive events were 0, 0.2 and 0.3% (median 0.25%) and absent expression of PDL1/HLA. In 3 pts with early progression on Nivo (< 5 mo), triple positive CTCs ranged 0.33-14.9% (median 5.05%) with CTCs from 2/3 pts positive for PDL1/HLA. **Conclusions:** We report the first identification of ccRCC CTCs using CAIX, CAXII and PAX8 as confirmatory markers. CTC frequency and PDL1/HLA expression is lower in Nivo responders versus pts with early progression. High but variable HLA expression suggests variant resistance mechanisms. The utility of theses predictive and pharmacodynamic biomarkers will be tested in the OMNIVORE trial.

4580 Poster Session (Board #258), Sun, 8:00 AM-11:30 AM

Checkpoint inhibitors in metastatic renal cell carcinoma patients including elderly subgroups: Results from the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC). *First Author: Steven Yip, University of Calgary, Calgary, AB, Canada*

Background: Immuno-oncology (IO) checkpoint inhibitor treatment outcomes are poorly characterized in the real world metastatic renal cell cancer (mRCC) patient population, including geriatric patients. **Methods:** Using the IMDC database, a retrospective analysis was performed on mRCC patients treated with IO, as listed below. Patients received one or more lines of IO therapy, with or without a targeted agent. Duration of treatment (DOT) and overall response rates (ORR) were calculated. Cox regression analysis was performed to examine the association between age as a continuous variable and DOT. **Results:** 312 mRCC patients treated with IO were included. In patients who were evaluable, ORR to IO therapy was 29% (32% first-, 22% second-, 33% third-, and 32% fourth-line treatment (Tx)). Patients treated with second-line IO therapy were divided into favorable, intermediate, and poor risk using IMDC criteria; the corresponding median DOT rates were not reached (NR), 8.6 mo, and 1.9 mo, respectively ($p<0.0001$). Based upon age, hazard ratios were calculated in the first- through fourth-line therapy setting, ranging from 1.03 to 0.97. **Conclusions:** The ORR to IO appears to remain consistent, regardless of line of therapy. In the second-line, IMDC criteria appear to appropriately stratify patients into favorable, intermediate, and poor risk groups for DOT. Premature OS data will be updated. In contrast to clinical trial data, longer DOT is observed in real world practice. Age may not be a factor influencing DOT.

Genomic instability and DNA damage repair in clear cell renal cell carcinoma. *First Author: Patrick Glen Pilie, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Kidney cancer accounts for 2-3% of all new cancers with clear cell renal cell carcinoma (ccRCC) the most common subtype. ccRCC is characterized by a high level of genomic instability, suggesting defective DNA damage repair (DDR). The most frequent genomic alteration in ccRCC involves loss of the 3p chromosomal arm which harbors the von Hippel Lindau gene (*VHL*), in addition to nearby genes *SETD2*, *BAP1*, and *PBRM.* We hypothesized that VHL loss leads to defective DDR as an early event in ccRCC carcinogenesis, giving way to a mutator phenotype. We posited that assessment of very early ccRCC tumors would inform us regarding the core mutations required to drive tumorigenesis in ccRCC, and that we could confirm these findings in appropriate model systems. **Methods:** We performed whole-exome (WES) DNA sequencing on 11 early-stage ccRCC tumors from 5 individuals, along with their matched normal DNA. We then analyzed ccRCC samples with and without somatic *VHL* mutations from the Cancer Genome Atlas (TCGA) for mutational load. Finally we assessed DDR signaling activity in renal proximal tubular cell lines (RPTEC) with *VHL/SETD2* knockdown and in murine embryo fibroblasts (MEFs) from *Vhl* and *Setd2*knockout mice treated with etoposide via γH2AX expression and direct repeat-green fluorescent protein reporter assay. **Results:** All 11 samples revealed loss of 3p with pathogenic germline or somatic mutation in remaining *VHL* allele. No mutations were found in genes frequently mutated in larger ccRCC, including *PBRM1*, *BAP1* or *SETD2*. WES revealed ~100 mutations/tumor, with no shared mutations across samples, even within the same individual. TCGA analysis showed similar mutational loads across ccRCC samples. MEFs with biallelic loss of *Vhl* and monoallelic loss of *Setd2* and RPTEC with *VHL* and *SETD2*knockdown displayed increased DNA damage with impaired homologous repair and increased non-homologous end joining (NHEJ). **Conclusions:** Early stage ccRCC tumors with loss of *VHL* and chr 3p demonstrate genomic instability and a mutator phenotype similar to more advanced ccRCC. Cell line models of early ccRCC show increased DNA damage with a greater reliance on error-prone NHEJ machinery. These defects could be targeted for synthetic lethal treatment strategies.

4582 Poster Session (Board #260), Sun, 8:00 AM-11:30 AM

Association of circulating tumor DNA (ctDNA) detection in metastatic renal cell carcinoma (mRCC) with tumor burden. *First Author: Manuel Caitano Maia, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

Background: In a series of 224 pts with advanced RCC, we have previously reported ctDNA detection in 79% of pts (Pal SK *et al* ASCO GU 2017). Clinical factors associated with detection are unknown. M**ethods:** Data was obtained from pts with radiographically confirmed stage IV RCC who received ctDNA profiling as a part of routine clinical care using a CLIAA-certified platform evaluating 73 genes. Detailed clinical annotation was performed, including assessment of Heng risk score, previous and current treatments and calculation of tumor burden using scan data most proximal to ctDNA assessment. Tumor burden was equated to the sum of longest diameter (SLD) of all measurable lesions. **Results:** 32 pts were assessed (M:F 19:13) with a median age of 62 (range, 34-84). 25 pts, 4 pts and 3 pts had clear cell, sarcomatoid and papillary histology, respectively. Heng risk was good, intermediate and poor in 13, 18 and 1 pt, respectively. Pts received a median of 2 lines of prior tx. Specifically, 4 pts were not on active therapy (tx), 16 pts were receiving VEGF-directed tx, 6 pts were receiving checkpoint inhibitors (CPIs) and 6 pts were receiving combined VEGF/CPI tx. ctDNA was detected in 16 pts (50%) with a median of 2 genomic alterations (GAs) per pt. No associations were found between Heng risk, histology or tx type and presence/absence of ctDNA. However, pts with detectable ctDNA had a higher SLD compared to pts with no detectable ctDNA (99.6 vs 50.0 mm; P = 0.041). Furthermore, when evaluated as a continuous variable, number of GAs was correlated with SLD (P = 0.023). *TP53* and *VHL* alterations were the most frequent GAs in this series, each occurring in 25% of the cohort. All 3 pts with brain metastases had ctDNA detected. **Conclusions:** With the caveat of a limited sample size, it appears that SLD (a surrogate for tumor burden) is higher in mRCC pts with detectable ctDNA, and increasing SLD may be associated with a higher number of GAs. Further validation of these findings may help identify appropriate pts for ctDNA assessment and maximize yield in clinical practice.

4583 Poster Session (Board #261), Sun, 8:00 AM-11:30 AM

Impact of geographic region on overall survival (OS) in patients with metastatic renal cell carcinoma (mRCC): Results from a pooled clinical trials database. *First Author: Andre Poisl Fay, PUCRS School of Medicine, Porto Alegre, Brazil*

Background: Health determinants vary according to the geographic region and may impact the outcomes of mRCC patients treated on clinical trials of targeted therapy. We investigate the OS by geographic region of mRCC patients treated in the targeted therapy era. **Methods:** We conducted a pooled analysis of mRCC patients treated on phase II and III clinical trials. Clinical characteristics and survival data were collected. Statistical analyses were performed using the Kaplan-Meier method and log-rank test in univariate analysis. **Results:** Overall, 4736 patients were included in the analysis. Patient characteristics differed according to geographic region (table). No statistically significant differences in OS were observed when comparing US/Canada (USC, reference) to other regions: Latin America (LA), Asia/Oceania/Africa (AOA), and Eastern Europe (EE). OS differed among patients enrolled on trials in the USC compared to Western Europe (WE) (20.3 vs.17.4 months, respectively; HR: 1.15; 95%CI 1.03-1.3 $p = 0.015$). All grade treatment-related adverse events (AE) were reported more frequently in USC. There were no significant differences in grade 3-5 AEs between groups. **Conclusions:** We highlight that despite differing baseline characteristics, OS was similar among most geographic regions. Factors such as disease biology, access to care, AE reporting, and quality of care that may contribute to potential differences in outcomes among regions need to be further characterized.

	USC (n = 1544) n(%)	AOA (n = 1254) n(%)	WE (n = 897) n(%)	EE (n = 792) n(%)	LA (n = 250) n(%)

Sunitinib in patients with metastatic renal cell carcinoma: Clinical outcome according to IMDC risk group. *First Author: Brian I. Rini, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: In a phase III study (NCT00083889), treatment-naïve patients (pts) with metastatic renal cell carcinoma (mRCC) of all prognostic risk groups were treated with sunitinib or interferon-α (IFN-α). Since sunitinib has become the reference standard of care and serves as the comparator in multiple randomized trials sometimes restricted to prespecified risk groups, a retrospective analysis of outcome according to prognostic group from the phase III study was performed. **Methods:** Investigator-assessed efficacy data were analyzed for pts based on risk group (International mRCC Database Consortium [IMDC] criteria). The objective was to determine objective response rate (ORR), median progression-free survival (mPFS), and median overall survival (mOS) benchmarks by risk group. **Results:** Of sunitinib-treated pts, 134 were favorable, 205 were intermediate, and 34 were poor risk. The median sunitinib treatment duration/median number of cycles was 16.7 mo/12 cycles, 11.0 mo/8 cycles and 2.6 mo/2.0 cycles for favorable-, intermediate-, and poor-risk pts, respectively. ORR, PFS, and OS benchmarks for sunitinib-treated pts are shown in the Table. In sunitinib-treated intermediate-risk pts with 1 vs 2 risk factors, respectively: ORR was 43.3% vs 40.8%, mPFS (95% confidence interval [95% CI]) was 11.2 (9.7–13.6) vs 8.5 (5.6–10.7) mo, and mOS (95% CI) was 28.2 (23.0–not estimable) vs 16.3 (13.2–19.4) mo. **Conclusions:** This retrospective analysis provides ORR, PFS, and OS benchmarks for current and future clinical trial interpretation in mRCC pts with different prognostic risk treated with sunitinib.

Endpoint	Favorable risk (n=134)	Intermediate risk (n=205)	Poor risk (n=34)
ORR, %	58.2	42.4	17.6
(95% CI)	(49.4–66.7)	(35.8–49.7)	(6.8–34.5)
PFS, mo	16.0	10.7	2.5
(95% CI)	(13.6–17.3)	(8.6–12.5)	(2.3–6.5)
PFS HR, mo (vs IFN-α; 95% CI)	0.57 (0.42–0.78)	0.47 (0.37–0.59)	0.91 (0.54–1.54)
OS, mo (95% CI)	NE (NE–NE)	23.0 (19.8–27.8)	5.1 (4.3–9.9)
OS HR, mo (vs IFN-α; 95% CI)	1.05 (0.66–1.67)	0.79 (0.62–1.03)	1.01 (0.64–1.60)

4585 Poster Session (Board #263), Sun, 8:00 AM-11:30 AM

Evaluation of disease-free survival as an intermediate metric for overall survival in localized renal cell carcinoma: A trial-level meta-analysis. *First Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

Background: Adjuvant trials aim to integrate systemic therapy earlier to increase cure rates over surgery alone. Overall survival (OS) is a critical endpoint for these studies but requires long durations to events and significant patient resources. We explored the potential use of disease-free survival (DFS) as an intermediate readout for OS in the adjuvant setting for localized renal cell carcinoma (RCC). **Methods:** We performed a systematic literature review following the PRISMA guidelines. Inclusion criteria required randomized controlled trials (RCT) for adjuvant systemic therapy in localized RCC, which reported on both DFS and OS. Data on hazard ratio (HR) and 5-year event-free rate from Kaplan-Meier estimates were extracted. We performed a trial level meta-analysis and correlated these estimates for OS and DFS, weighted by the number of DFS events. R-square > 0.7 would indicate a strong correlation and potential for surrogacy. **Results:** Thirteen RCTs encompassing 6,473 patients treated with various forms of systemic therapy were eligible for the analyses. Minimum follow-up was 40 months. There was a moderate correlation between 5-year DFS and 5-year OS rates (R-square = 0.49, 95% CI:0.15-0.68) and between treatment effects as measured by DFS and OS hazard ratios (R-square = 0.44, 95% CI:0.00-0.69). **Conclusions:** Across trials of adjuvant systemic therapy for localized RCC, we observed a moderate correlation between 5-year DFS and OS rates and between treatment effects (HRs) on these endpoints. Further granularity may be achieved using individual patient data to assess different and earlier time points for surrogacy than are commonly reported.

Summary of trial level correlations between DFS and overall survival.

Correlation	No of units	R-square	95% CI
Correlation between 5 yr OS and DFS	22*	0.49	0.15-0.68
Correlation between DFS and OS treatment effects (HR)**	11	0.44	0.00-0.69

*11 (trials) * 2 (arms) = 22 units **Natural log transformed

4586 Poster Session (Board #264), Sun, 8:00 AM-11:30 AM

Nivolumab treatment for patients with non-clear cell renal cell carcinoma: A multicenter retrospective analysis. *First Author: Vadim S. Koshkin, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: Nivolumab (Nivo) is approved for metastatic renal cell carcinoma (mRCC) refractory to prior antiangiogenic therapy. However, the clinical activity of Nivo in non-clear cell RCC subtypes remains unknown as these patients were not part of the trial population. **Methods:** Patients (pts) from 3 centers who received at least one dose of Nivo as monotherapy for mRCC between 12/2015 and 01/2017 were identified. All patients had histologically-confirmed non-clear cell histology. A retrospective analysis focusing on patient and treatment characteristics, objective response according to RECIST v1.1 and adverse events (AEs) was undertaken. **Results:** Twenty-three patients were identified. Median age was 59 years (33-82), 78% were male, 61% were white, 30% black and 9% Hispanic. MSKCC risk groups were 19% favorable, 67% intermediate, 14% poor. Most common histologies were Unclassified (48%) and Papillary (44%), followed by Collecting duct and Mucinous tubular and spindle cell carcinoma (MTSCC) (4% each). The majority of pts had ECOG PS 0 (57%) or 1 (33%). At diagnosis, 65% had metastatic disease; most common sites were lung (57%), retroperitoneal lymph nodes (35%), and liver or bone (26% each). Most pts (74%) had prior nephrectomy and had received one (74%) or > 1 (26%) prior systemic therapy, most commonly sunitinib (65%), pazopanib (30%) or axitinib (17%). No pts had prior IL-2, but one pt had atezolizumab on trial. After a median follow-up of 6.5 months (mos) and 8 Nivo doses, median PFS was 4.2 mos and median OS was not reached. Among 21 pts evaluable for best response, 6 (29%) had PR and 4 (19%) had SD. Median time to best response was 5.1 mos. At the time of analysis, 9 pts were still on Nivo, 2 were on treatment break, 8 pts had subsequent treatment after PD on Nivo, and 2 were lost to follow-up. Two of 23 pts died. Most common AEs ($> 10\%$, any grade) were fever (13%) and fatigue (13%). Nivo treatments were postponed in 6 pts due to intolerance and stopped in3 pts. There were no treatment-related deaths. **Conclusions:** Nivolumab monotherapy demonstrated a substantial objective response rate and was well tolerated in a heterogeneous population of treatment-refractory patients who had mRCC with non-clear cell histology.

4587 Poster Session (Board #265), Sun, 8:00 AM-11:30 AM

T cell infiltration (TCI) in matched renal biopsy (bx) and nephrectomy (nx) samples in renal cell carcinoma (RCC). *First Author: Haris Zahoor, Cleveland Clinic, Cleveland, OH*

Background: TCI in tumors has been investigated as a biomarker of response to checkpoint inhibitors. A neo-adjuvant trial of checkpoint inhibition in locally-advanced RCC is ongoing at Cleveland Clinic, where TCI in pre-treatment renal mass bx will be compared to post-treatment nx specimens. However, there are no data regarding the association of TCI in matched bx and nx samples without intervening treatment. Understanding this association will enable further study of this potential biomarker in future studies. **Methods:** Matched bx and nx samples (without intervening systemic therapy) were identified from patients with non-metastatic RCC. Selected tissue sections from bx and nx samples were reviewed, and marked for intra-tumoral lymphocytes by the Pathologist. Immunohistochemistry (IHC) was utilized to stain these selected tissue sections for T cell markers (CD3, CD4 and CD8), and additional immune markers including PD-1, PDL-1 and CD11b. Intra-tumoral staining was then quantified in the pre-marked tissue sections as counts per total tumor area surveyed. Spearman correlation (ρ) was used to measure the strength of association. **Results:** 30 matched pairs were investigated. The median interval between bx and nx was 2.8 (0.2-87.7) months. Clear cell was the most common histology (29/30; 97%). There was a positive correlation between the frequency of $CD8^+$T cells between matched bx and nx samples ($\rho = 0.39$; $p=0.03$). CD3, CD4 and CD11b did not show significant correlation. (Table) PD-1 (bx 4/29, nx 16/29) and PDL-1 (bx 5/28, nx 10/28) expression was positive in the minority of samples. **Conclusions:** Bx material can potentially be used to assess the degree of $CD8^+$ TCI in RCC nx samples. However the utility of bx evaluation for $CD4^+$TCI and expression of PD-1, PDL-1 and CD11b requires further study.

4588 Poster Session (Board #266), Sun, 8:00 AM-11:30 AM

Incidence of T3a upstaging and survival after partial nephrectomy: Size-stratified rates and implications for prognosis. *First Author: Arnav Srivastava, Johns Hopkins, Baltimore, MD*

Background: The use of partial nephrectomy (PN) to treat renal cell carcinoma has grown in the past decade, with expansion to larger tumors. Performing PN for larger tumors may increase the number of patients up-staged to pT3a after surgery, who may have underwent radical nephrectomy (RN), if known preoperatively. We aimed to estimate the proportion of patients up-staged to T3a disease after PN, stratified by size. We also compared size-stratified survival of up-staged pT3a patients to those with T1a, T1b, or T2 disease. **Methods:** From 1998 – 2013, we identified patients undergoing PN or RN from the Surveillance Epidemiology and End Results registries. The proportion of patients receiving PN found to have pT3a disease was quantified by size. Cox proportional hazards models compared cancer-specific (CSS) and overall survival (OS) for PN patients with pT1a, pT1b, and pT2 disease to size-stratified pT3a patients. Also, we compared PN patients with pT3a disease to RN patients with pT3a disease. **Results:** From the 28,854 patients undergoing PN, the estimated proportion up-staged to pT3a increased along with tumor size: 4.2% for T1a, 9.5% for T1b, and 19.5% for T2. Among those receiving PN, survival analysis showed worse CSS for up-staged pT3a patients versus stratified pT1a (HR = 1.87, p = 0.02), pT1b (HR = 1.91, p = 0.01), and pT2 (HR = 2.33, p = 0.01) patients. When assessing OS, only in tumors $<$ 4cm did the pT3a cohort demonstrate worse OS (HR = 1.25, p = 0.04). Comparing PN and RN for pT3a disease, size-adjusted analysis revealed no difference in CSS or OS. Lastly, among pT3a patients undergoing PN, patients with larger tumors, measuring 4 – 7cm (OS: HR = 1.44, p = 0.04) or 7 – 16cm (OS: HR = 2.64, p $<$ 0.01), had worse survival than those with tumors $<$ 4cm. **Conclusions:** A greater proportion of patients experience T3a up-staging after PN with increasing initial T stage. Up-staged pT3a patients have worse CSS after PN compared to those with similarly sized localized tumors. Also, pT3a patients after PN showed similar survival to pT3a patients after RN. However, pT3a patients undergoing PN had worse survival with increasing tumor size, reinforcing the need for improvements in identifying patients at risk of up-staging.

4589 Poster Session (Board #267), Sun, 8:00 AM-11:30 AM

Impact of perioperative chemotherapy and radiation for locally advanced penile squamous cell carcinoma (PSCC). *First Author: Amanda Redden Hathaway, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: While neoadjuvant chemotherapy preceding radical surgery (S) for PSCC appears to provide the most optimal outcomes, there are no randomized studies. The impact of triple-modality S plus perioperative chemotherapy (C) plus radiation (XRT) for PSCC is unclear. The differential outcomes provided by perioperative XRT vs. perioperative C are also unclear. Given the absence of prospective trials, we retrospectively analyzed the U.S. National Cancer Database (NCDB) to study this issue. **Methods:** Data from the NCDB was obtained for pts with locally advanced PSCC from 1998-2011. Patients who underwent S for PSCC pathologic stage $\geq$1 with data for receipt of perioperative C and/or XRT and follow-up were eligible for analysis. The following variables were evaluated: pathologic stage, age, Charlson Comorbidity Index (CCI), race, overall survival (OS), socioeconomic status based on median income of area of residence and therapy (S+C, S+XRT, S+C+XRT). Treatment patterns were described. Multivariate analyses (MVA) were conducted to determine the impact of factors on OS with P $<$ 0.05 considered significant. **Results:** A total of 418 pts were evaluable including 132 in the S+XRT group, 166 in the S+C group and 120 in the S+C+XRT group. The number of pts with stages 1, 2, 3, 4 and unknown were 26, 78, 146, 137 and 31, respectively. In the MVA, stage was independently significantly prognostic (p = 0.002), while age (p = 0.056) and CCI (p = 0.057) were trending significant. S+C+XRT was not statistically better than S+XRT (HR 1.37 [95% CI: 0.935 - 2.007]) or S+C (HR 0.834 [95% CI: 0.589 - 1.180]). Additionally, S+C was not associated with significantly different OS compared to S+XRT (HR 1.142 [95% CI: 0.790 - 1.652]). Limitations of a retrospective analysis apply. **Conclusions:** This is the largest retrospective study of perioperative therapy for locally advanced PSCC. Triple modality therapy (S+C+XRT) did not extend OS compared to dual modality therapy (S+C or S+XRT). Additionally, the analysis did not identify whether C or XRT should be preferred in pts receiving dual modality therapy. The phase II International Penile Cancer Adjuvant Trial (InPACT) will investigate these conundrums for this orphan malignancy.

TPS4590 Poster Session (Board #268a), Sun, 8:00 AM-11:30 AM

Phase 3 KEYNOTE-361 trial: Pembrolizumab (pembro) with or without chemotherapy versus chemotherapy alone in advanced urothelial cancer. *First Author: Thomas Powles, Barts Cancer Institute, London, United Kingdom*

Background: Only 5%-15% of patients (pts) with advanced bladder cancer attain long-term survival with standard first-line cisplatin-based chemotherapy. Programmed death 1 (PD-1)/PD-L1 inhibitors have proven effective in recurrent, advanced urothelial cancer. Emerging data suggest these agents may also be useful in the first-line setting. In KEYNOTE-052, first-line pembro, an anti–PD-1 antibody, demonstrated antitumor activity and acceptable safety in cisplatin-ineligible pts with advanced urothelial cancer. KEYNOTE-361 (NCT02853305) is a randomized, open-label, phase 3 study of pembro with or without chemotherapy versus chemotherapy alone in pts with advanced urothelial carcinoma. **Methods:** Key eligibility criteria include age $\geq$18 years; histologically or cytologically confirmed unresectable/metastatic urothelial carcinoma of the renal pelvis, ureter, bladder, or urethra; measurable disease (RECIST v1.1, investigator review); no prior systemic chemotherapy ([neo] adjuvant platinum-based chemotherapy with recurrence $>$ 12 months after completion is allowed); ECOG PS 0-2; and provision of a tumor sample for biomarker analyses. Pts will be randomly assigned 1:1:1 to receive pembro 200 mg every 3 weeks (Q3W), pembro + investigator's choice of chemotherapy (gemcitabine [1000 mg/m^2 on day 1 and 8 Q3W] + cisplatin [70 mg/m^2 Q3W]), or chemotherapy alone. Cisplatin-ineligible pts randomly assigned to chemotherapy will receive gemcitabine + carboplatin [AUC 5 Q3W]. Chemotherapy choice must be selected before randomization. Treatment will continue until progressive disease, unacceptable adverse events (AEs), or 35 cycles of pembro (pembro arms only). Response will be assessed Q9W for the first year and Q12W thereafter. AEs will be evaluated throughout and graded per NCI CTCAE v4.0. Primary end points are progression-free survival (RECIST v1.1 per central review) and overall survival; secondary end points include objective response rate and safety and tolerability. Efficacy outcomes will be compared for pembro vs chemotherapy and pembro + chemotherapy vs chemotherapy. Enrollment is ongoing; ~990 pts will be enrolled. Clinical trial information: NCT02853305.

TPS4591 Poster Session (Board #268b), Sun, 8:00 AM-11:30 AM

S1605: Phase II trial of atezolizumab in BCG-unresponsive non-muscle invasive bladder cancer. *First Author: Parminder Singh, Mayo Clinic Arizona, Phoenix, AZ*

Background: Radical cystectomy is the standard of care for patients with BCG-unresponsive high risk non-muscle invasive bladder cancer (NMIBC). Based on the reported efficacy of atezolizumab in metastatic urothelial carcinoma and the known expression of PD-L1 expression in NMIBC after BCG therapy, this trial will evaluate the activity of atezolizumab in BCG-unresponsive high risk NMIBC. **Methods:** This is a single arm phase II trial testing systemic atezolizumab (1200 mg IV) every 3 weeks for one year in 135 patients with BCG-unresponsive high risk NMIBC. The study will enroll 70 patients with CIS (with or without concomitant Ta/T1) and 65 with Ta/T1 only. Patients with CIS at baseline will undergo mandatory repeat biopsy at 6 months, and all other patients only for suspected recurrence. Patients with persistent CIS, high grade Ta/T1 recurrence or progression to muscle invasive or metastatic disease will be taken off treatment. The co-primary endpoints are: (1) complete response (CR) at 6 months in the CIS subgroup, and (2) event-free survival (EFS) at 18 months in the overall population. A hierarchical approach will be used to test the two co-primary endpoints. Secondary endpoints include duration of CR as well as progression-free, cystectomy-free, bladder cancer-specific and overall survival in all patients. Response will be correlated to expression of PD-L1 and CD8 by IHC, and to molecular subtypes and immune signatures by RNA-sequencing. Results: If $\geq$28 (40%) CIS patients respond, the agent will be considered promising. This design has a significance level of 4.6%, and a power of 96%. If the lower bound of the 90% confidence interval of the 18-month EFS excludes 20%, the investigators will conclude the regimen significantly improves EFS relative to historical data (type I error rate 0.05 and statistical power 0.93). Conclusion:Successful completion of this trial could lead to a new treatment paradigm for patients with BCG-unresponsive high risk NMIBC. Funding: NIH/NCI grants: CA180888, CA180819, CA180820, CA180821, and CA180863. Clinical trial information: NCT02844816.

TPS4592 **Poster Session (Board #269a), Sun, 8:00 AM-11:30 AM**

P3BEP (ANZUP 1302): An international randomised phase 3 trial of accelerated versus standard BEP chemotherapy for adult and paediatric male and female patients with intermediate and poor-risk metastatic germ cell tumours (GCTs). *First Author: Peter S. Grimison, Chris O'Brien Lifehouse, Sydney, Australia*

Background: Bleomycin, etoposide, cisplatin (BEP) administered 3-weekly x 4 remains standard 1st line chemotherapy for metastatic GCTs. Accelerating regimens by giving them 2-weekly rather than 3-weekly has improved cure rates in other cancers. This is the first international randomised clinical trial for intermediate and poor-risk metastatic extra-cranial GCTs involving both adult and paediatric age groups open to both males and females. We aim to determine if accelerated BEP is superior to standard BEP. **Methods:** DESIGN: Open-label, randomised, stratified multicentre, 2 stage, phase 3 trial. Primary endpoint for stage I (n = 150) is complete response rate (RR), and for entire trial (n = 500) is progression free survival (PFS). SAMPLE SIZE: 150 and 500 patients gives > 80% power to detect a 20% improvement in RRs and 7% absolute improvement in 2yr PFS, respectively. POPULATION: Males and females aged 11-45 yrs with intermediate or poor-risk metastatic GCTs of the testis, ovary, retroperitoneum or mediastinum for 1st line chemotherapy. TREATMENT:Randomisation 1:1 to 4 cycles of "standard BEP" or "accelerated BEP": cisplatin 20mg/m2 IV days 1-5; etoposide 100mg/m2 IV days 1-5; bleomycin 30000 IU IV weekly; and pegylated G-CSF 6mg SC on Day 6; given every 3 weeks or every 2 weeks respectively. Accelerated BEP arm receives 4 additional weekly doses of bleomycin. ASSESSMENTS: Response assessments at 30-day safety assessment, and 6 months from randomisation or after all post-chemotherapy intervention is completed. Regular follow-up to 5 years, then annually. Archival tumour tissue and baseline blood collected for translational substudies. STATUS: 27 sites open in ANZ, 34 patients recruited by February 2017. International collaborations with UK (led by Cambridge Clinical Trials Unit) and US (led by Childrens Oncology Group) confirmed with sites expected to open by early 2017, and more sites sought for stage 2. Funded by Cancer Council Australia and Cancer Australia. ANZUP supported by Cancer Australia and previously CINSW. ANZCTR: ACTRN12613000496718. Clinical trial information: NCT02582697.

TPS4593 **Poster Session (Board #269b), Sun, 8:00 AM-11:30 AM**

The ABC-study: A randomized phase III study comparing one course of adjuvant bleomycin, etoposide, and cisplatin (BEP) and one course of carboplatin AUC7 in clinical stage I seminomatous testicular cancer. *First Author: Torgrim Tandstad, St. Olav's University Hospital, Trondheim, Norway*

Background: Clinical stage I seminomatous testicular cancer is by far the most frequent presentation of testicular cancer. Treatment options include surveillance or adjuvant treatment, internationally one course of adjuvant carboplatin (AUC7) is the preferred adjuvant treatment. Tumor size and stromal invasion in the rete testis can be used to identify patients with a higher risk of relapse. Recent data have showed only a modest effect of adjuvant carboplatin in preventing relapse, and more potent adjuvant therapies should be explored to this group of patients. **Methods:** The ABC-study is a investigator initiated randomized, open, phase III study comparing standard adjuvant chemotherapy in the form of one course carboplatin AUC7 to one course of BEP (Bleomycin, etoposide and cisplatin), in patients with one or two risk factors. Based on SWENOTECA data from one course of adjuvant carboplatin AUC7 we estimate the relapse rate in patients with one or two risk factors to be 9 %. We consider a reduction in relapse free survival of 7 % to be the minimum difference that will lead to routine use of one course of adjuvant BEP. To demonstrate an improvement in relapse rate from 9 to 2 % with an $\alpha = 0.05$ and $\beta = 0.80$, 332 evaluable patients are required. We expect a dropout rate of maximum 5 %, and therefore intend to randomize a total of 348 patients. Enrollment in the study started in 2015, and as of February 1. 2017 a total of 66 patients have been enrolled. Accrual have been slower than expected, but the current accrual rate is about 6-7 patients a month. We invite institutions and collaboratory groups to participate in this study. NCT02341989. EUDRACT 2014-004075-23. Clinical trial information: NCT02341989.

TPS4594 **Poster Session (Board #270a), Sun, 8:00 AM-11:30 AM**

Avelumab plus axitinib vs sunitinib as first-line treatment of advanced renal cell carcinoma: Phase 3 study (JAVELIN Renal 101). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: The combination of a checkpoint inhibitor with an anti-VEGF agent is a promising treatment strategy for advanced renal cell carcinoma (aRCC). Avelumab is a fully human IgG1 anti–PD-L1 antibody with clinical activity in aRCC and other tumor types (eg, Apolo et al. ASCO 2016; Gulley et al. ECC 2015). Axitinib is an anti-VEGF receptor tyrosine kinase inhibitor approved for second-line treatment of aRCC (Rini et al. Lancet 2011) that has also shown clinical activity as a first-line (1L) therapy (Hutson et al. Lancet Oncol 2013). In an ongoing phase 1b study in treatment-naïve patients (pts) with aRCC, avelumab + axitinib administered at standard monotherapy doses showed a tolerable safety profile and encouraging antitumor activity (Larkin et al. ESMO 2016). JAVELIN Renal 101 is a randomized, multicenter, phase 3 study (NCT02684006) comparing avelumab + axitinib vs sunitinib in pts with treatment-naïve aRCC. **Methods:** The primary objective is to demonstrate superiority of avelumab + axitinib vs sunitinib in prolonging progression-free survival (PFS) in the 1L treatment of pts with aRCC. Eligibility criteria include: aRCC with a clear cell component, ECOG PS $\leq$1, no prior systemic therapy for advanced disease, and measurable disease per RECIST v1.1. Approximately 583 pts will be randomized 1:1 and stratified based on ECOG PS (0 vs 1) and region (US vs Canada/Europe vs rest of the world). Pts receive either avelumab 10 mg/kg IV Q2W + axitinib 5 mg orally BID continuously (cycle length 6 weeks) or sunitinib 50 mg orally once daily for 4 weeks followed by 2 weeks off. Treatment is discontinued for unacceptable toxicity or if any other criteria for withdrawal are met. Pts may continue treatment beyond progression (RECIST v1.1) if investigator-assessed clinical benefit is achieved and treatment is well tolerated. PFS is assessed by blinded central review. Secondary efficacy assessments include overall survival, objective response, disease control, duration of response, and time to response. Safety, PK, and biomarker analyses will also be performed. The trial is currently active at 103 sites across 12 countries and as of Feb 2017, more than 40% of patients have been enrolled. Clinical trial information: NCT02684006.

TPS4595 **Poster Session (Board #270b), Sun, 8:00 AM-11:30 AM**

A phase III trial to compare efficacy and safety of lenvatinib in combination with everolimus or pembrolizumab vs sunitinib alone in first-line treatment of patients (Pts) with metastatic renal cell carcinoma (RCC). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib (LEN) is a multikinase inhibitor of vascular endothelial growth factor (VEGF) receptor 1–3, fibroblast growth factor receptor 1–4, platelet-derived growth factor receptor alpha, and RET and KIT. Based on a phase 2 study (Motzer et al. *Lancet Oncol* 2015), LEN was approved in combination with everolimus (EVE) for treatment of metastatic RCC following 1 prior VEGF-targeted therapy. A phase 1b/2 study of LEN in combination with pembrolizumab (PEM) in pts with RCC LEN is also underway. We report the design of a multicenter, open-label, phase 3 trial of LEN plus EVE or PEM vs sunitinib (SUN; a standard therapy for RCC) as first-line treatment for advanced RCC. **Methods:** Pts aged $\geq$ 18 years with confirmed advanced RCC diagnosis, $\geq$ 1 measurable lesion per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1, Karnofsky Performance Status $\geq$ 70, controlled blood pressure, and adequate blood coagulation, renal, hepatic, and bone marrow function are eligible. Pts will be randomized 1:1:1 to receive LEN 18 mg/day + EVE 5 mg/day, LEN 20 mg/day + PEM 200 mg every 3 weeks, or SUN 50 mg/day (on a schedule of 4 weeks on treatment followed by 2 weeks off) until disease progression, unacceptable toxicity, withdrawal of consent, or study end. The primary endpoint is to show superiority of LEN+EVE or LEN+PEM over single-agent SUN as first-line treatment for advanced RCC in improving progression-free survival (PFS). Secondary endpoints include comparison of objective response rate, overall survival, PFS on next-line therapy, health-related quality of life, and safety and tolerability in pts receiving LEN+EVE or LEN+PEM vs SUN. Exploratory endpoints include PFS in the LEN+PEM arm using immune-related RECIST, comparison of duration of response, disease control rate, and clinical benefit rate in pts treated with LEN+EVE or LEN+PEM vs SUN, and analysis of the relationship between blood biomarkers and outcome. No interim analysis is planned for efficacy or futility. Enrollment of 735 pts is planned to achieve 90% power at 2-sided $\alpha = 0.05$ to detect a difference in $\geq$ 1 of the primary comparisons. Clinical trial information: NCT02811861.

TPS4596 Poster Session (Board #271a), Sun, 8:00 AM-11:30 AM

A phase III randomized study comparing perioperative nivolumab vs. observation in patients with localized renal cell carcinoma undergoing nephrectomy (PROSPER RCC). *First Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

Background: The anti-PD-1 antibody nivolumab (nivo) improves overall survival (OS) in metastatic treatment refractory RCC and is generally tolerable. In 2017, there is no standard adjuvant therapy proven to increase OS over surgery alone in non-metastatic (M0) disease. Mouse solid tumor models have revealed an OS benefit with a short course of neoadjuvant PD-1 blockade compared to adjuvant therapy. Two ongoing phase 2 studies of perioperative nivo in RCC patients (pts) have shown preliminary feasibility and safety with no surgical delays or complications. The PROSPER RCC trial will examine if the addition of perioperative nivo to radical or partial nephrectomy can improve clinical outcomes in pts with locally advanced RCC. With the goal of increasing cure and recurrence-free survival (RFS) rates in M0 RCC, we propose a three-pronged, multidisciplinary approach of presurgical priming with nivo followed by resection and adjuvant PD-1 blockade. **Methods:** Tumorbiopsy prior to randomization is mandatory to ensure the correct diagnosis and will permit unparalleled correlative science in this global, randomized, unblinded, phase 3 National Clinical Trials Network study. 766 pts with clinical stage ≥T2 or any node positive M0 RCC of any histology will be enrolled. The study arm will receive nivo 240mg IV for 2 doses prior to surgery followed by nivo adjuvantly for 9 months (q2 wks x 3 mo followed by q4 wks x 6 mo). The control arm will undergo the current standard of care: surgical resection followed by observation. Pts are stratified by clinical T stage, node positivity, and histology. There is 84.2% power to detect a 14.4% absolute increase in the primary endpoint of RFS from the ASSURE historical control of 55.8% to 70.2% at 5 yrs (HR 0.70). The study is also powered to detect a significant OS benefit (HR 0.67). Key safety, feasibility, and quality of life endpoints are incorporated. PROSPER RCC exemplifies team science with a host of planned correlative work to investigate the significance of the baseline immune milieu and changes after neoadjuvant priming and to identify predictive gene expression patterns. Additional collaborations are welcomed.

TPS4597 Poster Session (Board #271b), Sun, 8:00 AM-11:30 AM

Phase 3 KEYNOTE-426 trial: Pembrolizumab (pembro) plus axitinib versus sunitinib alone in treatment-naive advanced/metastatic renal cell carcinoma (mRCC). *First Author: Brian I. Rini, Cleveland Clinic, Cleveland, OH*

Background: Antiangiogenic agents, including sunitinib and axitinib, have shown clinically significant efficacy in patients (pts) with mRCC. Results from a phase 1b study in 52 pts suggest first-line pembro, an anti–programmed death 1 antibody, in combination with axitinib, has substantial antitumor activity in mRCC (objective response rate [ORR], 71%) and manageable toxicity. The phase 3, multicenter, open-label, randomized KEYNOTE-426 study (NCT02853331) is designed to evaluate the efficacy and safety of pembro plus axitinib versus sunitinib alone in pts with treatment-naive mRCC. **Methods:** Key eligibility criteria include age ≥18 years, histologically confirmed mRCC with clear cell component (with or without sarcomatoid features), measurable disease (RECIST v1.1, investigator review), no prior systemic therapy for advanced disease, Karnofsky performance status ≥70%, and provision of a tumor sample for biomarker analyses. Before randomization, pts will be stratified by International Metastatic RCC Database Consortium risk category and geographic region. 840 pts will be randomly assigned 1:1 to receive pembro 200 mg every 3 wk + axitinib 5 mg twice daily or sunitinib 50 mg once daily for 4 wk followed by 2 wk off. Treatment will continue until progressive disease, unacceptable adverse events (AEs), or withdrawal of consent. Pts in the pembro arm may receive up to 35 doses of pembro, after which axitinib-only treatment may continue. Imaging will be performed at wk 12, then every 6 wk for the first year, and every 12 wk thereafter. Bone scans will be performed at baseline, and if positive, repeated at wk 18, 30, 42, and 54, and every 24 wk thereafter. AEs will be monitored throughout and graded per National Cancer Institute Common Toxicity Criteria for Adverse Events, version 4.0. Primary end points are to compare progression-free survival (RECIST v1.1, central review) and overall survival between treatment arms. Secondary end points include the comparison of ORR, duration of response, disease control rate, safety, and patient-reported outcomes between arms. Enrollment is ongoing. Clinical trial information: NCT02853331.

TPS4598 Poster Session (Board #272a), Sun, 8:00 AM-11:30 AM

A phase III study of atezolizumab (atezo) vs placebo as adjuvant therapy in renal cell carcinoma (RCC) patients (pts) at high risk of recurrence following resection (IMmotion010). *First Author: Robert Uzzo, Fox Chase Cancer Center, Philadelphia, PA*

Background: Nephrectomy is the SOC in early RCC; however, the 5-y relapse rate is 30-40% in stage II or III pts, with tumor stage and grade correlating with survival and recurrence after surgery. Currently, there is a limited role for adjuvant therapy after nephrectomy in pts who have had complete tumor resection; observation is standard. In a Ph II first-line metastatic RCC study, treatment with single-agent atezo (anti–PD-L1) resulted in an ORR of 25%. Thus, IMmotion010, a Ph III, multicenter, randomized, placebo-controlled, double-blinded trial, will evaluate the efficacy and safety of atezo as adjuvant therapy in RCC pts who are at high risk of recurrence after resection (NCT03024996). **Methods:** Eligible RCC pts (clear cell or sarcomatoid histologies) will have undergone nephrectomy (radical or partial) and be at high risk of recurrence (T2 Grade 4, T3a Grade 3-4, T3b/c any Grade, T4 any Grade or TxN+ any Grade) or have had complete resection of limited metachronous/synchronous metastasis. Pts must show no residual disease or evidence of metastases by CT scan at enrollment. ECOG PS ≤ 1 and tumor specimens evaluable for PD-L1 will also be required. Pts will be randomized 1:1 to receive atezo 1200 mg IV q3w or placebo IV q3w for 16 cycles or 1 y; stratification will be by disease stage (T2/T3a vs T3b/c/T4/N+ vs metastasectomy), region (North America [excluding Mexico] vs rest of world) and PD-L1 status on tumor-infiltrating immune cells (IC; PD-L1 IC expression < 1% vs ≥ 1%). The primary endpoint is independent review facility (IRF)-assessed disease-free survival (DFS), defined as the time from randomization to the first documented recurrence event (local recurrence, new primary RCC, distant metastasis) or death. Secondary endpoints include OS, investigator-assessed DFS, IRF-assessed and investigator-assessed DFS in pts with ≥ 1% PD-L1 IC, disease-specific survival, distant metastasis-free survival and the 3-y rates of IRF-assessed DFS and investigator-assessed DFS. Safety and biomarkers will be evaluated. The planned analysis will occur when at least ≈ 65% of pts in the 2 populations have died. 664 pts will be enrolled at 150-200 sites worldwide. Clinical trial information: NCT03024996.

TPS4599 Poster Session (Board #272b), Sun, 8:00 AM-11:30 AM

A randomized, phase II efficacy assessment of multiple MET kinase inhibitors in metastatic papillary renal carcinoma (PRCC): SWOG S1500. *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: PRCC constitutes approximately 15% of RCC cases, and no standard of care exists for metastatic disease. Approved VEGF- and mTOR-directed therapies for clear cell RCC in metastatic PRCC (mPRCC) have generally been ineffective. Trials assessing sunitinib and everolimus in non-clear cell RCC show a numerical advantage in progression-free survival (PFS) with sunitinib therapy. Prospective studies evaluating sunitinib in mPRCC show a broad range of efficacy, with PFS ranging from 1.6-6.6 months. Another possible approach to treating mPRCC is to target the *MET* proto-oncogene, which is frequently altered across both type I and type II disease. SWOG 1500 is a randomized, phase II study which will compare sunitinib to three MET-directed therapies in pts with mPRCC. **Methods:** Eligible pts will have PRCC (type I, type II or NOS), Zubrod performance status 0-1, and measurable metastatic disease. Pts may have received up to 1 prior systemic therapy, with the exception of prior VEGF-directed treatments. Treated brain metastases are allowed. Tissue must be available for central pathologic review of papillary subtype. Pts will receive either oral sunitinib, cabozantinib, crizotinib or savolitinib in a 1:1:1:1 randomization, with stratification by (1) prior therapy (0 vs 1) and (2) PRCC subtype (type I vs type II vs NOS). The primary endpoint of the study is to compare PFS with sunitinib to PFS with MET-directed therapies. Secondary endpoints in the study include comparison of response rate, overall survival and safety profile. Translational aims of the study include correlation of clinical outcome with MET mutation, copy number and other markers of MET signaling. Radiographic assessment will be performed every 12 wks. Interim analyses are planned for each arm. A total of 275 pts will be enrolled, with 26 pts registered as of Jan 30, 2017. Clinical trial information: NCT02761057.

TPS4600 Poster Session (Board #273a), Sun, 8:00 AM-11:30 AM

Tivo-3: A phase 3, randomized, controlled, multi-center, open-label study to compare tivozanib hydrochloride to sorafenib in subjects with refractory advanced renal cell carcinoma (RCC). *First Author: Brian I. Rini, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: Tivozanib is a biochemically potent and selective VEGF tyrosine kinase inhibitor in clinical development in RCC. Other agents used for treatment of RCC inhibit multiple tyrosine kinases in addition to the VEGF receptor tyrosine kinase, leading to off-target toxicities such as fatigue, hand-foot syndrome, stomatitis, and neutropenia. The adverse event (AE) profile of tivozanib demonstrates minimal off-target toxicities. TIVO-1 (AV-951-09-301) was an open-label, randomized, controlled, multinational, multi-center, parallel-arm trial comparing tivozanib to sorafenib in patients with advanced RCC. The blinded independent radiological assessment showed the median progression free survival (mPFS) in the tivozanib arm to be 11.9 months (95% confidence interval (CI) [9.3, 14.7]), compared with 9.1 months (95% CI [7.3, 9.5]) in the sorafenib arm ($p = 0.042$, HR = 0.797). Overall survival had a negative trend, most likely due to a one-way crossover for patients randomized to sorafenib. This study is designed, in part, to demonstrate that the negative trend in OS was an artifact. **Methods:** Subjects with metastatic RCC who have failed 2 or 3 prior systemic regimens, one of which includes a VEGFR TKI other than sorafenib or tivozanib, will be randomized in a 1:1 ratio stratified by the IMDC risk category (favorable; intermediate; poor) and prior therapy (two VEGFR TKIs; a prior checkpoint inhibitor plus a prior VEGFR TKI; a prior VEGFR TKI plus any other systemic agent). The primary objective is to compare the progression-free survival (PFS) of subjects randomized to tivozanib with those randomized to sorafenib as assessed by blinded independent radiological review (IRR). Secondary endpoints are overall survival, objective response rate, and duration of response. Clinical trial information: NCT02627963.

TPS4601 Poster Session (Board #273b), Sun, 8:00 AM-11:30 AM

TARIBO trial: Cytoreductive nephrectomy in metastatic renal cell carcinoma patients treated with targeted agents. *First Author: Paolo Grassi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In the cytokine era cytoreductive nephrectomy (CN) has been shown to increase survival in patients (pts) with metastatic renal cell carcinoma (mRCC). Efficacy of tyrosine kinase inhibitors (TKIs), including first-line sunitinib and pazopanib has been demonstrated. It is unclear if similar survival benefit could be achieved without CN with TKIs since most of pts enrolled into phase III trials had undergone CN. **Methods:** A total of 270 mRCC pts will be randomized to receiveCN followed by TKIs vs upfront TKIs without CN. Patients will receive pazopanib 800 mg orally daily or sunitinib 50 mg daily, 4 weeks on/ 2 weeks off. The choice of TKI will be done according to investigator's clinical practice. Primary objective**: t**o compare clinical benefit, as measured by overall survival (OS), provided by CN followed by TKIs vs upfront TKIs in pts with mRCC. Secondary objectives: i) to compare clinical benefit, as measured by progression-free survival (PFS) and response rate (RR) provided by CN followed by TKIs vs upfront TKIs; ii) Safety; iii) Exploratory analyses: evaluation of the predictive role of circulating tumor cells count and circulating tumor DNA at baseline, before and after surgery (in pts undergoing CN), 24 weeks after randomization and at the time of disease progression. Key inclusion criteria: Favorable or intermediate MSKCC or Heng prognostic risk group; histological diagnosis of RCC with a clear-cell component; resectable asymptomatic mRCC with primary tumor in place; up to three different metastatic sites; $\geq$ 3 metastatic lesions. Key exclusion criteria: Widespread disease ($>$ or = 4 metastatic organ sites); disease suitable of metastasectomy ($<$ 3 lesions confined at one organ site). Statistical plan: The sample size was calculated in order to compare 5-year OS between subjects randomized to receive CN followed by TKIs and those randomized to receive upfront TKIs. A total of 191 deaths will yield 80% power to detect a hazard ratio of 1.5 of upfront TKIs vs CN followed by TKIs with an overall type 1 error of 0.05 (two-sided log-rank test). Such a HR corresponds to an increase in the 5-year OS, from an anticipated value of 10% for TKIs to 21.5% for CN followed by TKIs. To date 10/270 pts have been enrolled. Clinical trial information: NCT02535351.

5000 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Development and validation of a novel clinical-genomic risk group classification for prostate cancer incorporating genomic and clinicopathologic risk. *First Author: Daniel Eidelberg Spratt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: It is clinically challenging to integrate genomic classifier results that report a continuous numerical risk of recurrence into treatment decisions for prostate cancer (PCa). We aimed to develop a novel clinical-genomic risk system that can readily be incorporated into treatment guidelines for localized PCa. **Methods:** Four multi-center cohorts (n = 6928 men; 5937 prospective samples and 991 retrospective samples with long-term follow-up) were utilized to identify and validate our clinical-genomic risk system in radical prostatectomy (RP) samples and subsequently in pre-treatment biopsy samples. All patients' FFPE tissue underwent microarray analysis, and the expression values for 22 prespecified biomarkers that constitute Decipher were extracted. Cumulative incidence curves were constructed to estimate metastasis risk. C-indices were calculated to compare NCCN and CAPRA score to our clinical-genomic system. **Results:** With a median follow-up of 8 years for men in our RP cohort, the 10-year distant metastasis rates for NCCN low, favorable-intermediate, unfavorable-intermediate, and high-risk were 7.8%, 9.4%, 40.1%, and 41.4%, respectively. Our 3-tier clinical-genomic risk groups had 10-year distant metastasis rates of 3.7%, 30.7%, and 57.7%, for low, intermediate, and high-risk, which were validated in our pre-treatment biopsy cohort with 10-year rate of distant metastasis of 0%, 30.3%, and 63.2%, respectively. C-indices for the clinical-genomic system (0.84, 95%CI 0.62-0.92) were significantly improved over NCCN (0.71, 95%CI 0.59-0.84) and CAPRA (0.71, 95%CI 0.60-0.81) score. A total of 33.4% of men would be reclassified by the clinical-genomic system, and specifically 17.1%, 41.3%, and 19.4% of men in NCCN low, intermediate and high risk groups would be reclassified by our new system. **Conclusions:** The use of a readily available genomic classifier in combination with clinicopathologic variables can generate a simple to use 3-tier clinical-genomic risk system that is highly prognostic for distant metastasis, is more accurate than clinical risk, and can be easily incorporated into NCCN guidelines to inform treatment decisions.

5001 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Abiraterone + prednisone (Abi) +/- veliparib (Vel) for patients (pts) with metastatic castration-resistant prostate cancer (CRPC): NCI 9012 updated clinical and genomics data. *First Author: Maha Hussain, Northwestern University Robert H. Lurie Comprehensive Cancer Center, Chicago, IL*

Background: In preclinical CRPC models, PARP1 inhibition synergizes with AR targeted therapy, especially in ETS fusion-positive tumors. We hypothesized: 1. Co-targeting PARP-1 + AR is superior to AR inhibition and 2. ETS +ve predicts response. **Methods:** Pts had metastatic (mets) disease biopsy (bx), stratified by IHC-ETS status and randomized to Abi (Arm A) or Abi + Vel (Arm B). Primary endpoint: PSA response rate (RR > = 50% decline). Secondary endpoints: safety, objective RR (ORR), progression free survival (PFS), and molecular analysis including if DNA repair gene deficiency (DRD: *BRCA 1, BRCA 2, ATM, FANCA, PALB2, RAD51B, RAD51C*) predicts response. 148 pts stratified by IHC-ETS status were randomized to detect a 20% PSA RR improvement assuming a 5% 1-sided type I error and 80% power. An elastic net multivariable Cox model was used to analyze PFS. Mets bx underwent targeted exon sequencing and capture transcriptome analysis. **Results:** 72 pts were randomly assigned to Arm A and 76 to Arm B. PSA RR: Arm A 63.9%, Arm B 72.4% (p = 0.27). ORR: Arm A 45%, Arm B 52.2%, p = 0.51. Median PFS: Arm A 10.1 months (m), Arm B 11.3 m, p = 0.95. More Arm-B pts were on therapy for 12+ (45% vs 38%) and 18+ cycles (22% vs 17%). ETS status had no impact. Mets tissue sequencing (N = 80): 42 pts (53%) were ETS +ve, 19 (25%) had DRD, 47 (59%) had AR amplification/copy gain, 32 (40%) had PTEN mutation (mut), 33 (41%) had TP53 mut, 37 (46%) had PIK3CA activation (a) and 12 (15%) had WNT-a. Irrespective of arm pts with DRD had a higher PSA and ORR (> = 87%) vs wild type (58%, 39%; p = 0.013, p = 0.002, respectively), higher PSA decline rate of > = 90% (74% vs 26%, p = 0.0004) and longer median PFS (95% CI): DRD 16.6 m (11 - NR) vs wild type: 8 m (5.4 – 13.3); p = 0.02. PFS was longer in pts with normal PTEN (13.5 vs 6.2 m, p = 0.02), TP53 (13.3 vs 7.8 m, p = 0.04) and PIK3CA (10.3 vs 8.3 m, p = 0.03). Controlling for clinical factors, DRD, PTEN, TP53 and PIK3CA are associated with PFS in this order of importance. **Conclusions:** There was a modest trend in favor of Abi + Vel but no difference by ETS. Pts with DRD, normal PTEN,TP53 and PIK3CA had better PFS raising new hypotheses regarding the importance of integrating molecular analysis in therapeutic trials. Clinical trial information: NCT01576172.

5002 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

A randomized phase II cross-over study of abiraterone + prednisone (ABI) vs enzalutamide (ENZ) for patients (pts) with metastatic, castration-resistant prostate cancer (mCRPC). *First Author: Kim N. Chi, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: ABI and ENZ are indicated as 1st line therapy for mCRPC but have not been directly compared. Optimal sequencing of these agents has not been prospectively evaluated and predictive biomarkers are lacking. **Methods:** Multicenter, phase 2 study randomizing treatment-naïve mCRPC pts to ABI vs ENZ, with cross over at PSA progression. Primary endpoints: response and time to PSA progression (TTPP, PCWG3 criteria) after 2nd line therapy. Reported here are secondary endpoints: PSA ≥50% decline (PSA50) from baseline, TTPP with 1stline therapy, and correlation with deep targeted sequencing of 73 mCRPC genes in circulating tumor DNA (ctDNA). **Results:** Accrual completed October 2016 with 202 pts randomized (ABI: ENZ = 101:101). Median follow-up 12.8 months. Baseline characteristics were similar between arms: median for age was 75 years (range 49-94), PSA 36.1 (1.7-2817), HGB 130 (89-165), ALK PHOS 105 (31-6600), LDH 207 (77-3098). ECOG PS was 0-1 in 83%, presence of metastases in bone/liver/lung in 83%/6%/10%. With 1stline therapy for ABI vs ENZ, PSA50 at 12 weeks was 53% vs 73% (P = 0.004), no PSA decline occurred in 21% vs 15% (P = 0.243), and median TTPP was 7.4 vs 8.0 months (HR = 0.88, 95% CI 0.61, 1.27). Baseline ctDNA fraction was >2% in 60% of patients, and associated with worse TTPP (HR 1.80, P=0.005). Baseline pathogenic ctDNA alterations in AR, TP53, RB1, and DNA repair (BRCA2, ATM) genes were associated with a shorter TTPP (univariate analysis: TABLE). On multivariate analysis including clinical factors, TP53 and BRCA2/ATM alterations remained significant (HR = 2.54 (95%CI 1.55-4.19) and HR = 2.68 (1.58-4.54)). Pts with a PSA increase as best response were enriched for alterations in DNA repair (P <0.001), TP53 (P = 0.005), RB1 (P = 0.04), and (in 1 pt) a genomically truncated AR. **Conclusions:** There was a difference in PSA response for 1stline ABI vs ENZ, but no difference for TTPP. Baseline pathogenic ctDNA alterations, particularly in TP53 and BRCA2, identify pts with poor outcomes. Clinical trial information: NCT02125357.

ctDNA	HR (95%CI) for TTPP (altered vs. not)	P
DNA Repair	4.13 (2.55, 6.68)	<0.001
TP53	2.84 (1.90, 4.23)	<0.001
AR	2.04 (1.39, 3.00)	<0.001
RB1	1.96 (1.28, 3.00)	0.002

Adding abiraterone for men with high-risk prostate cancer (PCa) starting long-term androgen deprivation therapy (ADT): Survival results from STAMPEDE (NCT00268476). *First Author: Nicholas D. James, Queen Elizabeth Hospital, Coventry, United Kingdom*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, June 3, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

5004 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

A phase IV, randomized, double-blind, placebo (PBO)-controlled study of continued enzalutamide (ENZA) post prostate-specific antigen (PSA) progression in men with chemotherapy-naive metastatic castration-resistant prostate cancer (mCRPC). *First Author: Gerhardt Attard, The Institute of Cancer Research and The Royal Marsden Hospital, Sutton, United Kingdom*

Background: We hypothesized resistance to the androgen receptor inhibitor ENZA is due to increases in androgens and can be overcome by combination with the androgen synthesis inhibitor abiraterone (abi). The phase 4 PLATO trial (NCT01995513) is evaluating the safety and efficacy of continued ENZA + abi/prednisone (abi/P) vs PBO + abi/P after PSA progression on ENZA. **Methods:** In Period (P) 1, men with chemotherapy-naïve mCRPC received ENZA (160 mg); men with no PSA increase from baseline at wk 13 and 21 continued treatment until PSA progression (≥ 25% increase and ≥ 2 ng/mL above nadir). Eligible men were then randomized 1:1 in P2 to ENZA + abi/P (1000 mg/10 mg) or PBO + abi/P. The primary endpoint (EP) was progression-free survival (PFS; radiographic or unequivocal clinical progression, or death on study) in P2, with a prespecified sensitivity analysis of radiographic PFS (rPFS); protected secondary EPs were time to PSA progression (TTPP) and PSA response ≥ 50% in P2. **Results:** 509 men enrolled in P1. At data cutoff (Oct 7, 2016), 84 were active, 174 discontinued, and 251 were randomized in P2 (ENZA + abi/P, n = 126; PBO + abi/P, n = 125). Median treatment duration in P2 was 5.6 mo for both arms. PFS event by radiographic/clinical/death was 38%/25%/2% for ENZA + abi/P and 55%/18%/1% for PBO + abi/P. Median PFS was 5.7 mo for ENZA + abi/P and 5.6 mo for PBO + abi/P (hazard ratio [HR], 0.83; 95% confidence interval [CI], 0.61, 1.12; $P = 0.22$). Median TTPP was 2.8 mo for both arms (HR, 0.87; 95% CI, 0.62, 1.24; $P = 0.45$). PSA response rate was 0.8% for ENZA + abi/P and 2.5% for PBO + abi/P ($P = 0.31$). Median rPFS was 10.0 mo for ENZA + abi/P and 7.0 mo for PBO + abi/P (HR, 0.67; 95% CI, 0.47, 0.94; $P = 0.02$). The most common (≥ 15%) adverse events for ENZA + abi/P vs PBO + abi/P were back pain (21% vs 23%), hypertension (20% vs 7%), nausea (17% vs 9%), and fatigue (14% vs 15%). **Conclusions:** ENZA + abi/P post PSA progression on ENZA was associated with increased hypertension and nausea and did not result in a statistically significant improvement in composite PFS. The signal seen in rPFS needs further evaluation. Clinical trial information: NCT01995513.

5005 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Clinical factors associated with AR-V7 detection in ARMOR3-SV, a randomized trial of galeterone (Gal) vs enzalutamide (Enz) in men with AR-V7+ metastatic castration-resistant prostate cancer (mCRPC). *First Author: Mary-Ellen Taplin, Dana-Farber Cancer Institute, Boston, MA*

Background: Presence of the AR-V7 splice variant may predict resistance to Enz and abiraterone in men with mCRPC. Gal is an oral agent that disrupts AR signaling via AR degradation, CYP17 lyase inhibition, and AR antagonism. ARMOR3-SV was designed to test the hypothesis that in mCRPC patients with AR-V7+ CTCs, Gal could improve radiographic progression-free survival (rPFS) versus Enz. **Methods:** In this randomized, open-label, multicenter phase 3 study (NCT02438007), men with treatment-naïve mCRPC were screened for CTC-specific AR-V7 (Qiagen), and AR-V7+ men were randomized 1:1 to Gal or Enz. rPFS (by independent blinded central review) was the primary endpoint. Planned sample size was 148, with 120 rPFS events to achieve 90% power to detect a hazard ratio of ≤0.55. **Results:** 953 patients were screened globally for AR-V7 from Sept 2015 through study closure; 73 men (8%; 95% CI 6-10%) were AR-V7+, 250 (26%) AR-V7–, and 630 (66%) had no CTCs/AR present (unevaluable). AR-V7 detection was associated with higher PSA levels (> vs < median; $P < 0.01$), more bone metastases (> 20 vs 11-20 vs 6-10 vs 0-5; $P < 0.01$), presence of M1 disease at diagnosis (dx) (yes vs no; $P = 0.04$), shorter time from dx to screening (< vs > median; $P < 0.01$), higher ECOG (≥1 vs 0; $P = 0.02$), prior antiandrogen use (yes vs no; $P < 0.01$) and prior docetaxel use (yes vs no; $P < 0.01$). Among the AR-V7+ men, 38 were randomized (19 Gal, 19 Enz), 31 screen failed, and 4 were discontinued from screening at study halt. Baseline characteristics were balanced. On the recommendation of the DSMB, the study was closed early as it was unlikely to meet its primary endpoint. At the time of the study closure, in the Gal and Enz arms respectively, median time on therapy was 2.0 vs 2.8 mo, median time to PSA progression (PCWG1) was 3.9 vs 3.8 mo, PSA_{50} response rates in evaluable patients were 2/16 (13%) and 8/19 (42%), and there were no new safety signals. **Conclusions:** In treatment-naïve mCRPC patients, AR-V7 detection is more common in men with higher disease burden and portends a poor prognosis. Novel study designs and alternative treatment approaches are urgently needed for AR-V7+ mCRPC patients. Clinical trial information: NCT02438007.

5006 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Phase 3 prognostic analysis of the automated bone scan index (aBSI) in men with bone-metastatic castration-resistant prostate cancer (CRPC). *First Author: Andrew J. Armstrong, Division of Medical Oncology and Urology, Duke Cancer Institute, Duke University, Durham, NC*

Background: Quantitative measures of metastatic bone disease are needed in men with mCRPC. We recently demonstrated the validity/reproducibility of a computational approach to bone scan imaging that employs artificial intelligence called the automated BSI (aBSI), which quantifies the percent of skeletal mass involved by cancer. We aimed to extend the prognostic validation of aBSI in a multinational prospective phase 3 clinical study of men with bone-metastatic CRPC. **Methods:** Whole-body bone scans were acquired at screening in a placebo-controlled phase 3 trial of men with mCRPC and bone metastases and treated with tasquinimod/placebo (n = 1,245). The prospective aBSI biomarker analysis plan was locked in Sept 2014 prior to treatment unblinding. All scans generated at 241 trial sites in 37 countries were assessed for image quality and analyzed using the EXINI $bone^{BSI}$ v.2 software and were blindly associated with outcomes. Baseline aBSI was evaluated for its independent prognostic association with overall survival (OS), radiographic progression-free survival (rPFS), and symptomatic skeletal related events (SSEs). **Results:** The aBSI-population (721 pts) was representative of the entire trial population based on patient characteristics at screening and OS outcomes. Median aBSI was 1.07 (SE 0.05). The aBSI-population was divided into quartiles (n = 180-181) with aBSI-levels of 0 - 0.3 (Q1); > 0.3 - 1.1 (Q2); > 1.1 - 4.0 (Q3); and > 4.0 (Q4) and median OS ranging from 35 months (Q1) to 13 mo (Q4) ($p < 0.0001$). Baseline aBSI was significantly associated with OS (HR 1.2 per doubling of BSI; $p < 0.0001$) and remained independently associated with OS after adjustment for treatment, PSA, CRP, LDH and albumin. Baseline aBSI was also strongly associated with rPFS ($p = 0.0005$), time to symptomatic progression ($p < 0.0001$), and time to SSE ($p = 0.001$). **Conclusions:** This analysis represents the first phase 3 evaluation of aBSI as a clinically validated prognostic biomarker for OS, rPFS, and SSEs in men with bone-metastatic CRPC, providing independent prognostic information over commonly measured clinical characteristics. Clinical trial information: NCT01234311.

5007 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Circulating tumor cell (CTC) number as a response endpoint in metastatic castration resistant (mCRPC) compared with PSA across five randomized phase 3 trials. *First Author: Glenn Heller, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Radiographic progression and overall survival (OS) are the traditional clinical benefit measures for mCRPC trials. Reliable indicators of response that occur early are a critical unmet need in practice and clinical research. We explored a week 13 CTC and prostate-specific antigen (PSA) endpoint relative to baseline in 5 prospective randomized phase 3 registration trials that enrolled 5912 pts. OS was the primary endpoint. **Methods:** CTC number (CellSearch) and PSA values in patients who survived at least 13 weeks were evaluated as response endpoints in COU-AA-301, AFFIRM, ELM-PC-5, ELM-PC-4 and COMET-1. Pts with missing values at week 13 were considered non-responders. The endpoints considered are shown in Table 1. **Results:** The discriminatory strength of the response endpoints with respect to OS was estimated using the weighted c-index. To summarize discrimination results for each measure, the mean and the standard deviation based on the weighted c-indices from the 5 studies were computed. **Conclusions:** CTC0 and CTC conversion endpoints had the highest discriminatory power for OS relative to the % decline in CTC or PSA endpoints. The percent of pts eligible and evaluable for the CTC0 endpoint was significantly higher than the conversion endpoint, 75% vs. 51%, respectively. These two absolute measures of CTC can be considered meaningful response indicators in mCRPC clinical trials.

Response	Total survived 12 wks with a baseline value	Total eligible for response	Average proportion eligible from baseline evaluable	Baseline evaluability for response	Week 13 Response criteria
CTC0	4196	3158	0.75	≥1	0
CTC Conversion	4196	2152	0.51	≥5	≤4
% Change CTC	4196	2152	0.51	≥5	30, 50 or 70% decrease
% Change PSA	5464	4995	0.91	≥10ng/mL	30, 50 or 70% decrease

CTC0=No detectable CTC at W13.

5008 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Duration of androgen deprivation therapy in high risk prostate cancer: Final results of a randomized phase III trial. *First Author: Abdenour Nabid, Centre Hospitalier Régional Universitaire, Sherbrooke, QC, Canada*

Background: Long-term androgen deprivation therapy (ADT) combined with radiotherapy (RT) is a standard treatment for patients with high-risk prostate cancer (HRPC). However, the optimal duration of ADT is not yet defined. The aim of this randomized trial (Clinical Trials.gov, #NCT00223171) was to compare outcomes of RT combined with either 36 or 18 months of ADT. **Methods:** Patients with HRPC were randomized to pelvic and prostate RT combined with 36 (arm 1) or 18 months (arm 2) of ADT. Overall survival (OS) and quality of life (QoL) were primary end points. OS rates were compared with Cox Regression model and QoL data were analyzed through mixed linear model. **Results:** 630 patients were randomized, 310 to arm 1 and 320 to arm 2. With a median follow-up of 9.4 years, 290 patients had died (147 arm 1 vs. 143 arm 2). The 10-year OS rate was 62.4% (95% confidence interval [CI] 56.4%, 67.8%) for arm 1 and 62.0% (95% CI 56.1%, 67.3%) for arm 2 ($p = 0.8412$) with a global hazard ratio (HR) of 1.024 (95% CI 0.813-1.289, $p = 0.8411$). QoL analysis showed a significant difference ($p < 0.001$) in 6 scales and 13 items favoring 18 months ADT with two of them presenting a clinically relevant difference in mean scores of ≥ 10 points. **Conclusions:** In HRPC, ADT combined with RT can be safely reduced from 36 to 18 months without compromising outcomes or QoL. 18 months of ADT represents a new standard of care in HRPC. Funded by AstraZeneca Pharmaceuticals Clinical trial information: NCT00223171.

5009 Poster Discussion Session; Displayed in Poster Session (Board #83), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Need for re-evaluation of current guidelines based on results from germline genetic testing in prostate cancer. *First Author: Piper L.W. Nicolosi, Invitae, San Francisco, CA*

Background: Inherited risk for prostate cancer (PCa) is potentially associated with more aggressive disease. Recent data indicate that DNA repair gene abnormalities may be much more common than previously appreciated, especially BRCA2, ATM, CHEK2, BRCA1, RAD51D, and PALB2. Herein, we investigate the efficacy of a targeted gene panel in men with PCa and evaluate clinical factors in relationship to current guidelines for genetic screening. **Methods:** DNA sequencing and exon-level copy number analysis were performed in 1158 PCa patients (pts) between 2013 and 2016 at a commercial diagnostic laboratory. The genes requisitioned varied but consistently included 14 genes on a hereditary PCa panel, most of which were DNA repair genes. Evaluation included Gleason scores and eligibility for genetic screening based on any NCCN testing criteria in pts with positive findings (pathogenic, likely pathogenic, and risk allele). **Results:** Pathogenic findings were identified in 199 of 1158 (17.2%) pts, 13 pts (1.0%) had two variants. Roughly 75% of detected variants were in genes on the hereditary PCa panel, of which 34.4% were BRCA1/2. Positive variants in HOXB13, a gene associated only with PCa risk, were identified in eight (3.8%) pts. DNA mismatch repair variants, alterations with substantial known therapeutic implications, were detected in 1.7% of samples. A total of 12.4% of pts with Gleason scores of ≤ 6, compared with 15.4% of those with scores of ≥ 7 had a pathogenic variant. Within this cohort, 126 (63%) patients with positive results were eligible for genetic testing based on currently available NCCN guidelines, whereas 73 (37%) would not have qualified. **Conclusions:** Current NCCN guidelines and Gleason scores cannot be used to reliably stratify PCa pts for the presence/absence of pathogenic germline variants. Most positive results identified in this study have important management implications for pts and their families. The percentage of pts with germline variants who did not meet current genetic screening criteria underscores the need for revisiting current guidelines which cannot, at this time, reliably be used to predict pathologic findings on genetic testing.

5010 Poster Discussion Session; Displayed in Poster Session (Board #84), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Next-generation sequencing (NGS) of tissue and cell free DNA (cfDNA) to identify somatic and germline alterations in advanced prostate cancer. *First Author: Michael L. Cheng, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: With the goal of accelerating enrollment onto appropriate clinical trials, we performed prospective genomic characterization of pts with advanced prostate cancer. Given the long natural history and osseous disease predominance, we also analyzed plasma cfDNA to assess the feasibility of identifying targetable alterations in pts for whom adequate tumor tissue was unavailable. **Methods:** 1038 tumors from 896 pts along with matched normal DNA were analyzed with a capture-based NGS assay (MSK-IMPACT) targeting 341–468 genes. In 5/2015, the protocol was amended to allow pts to opt-in for a formal germline analysis of 76 genes associated with heritable cancer risk. In select pts, plasma cfDNA was collected and analyzed using the same assay. **Results:** Between 2/2014 and 2/2017, 576 primary tumors and 462 metastases were sequenced. The most notable finding was the high frequency of known or likely pathogenic germline and somatic mutations in genes that regulate DNA damage response (DDR). In the subset with both tumor and germline analysis, 28.84% (169/586) had a DDR mutation identified compared to only 10.65% (33/310) of pts with somatic only analysis. In the subset with tumor and germline analysis, 9.39% (55/586) had somatic only DDR mutations and 16.38% (96/586) had germline only DDR mutations, including 8 pts with two germline mutations. 3.07% (18/586) had co-occurring somatic and germline DDR mutations, with only 0.68% (4/586) involving the same DDR gene (all BRCA2). Prostate cancer had the highest tissue failure rate among the overall MSK-IMPACT solid tumor cohort, and bone biopsy-derived tissue was successfully sequenced in only 42% of pts. Profiling of cfDNA did identify somatic DDR or AR mutations in 12.5% (4/32) of pts without adequate tumor for analysis. **Conclusions:** This prospective genomic profiling effort identified frequent somatic and germline DDR mutations that may guide PARPi or platinum therapy. Both somatic and germline analyses were required to identify all pts with likely pathogenic DDR alterations. NGS-based cfDNA analysis is feasible in advanced prostate cancer and may identify mutations missed by tumor only sequencing.

Whole exome sequencing (WES) of circulating tumor DNA (ctDNA) in patients with neuroendocrine prostate cancer (NEPC) informs tumor heterogeneity. *First Author: Himisha Beltran, Weill Cornell Medical College, New York, NY*

Background: We recently identified mechanisms underlying the clonal evolution of castration-resistant prostate adenocarcinoma (CRPC-Adeno) to a neuroendocrine resistance phenotype (Beltran et al, *Nat Med* 2016). We aimed to develop a non-invasive approach to identify patients that are developing NEPC. **Methods:** We performed whole exome sequencing of matched ctDNA, germline DNA, and metastatic biopsies from patients with CRPC-Adeno and NEPC. After applying ad hoc partial duplication filtering, we used FACETS and extended CLONET to calculate the fraction of tumor DNA and clonality of genomic lesions. **Results:** 64 CRPC patients were prospectively enrolled. The spectrum of alterations captured by WES of ctDNA was consistent with those commonly observed in CRPC validating the feasibility of the approach. The similarity of copy number alterations between tumor tissue and ctDNA was higher in NEPC compared to CRPC-Adeno ($p = 0.0001$) suggesting less heterogeneity in NEPC. There was enrichment of *RB1* and *TP53* loss in NEPC ctDNA and *AR*gains in CRPC-Adeno. The overall fraction of mutations shared by ctDNA and tumoral tissue was ~80%. We compared three different tumor biopsy time-points of patient PM161—CRPC-Adeno (lymph node), CRPC-Adeno (bone), NEPC (liver). Unexpectedly the baseline ctDNA profile (at time of CRPC-Adeno) displayed genomic features most similar to the NEPC liver biopsy. These data suggest that NEPC alterations are detectable in the circulation potentially prior to the development of NEPC clinical features. We compared the ctDNA of another patient PM0 with 6 sites of NEPC metastases obtained 6 days later at autopsy; the relative contribution of tumor alterations in ctDNA was highest for the liver metastasis (similarity 0.59) versus other sites suggesting differential contribution of metastatic sites in the circulation, with implications for the interpretation of single site clinical biopsies. **Conclusions:** This is the first study to show that WES of ctDNA is feasible in CRPC and can help elucidate intra-patient heterogeneity and identify the spectrum and frequency of NEPC genomic changes. ctDNA may improve the detection of patients transforming towards NEPC.

The benefit of combining docetaxel to androgen deprivation therapy in localized and metastatic castration-sensitive prostate cancer as predicted by ERG status: An analysis of two GETUG phase III trials. *First Author: Shanna Rajpar, Institut Gustave Roussy, Villejuif, France*

Background: Combining docetaxel to androgen deprivation therapy (ADT) improves survival in metastatic castration-sensitive prostate cancer (CSPC) (Vale C, Lancet Oncol 2016; 17: 243-56) and it also improves relapse-free survival (RFS) in high-risk localized CSPC (Fizazi K, Lancet Oncol 2015; 16: 787-94). However it is unlikely that all patients (pts) derive a benefit from docetaxel treatment and identifying predictive biomarkers remains a major unmet need. A subset of prostate cancers contains TMPRSS2-ERG gene fusions leading to ERG overexpression. **Methods:** Pre-treatment prostate core biopsies were collected from 255/413 pts and 79/385 pts enrolled respectively in the GETUG 12 and GETUG 15 (Gravis G, Eur Urol 2016; 70: 256-62) phase 3 trials testing early docetaxel in high-risk localized and metastatic CSPC. ERG, PTEN, Ki67 and Rb expression was assessed using immunohistochemistry. RFS curves were compared using the Logrank test. **Results:** The median age was 63 years (46-77) and 62 years (49-76) in GETUG 12 and GETUG 15. ERG staining was positive in 88/191 (46%) and 33/79 (42%) pts with available tissue, respectively. In GETUG 12, docetaxel-based chemotherapy was associated with improved RFS in pts with ERG+ expression (HR = 0.55 [0.29-1.03]; 6-year RFS : 80% ADT+ docetaxel vs 68% ADT alone), but not in pts with ERG- (HR = 1.10 [0.66-1.85]; 6-year RFS 55% ADT+docetaxel vs 60% ADT alone), interaction test: p = 0.02. Similar findings were observed in GETUG 15, which was used as a validation set: the median RFS was 10.7 (6.5-14.3) and 18.8 (9.8-41) months in pts with ERG+ cancers receiving ADT alone and ADT+docetaxel, and 10.6 (4.8-25.3) and 13.2 (9.4-24) months in pts with ERG- cancers. In contrast, no difference in patient outcome by docetaxel treatment was observed by PTEN, Ki67 and Rb expression. **Conclusions:** Docetaxel-related benefit in men with CSPC is predicted by ERG expression. This biomarker may help better select pts for docetaxel treatment.

The aggressive variant prostate carcinoma (AVPC) molecular signature (-MS) and platinum-sensitivity in castration resistant prostate cancer (CRPC). *First Author: Ana Aparicio, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The AVPC are a subset of prostate cancers that share the clinical, therapy response and molecular profiles of the small cell prostate carcinomas, a histological variant of the disease that responds poorly to androgen receptor directed therapies. The AVPC are characterized by a molecular signature of combined tumor suppressor defects ($\geq$ 2 alterations in Tp53, RB1 and/or PTEN by immunohistochemistry or genomic analyses). We conducted a randomized phase II study of cabazitaxel (CAB) plus or minus carboplatin (CARB) in men with CRPC and asked whether the AVPC-MS predicted for platinum benefit. **Methods:** 160 men with metastatic CRPC were randomized 1:1 to receive IV CAB (25 mg/m2) or CAB/CARB (25 mg/m2; AUC4) Q21 days with growth factor support until disease progression, unacceptable toxicity or for up to 10 cycles. Imaging occurred every 2 cycles. The primary endpoint was progression free survival (PFS). 73 tumor samples obtained within 1 year of registration from 65 of the 160 patients (pts) were stained for Tp53, RB1, PTEN, AR-N terminus, AR-C terminus and Ki67. DNA of sufficient quantity for sequencing was extracted from 27 tumors and 70 plasma samples. **Results:** At a median follow up of 21.6 months (mo), median PFS (mPFS) in the overall population (n = 160) is 4.6 mo (95% CI 3.5, 5.8) with CAB vs 7.4 mo (95% CI 5.6, 8.3) with CAB/CARB (p = 0.004). Men with AVPC-MS-positive tumors had a mPFS of 4.5 mo (95%CI 1.5, NA) with CAB [n = 9] vs 8.0mo (95%CI 6.11-9.7) with CAB/CARB [n = 23] (p = 0.0036) whereas men with AVPC-MS-negative tumors had a mPFS of 6.8mo (95%CI 5.2, NA) with CAB [n = 12] vs 5.4mo (95%CI 3.72, NA) with CAB/CARB [n = 12] (p = 0.1445). Analysis of plasma DNA samples is ongoing and will be presented at the meeting. **Conclusions:** The AVPC-MS identifies a subset of men platinum-sensitive CRPC tumors. These findings should serve as the foundation for a therapeutically relevant classification of prostate cancer. Clinical trial information: NCT01505868.

5014 Poster Discussion Session; Displayed in Poster Session (Board #88), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Post hoc analysis of a phase III study to test the association between circulating *methylated glutathione s transferase (mGSTP1)* DNA levels and response to docetaxel (DTX) in metastatic castration resistant prostate cancer (mCRPC). *First Author: Kate Lynette Mahon, Chris O'Brien Lifehouse, Camperdown, Australia*

Background: *GSTP1* inactivation is associated with CpG island hypermethylation in > 99% prostate cancers. Detection of circulating *mGSTP1* DNA predicts response to DTX and overall survival (OS) in phase I/II mCRPC cohorts. This post hoc analysis of a phase III study aims to test the association between circulating *mGSTP1* DNA levels and outcomes. **Methods:** The phase III SYNERGY study tested DTX +/- custirsen as 1st line chemotherapy in mCRPC (n = 1022) with no OS benefit in the experimental arm. Serum samples were taken at baseline (BL) and preC3 of DTX +/- custirsen from 600 patients (pts) enrolled on the SYNERGY study. *mGSTP1* levels in free DNA were measured using a sensitive methylation specific PCR assay and correlated with PSA response, time to PSA progression (TTP) and OS. **Results:** On interim analysis of 300 pts, serum *mGSTP1* was detectable at BL in 80% and preC3 in 44%. Undetectable preC3 *mGSTP1* correlated with a $\geq$30% fall in PSA within 3m of starting DTX (p < 0.001). Detectable BL and preC3 *mGSTP1* predicted shorter TTP after DTX (BL; HR 1.6 95%CI 1.1-2.3; p = 0.01 and preC3 HR 2.2 95%CI 1.6-2.9; p < 0.001). Detectable *mGSTP1* at both time points predicted shorter OS (BL; median OS 18.4 vs 33.1m, HR 2.4 95%CI 1.6-3.7; p < 0.001 and preC3; median OS 13.9 vs 29m, HR 2.7 95%CI 2.0-3.6; p < 0.001). In those with detectable BL *mGSTP1*, 50% had undetectable preC3 *mGSTP1* predicting > 30% fall in PSA within 3m (p < 0.001), improved TTP (HR 0.40 95%CI 0.29-0.57; p < 0.001) and improved OS (25.2 vs 13.9 m HR 0.38 95%CI 0.28-0.51; p < 0.001). On multivariable analysis including Hb, Karnofsky PS, LDH, PSA and visceral metastases, detectable preC3 *mGSTP1* independently predicted shorter TTP (HR 1.9 95%CI 1.4-2.6; p < 0.001). Detectable *mGSTP1* at both time points independently predicted OS (BL; HR1.8 95%CI 1.2-2.8; p = 0.006 and preC3; HR 2.2 95%CI 1.6-3.0; p < 0.001). Results from the full cohort of 600 pts will be available for presentation at the meeting. **Conclusions:** This study should validate circulating *mGSTP1* DNA as a marker of therapeutic benefit and prognosis in men with mCRPC receiving DTX and could be utilized for clinical management.

5015 Poster Discussion Session; Displayed in Poster Session (Board #89), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Clinical outcome of metastatic castration-resistant prostate cancer (mCRPC) patients (pts) with a post-treatment circulating tumor cell (CTC) of 0 vs CTC > 0: Post hoc analysis of COU-AA-301. *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Assessment of radiographic response by RECIST in the majority of mCRPC pts is limited by the lack of measurable disease. Changes in CTC counts (CTCs) enumerated using Veridex CellSearch from unfavorable at baseline (BL [$\geq$ 5 cells/7.5 mL]) to favorable ($\leq$ 4) are prognostic for survival, and the test is FDA cleared as an aid in the monitoring of metastatic PC. The CTC cutpoint of $\geq$ 5 excludes many pts from response assessment. Examining CTCs alone and in combination with other biomarkers as a potential surrogate for clinical benefit was a secondary objective of COU-AA-301, a phase 3 trial of abiraterone acetate + prednisone vs prednisone alone in mCRPC. **Methods:** Pts from both treatment (tmt) groups with BL CTC > 0 were combined to assess CTC = 0 as a response criterion. Association between CTC response, defined as BL CTC > 0 and post-BL CTC = 0, and clinical outcomes was assessed. CTCs were determined at BL and 4, 8, and 12 wks. Pts with BL CTC > 0 and missing post-tmt CTCs were considered nonresponders. Radiographic response was first assessed at Wk 12. Overall survival (OS) was estimated using the Kaplan-Meier method. **Results:** Among739 pts with BL CTC > 0, 141 had measurable disease. At Wk 12, 19% (141/739) of pts were CTC responders and 81% (598/739) were CTC nonresponders. Among CTC responders, 74% (104/141) had stable disease or better by RECIST; 26% (37/141) were either not evaluable or had disease progression by RECIST. Median OS was 23.8 and 10.0 mos for CTC responders (n = 141) and nonresponders (n = 598), respectively. Among pts with liver and/or lung metastases, 86% (24/28) of CTC responders at Wk 12 had stable disease or better by RECIST; 14% (4/28) had disease progression by RECIST. Median OS was 19.9 and 7.1 mos for CTC responders (n = 28) and nonresponders (n = 127), respectively. Similar results were observed in Wk 8 CTC responders. **Conclusions:** For mCRPC pts with BL CTC > 0, CTC response on tmt (CTC = 0) is associated with longer survival and could be considered a response criterion. Additional analysis is required to fully characterize the relationship between CTC = 0 and objective response by RECIST in pts with measurable disease. Clinical trial information: NCT00638690.

Association of androgen receptor (AR) gene status in plasma DNA with outcome on enzalutamide in chemotherapy-naive metastatic castration-resistant prostate cancer (mCRPC): Exploratory results from the PREMIERE trial—On behalf of SOGUG. *First Author: Enrique Grande, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Building on previous discoveries studying *AR* status in plasma (Carreira S, Sci Transl Med 2014, Romanel A, Sci Transl Med 2015) and following a road-map for biomarker development, we aimed to clinically qualify *AR* status in chemotherapy-naïve mCRPC using an optimized multiplex droplet digital PCR (ddPCR) assay (Condeduca et al.;ASCO2017; Abstract#). **Methods:** Between February and November 2015, 98 asymptomatic or oligo-symptomatic chemotherapy-naïve mCRPC patients were recruited in 16 Spanish hospitals. Tissue and blood samples were required at study entry. Although initially designed to study the predictive value of TMPRSS2-ETS, data emerging after the trial was initiated led the group to prioritize alternative predefined exploratory biomarkers, including plasma *AR*and CTC characterization (Grande E. ESMO 2016 & Font A. et al; ASCO2017; Abstract #). Outcome measures included PSA-progression-free survival (sPFS), radiographic progression-free survival (rPFS) and overall survival (OS). Cox regression was used for survival analyses and Fisher's exact test for PSA response. **Results:** Ninety-four patients had plasma DNA available for analysis. At baseline, *AR* gain was present in 11 pts (12%) and CTCs in 35 (37%). *AR* gain in CTC-positive and negative patients was 20% and 7%, respectively. At first interim analysis and with a median follow-up of 10.6 months, detection of AR gain was associated with worse sPFS (median, 3.60 versus 15.5 m, HR, 4.33; 95% CI 1.94-9.68; $P < 0.001$), rPFS (median, 3.90 m versus not reached HR, 8.06; 95% CI, 3.26-19.93; $P < 0.001$) and OS (medians not reached, HR, 11.08; 95% CI, 2.16-56.95; $P = 0.004$). These results were independently associated in multivariate analysis including cfDNA and CTCs for all described endpoints. *AR* gain patients were less likely to have a ≥50% decline in PSA (OR, 4.93; 95% CI, 1.30-18.75; $P = 0.025$). **Conclusions:** Detection of *AR* gain in plasma using a robust multiplex ddPCR method predicts an adverse outcome in chemotherapy-naïve mCRPC. Further prospective randomized studies are warranted. Clinical trial information: NCT02288936.

Phase II study of bipolar androgen therapy (BAT) in men with metastatic castration-resistant prostate cancer (mCRPC) and progression on enzalutamide (enza). *First Author: Benjamin A. Teply, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Androgen receptor (AR) overexpression is a common adaptive resistance mechanism in mCRPC. High dose testosterone in this setting may induce tumor responses and restore normal AR expression. To evaluate BAT, we enrolled men with mCRPC progressing on enza to assess (1) responses to BAT and (2) enza re-challenge after BAT. **Methods:** Eligible men had minimally symptomatic mCRPC with progression on enza. Subjects received testosterone cypionate 400mg IM every 28d and continued gonadal suppression, until progression. Subjects were evaluated with PSAs each cycle, and CT/bone scans every 3 cycles. Upon progression on BAT, men were re-challenged with enza. The co-primary endpoints were > 50% PSA responses (PSA_{50}) to BAT and PSA_{50} to enza re-challenge. The null hypothesis was a PSA_{50} rate of 5% for both endpoints, with alternative hypotheses of 20% to BAT and 25% to enza. 30 subjects were required for 90% and 83% power, respectively, with overall type 1 error of 0.1. Secondary endpoints were safety, objective response, progression-free survival (PFS), and effect on circulating tumor cell-based AR and AR-V7 expression. **Results:** 30 eligible subjects were accrued (2014-2016). No dose limiting toxicities were seen. 2 subjects had transient pain flares after BAT initiation. Common grade 1-2 adverse events (AE) were musculoskeletal pain (40%), increased hemoglobin (37%), breast tenderness (17%) and rash (17%). 3 Grade 3-4 AE potentially attributable to BAT occurred (pulmonary embolism, NSTEMI, and urinary obstruction). 9/30 men (30% [95% CI: 17-48%]) achieved a PSA_{50} to BAT. 5/14 men (36%) with measurable disease had an objective response by RECIST 1.1. The median clinical/radiographic PFS on BAT was 8.6 months. 21 subjects proceeded to enza re-challenge, yielding 15 PSA_{50} responses (54% by intention to treat [95% CI: 34-69%]), with a PFS of 4.8 months. 1/3 AR-V7+ subjects responded to BAT, and all had decreased AR-V7/AR ratios (2 converted to AR-V7-) after 3 cycles. **Conclusions:** The study met its primary endpoints, demonstrating preliminary efficacy of BAT in men with progressive mCRPC after enza. A randomized study comparing BAT to enza in mCRPC is ongoing. Clinical trial information: NCT02090114.

Extended versus limited pelvic lymphadenectomy during radical prostatectomy for intermediate- and high-risk prostate cancer: Early outcomes from a randomized controlled phase III study. *First Author: Jean Felipe Prodocimo Lestingi, Sao Paulo State Cancer Institute - University of Sao Paulo, São Paulo, Brazil*

Background: The role of extended pelvic lymph node dissection (ePLND) in treating prostate cancer (PCa) patients remains controversial, mainly by the lack of RCTs. **Methods:** Patients with D'Amico intermediate or high risk PCa, absence of bone metastasis and no previous treatment were prospectively computer randomised to undergo extended or limited PLND (1:1) during radical prostatectomy. Limited PLND (lPLND) included the obturator chain bilaterally; ePLND involved bilaterally chains: obturator, external-, internal-, common-iliac and pre-sacral. Surgical specimens and each chain were analyzed separately, according to College of American Pathologists. All patients signed a free and informed consent and local ethics committee approved the study. The primary endpoint was biochemical recurrence-free survival, analysed in the intention-to-treat population. This trial is registered with ClinicalTrials.gov, number NCT01812902. **Results:** Since May 2012 until August 2016, 291 patients were randomly assigned, 145 to ePLND and 146 to lPLND. Preoperative data were comparable between groups. Median follow-up was 35.2 months. EPLND increased significantly operative time (54 minutes), estimated blood loss (100 mL), length of hospital stays (1 day) [$p \leq 0.001$], transfusion rate [$p = 0.05$] and postoperative complications according to Clavien scale [$p = 0.03$]. There was no difference in Pathologic Gleason grade, T stage or positive surgical margin. On ePLND and lPLND groups, 59.3% and 61.7% were staged ≥ pT3a, respectively. EPLND and lPLND yielded median (mean) 17 (19.8) and 3 (4.1) nodes, respectively ($p < 0.001$). EPLND showed 6.3 times more lymph node metastases ($p < 0.001$) and only it was able to show positive nodes in intermediate risk. There were no difference in biochemical recurrence (PSA ≥ 0.2 ng/mL) using Kaplan-Meyer method ($p = 0.4$), Radiotherapy, Androgen Deprivation Therapy, bone metastases or death. **Conclusions:** Extended lymphadenectomy in intermediate- and high-risk prostate cancer patients is associated with better tumor staging, increased morbidity and no oncological benefits in this initial short follow-up time. Clinical trial information: NCT01812902.

5019 Poster Discussion Session; Displayed in Poster Session (Board #93), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Adjuvant androgen deprivation (AD) +/- mitoxantrone + prednisone (MP) in patients with high-risk prostate cancer (PC) post radical prostatectomy (RP): Phase III intergroup trial S9921. *First Author: Maha Hussain, Northwestern University Robert H. Lurie Comprehensive Cancer Center, Chicago, IL*

Background: Patients (pts) with high-risk PC post RP are at risk of systemic relapse with related morbidity/mortality. Adjuvant AD can reduce this risk. In 1999, based on available data, we hypothesized that adjuvant MP + 2 years (ys) of AD can further reduce mortality. **Methods:** Eligible pts had cT1-T3, N0 PC with post RP >= 1 high risk factors defined as Gleason sum (GS) ≥ 8, pT3b, pT4, pN+, GS 7 + positive margin or any of these preoperative findings (in pts with neoadjuvant AD): preoperative PSA of > 15 ng/ml, bx GS score > 7, or PSA of > 10 ng/ml + bx GS > 6. Pts had to have post RP PSA = < 0.2 ng/ml, were stratified by T, N, GS, and adjuvant radiation plan and randomized: Arm 1 AD (bicalutamide + goserelin for 2 ys) or Arm 2 AD + 6 cycles m 12 mg/m^2 + P 5mg BID. Primary endpoint: overall survival (OS). Median OS was estimated to be 10 ys in AD arm requiring 680 pts/arm to detect a hazard ratio (HR) of 1.30 with 92% power and one-sided $\alpha = 0.05$. **Results:** 983 pts (961 eligible intent to treat) with median age 60 ys and median PSA 7.6 ng/ml were randomized to AD or AD + MP from 10/99 -1/07 when the DSMC recommended stopping accrual due to higher leukemia rate in Arm 2. 16% had N1 (Group "Gr" 1), 61% GS ≥8 or pT3b (Gr 2),23% other risk factors (Gr 3). Median time to testosterone recovery was 9.5 months. Median follow-up (f/u) 11.2 ys. **Conclusions:** OS was higher than anticipated in both arms; MP did not improve OS and increased other malignancy risk. These data illustrate that systemic therapy benefit cannot be extrapolated from different disease stages and the importance of adequate f/u in adjuvant PCa trials. The remarkable DFS and 10 y OS, irrespective of risk extent, may be result of risk definition, and/or 2 ys AD. Pending definitive data 2 ys adjuvant AD for high-risk PCa post RP is a reasonable option to consider. Clinical trial information: NCT00004124.

Outcome	Arm 1: N = 481	Arm 2: N = 480	P Value	Hazard ratio (95% CI) Arm 2 vs. 1
Survival (10 yr %)	87%	86%	P = 0.70	HR = 1.06 (0.79, 1.43)
DFS (10 yr %)	72%	72%	P = 0.94	HR = 1.01 (0.80, 1.27)
Grade > = 3 AE	30%	56%	< 0.0001

Stereotactic ablative radiation therapy for the treatment of oligometastatic prostate cancer. *First Author: Phuoc T. Tran, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: The importance of local treatment in oligometastatic prostate cancer (OPC) is unknown. Stereotactic ablative radiotherapy (SABR) is highly focused, high-dose radiation that is well suited for treatment of oligometastases. Here we report on the safety and preliminary clinical outcomes of SABR in a modern cohort of OPC men. **Methods:** Eighty four men who satisfied criteria of OPC diagnosed on imaging underwent consolidative SABR were then followed prospectively on our IRB approved registry by our GU multidisciplinary team. We collected demographic, clinical, toxicity and efficacy information. We examined the first 66 men in this preliminary report to allow for a minimum of 4.5 months follow-up. SABR was delivered in 1-5 fractions of 5-18 Gy. Kaplan-Meier method was used to assess local progression-free survival (LPFS), biochemical progression-free survival (bPFS; PSA nadir+2), distant progression free survival (DPFS), ADT-free survival (ADT-FS) and time-to-next intervention (TTNI). **Results:** Of the 66 OPC patients analyzed, 25 (38%) men presented as synchronous OPC and the remaining 41 had recurrent OPC. Median and mean follow-up was 61 and 66 weeks, respectively. Patient and disease factors as listed in the Table. Crude Grade 1 and 2 acute toxicities were 36% and 11%, respectively, with no Grade $>$ 2 toxicity. SABR was delivered to 134 metastases: 89 bone (66%), 40 nodal (30%) and 5 (4%) visceral metastases. Overall LPFS at 1-year was 92%. The bPFS and DPFS at 1-year were 69% and 69%, respectively. Median TTNI was not reached yet. Of the 18 men with hormone sensitive prostate cancer who had their ADT deferred, 11/18 (56%) remain free of disease following SABR (1-year ADT-FS was 78%) and in 17 castration resistant men, 11 had $>$ 50% PSA declines with 1-year TTNI of 30% with a median of 45 weeks. **Conclusions:** Consolidative SABRfor OPCis feasible and well tolerated. The preliminary clinical outcomes in our series is limited by heterogeneity and size but our data suggests that this approach is worthy of further prospective study.

Table. Patient and disease properties (n = 66).

Factors	n (%)	Median (range)
Age		65 (47-84)
HSPC	49 (74)	
CRPC	17 (26)	
Concurrent ADT	53 (80)	
Pre-SABR PSA (ng/mL)		1.2 ($<$ 0.1-96)

5021 Poster Session (Board #95), Mon, 1:15 PM-4:45 PM

A randomized phase II study of pelareorep (REO) plus docetaxel vs. docetaxel alone in patients with metastatic castration resistant prostate cancer (mCRPC): Canadian Cancer Trials Group study IND 209. *First Author: Bernhard J. Eigl, BC Cancer Agency, Vancouver, BC, Canada*

Background: Pelareorep (REO) is an oncolytic virus with in vitro and in vivo activity in many cancers, including prostate. It has in vitro synergism with microtubule targeted agents especially taxanes. We undertook a clinical trial to evaluate REO in mCRPC patients (pts) receiving docetaxel. **Methods:** In this randomized, open-label multicenter phase II study, pts received docetaxel 75mg/m2 on day 1 of a 21-day cycle in combination with REO given as 3x1010 TCID50 IV daily on days 1-5 (arm A), or alone (arm B). The primary endpoint was 12-week lack of disease progression (LPD) rate. Secondary endpoints included objective response rate; survival; circulating tumor cell (CTC) enumeration at 0, 6 and 12 weeks; PSA response rate and biomarkers. **Results:** Eighty-five pts were randomized. Median age was 69, ECOG performance status (PS) was 0/1/2 in 31%/66%/3% of pts. Bone/regional lymph node/liver metastases were present in 98%/24%/6% of pts. More pts in arm A had poor prognostic factors for survival at baseline (median prognostic index 1.44 vs. 1.29). The median number of cycles delivered for arms A/B was 7/9 (range 1-10 and 1-13). In arm A, 51%/68% of pts received $\geq$90% of planned dose intensity of docetaxel/REO respectively, vs. 76% of pts for docetaxel in arm B. Adverse events (AE) were as expected for docetaxel therapy but more prevalent in arm A (grade 3 or higher all AEs 80 vs. 74%). A higher rate of grade 4 febrile neutropenia was noted in arm A (7 vs. 0%) but may represent virus related fevers. The 12-week LPD rate was 61% and 52.4% in A/B respectively (p = 0.51). OS was worse in arm A vs. B (HR 1.95; 95% CI 0.94-4.06; p = 0.07 after adjusting for age, PS and baseline prognostic score). There was no difference between arms in CTC favourable status at any timepoint. No survival benefit of REO with D was found in any subset from the biomarker analysis. **Conclusions:** While the combination of REO with D for patients with mCRPC was tolerable and LPD rate was comparable in both arms, docetaxel dose intensity and survival were inferior and so this combination, as tested, does not merit further study. Clinical trial information: NCT01619813.

5022 Poster Session (Board #96), Mon, 1:15 PM-4:45 PM

Development and validation of a prognostic model for overall survival in chemotherapy-naive men with metastatic castration-resistant prostate cancer (mCRPC) from the phase 3 prevail clinical trial. *First Author: Andrew J. Armstrong, Division of Medical Oncology and Urology, Duke Cancer Institute, Duke University, Durham, NC*

Background: Prognostic models require updating to reflect contemporary medical practice. In a post hoc analysis of the phase 3 PREVAIL trial (enzalutamide vs placebo), we identified prognostic factors for overall survival (OS) in chemotherapy-naive men with mCRPC. **Methods:** Patients were randomly divided 2:1 into training (n = 1159) and testing (n = 550) sets. Using the training set, 23 predefined candidate prognostic factors (including treatment) were analyzed in a multivariable Cox model with stepwise procedures and in a penalized Cox proportional hazards model using the adaptive least absolute shrinkage and selection operator (LASSO) penalty (data cutoff June 1, 2014). A multivariable model predicting OS was developed using the training set; the predictive accuracy was assessed in the testing set using time-dependent area under the curve (tAUC). The testing set was stratified based on risk score tertiles (low, intermediate, high), and OS was analyzed using Kaplan-Meier methodology. **Results:** Demographics, disease characteristics, and OS were balanced between the training and testing sets; median OS was 32.7 months for both datasets. There were no enzalutamide treatment-prognostic factor interactions (predictors). The final multivariable model included 11 prognostic factors: prostate-specific antigen, treatment, hemoglobin, neutrophil-lymphocyte ratio, liver metastases, time from diagnosis to randomization, lactate dehydrogenase, $\geq$ 10 bone metastases, pain, albumin, and alkaline phosphatase. The tAUC was 0.74 in the testing set. Median (95% confidence interval [CI]) OS for the low-, intermediate-, and high-risk groups (testing set) were not yet reached (NYR) (NYR–NYR), 34.2 months (31.5–NYR), and 21.1 months (17.5–25.0). The hazard ratios (95% CI) for OS in the low- and intermediate-risk groups vs the high-risk group were 0.20 (0.14–0.29) and 0.40 (0.30–0.53), respectively. **Conclusions:** Our validated prognostic model incorporates factors routinely collected in chemotherapy-naive men with mCRPC treated with enzalutamide and identifies subsets of men with widely differing survival times. Clinical trial information: NCT01212991.

5023 Poster Session (Board #97), Mon, 1:15 PM-4:45 PM

Impact of timing of administration of bone supportive therapy on pain palliation from radium-223. *First Author: Kelly Khai Li Yap, Keck School of Medicine of University of Southern California, Los Angeles, CA*

Background: Skeletal-related events (SREs) drive morbidity in patients with metastatic castration-resistant prostate cancer (mCRPC). In the ALSYMPCA study, Radium-223 (Ra223) was found to palliate pain in addition to prolonging survival and reducing SREs. Earlier onset of pain relief was noted when zoledronic acid (ZA) was administered within 24-48 hours of samarium; we evaluated whether the timing of bone supportive therapy (BST) affected pain palliation fromRa223. **Methods:** We identified patients who received Ra223 at University of Southern California or Mayo Clinic Arizona. Data extracted: Ra223 administration dates, pain scores, pain medications, ZA or denosumab administration dates, alkaline phosphatase (ALP) levels, prostate specific antigen (PSA) levels, and concurrent prostate cancer therapy. Patients were evaluable for pain response if they had at least 2 pain scores documented before and after Ra223 with pain medication use data. Pain response was defined as $>$ 2 point decrease in pain on a 10 point scale; flare was defined as $>$ 2 point increase followed by return to baseline or lower. **Results:** Of 65 patients, 20 had baseline pain score $>$ 0 and 34 were evaluable. Median #doses Ra223 was 5 (range 2-6). 18 patients received concurrent abiraterone (abi) or enzalutamide (enza), 16 did not. Pain response occurred in 6/6 (100%) patients who received BST within 1 month prior to first Ra223 dose and 4/8 (50%) patients who did not receive BST. Pain flare occurred in 6/21 patients (29%) without BST and 2/13 (15%) with BST. 6/10 (60%) patients with pain response had ALP decline but there was no consistent pattern of ALP changes in patients with flare. 8/8 patients with pain response had no PSA decline (6 increased, 2 stable). 6/12 (50%) and 2/22 (9%) patients on abi/enza had pain response and flare respectively, and 4/8 (50%) and 6/19 (32%) patients without concurrent abi/enza had response/flare. **Conclusions:** BST within 1 month prior to first Ra223 may be associated with increased likelihood of pain palliation and may prevent pain flare. PSA/ALP changes do not predict pain response. Concurrent use of abi/enza does not increase the likelihood of pain response and may decrease the likelihood of flare.

5024 Poster Session (Board #98), Mon, 1:15 PM-4:45 PM

***BRCA1/2* reversion mutations in prostate cancer identified from clinical tissue and liquid biopsy samples.** *First Author: Sugganth Daniel, Foudation Medicine, Inc., Morrisville, NC*

Background: Prostate tumors with genomic alterations (GA) in *BRCA1* or *BRCA2* (*BRCA*) may be sensitive to treatment with PARP inhibitors (PARPi). However, secondary reversion mutations (revGA) can arise that may restore *BRCA* function and underlie reduced sensitivity to PARPi or platinum (Pt)-based therapy. Comprehensive genomic profiling (CGP), using either tissue or liquid biopsies, can detect the variety of clinically relevant revGA that can arise. **Methods:** DNA extracted from FFPE tumor tissue or blood samples obtained during routine clinical care for 1911 patients with predominantly relapsed, refractory or metastatic prostate carcinoma was analyzed by hybrid-capture, next-generation sequencing for all classes of GA: base substitutions, indels, rearrangements, and copy number changes. RevGA were any GA that could restore the reading frame if in cis with a nonsense or frameshift (fs) GA. **Results:** 216/1911 (11.3% ± 1.4%) tumors had ≥1 deleterious *BRCA* GA. Of these, 7 samples harbored potential revGA in *BRCA1* (1) or *BRCA2* (6): prostate acinar adenocarcinoma (5), neuroendocrine carcinoma (1), or undifferentiated carcinoma (1). Of these, 2 samples were liquid biopsies (blood), 4 were FFPE tissue samples (liver), and 1 sample was a bone marrow core biopsy. All samples with revGA were metastases. Potential revGA were of 3 types: overlapping indel (4), compensatory fs (2), and missense (1). One case harbored 2 revGA, an overlapping indel and a compensatory fs. Alteration frequencies for *TMPRSS2* (fusions), *PTEN*, and *AR* were similar with or without *BRCA* mutations; revGA-positive samples had a modest increase in *PTEN* alterations (42.9% vs 33.8%, NS). The frequency of *CDK12* alterations was significantly reduced in *BRCA*-mutated tumors (0.9% vs 6.9%, p = 0.00002). Clinical histories for patients with reversion mutations will be presented. **Conclusions:** CGP of 1911 prostate carcinomas reveals ≥1 deleterious *BRCA1/2* in 11.3% of samples. From these, a series of 7 cases, all metastases, with co-occurring potential revGA were identified. Although rare, revGA can be acquired during treatment and may underlie resistance to PARPi or Pt-based therapy. *BRCA* revGA can be detected from both tissue and liquid biopsies.

Combination of PDL-1 and PARP inhibition in an unselected population with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Fatima Karzai, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: About 30% of sporadic mCRPC has defects in DNA repair pathways which may confer sensitivity to PARP inhibition. There is limited data about PDL1 inhibition in mCRPC. We hypothesize increased DNA damage by olaparib (O) will complement anti-tumor activity of immune checkpoint blocking antibody, durvalumab (D), in mCRPC:NCT02484404. **Methods:** Single arm pilot study with accrual of 25 patients (pts) with mCRPC and biopsiable disease. Prior treatment with enzalutamide and/or abiraterone is required. D is given at 1500 mg iv q28 days + O 300 mg po q12 h. Primary endpoint is PFS. Pretreatment and on-study core biopsies undergo mutational analysis. **Results:** 10 pts have enrolled (median age 65 yr [range 51-79], median baseline PSA: 85.78 [22.17-809.9 ng/mL]). 7 pts have GS ≥ 8. Grade 3/4 adverse events include anemia 2/7 (29%), thrombocytopenia, lymphopenia, neutropenia, nausea, fatigue, UTI, and lung infection [1/7 each, (14%)]. 5/7 pts (71%) on-study >2 months (mos) have PSA declines > 50%. Median PFS is 7.8 mos (95% CI: 1.8 mos-undefined). **Conclusions:** Preliminary data shows D+O is well tolerated with activity in an unselected population. Accrual is ongoing with biomarker analysis. Clinical trial information: NCT02484404.

Time on-study (mos)	Disease Location	Prior treatments	Mutation	Best PSA response
7	Bone and soft tissue/viscera (A)	androgen deprivation therapy (ADT), enzalutamide/PROSTVAC, docetaxel, abiraterone	None identified in DNA damage repair pathways (NI)	-79%

5027 Poster Session (Board #101), Mon, 1:15 PM-4:45 PM

Time to metastasis or death in non-metastatic castrate resistant prostate cancer (nmCRPC) patients by National Comprehensive Cancer Network (NCCN) risk groups. *First Author: Brian Macomson, Janssen Scientific Affairs, LLC, Horsham, PA*

Background: Interventions in nmCRPC are the last defense against metastasis, which drives health care cost and mortality. To assess the value of such interventions we must analyze risk factors for metastasis and death. **Methods:** This was a retrospective study of data (Optum electronic health record database, 2007 – 2016) from men with a prostate cancer diagnosis, 2 rising PSA levels ≥1 week apart, castrate level (< 50 ng/dL) testosterone (T) and no ICD-9/10 code or therapy indicating metastasis. Gleason grade (G) and PSA data up to and including nmCRPC index date (ie, date of 2nd PSA rise) were used to assign NCCN risk groups: Low (G ≤6 and PSA < 10 ng/mL), Intermediate (IM) (G = 7 or 10 ≤ PSA ≤ 20 ng/mL) or High (G ≥ 8 or PSA > 20 ng/mL). The LP/NG group comprised men with PSA < 10 ng/mL (LP) and missing G (NG). A Cox proportional hazard model, adjusted for age, race, comorbidity index score, T level, therapy type and bone scans was used to compare LP/NG, IM and High with the Low risk group. **Results:** Among 1008 men with nmCRPC (mean age 76 years; 12% African American), 553 developed metastases and 430 died during follow-up. Mean time to metastasis was 28, 22, 15, 13 months in the Low, LP/NG, IM, and High groups, respectively. In the Low group, 9 of 29 (31%) men developed metastases, vs 131/285 (46%) in the LP/NG group (hazard ratio [HR] = 1.70, 95% confidence interval [CI]: 0.86-3.35), 175/320 (55%) in the IM group (HR = 2.52, 95% CI: 1.28-4.91) and 238/374 (64%) in the High group (HR = 3.63, 95% CI: 1.85-7.10). Mean time to death was 32, 30, 24, 21 months in the Low, LP/NG, IM, High groups, respectively. There were 8 deaths in the Low group (27.6%), vs 101 (35.4%) (HR = 1.35, 95% CI: 0.65-2.79) in the LP/NG group, 124 (38.8%) (HR = 1.79, 95% CI: 0.87-3.70) in the IM group and 197 (52.7%) (HR = 2.96, 95% CI: 1.45-6.05) in the High group. The High risk group was more likely to develop metastasis during the first year and die within the first 2 years. **Conclusions:** Metastasis and death occurred earlier and more frequently in the Intermediate and High groups relative to the Low risk group. These findings may further inform diagnostic and management strategies for combating disease progression.

5028 Poster Session (Board #102), Mon, 1:15 PM-4:45 PM

Real-world outcomes in second-line treatment of metastatic castration-resistant prostate cancer (mCRPC): The Prostate Cancer Registry. *First Author: Simon Chowdhury, Guy's Hospital, London, United Kingdom*

Background: The Prostate Cancer Registry is a prospective, international observational study that began in June 2013 and will assess the characteristics and management of > 3000 mCRPC patients (pts) in routine clinical practice for ≤ 3 years. **Methods:** Data were collected from men with mCRPC irrespective of treatment (tx). This interim analysis reports baseline characteristics, txs and outcomes in pts with ≥ 12-month follow-up receiving second-line mCRPC tx following docetaxel as the only prior mCRPC tx. **Results:** The most commonly initiated second-line mCPRC txs (n ≥ 50) were abiraterone acetate + prednisone (AAP, n = 177), enzalutamide (ENZ, n = 94), or cabazitaxel (CAB, n = 70). Characteristics and outcomes are shown in the table below. TTP was not significantly different for AAP vs ENZ, AAP vs CAB or ENZ vs CAB (propensity score adjusted $p = 0.5954$, $p = 0.5888$ and $p = 0.4808$, respectively). **Conclusions:** In this real-world study, clinical outcomes reveal that, in pts receiving second-line mCRPC tx after docetaxel, TTP was similar across tx groups; QoL improved most in AAP and ENZ groups and no deterioration was observed most in AAP and CAB groups. Clinical trial information: NCT02236637.

Tx	AAP (n = 177)	ENZ (n = 94)	CAB (n = 70)

5029 Poster Session (Board #103), Mon, 1:15 PM-4:45 PM

Rovalpituzumab tesirine (Rova-T) as a therapeutic agent for Neuroendocrine Prostate Cancer (NEPC). *First Author: Loredana Puca, Weill Cornell Medical College, New York, NY*

Background: TheNotch ligand Delta like ligand 3 (DLL3) is aberrantly expressed on the cell surface of small cell lung cancer (SCLC), and the DLL3-antibody drug conjugate, Rova-T, has shown promise for patients with SCLC (Rudin et al, Lancet Onc 2017). NEPC is a late stage subtype of castration resistant prostate cancer with limited therapeutic options. Based on clinical and molecular similarities with SCLC, we investigated expression of DLL3 and the use of Rova-T in NEPC. **Methods:** We evaluated mRNA and/or protein expression of DLL3 in a cohort of 395 patients (535 samples) ranging from benign prostate (BEN), localized prostate adenocarcinoma (PCA), castration resistant adenocarcinoma (CRPC), and NEPC and correlated with pathologic and genomic features. Prostate cancer cell lines and patient-derived organoids were treated with Rova-T (SC16LD6.5) in vitro and in vivo. **Results:** DLL3 was expressed at the mRNA and/or protein level in 0/143 BEN (0%), 4/266 PCA (1%), 8/76 CRPC (10%), 33/50 NEPC (66%). DLL3 IHC was of higher intensity in NEPC and co-localized with classical NE marker expression (SYP, CGA). DLL3 was amongst the most differentially expressed genes by RNA-seq in NEPC versus CRPC ($p = < 0.0001$, fold change = 71), correlated with ASCL1 expression ($r = 0.88$) and RB1 genomic loss (83%), and inversely with AR expression. Although treatment with the Notch inhibitor DAPT suppressed Notch target gene expression in NEPC, DAPT did not have significant effect on cellular proliferation. siRNA knockdown of DLL3 or DAPT did not alter AR signaling or NE markers. Rova-T (SC16LD6.5) was active in DLL3-positive NEPC cell lines with an IC50 of 580pM compared to the control IgG1LD6.5 (IC50 = 6.3nM), whereas CRPC lines were insensitive. **Conclusions:** DLL3 is a cell surface protein aberrantly expressed in the majority of NEPC and a subset of CRPC, and is not expressed in primary prostate cancer or benign tissues. The DLL3 antibody-drug conjugate Rova-T demonstrates preferential preclinical activity in NEPC compared to prostate adenocarcinoma. These data support further investigation of Rova-T as a potential therapeutic agent for NEPC. A phase I trial with dedicated NEPC arm is currently accruing patients (NCT02709889).

5030 Poster Session (Board #104), Mon, 1:15 PM-4:45 PM

Outcomes of metastatic castration-resistant prostate cancer (mCRPC) patients (pts) treated with different new agents (NAs) sequence in post-docetaxel (DOC) setting: Final analysis from a multicenter Italian study. *First Author: Orazio Caffo, Medical Oncology, Santa Chiara Hospital, Trento, Italy*

Background: Abiraterone acetate (AA), cabazitaxel (CABA), and enzalutamide (ENZ) may prolong survival in mCRPC pts progressing after DOC, although it is not clear how to use NAs to best exploit their efficacy and avoiding their possible cross resistances. In 2015, we reported the outcomes of a series of 260 mCRPC pts, receiving at least 2 NAs, after DOC progression in routine clinical practice (Eur Urol. 2015;68:147-53). In the present study we updated the analysis with longer follow-up and by assessing a larger series of pts. **Methods:** Based on a multi-institutional collaboration, we collected data of pts who received at least 2 NAs after DOC: we assessed biochemical (bRR) and objective response rates (oRR) and progression free survival (PFS) of each NA by treatment line; moreover, we evaluated the overall survival (OS) from the second line start by sequence strategy. For the OS analysis we differentiated three different types of NAs sequences after DOC: one new hormone agent (AA or ENZ) followed by CABA (NHA→CABA); CABA followed by AA or ENZ (CABA →NHA); one NHA followed by the other NHA (NHA →NHA). **Results:** A consecutive series of 476 mCRPC pts with bone (86%), nodal (56%) or visceral (15%) mets, was collected. All received NAs as 2nd and 3rdline after DOC. The outcomes by both treatment lines and NAs are detailed in the table. We observed a statistically significant difference in terms of OS when compared the three sequence strategies: the median OS of pts treated with NHA→CABA, CABA→NHA, and NHA→NHA was respectively 12.9 mos, 14.2 mos, and 8.8 mos, respectively ($p = 0.01$). **Conclusions:** At our knowledge this retrospective study reports the highest number of pts treated post-DOC with at least 2 NAs. Our data confirmed that the activity of NAs decreased in the 3rd line compared to the 2nd line and suggested a cumulative OS advantage when CABA is used in the sequence.

	Second line				Third line			
	# pts	bRR	oRR	Median PFS	# pts	bRR	oRR	Median PFS
AA	261	39.8%	17.6%	7.9 mos	136	29.4%	15.4%	6.1 mos
CABA	151	35.7%	15.9%	6.1 mos	220	27.7%	12.2%	4.7 mos
ENZ	64	48.4%	15.6%	6.2 mos	120	23.3%	9.1%	3.7 mos

5031 Poster Session (Board #105), Mon, 1:15 PM-4:45 PM

Circulating tumor cell subsets and macrophage polarization to predict efficacy of cabozantinib in advanced prostate cancer with visceral metastases. *First Author: Edwin M. Posadas, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: The presence of VM in metastatic, castration-resistant prostate cancer (mCRPC) predicts poor survival. Cabozantinib (cabo) is a multi-kinase inhibitor that has clinical activity that did not improve survival in an unselected mCRPC population. Subgroup analyses suggested that the benefit may exist for patients (pts) with mCRPC-VM. The effect of cabo includes the tumor microenvironment, monocytes in particular, which in turn can alter tumor behavior. **Methods:** We conducted a single-arm study of cabo in men with mCRPC-VM. Pts received cabo 60 mg daily. Radiographs were used to assess response. Correlative blood samples were collected for the enumeration and characterization of circulating tumor cells using the NanoVelcro Assay and analysis of circulating monocytes by FACS. **Results:** A total of 17 pts enrolled with 16 evaluable for response. At 12 weeks, 19% experienced partial responses (PR), 44% stable disease (SD), and 38% progressive disease. The clinical benefit rate (PR+SD) at 12 weeks was 63%. Safety profile was consistent with previous reports. CTCs were detected in 80% of pts. NanoVelcro CTC counts showed reduction by week 8 in both PR+SD (88%) and PD (71%) groups with re-emergence at progression. Among pts with liver metastases, very-small-nuclear CTCs ($< 8.5\ \mu m$) were seen in 29% of pts with clinical benefit compared to 60% in non-benefiters. Analysis of monocyte polarization after initiation of therapy showed that reduction of M1 polarization was associated with improvement in bone pain and/or bone scan. **Conclusions:** In heavily-pretreated mCRPC-VM, cabo provided clinical benefit with acceptable toxicity. Circulating biomarkers related to both tumor and microenvironment may be useful in identifying patients who benefit from this type of therapeutic approach. Clinical trial information: NCT01834651.

5032 Poster Session (Board #106), Mon, 1:15 PM-4:45 PM

Efficacy, safety, tolerability, and pharmacokinetics of EPI-506 (ralaniten acetate), a novel androgen receptor (AR) N-terminal domain (NTD) inhibitor, in men with metastatic castration-resistant prostate cancer (mCRPC) progressing after enzalutamide and/or abiraterone. *First Author: Kim N. Chi, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: EPI-506 (ralaniten acetate) is a first-in-class small molecule transcription inhibitor of the AR NTD. Nonclinical studies demonstrated activity against both full length and resistance-related AR species, including AR-v7. **Methods:** Open-label, single-arm, Phase 1/2 study evaluating EPI-506 administered orally once-daily. The Phase 1 is a 3+3 design to establish the safety, pharmacokinetic (PK) profile, and recommended phase 2 dose of EPI-506. Anti-tumor activity is also evaluated. Inclusion criteria included: mCRPC with progression after ≥1 line of hormonal therapy or chemotherapy, and progression on enzalutamide and/or abiraterone. **Results:** Eighteen patients (pts) have been enrolled in the dose escalation phase over 5 dose levels (80, 160, 320, 640, 1280 mg). Median age was 71 (range 58-87). Prior treatments included enzalutamide only (N = 7), abiraterone only (N = 2) or both (N = 9). Six pts have had prior chemotherapy. Seven pts have discontinued due to disease progression and 2 pts due to adverse events (AEs): Grade 4 elevated amylase (related) and Grade 4 gastrointestinal bleeding (unrelated). Median exposure was 98.5 days (range 26-338). Most frequently reported treatment emergent AEs were diarrhea (N = 7), nausea (N = 5) and fatigue (N = 3). One Grade 3 AE (AST elevation) at 1280 mg and one Grade 4 AE (increased amylase) at 640 mg were reported. PK data demonstrate a dose-proportional profile for C_{max} and AUC coupled with an initial negative food effect up to 640 mg. At week 4 of continuous dosing, 3 of 18 evaluable pts demonstrated PSA declines ranging from 9 to 18% receiving doses ≥640 mg. **Conclusions:** EPI-506 is well-tolerated with a favorable safety profile. PK indicates dose-proportionality. PSA declines have been observed at doses associated with sub-therapeutic exposure in preclinical studies. This study is the first to evaluate targeting the AR NTD, a region critical for transcriptional function of all known AR species. Clinical trial information: NCT02606123.

5033 Poster Session (Board #107), Mon, 1:15 PM-4:45 PM

Efficacy of cabazitaxel (CABA) rechallenge in heavily-treated patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Constance Thibault, European George Pompidou Hospital, Paris, France*

Background: Only 2 chemotherapies have shown an overall survival (OS) benefit in mCRPC: docetaxel (DOC) and CABA. In patients (pts) previously treated with a new hormonal therapy (NHT: enzalutamide or abiraterone), DOC and CABA, therapeutic options are limited. We previously reported some activity of DOC rechallenge in good responders to first-line DOC. We present here the results of a retrospective study evaluating the efficacy and safety of CABA rechallenge. **Methods:** Records of 70 mCRPC pts rechallenged with CABA were collected in 17 centers (France, Italy, UK, Austria). To be included, pts should have previously received DOC, NHT and CABA with a good response to CABA. **Results:** Of these 70 pts, 52 received DOC-NHT-CABA, 15 DOC-CABA-NHT and 3 NHT-DOC-CABA. At rechallenge, 83% had a high-volume disease (CHAARTED definition), 10% had visceral mets, 66% consumed narcotic analgesics, 68 % were ECOG 0-1 and median neutrophil/lymphocyte ratio (NLR) was 3.1. CABA was rechallenged for a median of 6 cycles (25 mg/m^2 q3w, 59%; 20 mg/m^2, 27%; 16 mg/m^{2}q3w 11%) with prophylactic G-CSF in 47%. Median time from last CABA cycle was 8.6 months (mo). CABA rechallenge had an acceptable tolerability: 7 pts (10%) had grade 3-4 toxicity (neutropenia). Data on efficacy are reported in Table 1. Median progression-free survival (PFS) was 11.3 mo with DOC, 12 mo with NHT, 11.9 mo with first CABA (median 8 cycles), and 7.8 mo with CABA rechallenge. Median OS calculated from the first life-extending therapy was 59.9 mo (95% CI 47.8; 66.4). **Conclusions:** This retrospective cohort of heavily treated mCRPC pts suggests that CABA rechallenge has a good activity with a manageable toxicity. CABA rechallenge might be an option in heavily treated pts still fit to receive chemotherapy.

Efficacy of CABA and CABA rechallenge.

	CABA	CABA rechallenge
Best clinical benefit*		
Improved	51%	34%
Stable	46%	48.5%
Progression	3%	17.5%

5034 Poster Session (Board #108), Mon, 1:15 PM-4:45 PM

Circulating tumor cells (CTCs) N-terminal androgen receptor expression to identify patients (pts) with castrate resistant prostate cancer (CRPC) who are more sensitive to chemotherapy. *First Author: Susan F. Slovin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Loss of the retinoblastoma tumor suppressor (RB) function was identified as a major means to develop CRPC; the expression of the androgen receptor (AR) is under stringent RB control; and tumors devoid of RB function are hypersensitive to treatment with chemotherapy. Exploratory analysis evaluated baseline N-terminal AR expression in CTCs in men with chemotherapy-naïve CPRC and correlated to changes in PSA, leading us to inquire if this biomarker may identify pts sensitive to chemotherapy. **Methods:** In a multicenter phase II randomized trial of approved doses of abiraterone acetate/prednisone (AA-Arm 1) or combination AA and standard doses of cabazitaxel (AA/CBZ-Arm 2). Patients on AA received CBZ upon progression. Baseline CTCs were obtained on all pts and expression of N-terminal AR expression was performed by Epic Sciences. Positive AR N-terminal expression (AR$^+$) was based on the presence of at least 1 CTC or CK$^-$ cell with AR N-terminal signal expression above the 3.0 positivity threshold. Serial PSAs were determined at baseline and every 3 weeks with routine labs and imaging every 12 weeks. **Results:** To date, 42 of 80 pts have been enrolled: 22 pts to AA, and 20 pts to AA/CBZ. Both regimens were well tolerated with 8/42 (19%) pts experiencing treatment-related grade 3 or 4 toxicities. Blood from 35 patients underwent CTC analysis. Seventy-seven percent of pts (27/35) had detectable CTCs; 11 of 35 pts (31%) had AR overexpression. Of the pts with AR+ CTCs, 1/5 pts treated with AA, and 5/6 pts treated with AA/CBZ had a PSA decline > 50% from baseline. **Conclusions:** Real-time CTC analysis of N-terminal AR expression was feasible and data suggests that this may identify a cohort of pts who may benefit from the combination of CBZ with AA. Further studies are ongoing to evaluate whether cellular heterogeneity and RB expression in CTCs play a role in identifying pts who would benefit from chemotherapy. The trial is coordinated by the Prostate Cancer Clinical Trials Consortium, LLC and funded by Sanofi US Services Inc. and Prostate Cancer Foundation. Clinical trial information: NCT02218606.

5035 Poster Session (Board #109), Mon, 1:15 PM-4:45 PM

Phase 2 biomarker-driven study of ipilimumab plus nivolumab (Ipi/Nivo) for ARV7-positive metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Karim Boudadi, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: ARV7+ mCRPC is an aggressive phenotype with a median PFS of 3-4 mo and OS of 7-9 mo. We hypothesized that ARV7+ tumors would be enriched for DNA repair mutations, rendering them more responsive to combined immune checkpoint blockade. **Methods:** We enrolled 15 mCRPC pts with ARV7+ CTCs (using a CLIA-certified assay) into a single arm phase 2 study. Pts received Nivo 3 mg/kg plus Ipi 1 mg/kg every 3 wk x 4 doses, then maintenance Nivo 3 mg/kg every 2 wk. Targeted sequencing for DNA repair defects was performed on pretreatment tumor biopsies (n=11) or cell-free DNA (n=4). Primary endpoint: PSA_{50}response rate. Secondary endpoints: objective response rate (ORR) in pts with measurable disease, durable PFS (lack of progression ≥24 wk), PSA-PFS, radiographic (r) PFS, overall survival (OS), and frequency/intensity of AEs. **Results:** 15 ARV7+ men were enrolled, with median f/u 8.4 (range 1.9–10.5) mo. Median age was 65, 47% had ECOG ≥1, median PSA was 115 ng/mL, 67% had visceral/nodal mets, all had bone mets, and 60% had ≥4 prior regimens for mCRPC. Mean ARV7/AR ratio was 23% (range 3–75%). 6/15 men (40%) had pathogenic DNA repair gene mutations (*BRCA2, ATM, MSH6, FANCM, FANCA, POLH*). Overall, the PSA_{50}rate was 1/15 (7%), ORR was 2/8 (25%), durable PFS rate was 3/15 (20%), PSA-PFS was 3.0 (95%CI 2.1–4.9) mo, rPFS was 3.9 (95%CI 2.8–5.5) mo, and OS was 9.5 (95%CI 7.2–NA) mo. Outcomes appeared better in DNA repair deficient (DRD+) tumors vs. DNA repair proficient (DRD–) tumors (TABLE). 15 grade 3-4 treatment-related AEs occurred in 7/15 (46%) men (including 2 hepatitis, 2 colitis, 1 pneumonitis); there were no treatment-related deaths. **Conclusions:** In this first study targeting ARV7+ mCRPC, treatment with Ipi/Nivo had acceptable safety and encouraging efficacy, particularly in men with DRD+ tumors. DNA repair mutations may be enriched in ARV7+ prostate cancer. Clinical trial information: NCT02601014.

	DRD+ Tumors (N=6)	DRD– Tumors (N=9)	HR (95%CI)	*P*
PSA_{50}	17%	0%		0.400
ORR	40% (2/5)	0% (0/3)		0.464

5036 Poster Session (Board #110), Mon, 1:15 PM-4:45 PM

Assessment of quality of life (QOL), cognitive function and depression in a randomized phase II study of abiraterone acetate (ABI) plus prednisone (P) vs enzalutamide (ENZA) for metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Daniel Khalaf, BC Cancer Agency, Vancouver, BC, Canada*

Background: ABI + P and ENZA treatments are associated with side effects that may impair QOL. ENZA has been associated with cognitive and memory impairment. There has been no direct comparison between these agents and their effect on these domains. **Methods:** Randomized phase II trial of ABI + P vs ENZA as 1st-line therapy for mCRPC (ClinicalTrials.gov: NCT02125357). FACT-P QOL questionnaire, patient health questionnaire (PHQ-9) and Montreal Cognitive Assessment (MoCA) were completed throughout the study. The proportion of patients with a clinically significant change in FACT-P (10 points total FACT-P score, 3 points FACT-P subscales), worsening of PHQ-9 depression symptom severity (none = 0-4, mild = 5-9, moderate = 10-14, moderate-severe = 15-19, severe ≥20) and decline in MoCA cognitive impairment level (normal = 27-30, mild = 18-26, moderate = 10-17, severe < 10) at week 12 was compared between study arms for this analysis. **Results:** From 202 patients (pts) accrued, there were 162, 145 and 142 pts with baseline and 12-week FACT-P, PHQ-9 and MoCA assessment. Median baseline FACT-P, PHQ-9 and MoCA scores were similar in both arms. From baseline to 12 weeks, the median total FACT-P score improved in the ABI + P arm (115 to 128, P = 0.02), but there was no change in the ENZA arm (114 to 114, P = 1.00). There was a higher rate of significant worsening for the physical well-being (PWB) subscale for ENZA vs ABI + P (TABLE), but not for the other FACT-P subscales. There was a higher rate of worsening in depression severity in the ENZA arm (TABLE), although worsening to a moderate-severe/severe level occurred in only 2 patients. There was also a trend for worsening in cognitive impairment for the ENZA arm (TABLE). **Conclusions:** These data suggest there are distinct differences between ABI + P vs ENZA and their effects on QOL, mood symptoms and cognitive function. Clinical trial information: NCT02125357.

	At 12 weeks of treatment				
	ABI + P		ENZA		
	Unchanged/ Improved	Worsened	Unchanged/ Improved	Worsened	P
Total FACT-P score	92%	8%	84%	16%	0.099
FACT-P PWB subscale	94%	6%	71%	29%	0.0004
PHQ-9 depression severity	93%	7%	74%	26%	0.003
MoCA impairment level	94%	6%	84%	16%	0.06

5037 Poster Session (Board #111), Mon, 1:15 PM-4:45 PM

Avelumab in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Farhad Fakhrejahani, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Despite recent progress, mCRPC remains a lethal disease. While programmed cell death 1 (PD-1) and PD-1 ligand (PD-L1) inhibitors have shown activity in variety of cancers, to this point there is minimal evidence of activity in mCRPC. This is a report of avelumab, anti-PDL1 in mCRPC patients (pts). **Methods:** This is an expansion cohort of the first in human, phase I trial (JAVELIN Solid Tumor; EMR100070-001) that evaluated 10 mg/kg of avelumab in pts with mCRPC who had progressive disease (PD) on previous treatment. Pts who had PD on an androgen receptor antagonist (ARA) could enroll on trial and continue their ARA. Avelumab was administered as a 1-hour intravenous infusion every 2 weeks (w) with restaging scans every 6 w. Prostate cancer working group 2 criteria were used to determine PD. **Results:** 18 patients were enrolled on this cohort; the median age of pts was 67 years. Median on study PSA was 11ng/mL. 11 pts had Gleason score (GS) $\geq$ 8 and 7 had GS of 7. 3 pts had previous chemotherapy with docetaxel, 8 pts received previous vaccine treatment including 4 pts with sipuleucel-T and 4 pts with Prostvac. Overall avelumab treatment appears safe and tolerable. 15 pts experienced grade $\leq$ 2 treatment related adverse events (TRAEs), fatigue being the most common one. 4 pts developed treatment related hypothyroidism, 3 with grade 2 and 1 with grade 1. In addition, 2 pts had grade 3 asymptomatic TRAEs (amylase & lipase elevations). 7 pts had stable disease (SD) $>$ 24 w post treatment, 6 pts had PD after first restaging scans at 6 w which was reconfirmed in 2nd restaging scan at 12 w. PSA doubling time (PSADT) prior to avelumab was compared with PSADT after 3 months (m) of treatment. Among 17 pts with available data, 3 pts had a prolonged PSADT which was defined at 3 m (twice as high as on-study PSADT), 7 pts had stable PSADT and 7 had decreased PSADT. 5 of 18 pts enrolled while on enzalutamide with a rising PSA. Among these pts 1 had prolonged PSADT, 2 had a stable PSADT and 2 with decreased PSADT after 3 m of follow up. 3 of 5 pts had SD $>$ 24 m, 1 had SD for 13 w and 1 had PD at first restaging scans. **Conclusions:** These data provide safety data of avelumab on a population of pts with mCRPC. Immune analysis is under way to determine correlation with immune responses in the pts on this trial that had prolonged SD. Clinical trial information: NCT01772004.

5038 Poster Session (Board #112), Mon, 1:15 PM-4:45 PM

Phase 1 study of the PSMA-targeted small-molecule drug conjugate EC1169 in patients with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: Prostate-specific membrane antigen (PSMA) is highly expressed in prostate cancers, but not in most normal tissues, making it a potential therapeutic target. We are conducting a two-part phase 1 dose escalation/expansion study of EC1169, a PSMA-targeted conjugate of the microtubule inhibitor tubulysin B hydrazide in mCRPC. The utility of the PSMA-targeted companion imaging agent ^{99m}Tc-EC0652 is also being evaluated as a patient selection tool. The safety, efficacy, and imaging-based PSMA selection strategy are being investigated in Part A (dose escalation) and Part B (2-stage, 2-cohort expansion). **Methods:** Part A pts were eligible if they progressed on abiraterone or enzalutamide, and were treated with a taxane. EC1169 was administered as an IV bolus on days 1, 8 every 21 days. Part B pts are enrolled in 1 of 2 cohorts, mCRPC taxane naïve (cohort 1, 45 pts) and taxane exposed (cohort 2, 40 pts). Prior to treatment, pts undergo a ^{99m}Tc-EC0652 SPECT scan. The primary endpoint of Part B is median radiographic progression-free survival (rPFS). Other study evaluations are OS, PSA, and CTC-based biomarkers. **Results:** Part A is now complete: the RP2 dose is 6.5 mg/m^2, on the basis of non-DLT transaminitis. 20 Part A/B pts have been treated at the RP2 dose (7 taxane naïve, 13 taxane exposed). Median age is 69 (range: 59-82). Median number of cycles is 2 (range: 1-7). 10 pts (50%) reported at least 1 treatment related AE. Most treatment related AEs are Gr1 and 2; G3 thrombocytopenia, fatigue, and constipation have occurred in 1 pt each. No Grade 4 treatment related AEs have been reported. No DLT or toxicity requiring dose reductions occurred. Four taxane-exposed pts in Part B have reached their first 9 wk radiographic assessment, of which two have soft tissue disease. One of those two patients (50%) has achieved an unconfirmed RECIST PR. **Conclusions:** The RP2 dose of EC1169 is 6.5 mg/m^2. EC1169 has been well tolerated in 20 pts at the RP2 dose. Imaging with ^{99m}Tc-EC0652 suggests excellent disease localization supporting a PSMA-targeted therapeutic strategy. There is evidence of anti-tumor activity in both the dose escalation and expansion cohorts. Clinical trial information: NCT02202447.

5039 Poster Session (Board #113), Mon, 1:15 PM-4:45 PM

Prognostic value of free testosterone (FT) levels during chemotherapy with carboplatin plus weekly docetaxel in metastatic castration- and docetaxel-resistant prostate cancer (mDRPC). *First Author: Christoph Reuter, Department of Hematology, Hemostaseology, Oncology, and Stem Cell Transplantation, Medizinische Hochschule Hannover, Hanover, Germany*

Background: Carboplatin plus docetaxel (DC) may be effective in mDRPC. Platinum(II)-complexes interfere with steroid biosynthesis lowering testosterone levels by inhibiting the cholesterol side chain cleavage enzyme (CYP11A1), 3β-hydroxysteroid dehydrogenase (HSD3B1,2) and 17α hydroxylase/C17,20-lyase (CYP17A1). **Methods:** Docetaxel failure/resistance was defined according to the Prostate Cancer Working Group (PCWG2 2007) criteria. Treatment consisted of at least two cycles of carboplatin AUC5 iv for 30 min on day 1 every 4 weeks (q4w), docetaxel at a dose of 35 mg/m2 iv for one hour on days 1, 8, (15) plus prednisone 2x5mg/day orally after receiving informed consent until disease progression or occurrence of intolerable adverse effects. Efficacy measures were done following PCWG2 recommendations. Free testosterone levels were measured before (n = 77) and during DC chemotherapy (n = 69). **Results:** Of the 100 pts. treated since February 2005, 96% had bone metastases, 45% had lymph node, 27% liver and 21% lung involvement. At the time of the current analysis, the median follow-up was 13.6 months, 93 pts. had died and 97 had progressive disease. The objective response rate was 36.5% in the 63 pts. with measureable disease. Response of prostate-specific antigen ($\geq$50%) was observed in 50% of patients. Median progression-free survival (PFS) for all patients was 6.9 months (CI 95% 5.5, 8.3) and median OS was 15.4 months (CI 95% 11.5, 19.4). The most common reversible grade 3/4 toxicity was leukopenia/ neutropenia (40/32%). Median free testosterone levels were 0.61 pg/ml before and $<$ 0.18 pg/ml during carboplatin/docetaxel treatment (nadir levels, $p < 0.001$; detection limit $<$ 0.18 pg/ml). Median serum androgene levels (T+DHT) were 0.1 ng/ml before and below the detection limit of $<$ 0.05 ng/ml during DC treatment. In multivariate analyses, LDH, PSA response, free testosterone nadir levels below the detection limit ($<$ 0.18 pg/mL) during DC treatment were associated with longer OS ($p < 0.05$). **Conclusions:** These data suggest that carboplatin plus weekly docetaxel may be an important salvage treatment option for DRPC patients.

5040 Poster Session (Board #114), Mon, 1:15 PM-4:45 PM

A phase II trial of abiraterone acetate (AA) without prednisone in castration resistant prostate cancer (CRPC). *First Author: Rana R. McKay, Dana-Farber Cancer Institute, Boston, MA*

Background: AA blocks CYP17 and suppresses adrenal androgens and glucocorticoids. Given the risk of mineralocorticoid excess (ME), AA is administered with corticosteroids. In this phase II multicenter, single-arm study, we assess the safety of AA without steroids in CRPC. The primary objective is to determine the proportion of men requiring prednisone to manage ME. **Methods:** Eligible patients had CRPC with controlled blood pressure (BP) ($<$ 140/90 on $\leq$3 agents) and a normal or $\geq$3.5 mmol/L potassium. Patients initially received AA (1000 mg daily) alone. Patients who developed a BP $\geq$ 140/90 were treated with anti-hypertensives (HTN) and/or a mineralocorticoid antagonist (MA) prior to steroids. Hypokalemia was treated with supplementation or a MA. Patients with persistent or severe ME were initiated on prednisone (5 mg twice daily). To assess response to steroids, prednisone was added to AA at PSA progression. Therapy was continued until radiographic progression, toxicity, or withdrawal. **Results:** 60 patients were enrolled of whom 51 (83%) had metastases 16 (27%) received prior chemotherapy, 6 (10%) enzalutamide, and 4 (7%) ketoconazole. Grade (G) 3-4 adverse events (AEs) of interest included HTN (G3 n = 8, 13%; G4 n = 1, 2%), hypokalemia (G3 n = 4, 7%; G4 n = 0), fatigue (G3 n = 1, 2%; G4 n = 0). There was no G $\geq$3 edema. 9 patients (15%) initiated prednisone for toxicity: HTN (n = 3, 5%), hypokalemia (n = 4, 7%), fatigue (n = 2, 3%). Baseline PSA was 15.4 ng/mL. Time to nadir PSA was 2.5 months (IQR 1.4, 6.3) and median nadir PSA was 2.1 ng/mL. 67% of patients (n = 40) experienced a $\geq$50% PSA decline and 35% (n = 21) experienced a $\geq$90% decline. 19 patients (32%) initiated prednisone for PSA progression. Median time to prednisone initiation in patients with PSA progression was 6.1 months (IQR 4.9, 11.7); 5 patients (8.3%) had a PSA decline and 1 achieved a $\geq$50% decline. Levels of corticosteroids will be reported. **Conclusions:** In CRPC, AA without steroids is feasible, however clinically significant AEs, particularly HTN, can occur in a minority of patients. HTN and hypokalemia can be treated with anti-HTN agents or potassium without steroids in the majority. Use of AA without prednisone needs to be balanced with the potential risk of toxicity. Clinical trial information: NCT02025010.

5041 Poster Session (Board #115), Mon, 1:15 PM-4:45 PM

Clinical activity and safety of ASN001, a selective CYP17 lyase inhibitor, administered without prednisone in men with metastatic castration-resistant prostate cancer (mCRPC): A phase 1/2 clinical trial. *First Author: Jorge A. Garcia, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: ASN001 is a novel, non-steroidal, potent inhibitor of CYP17 lyase that selectively inhibits synthesis of testosterone over cortisol in the adrenals to avoid the need for co-administration of prednisone. ASN001 also exhibits high oral bioavailability and low potential for drug-drug interaction. **Methods:** This Phase (Ph) 1/2 clinical trial in men with progressive mCRPC evaluates once-daily, oral ASN001 at escalating doses of 50, 100, 200, 300 and 400 mg (NCT02349139). While Ph 1 also allowed enrollment of pretreated patients, no prior enzalutamide (ENZA) or abiraterone (ABI) is permitted in Ph 2. Endpoints include maximum dose (MTD) and dose limiting toxicities, recommended Ph 2 dose, PK, effect on steroid hormone biosynthesis and clinical efficacy (PSA and imaging). **Results:** To date, 26 mCRPC pts have been enrolled. No prednisone was administered and no mineralocorticoid excess has been reported. Overall, ASN001 was well tolerated. Most drug-related adverse events were Gr 1/2 and included fatigue, constipation and nausea. At 400mg, two pts experienced asymptomatic, reversible Gr 3 ALT/AST elevation, but no recurrence when retreated at 300mg. Enrollment of ABI/ENZA naïve patients continues at lower doses to further evaluate safety and efficacy. Testosterone decrease to below quantifiable limits and DHEA decrease of up to 80% was observed. Systemic exposure was high (C_{max}, AUC and $T_{1/2}$ at 300 mg QD were 6.7 μM, 80 μM.h and 21.5 h, respectively). Stable disease up to 18+ months has been observed despite prior ABI and ENZA exposure. PSA decline of $>$ 50% (up to 93% decline) and up to 37+ wks duration was observed in 3 of 4 ABI/ENZA naïve patients at starting doses of 300/400mg. **Conclusions:** Overall, ASN001 was safe and well tolerated. Prednisone co-administration was not needed. Encouraging preliminary evidence of efficacy is reflected by PSA declines in evaluable mCRPC pts not pretreated with ABI or ENZA and by durable disease stabilization in refractory disease. Enrollment is ongoing at doses below 400mg QD in ABI/ENZA naïve mCRPC pts. Updated and detailed results will be presented at the meeting. Clinical trial information: NCT02349139.

5042 Poster Session (Board #116), Mon, 1:15 PM-4:45 PM

Patient (pt) characteristics and treatment patterns in the radium (Ra)-223 REASSURE observational study. *First Author: Celestia S. Higano, University of Washington Fred Hutchinson Cancer Center, Seattle, WA*

Background: Ra-223, a targeted alpha therapy, prolonged survival with good safety in metastatic castration-resistant prostate cancer (mCRPC) in the phase 3 ALSYMPCA trial. REASSURE will evaluate Ra-223 short- and long-term safety in routine clinical practice settings. This is the first planned interim analysis (median 7 mo observation). **Methods:** This global, prospective, single-arm, observational study enrolled pts with mCRPC with bone metastases (mets) for whom Ra-223 therapy was planned. Follow-up will continue up to 7 years after last Ra-223 dose. **Results:** 1106 pts (437 N. America, 665 Europe, 4 not recorded) enrolled from 2 Sep 2014 to 22 Sep 2016. Baseline data are available from 583 pts receiving 1st- (1L), 2nd- (2L), or ≥3rd-line (≥3L) Ra-223 for mCRPC(Table). The majority of pts (n=369, 63%) completed 5–6 doses (1L, 70%; 2L, 64%; ≥3L, 49%); median 6 doses (1L,6; 2L, 6; ≥3L, 4). Treatment-emergent drug-related AEs occurred in 215 pts (37%). Post-treatment grade 3/4 thrombocytopenia occurred in 14 pts (2.4%) and anemia in 45 (7.7%). **Conclusions:** In routine clinical practice, Ra-223 was associated with no short-term safety concerns and appeared to be used in pts with less advanced mCRPC than in ALSYMPCA. The majority of pts on 1L/2L Ra-223 therapy received 5–6 doses. Ra-223 was often used with abiraterone or enzalutamide, but not chemotherapy. The next interim analysis in 2019 will report long-term safety and outcomes on all pts. Clinical trial information: NCT02141438.

Androgen deprivation therapy in the treatment of prostate cancer and dementia risk: A systematic review and meta-analysis. *First Author: Kevin Thomas Nead, Department of Medicine, Hospital of the University of Pennsylvania, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Androgen deprivation therapy (ADT) to treat prostate cancer may be associated with an increased risk of dementia, but existing studies have shown conflicting results. Here we conduct a systematic review and meta-analysis on the association of ADT in the treatment of prostate cancer with the risk of dementia. **Methods:** We conducted a systematic review of articles reporting the outcome of dementia among individuals with prostate cancer in those exposed to ADT versus a lesser-exposed comparison group (e.g. no ADT, intermittent ADT) using the PRISMA statement guidelines. Two authors independently carried out searches in PubMed (1966–present), Web of Science (1945–present), Embase (1966–present), and PsycINFO (1806–present). The search was undertaken December 4th, 2016. We assessed the validity of each study per the Newcastle-Ottawa Scale criteria. We meta-analyzed studies reporting an effect estimate and controlling for confounding.Random- or fixed-effects meta-analytic models were used in the presence or absence of heterogeneity, respectively, per the I^2statistic. Small study effects were evaluated using Egger and Begg's tests. **Results:** Nine studies were included in the systematic review. Seven studies reported an adjusted effect estimate for dementia risk. A random-effects meta-analysis of studies reporting any dementia outcome, which included 50,541 individuals, showed an increased risk of dementia among ADT users (hazard ratio [HR], 1.47; 95% confidence interval [CI], 1.08–2.00; p = 0.02). We separately meta-analyzed studies reporting all-cause dementia (HR, 1.46; 95% CI, 1.05–2.02; p < 0.001) and Alzheimer's disease (HR, 1.25; 95% CI, 0.99–1.57; p = 0.06). The I^2statistic to evaluate the proportion of heterogeneity due to study variation was 76% (95% CI, 47–89; p < 0.001) for the primary analysis. There was no evidence of bias from small study effects (Egger, p = 0.19; Begg, p = 1.00). **Conclusions:** The currently available combined evidence suggests that ADT in the treatment of prostate cancer may be associated with an increased risk of dementia. The potential for neurocognitive deficits secondary to ADT should be discussed with patients and evaluated prospectively.

5045 Poster Session (Board #119), Mon, 1:15 PM-4:45 PM

Trop-2 expression on treatment resistant cancer cells in castrate-resistant prostate cancer (CRPC) as a predictive biomarker for targeted therapy. *First Author: Kimberly Peihsi Ku, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Trophoblastic cell-surface antigen (Trop-2) is a transmembrane glycoprotein that is highly expressed in many solid tumors. Sacituzumab govitecan (IMMU-132) is an antibody-drug conjugate of an anti-Trop-2 humanized antibody with SN-38. Early clinical trials have shown high response rates in a broad range of diseases including triple negative breast and urothelial cancers. We evaluated Trop-2 expression in tumor biopsies and circulating tumor cells (CTCs) from men with mCRPC (metastatic castrate-resistant prostate cancer). **Methods:** Trop-2 expression was evaluated from mCRPC biopsies from patients (Pts) treated with abiraterone acetate (AA) on the PROMOTE clinical trial, CTCs from a separate cohort treated with either enzalutamide or AA. Trop-2 CTCs were compared with EpCAM captured CTCs using a microscale technology termed the VERSA (Vertical Exclusion-based Rare Sample Analysis) platform to compare protein and gene expression signatures of resistance to these agents. **Results:** RNA sequencing identified Trop-2 gene expression in > 70% of metastatic biopsies. The AR splice variant V7 was found in 48 biopsies that also expressed Trop-2. Trop-2 expression was not altered by treatment with AA at 12 weeks. The number of CTCs captured from 25 pts with Trop-2 or EpCAM were closely correlated (R^2= 0.84). Gene expression analysis showed similar patterns of expression for the TROP-2 and EPCAM captured cells. AR splice variant expression (AR-V7, AR-V9) in Trop-2 and EpCAM CTCs was detected in 33% of patients. Expression of neuroendocrine markers was identified in 40% of Trop-2 CTCs. **Conclusions:** Trop-2 is frequently expressed in mCRPC and co-expressed in tumors that express AR splice variants. Trop-2 CTCs are detected in CRPC pts previously treated with AA or Enzalutamide that also express multiple AR splice variants and neuroendocrine markers. The results support Trop-2 expression as predictive biomarker of sensitivity to targeted therapies tumors resistant to AA or Enzalutamide. Men with mCRPC are being enrolled on a Phase I trial with IMMU-132, and multi-site Phase II clinical trial in men who have progressed on AA or Enzalutamide is being finalized.

5046 Poster Session (Board #120), Mon, 1:15 PM-4:45 PM

Sipuleucel-T (sip-T) to induce cytolytic T lymphocyte (CTL) activity against target antigens in men with hormone-sensitive and castration-resistant prostate cancer (CRPC). *First Author: Charles G. Drake, Columbia University Herbert Irving Comprehensive Cancer Center, New York, NY*

Background: Sip-T is an FDA-approved autologous cellular immunotherapy for patients with asymptomatic or minimally symptomatic metastatic CRPC (mCRPC), manufactured from peripheral blood mononuclear cells (PBMCs) cultured with the immunogen PA2024 (prostatic acid phosphatase [PAP] conjugated to granulocyte macrophage colony-stimulating factor). Treatment with sip-T induces cellular and humoral immune responses to both PA2024 and PAP (Antonarakis, ASCO 2015; Petrylak, ECC 2015; Small *Clin Cancer Res* 2015). To further elucidate the mechanism of sip-T–induced immune responses, we evaluated proliferative and cytolytic characteristics of PA2024- and PAP-specific T cells. **Methods:** Antigen-specific proliferation of CD4 (T helper [T_H]) and CD8 (CTL) T cells was quantified using flow cytometry. To assess CTL lytic activity, cell-surface CD107a expression, indicating lysosomal fusion with the cell membrane and expulsion of lytic enzymes, was measured after stimulation with PAP or PA2024. CTL lytic activity was assessed in 13 patients (from 3 sip-T trials [NCT01431391, NCT01981122, and NCT01487863] in hormone-sensitive PC and mCRPC patients) and 1 healthy donor (control). **Results:** In sip-T–treated patients, a significant increase in proliferation of both CTLs and T_H cells was detected in response to PA2024 ($p < 0.05$) and PAP ($p < 0.10$) at week 6 compared with baseline. Increased PA2024-specific proliferation was maintained in T_H cells through week 26 ($p < 0.05$). CTL CD107a expression increased in sip-T patient samples stimulated with PAP and PA2024 but not in the healthy donor control. Preliminary analyses suggest that patients with longer overall survival (OS) may have greater CTL CD107a activity. **Conclusions:** Sip-T treatment was associated with well-maintained antigen-specific cellular responses, including robust CTL responses, demonstrating sip-T induces antigen-specific tumor lysis and providing a biologic basis for OS benefit in mCRPC patients. Ongoing work will examine whether patients with longer OS display greater CTL activity. Clinical trial information: NCT01431391; NCT01981122; NCT01487863.

5047 Poster Session (Board #121), Mon, 1:15 PM-4:45 PM

Comparison of biochemical recurrence free survival after radical prostatectomy triggered by grade reclassification on active surveillance, and men newly diagnosed with similar grade disease. *First Author: Clarissa P. Diniz, The Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Evaluate the biochemical recurrence free survival (bRFS) in men after radical prostatectomy (RP) triggered by Gleason score (GS) grade reclassification (GR) during active surveillance (AS) in order to inform patient decisions. **Methods:** We conducted a retrospective analysis of men undergoing RP from 1995 - 2015 at Johns Hopkins and identified 4 groups; 94 men in AS that underwent RP following GR from Gleason score (GS) 6 to GS $\geq$ 7(3+4) [grade groups $\geq$ 2], 3,504 men that underwent IRP following a diagnosis of grade groups $\geq$ 2, 56 men in AS that underwent RP following GR to GS 7(3+4) [grade group 2], and 1,979 men that underwent IRP following a diagnosis of grade group 2. The outcome of interest was bRFS, assessed using Kaplan Meir analysis and a multivariate Cox regression model. **Results:** Men on AS had a lower PSA density distribution (0.11 vs. 0.13, p = 0.022; 0.12 vs. 0.12, p = 0.043), and a higher proportion of low volume cancers (46.2% vs. 15.3%, 46.4% vs. 16.7%, both $p < 0.001$) as compared to the IRP groups for both biopsy grade groups $\geq$ 2 and biopsy grade group 2, respectively. The proportions of men with biochemical recurrence (BCR) in the AS and IRP groups were 13.8% vs. 29.1% (p = 0.008 for grade groups $\geq$ 2) and 8.9% vs. 21.7% (p = 0.022 for grade group 2), respectively. One, 5, 10-year bRFS for men in the AS group vs the IRP group was 97.9%, 76.6%, 69.0% vs 85.5%, 65.1% ,54.2%%, respectively for biopsy grade groups $\geq$ 2 (log-rank test, p = 0.009), and 96.4%, 89.6%, 89.6% vs 91.2%, 74.0%, 63.9%, respectively for biopsy grade group 2 (log-rank test, p = 0.071). For biopsy grade groups $\geq$ 2, there was no significant difference in BCR between groups after adjustment for age at treatment, biopsy extent of cancer, and PSA density; HR = 0.78 (95% CI 0.43 – 1.43, p = 0.426). **Conclusions:** AS patients that are reclassified to grade groups $\geq$ 2 have no greater risk of treatment failure as compared to men newly diagnosed with similar grades. These data could help inform decisions regarding management of low grade prostate cancer.

5048 Poster Session (Board #122), Mon, 1:15 PM-4:45 PM

Predictors of post-surgical race-specific prostate cancer progression. *First Author: Jennifer Cullen, Center for Prostate Disease Research, Rockville, MD*

Background: Disparity in prostate cancer (CaP) incidence and mortality for African American (AA) versus Caucasian American (CA) men may reflect tumor biology, comorbidity, treatment, follow-up care, and/or health care access. In a racially diverse cohort of patients undergoing radical prostatectomy (RP), this study examined how race, comorbidity, and PSA doubling time (PSADT) impact CaP progression. **Methods:** Enrollees in the Center for Prostate Disease Research (CPDR) Multi-Center National Database from 1989-2014 who underwent RP within 12 months of CaP diagnosis were eligible. Biochemical recurrence (BCR) was defined as PSA $\geq$0.2 ng/mL post-RP. Comorbid conditions included coronary artery disease (CAD), cerebral vascular incident (CVI), Type II diabetes (DB), hypertension (HT), elevated cholesterol (EC), lung disease (COPD), prostatitis (PS), renal insufficiency (RI) and other cancer (OC). Multivariable Cox proportional hazards (PH) analysis was used to examine comorbid conditions (yes vs. no) and PSADT ($<$ 3, 3-8.9, 9-14.9, and $\geq$15 mos) to predict BCR, controlling for age at RP, D'Amico risk stratum, pathology features, and adjuvant treatment. **Results:** A total of 6,785 patients were eligible; 22% AA and 78% CA. Median age and follow-up was 62 and 6.1 years, respectively. Across race, comparable median follow-up time, distributions of pathologic features and adjuvant treatments were observed. However, AA vs. CA patients had greater HT (53 vs. 39% $p < 0.0001$), DB (17 vs. 7%, $p < 0.0001$), and RI (3 vs. 1%, p = 0.002). Alternatively, CA vs. AA patients had greater CVD (10 vs. 7%, p = 0.0008) and OC (3 vs. 0.5%, $p < 0.0001$). Cox PH analysis showed poorer BCR-free survival for AA vs. CA men (HR = 1.28, CI = 1.11, 1.48, p = 0.0009) adjusting for D'Amico risk stratum, pathology, and treatment. PSADT, not comorbidity, was a critical predictor of BCR, with poorest outcome at extremes: HR PSADT $<$ 3 vs. $>$ = 15 months = 41.5, CI = 33.6, 51.3, $p < 0.0001$). **Conclusions:** Despite comparable health care access and distribution in clinical risk stratum and pathology features, race persisted in predicting poor CaP outcome. Disparate comorbidity for AA and CA men did not eliminate this difference. PSADT remained the most striking determinant of poor BCR-free survival.

5049 Poster Session (Board #123), Mon, 1:15 PM-4:45 PM

Circulating tumour cells and survival in abiraterone- and enzalutamide-treated patients with castration-resistant prostate cancer. *First Author: Bram De Laere, Center for Oncological Research (CORE), University of Antwerp, Antwerp, Belgium*

Background: A heterogeneous landscape of patients with metastatic castration-resistant prostate cancer (mCRPC) exists in current clinical practice. We investigated the prognostic value of CTC enumeration and dynamics, in the context of second-line endocrine therapies (i.e. abiraterone or enzalutamide). **Methods:** In a prospective, multicentre study blood samples were collected from patients with mCRPC at baseline (n = 147) and follow-up (n = 95/147 (64.6%)). At baseline, patients were stratified in favourable ($<$ 5 CTCs/7.5mL) and unfavourable ($\geq$5 CTCs/7.5mL) groups, whereas at follow-up, in those demonstrating a stable, in- or decreasing CTC count. PFS and OS were compared between groups. PSA changes at 10-12 weeks were evaluable in 83 patients. **Results:** Patients with $\geq$5 CTCs/7.5 mL (n = 59) at baseline had a shorter PFS (3.9 vs. 11.3 months, $p< 0.0001$) and OS (9.34 months vs. not reached, $p< 0.0001$). Patients demonstrating increasing CTCs (n = 21) on therapy had a shorter PFS (4.03 vs. 10.36 vs. 13.08 months, $p < 0.0001$) and OS (11.2 months vs. not reached, $p < 0.0001$), compared to patients with decreasing (n = 41) and stable (n = 33) CTCs, respectively. Multivariate Cox regression showed that the number of CTCs (HR (95%CI): 1.0054 (1.0006–1.010), p= 0.0260) and an increasing follow-up CTC count (HR (95%CI): 2.8987 (1.2856–6.536), p= 0.0103) were independent predictors of PFS. CTC increase was the sole independent predictor for OS (HR (95%CI): 7.3512 (1.7953–30.101), p= 0.0055). At 10-12 weeks, a PSA response of $\geq$30% and $\geq$50% was achieved in 46/83 (55.4%) and 33/83 (39.8%) patients, respectively, which was statistically different between chemo-naive or -pretreated patients ($\geq$30%: p= 0.0395), patients with increasing, stable or decreasing CTC counts ($\geq$30%: p= 0.0019; $\geq$50%: p= 0.0032), and patients with increasing or stable/decreasing CTC counts ($\geq$30%: p= 0.0006; $\geq$50%: p= 0.0014). **Conclusions:** CTC levels are associated with PFS and OS in mCRPC patients, starting a new line of endocrine therapy. Follow-up CTC enumeration is associated with PSA response and its dynamics is an independent predictor of PFS and OS, thereby demonstrating the pharmacodynamic properties of CTCs.

5050 Poster Session (Board #124), Mon, 1:15 PM-4:45 PM

***HSD3B1* genotype and response to androgen deprivation therapy for biochemical recurrence after radiotherapy for localized prostate cancer.** *First Author: Jason W. D. Hearn, University of Michigan, Ann Arbor, MI*

Background: The enzyme encoded by the *HSD3B1*(1245C) variant allele has been shown to promote castration-resistant prostate cancer by increasing intratumoral dihydrotestosterone synthesis. In the setting of biochemical recurrence (BCR) following prostatectomy, inheritance of the variant allele has been associated with inferior clinical outcomes for men treated with androgen deprivation therapy (ADT). Whether the same is true in the context of BCR after radiotherapy (RT) is unknown. **Methods:** We determined *HSD3B1* genotype retrospectively in men treated with ADT for post-RT BCR using an established biorepository at a large academic center. We analyzed time-to-progression (TTP), time-to-metastasis (TTM), and overall survival (OS) according to *HSD3B1*genotype using an additive genetic model with the log-rank trend test. Multivariable analyses (MVA) were performed to adjust for known prognostic factors with Cox regression. **Results:** We identified 218 men treated with ADT for BCR after RT, of whom 213 (98%) were successfully genotyped (46%, 45% and 9% carrying 0, 1, and 2 variant alleles, respectively). Median follow-up was 7.9 years (yrs). Demographic and treatment factors were similar across genotypes. Median TTP was 2.3 (95% CI: 1.6, 3.1) yrs in men who inherited 0 variant alleles, 2.3 (1.5, 3.3) yrs with 1 variant allele, and 1.4 (0.7, 3.3) yrs with 2 variant alleles (P = 0.683). Median TTM diminished with the number of variant alleles inherited (7.4 [6.7, 9.7], 5.8 [4.9, 6.5] and 4.4 [3.0, 5.7] yrs, respectively (P = 0.030). No difference in OS was detected (P = 0.305). On MVA with 0 variant alleles as the reference, the adjusted hazard ratio (HR) for metastasis was (1.19 [0.74, 1.92]; P = 0.480) for 1 allele and (2.01 [1.02, 3.97]; P = 0.045) for 2 alleles. MVA did not demonstrate significant differences in TTP or OS. **Conclusions:** The *HSD3B1*(1245C) allele that enhances dihydrotestosterone synthesis is associated with time-to-metastasis in men treated with ADT for BCR after RT for prostate cancer. Notably, 49% of men had received prior ADT as part of local therapy and 56% received an anti-androgen during ADT for BCR, which may blunt the effect of the variant allele.

5051 Poster Session (Board #125), Mon, 1:15 PM-4:45 PM

Clinical implications of the 2012 US Preventive Services Task Force (USPSTF) PSA screening recommendation in prostate cancer diagnoses and 5-year survival at a Minnesota safety net health care system. *First Author: Kevin Gale, Hennepin County Medical Center, Minneapolis, MN*

Background: Prostate specific antigen (PSA) screening for prostate cancer has declined following the USPSTF 2012 recommendation. How screening rates and prostate cancer diagnoses have subsequently changed in a racially diverse patient population is not well defined. In this study, we aim to determine the impact of the USPSTF screening recommendation in the Hennepin Healthcare System (HHS) in the state of Minnesota. **Methods:** A single-institution retrospective analysis of data from our electronic health record, to identify the characteristics of PSA screening and new prostate cancer diagnoses for men ≥50 years between 2008 and 2015. Data before and after May 2012 were compared. P-values were calculated using binominal and generalized linear models. **Results:** Nearly 22,000 patients underwent PSA screening from 2008 to 2015. PSA screening rates decreased after May 2012 for the four largest demographics represented ($p < 0.001$). Hispanics and Blacks were more likely to be screened when compared to Whites and Asians ($p < 0.05$). 319 cases of prostate cancer were diagnosed from 2008 to 2015 with 87 cases (27.3%) diagnosed by PSA-screening. The number needed to screen to diagnose one patient with prostate cancer at HHS was 137.5, and 9.5% of patients (1146 patients) had a false positive PSA that led to further testing or a biopsy. $56,090 was spent in screening costs per diagnosis of early stage prostate cancer via screening. Patients diagnosed from screening were less likely to present with high Gleason scores (8-10) compared to non-screening diagnosis (8% vs 23.3%, $p < 0.01$). The 5-year survival percentage (prostate cancer mortality) was improved for those patients diagnosed by PSA screening vs the non-screened group (100% vs 89.3%, $p < 0.05$). **Conclusions:** PSA screening has declined at HHS since the USPSTF recommendation against prostate cancer screening. Implementation of PSA screening in our healthcare system is expensive and leads to a high number of false positives. Despite this, the 5-year survival from prostate cancer is significantly higher when patients are diagnosed by PSA screening.

5052 Poster Session (Board #126), Mon, 1:15 PM-4:45 PM

Association of CTC detection by AdnaTest with outcome on enzalutamide in chemotherapy-naïve castration-resistant prostate cancer: Exploratory results from PREMIERE—A SOGUG trial. *First Author: Albert Font Pous, Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Badalona, Spain*

Background: Circulating tumor cells (CTCs) enumeration using CellSearch correlates with clinical outcome in prostate cancer, but is limited for gene expression analysis. AdnaTest ProstateCancer is a commercially available CTC immune-enrichment and PCR-related detection method that allows gene expression studies (Antonarakis E, NEJM 2014). It has demonstrated incremental detection of CTCs in patients with no CTCs identified by CellSearch (Samoila A, ASCO 2013) but needs to be clinically qualified. There is a strong need for studies to assess the association with the clinical outcome in CRPC. **Methods:** Between February and November 2015, 98 asymptomatic or oligo-symptomatic chemotherapy-naïve mCRPC pts were recruited in 16 institutions. Although initially designed to study the predictive value of TMPRSS2-ETS, data emerging after the trial was initiated led the group to prioritize alternative predefined exploratory biomarkers, including plasma *AR* (Grande E, ASCO 2017 #) and CTC characterization (Grande E, ESMO 2016). Outcome measures included PSA-PFS (sPFS), radiographic PFS (rPFS) and OS. Cox regression was used for survival analyses and Fisher's exact test for PSA response. **Results:** Ninety-eight patients had CTC blood samples available. CTCs were detected at baseline, 12 weeks and progression in 36% (35/98), 27% (26/95) and 78% (32/41), respectively. The CTC conversion rate (positive to negative after 12 w) was 43% (15/35). All CTC conversions had ≥50% decline in PSA (15/15) whereas only 35% (7/20) of pts with persistent CTCs. At first interim analysis, with a median follow-up of 10.6 months, detection of CTCs at baseline was associated with worse sPFS (median, 7.59 m versus NR, HR, 3.67; 95% CI 1.90-7.10; $P < 0.001$), rPFS (median, 12.9 m versus NR; HR, 7.61; 95% CI, 2.80-20.64; $P < 0.001$) and OS (medians NR, HR, 9.51; 95% CI, 1.11-81.52; P = 0.0398). CTC positive pts were less likely to have a ≥90% decline in PSA (OR, 2.88; 95% CI, 1.13-7.72; P = 0.02). **Conclusions:** CTC detection using AdnaTest is associated with an adverse outcome in chemotherapy-naïve asymptomatic or oligo-symptomatic mCRPC pts. Clinical trial information: NCT02288936.

5053 Poster Session (Board #127), Mon, 1:15 PM-4:45 PM

Genome-wide analysis of metastases to reveal association of pathway activation with abiraterone acetate/prednisone (AA/P) primary resistance and cell cycle proliferation pathway activation with response duration in metastatic castrate resistant prostate cancer (mCRPC). *First Author: Manish Kohli, Mayo Clinic, Rochester, MN*

Background: Genomic aberrations associated with resistance/response to AA/P are not known. In a prospective study we assessed whole-exome/RNA-seq based aberrations in CRPC metastatic biopsies for identifying molecular markers associated with primary resistance and response duration. **Methods:** Sequencing of metastatic biopsies was performed for analyzing molecular aberrations that predict primary resistance (defined as progression at 12-weeks of therapy (non-responders) using PSA, RECIST, bone scan criteria per PCWG2). Gene network analysis was performed in genes mutated more frequently in non-responders and in genes differentially expressed between non-responders and responders using a "risk ratio" (RR) of ≥2. Cox regression models with multiple gene network pathways were used for determining association with time to treatment change (TTTC). **Results:** Of 92 enrolled pts 82 had complete whole-exome, RNA-seq & 12-week outcome data available for analysis. At 12-weeks 33/82 had progressed. Using a RR of ≥2, 113 genes were more frequently mutated in non-responders & 292 in responders. In non-responders, gene network analysis revealed frequent mutations in *Wnt/β*-catenin pathway genes; frequent deletion of negative regulators of *Wnt* pathway (*DKK4*, *SFRP2*, *LRP6)*. Gene expression analyses revealed significantly reduced expression levels of *Wnt/β*-catenin pathway inhibitors and increased expression levels of cell cycle proliferation (CCP) genes in non-responders. Median study follow up was 32 months during which time 58/82 pts progressed and switched treatments. Median TTTC was 10.1 months (IQR: 4.4-24.1). In multivariate analysis CCP scores of ≥50 predicted shorter TTTC (HR = 2.11, 95% CI: 1.17-3.80; p = 0.01). **Conclusions:** In metastases *Wnt/β*-catenin pathway activation is associated with primary AA/P resistance and increased CCP with acquired drug resistance. These findings offer molecular based predictive biomarkers in CRPC stage treatment. Clinical trial information: NCT#01953640.

5054 Poster Session (Board #128), Mon, 1:15 PM-4:45 PM

The immunomodulatory protein Dickkopf-1 (DKK1) defines a non-neuroendocrine subtype of metastatic castration-resistant prostate cancer (mCRPC) with low AR and low PSA expression. *First Author: David Wise, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Advanced stagemCRPC can manifest AR-signaling independent growth typified by loss of AR and/or PSA expression in the absence of neuroendocrine (NE) features on biopsy. We sought to identify therapeutically relevant biomarkers of this highly resistant prostate cancer subtype. **Methods:** An unbiased differential gene expression analysis of non-neuroendocrine mCRPC biopsies was carried out comparing patients with AR^{low} to patients with AR^{high} disease in a discovery cohort (SU2C/PCF, 18 pts: 8 AR^{low}, 10 AR^{high}) and validation cohort (Fred Hutchinson, 76 pts: 12 AR^{low}, 64 AR^{high}). The AR and NE status of the biopsies were defined by AR and PSA mRNA expression and gene signatures representative of AR activity and NE lineage. An RNA sequencing-based signature of immune cell subsets was calculated using the *Cibersort* algorithm. **Results:** Differential gene expression analysis identified the secreted Wnt antagonist, DKK1, as significantly upregulated in AR^{low} cases compared to AR^{high} cases (11.2 RPKM vs. 0.28 RPKM, $p < 0.03$) in our discovery cohort and confirmed in our validation cohort (9.2 FPKM vs. 0.99 FPKM, $p < 0.001$). DKK1 protein was also found to be increased in non-neuroendocrine AR^{low} relative to AR^{high} prostate cancer in vitro cell and organoid models (858 pg/mg total protein vs. 2 pg/mg total protein, $p < 0.05$) and patient-derived xenografts (28.6 FPKM vs. 0.78 FPKM, $p < 0.0001$). Consistent with the role of DKK1 as a negative modulator of anti-tumor immunity, patient biopsies with the highest quartile of DKK1 expression showed an RNA signature consistent with lower levels of active NK cells (0.2% vs. 1.8%, $p < 0.005$), and lower levels of CD8+ T cells (3.7% vs. 9.7%, $p < 0.005$) compared to those with the lowest quartile of DKK1 expression. **Conclusions:** DKK1 represents a secreted biomarker that is disproportionately enriched in non-neuroendocrine mCRPCs that lack AR expression. Because DKK1 has been implicated as a suppressor of anti-tumor immunity and is a target of an existing neutralizing antibody, our results support the clinical evaluation of the role of DKK1 blockade in DKK1-positive AR-negative prostate cancer.

5055 Poster Session (Board #129), Mon, 1:15 PM-4:45 PM

The plasma lipidome in castration-resistant prostate cancer. *First Author: Lisa Horvath, Chris O'Brien Lifehouse, Sydney, Australia*

Background: Biomarker studies of metastatic castration-resistant prostate cancer (CRPC) have mainly focused on changes in the cancer, however, the host environment and its interactions with cancer is increasingly important, especially given the increasing association of PC outcomes and obesity. We sought associations between the plasma lipidome and clinical outcome in CRPC. **Methods:** Plasma samples were obtained from a Phase 1 discovery cohort of 96 CRPC patients before and after the first cycle of docetaxel chemotherapy. Lipidomic profiling of the plasma samples was performed by liquid chromatography and electrospray ionisation-tandem mass spectrometry. Results were subsequently assessed in a Phase 2 validation cohort of 63 CRPC patients. **Results:** Lipidomic profiling detected 323 lipid species in plasma samples from the Phase 1 cohort. Patients could be classified into two subgroups with significant survival differences according to their baseline lipidomic profiles (median overall survival 13.7 vs 21.7 months; HR 2.31, 95% CI 1.44-3.68, $p = 0.0005$). The baseline levels of 46 lipids were individually prognostic ($p < 0.01$) and predominantly sphingolipids. A prognostic three-lipid signature was derived (ceramide (d18:1/24:1), sphingomyelin (d18:2/16:0), phosphatidylcholine (16:0/16:0)) (11.7 versus 21.7 months, $p = 0.00001$; HR 2.94, 95% CI 1.80-4.81, $p = 0.00002$). The signature was associated with shorter overall survival in the Phase 2 cohort (HR 4.78, 95% CI 2.06-11.1, $p = 0.0003$), and was an independent prognostic factor when modeled with clinicopathological factors and metabolic characteristics (BMI, cholesterol and triacylglycerol). The AUC of ROC analysis of 12 month survival for a clinicopathological model (AUC 0.70, 95% CI 0.54-0.87, $p = 0.03$) was enhanced by the addition of the 3-lipid signature (AUC 0.73, 95% CI 0.57-0.89, $p = 0.01$). **Conclusions:** Our study is the first to comprehensively profile the plasma lipidome of men with CRPC using cutting-edge lipidomic profiling technology, to identify a plasma lipid signature that can reproducibly predict outcome in CRPC and can improve on clinicopathological models. Therapeutic modulation of the levels of these lipids by targeting their metabolic pathways may improve patient outcome.

5056 Poster Session (Board #130), Mon, 1:15 PM-4:45 PM

Incidence of intrathoracic (IT) metastases detected by ^{68}Ga-PSMA-11 PET in early stage prostate cancer (PC). *First Author: Rahul Raj Aggarwal, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Standard imaging in early stage PC has focused on detecting metastases (mets) within the abdomen and pelvis. The incidence of IT mets (lung, mediastinal, or supraclavicular) mets is unknown, but presumed to be negligible. Whole body ^{68}Ga-PSMA PET has greater sensitivity compared to conventional imaging, affording the opportunity to estimate the incidence of IT mets. **Methods:** Newly diagnosed or biochemically recurrent (BCR) PC patients (pts) with apparent localized disease on standard imaging were enrolled on a prospective study of ^{68}Ga-PSMA PET imaging between June 2015 and January 2017 and were analyzed for incidence of IT mets. Positive lesions were defined as uptake higher than blood pool. When appropriate, patients underwent confirmatory biopsy of the PSMA-avid IT lesions. **Results:** 364 pts underwent ^{68}Ga-PSMA PET imaging, including 121 (33%) pts with newly diagnosed PC and 243 (67%) pts with BCR. 145 pts (40%) had at least 1 PSMA-avid metastasis. PSMA-avid IT mets were detected in 20 pts (5.5% of overall cohort; 13.8% of those with ≥ 1 PET-positive mets), including 3 newly diagnosed (2.5%) pts and 17 (7.0%) pts with BCR. 9 of 20 pts (45%) had IT mets as the only detectable site of metastasis on PET. Biopsy of the PSMA-avid IT lesion was found to harbor PC in 5/5 patients (100%). Sites of detection included: supraclavicular node, n = 9 (2.5%); mediastinal node(s), n = 10 (3.6%), and visceral lung, n = 4 (1.0%). In the entire study cohort of 364 pts, 43% of pts had a Gleason Score ≥ 8 at diagnosis, median PSA was 4.87 ng/mL (range: 0.04 – 83.7), and the median PSA doubling time was 6.2 months (range: 0.4 – 78.3) in patients with BCR. There were no significant differences in PSA, PSA doubling time, Gleason grade, or stage between patients harboring IT metastases vs. those who did not. **Conclusions:** IT mets are detected by ^{68}Ga-PSMA PET imaging at an appreciable frequency in early stage PC with apparent localized disease by conventional imaging, which may significantly impact management in these cases. Further studies are warranted to validate these findings and determine the optimal strategy for the detection and treatment of supradiaphragmatic metastases in newly diagnosed and biochemically recurrent PC. Clinical trial information: NCT02918357.

5057 Poster Session (Board #131), Mon, 1:15 PM-4:45 PM

Effect of Ga-68 PSMA-11 PET on management in patients with recurrent prostate cancer. *First Author: Tom Hope, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: PET imaging of prostate specific membrane antigen (PSMA) has been shown to have a higher sensitivity and specificity compared to conventional imaging. The objective was to evaluate the impact of PSMA PET on the management of prostate cancer patients with biochemical recurrence following local therapy. **Methods:** In our initial Ga-68-PSMA-11 PET protocol (NCT02611882), 150 patients with biochemical recurrence were imaged. 63 patients were imaged using PET/CT (GE Discovery VCT) and 63 patients using PET/MRI (GE Signa 3.0T PET/MRI). 110 patients received Lasix injections. Referring clinicians filled out a pretreatment management form and a management form based on the imaging results. Changes in management were graded as major, minor, no change or unknown based upon the responses. **Results:** We received both pre and post imaging forms in 126 patients, for an 84% response rate. The average PSA in the population was 5.9 ± 5.4 ng/mL with an average doubling time of 9.7 ± 11.0 months, and 60 patients had a PSA of less than 2.0 at the time of imaging. The average time between prior treatment and imaging (RP and/or radiation) was 5.3 ± 5.4 years, with 46 patients imaged within two years of their most recent treatment. 43 patients had a prior prostatectomy, 41 prior radiation, and 33 patients had both. 103 patients (82%) had disease localized on PSMA imaging. Of the 126 patients, 67 (53%) of the imaging studies resulted in a major change in management. The most common major change was converting from active surveillance to radiation therapy (15 patients, 12%), changing from ADT to radiation therapy (16 patients, 13%), and converting from radiation therapy to either active surveillance (6 patients, 5%) or to ADT alone (3 patients, 2%). 10 patients (8%) had a minor change, 42 patients (33%) had no change, and 7 patients (6%) had an unknown change in management. **Conclusions:** The results of our surveys demonstrate a substantial impact of PSMA PET on the intended patient management. The majority of changes involved converting a targeted therapy to systemic treatment or systemic treatment to a targeted therapy. Prospective studies are warranted to determine whether directed treatment towards PSMA-avid lesions affects long-term disease outcomes. Clinical trial information: NCT02611882.

5058 Poster Session (Board #132), Mon, 1:15 PM-4:45 PM

Whole blood androgen receptor (AR) variant (ARV12, ARV14) expression and overall survival (OS) in metastatic castrate resistant prostate cancer (mCRPC). *First Author: Karthik Giridhar, Mayo Clinic, Rochester, MN*

Background: The detection of full length AR (AR-FL) or AR variants (AR-Vs) in blood and association with outcomes in mCRPC is unknown. We compared whole blood mRNA expression of AR-FL and AR-Vs to circulating tumor cells (CTCs) for predicting OS and time to treatment failure (TTF). **Methods:** We isolated RNA from whole blood collected in PAXgene RNA tubes and concurrent metastatic tissue biopsy from 51 men with mCRPC prior to initiation of abiraterone acetate in a prospective clinical trial (NCT#01953640). Whole transcriptome sequencing (RNAseq) was performed on blood samples and paired biopsies to detect AR-FL, ARV1, ARV3, ARV7, ARV8, AR12, ARV14, and ARV45. Reads were aligned to the GRCh38 reference genome with the spliced-alignment TopHat2 package. The Pearson correlation coefficient was calculated between AR-FL in blood and matched bone biopsy. CTCs were determined using the CELLSEARCH assay. Cox proportional hazard regression analysis was performed on AR-FL, each AR-V, and CTCs for association with OS and TTF. We compared the area under the curve (AUC) using CTCs alone to a multivariable model that included AR-Vs for predicting OS. **Results:** The median follow up was 3.0 years, (range 0.3-3.5); the median CTC count was 3 (range 0-372); 34/53 men were deceased. Blood based AR-FL or AR-Vs were detected in 50/53 patients with following distribution: AR-FL (41/53), ARV3 (9/53), ARV45 (8/53), ARV12 (4/53), ARV14 (4/53), ARV7 (2/53), and ARV8 (2/53). Whole blood AR-FL transcripts were highly correlated to paired bone biopsy (r^2= 0.76). Elevated transcripts of either ARV12 or ARV14 were associated with decreased OS [hazard ratio (HR) 3.46, p = 0.006]. CTC count ≥5 was associated with poorer OS [HR 3.42, p = 0.02] and shorter TTF [HR 3.52, p = < 0.001]. Adjusting for CTC counts, in a multivariate model, blood AR12 expression was associated with poor OS [HR = 6.33, p = 0.009]. AR12 and CTCs trended toward improved AUC compared to CTC alone (0.78 vs 0.71, p = 0.07). **Conclusions:** AR-FL and AR-Vs are detectable in whole blood and are highly correlated with metastatic bone AR-FL expression. AR-Vs may add to prognostication in mCRPC and further validation is needed. Clinical trial information: NCT#01953640.

5059 Poster Session (Board #133), Mon, 1:15 PM-4:45 PM

Ten-year overall and prostate cancer (PCa)-specific mortality in high-risk patients after high-dose-rate brachytherapy combined with external beam radiation therapy (HDR-BT/EBRT) compared with EBRT alone. *First Author: Trude Baastad Wedde, Oslo University Hospital, Oslo, Norway*

Background: The effect of dose-escalation with HDR-BT boost for high-risk PCa is not known. The objective is to compare 10-year PCa-specific mortality (PCSM) and overall mortality (OM) in non-metastatic patients treated with HDR-BT/EBRT (2004-2010) to EBRT alone (historical RCT, SPCG-7, 1996-2003). **Methods:** HDR-BT boosts (10 Gy x 2) were given 2 weeks apart followed by 50 Gy conformal EBRT (2 Gy x 25) to the prostate and seminal vesicles (assuming alpha/beta ratio of 3, EQD2 = 102 Gy). The HDR-BT/EBRT group (N:325) received Androgen Deprivation Therapy (ADT) for a total of 2 years. Patients in the control group (N:296) received 70 Gy (2Gy x 35) to the prostate and seminal vesicles with lifelong Anti-Androgen Treatment (AA). cT1-cT2 vs cT3 tumours and Gleason score 6-7 vs 8-10 were analysed. For each treatment group PCSM and OM were established by Kaplan-Meier (KM) analyses, and inter-treatment differences were tested by the logrank tests. Cox regression analysis evaluated the significance of available pre-treatment variables. Significance level $p < 0.05$. **Results:** In both groups the median age was 66 years. Median follow-up was 104 (range 13-120) and 120 (range 3-120) months for the HDR-BT/EBRT and EBRT groups respectively. KM plots revealed an 1.8% risk of PCSM in the HDR-BT/EBRT patient group and an 8.4% risk in the EBRT cohort (p = 0.001). For OM, the figures were 12.3% in the HDR-BT/EBRT group compared to 23.3% in the EBRT group (p = 0.014). In the Cox regression analysis, treatment (HR = 3.9, CI95% 1.8-8.3) and Gleason score (HR = 3.2, CI95% 1.8-5.9) were significantly associated with PCSM whilst T-stage, age and PSA levels were not. Treatment (HR = 1.7, CI95% = 1.1-2.6) was the only factor significantly associated with OM. **Conclusions:** In men with high-risk PCa dose-escalation with HDR-BT/EBRT compared to EBRT alone resulted in a significantly decreased risk of 10-year PCSM and OM despite shorter length of hormonal therapy. PCSM was significantly influenced by both Gleason score and type of treatment, whereas treatment remained the only significant covariate for OM.

5060 Poster Session (Board #134), Mon, 1:15 PM-4:45 PM

Association of androgen receptor (AR) status in plasma DNA with outcome on enzalutamide (enza) or abiraterone (abi) for castration resistant prostate cancer (CRPC). *First Author: Vincenza Conteduca, Centre for Evolution and Cancer, The Institute of Cancer Research, London SW7 3RP, UK, London, United Kingdom*

Background: There is an urgent need to identify biomarkers to guide personalized therapy in CRPC. We aimed to clinically qualify the association of *AR* status in plasma DNA with worse outcome in pre- and post-docetaxel (doc) CRPC. **Methods:** We used droplet digital (dd)PCR to assess *AR* copy number (CN) and mutations (mut) (2105T > A (p.L702H) and 2632A > G (p.T878A) status in plasma DNA from 171 patients (pts) treated with abi/enza in biomarker protocols at 2 institutions. The aim to evaluate plasma *AR* was defined after sample collection but prior to analysis. **Results:** We first optimised multiplex ddPCR to accurately define *AR* status and identified an *AR* CN cutpoint = 2.01 as having the greatest likelihood to split pts into 2 prognostic groups. We confirmed a strong agreement between ddPCR and NGS for quantitating *AR* CN and mut allelic frequency (Bland-Altman test: mean difference -0.02 95%CI -2.45 to 2.41; mean difference -0.01 95%CI -0.015 to 0.016 respectively). *AR* CN gain was observed in 10 (14%) pre- and 33 (34%) postdoc pts and associated with a worse OS (HR 3.98 95%CI 1.74-9.10 p < 0.001; HR 3.81 95%CI 2.28-6.37 p < 0.001 respectively), PFS (HR 2.18 95%CI 1.08-4.39 p = 0.03; HR 1.95 95%CI 1.23-3.11 p = 0.01 respectively) and PSA decline ≥50% (OR 4.7 95%CI 1.17-19.17 p = 0.035; OR 5.0 95%CI 1.70-14.91 p = 0.003 respectively). *AR* mut were observed in 8 (11%) postdoc but no pre-doc abi-treated pts and also associated with worse OS (HR 3.26 95%CI 1.47-not reached p = 0.004). There was no interaction between *AR* and doc status (p = 0.83 for OS, p = 0.99 for PFS). Multivariate analysis, adjusting for *AR* CN and mut, previous doc, double stranded DNA concentration, LDH, confirmed *AR* status was independently associated with OS (HR 3.77 95%CI 2.42-5.88 p < 0.001 and HR 2.76 95%CI 1.26-6.07 p = 0.011 for *AR* CN and mut respectively) and PFS (HR 1.96 95% CI 1.32-2.93 p = 0.001). **Conclusions:** Plasma *AR* status assessment using multiplex ddPCR identifies CRPC with worse outcome to enza/abi in pre/postdoc CRPC. Additional clinical qualification is available from the PREMIERE study (Grande et al;ASCO2017;Abstract#). Prospective evaluation of treatment decisions based on plasma *AR* is now required.

5061 Poster Session (Board #135), Mon, 1:15 PM-4:45 PM

Comprehensive molecular profiling of multi-focal prostate cancer and concomitant lymph node metastasis: Implications for tissue-based prognostic biomarkers. *First Author: Simpa Samuel Salami, University of Michigan, Ann Arbor, MI*

Background: Current tissue-based prognostic biomarker assays claim that assessment of a single biopsy focus is sufficient to predict disease behavior. We analyzed and compared the genetic profiles of multifocal prostate cancer (PCa) with concordant lymph node metastasis (LNM) to determine if expression-based prognostic tests are robust to multifocality. **Methods:** This IRB-approved study comprised patients who underwent radical prostatectomy and lymph node dissection that revealed N1 or discordant multifocal (low- and high-grade foci) disease. DNA and RNA were co-isolated from each tumor focus pre-identified on formalin fixed paraffin embedded specimens. High depth, targeted DNA and RNA next generation sequencing was performed to characterize the molecular profile of each sample, using the Oncomine Comprehensive (11 patients) or Comprehensive Cancer (DNA, 3 patients) Panels and a custom targeted RNAseq panel comprising genes for deriving prognostic signatures. **Results:** A total of 67 primary tumor and 17 LNM foci from 14 patients were analyzed. We observed significant intra- and inter-patient molecular heterogeneity. For example, in patient #1, while all 4 regions of high-grade primary tumor showed *TP53* somatic mutations and some copy number alterations (CNAs) with two samples from the LNM, tumor areas near the positive margin showed more complete concordance than intraprostatic regions. Critically, a low-grade primary tumor focus in this case showed no somatic mutation or CNA overlap with the high-grade or LNM samples. In patient #4, all tumor and LNM foci shared a large number of somatic mutations, including a frameshift mutation in *PTEN*, with no high level CNA, consistent with a hypermutated genotype. By targeted RNAseq, low- and high-grade tumors from the same patient showed distinct expression profiles using genes included in prognostic signatures. **Conclusions:** Our results challenge the claim that expression-based prognostic tests are robust to multifocality. Further studies are needed to better characterize the biologically dominant lesion in multifocal PCa and hold promise for the development of improved prognostic biomarkers.

5062 Poster Session (Board #136), Mon, 1:15 PM-4:45 PM

Association of loss of tumor suppressor ZFP36 with lethal prostate cancer. *First Author: Christopher Sweeney, Department of Medical Oncology, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: Inflammation has been linked to prostate cancer (PCa) progression which may be mediated by the transcription factor nuclear factor kappa B (NFκB). Using a bioinformatic screen focused on NFκB pathway activation in lethal PCa, we identified the tumor suppressor *ZFP36* as a key node of the NFκB network. We also showed in vitro that *ZFP36* expression was inversely associated with both NFκB-controlled gene levels and proliferation and sensitivity to enzalutamide. We examined the role of *ZFP36* and PCa progression in patient cohorts. **Methods:** The association between low mRNA expression of *ZFP36* (levels in the lower quartile) and lethal PCa (defined as metastatic disease or death) was assessed with logistic regression among men with localized PCa in two independent cohorts treated with radical prostatectomy (RP). The discovery cohort was RP samples from Health Professional Follow-up Study and Physicians Health Study and the validation cohort was RP samples from Cleveland Clinic, Mayo Clinic, Johns Hopkins and MSKCC. In a third cohort from Cornell University, *ZFP36* expression levels were assessed in RP samples from patients with localized PCa and biopsies of metastatic castration resistant prostate cancer (mCRPC). **Results:** Table 1 shows men with localized PCa and lower quartile of tumor *ZFP36* expression had a nearly 2-fold higher risk of lethal PCa after adjusting for known clinical and histological prognostic features (age, RP Gleason score, T-stage); an association confirmed in the validation cohort. *ZFP36* gene expression was also significantly lower in mCRPC (n=53) compared with a localized RP cohort (n=68) (p-value <0.0001). **Conclusions:** In humans lower *ZFP36* in RP specimens is associated with clinically significant risk of lethal PCa after treatment with curative intent and lower *ZFP36*levels are found in metastatic tissue.

	HPFS/PHS Cohort (Discovery)	Multi-institutional (Validation)
Platform	Affymetrix HuGene 1.0 ST	Affymetrix HuExon 1.0 ST

5063 Poster Session (Board #137), Mon, 1:15 PM-4:45 PM

A 17-gene panel for prediction of adverse surgical pathology in the setting of MRI-guided prostate biopsy. *First Author: Amirali Salmasi, University of California, Los Angeles, Los Angeles, CA*

Background: A 17 gene panel (Oncotype Dx Genomic Prostate Score, GPS) has been validated as an independent predictor of adverse pathology (AP, defined as pathological GS 4+3 or higher and/or pT3+) in men treated with radical prostatectomy (RP) for prostate cancer (PCa). Multiparametric Magnetic Resonance Imaging (mpMRI) may help guide prostate biopsies. We explored synergies between GPS and mpMRI to aid in PCa management decisions. **Methods:** A cohort of men with NCCN Low and Intermediate-Risk PCa who were managed with RP was identified from a clinical database. Patients were required to have had a simultaneous mpMRI-guided and systematic biopsy and to have undergone RP within 6 months. Biopsy tissue of the highest Gleason pattern was used for calculation of GPS. The primary endpoint was AP. Secondary endpoints included the range of GPS within UCLA prostate MRI risk groups and median GPS when there was discrepancy between MRI and systematic biopsy Gleason Score (GS). Logistic regression models were fit to evaluate the relationship between GPS (per 20 units) and AP. **Results:** 134 men met criteria for the primary endpoint. Median age was 62 years (range 46-77). NCCN Low & Intermediate-Risk PCa was present in 16%, and 84% of men, respectively. Biopsy GS 3+3/3+4/4+3 was present in 19%, 67%, and 13%, respectively. In a univariable model, GPS was associated with AP (OR 3.8, 95% CI 2.1 to 7.4, $p < 0.001$). After adjustment for highest biopsy GS and clinical T-stage, GPS remained significantly associated with AP (OR 3.4, 95% CI 1.8 to 6.8, $p = 0.0004$). A wide and overlapping distribution of GPS was noted across UCLA MRI prostate risk groups, indicating that GPS provides information that is distinct from what can be determined from mpMRI. When there was a discrepancy between mpMRI and systematic biopsy GS, mpMRI targeted lesions with higher GS had higher median GPS (33, range 13-70) than systematic biopsies with higher GS (median GPS 25, range 15-55). **Conclusions:** GPS provides independent and complementary prognostic information to mpMRI-guided biopsies. The combination of mpMRI for biopsy guidance and GPS for molecular analysis may optimize prediction of AP and improve patient selection for treatment versus surveillance.

5064 Poster Session (Board #138), Mon, 1:15 PM-4:45 PM

P53 status in primary tumor predicts efficacy of first-line abiraterone and enzalutamide in castration-resistant prostate cancer patients. *First Author: Benjamin Louis Maughan, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: We tested whether tissue-based analysis of p53 and PTEN genomic status, measured predominantly in primary tumor samples, may be predictive for sensitivity to abiraterone and enzalutamide in castration resistant prostate cancer (CRPC). **Methods:** We performed a retrospective analysis of 309 consecutive patients with CRPC treated with first-line abiraterone or enzalutamide. Of these, 116 men (38%) had available tumor tissue for analysis, and formed the basis of this study. Deleterious *TP53* missense mutations and *PTEN* deletions were interrogated using genetically validated immunohistochemical assays for p53 protein nuclear accumulation and PTEN protein loss. OS and PFS were compared between patients with and without p53 and/or PTEN alterations. **Results:** 46% of evaluable cases had PTEN loss and 27% had p53 nuclear accumulation. 45% (53/118) of cases underwent targeted next generation sequencing and p53 nuclear accumulation was 91% sensitive and 90% specific for underlying *TP53* missense mutation. OS and PFS did not differ significantly according to PTEN status but were associated with p53 status. Median OS was 15.8 months (95% CI, 15.8–23.9) and 28.7 months (95% CI, 28.7–42.7) for men with and without p53 nuclear accumulation, respectively (HR 1.98; P = 0.007). Median PFS was 5.5 months (95% CI, 3.53–10.5 months) and 10.2 months (95% CI, 7.37–13.3 months) in men with and without p53 nuclear accumulation, respectively (HR 1.73; P = 0.013). In multivariable analyses, p53 status was independently associated with both OS (HR 2.13; P = 0.016) and PFS (HR 1.83; P = 0.034). This effect was also seen in the subset of patients with prostatectomy tissue only. In patients with p53 nuclear accumulation median PFS ($p < 0.001$) and median OS ($p < 0.001$) were decreased compared to wild-type patients. No effect was seen with PTEN loss in either PFS ($p = 0.12$) or OS ($p = 0.50$). **Conclusions:** p53 status may be a biomarker of sensitivity to novel hormonal therapies in CRPC. PTEN was not a biomarker of sensitivity in our study. These results require prospective validation.

5065 Poster Session (Board #139), Mon, 1:15 PM-4:45 PM

Linking tumor mutational load to clinical responses to ipilimumab (IPI) in men with advanced prostate cancer (PCa). *First Author: Sumit Kumar Subudhi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tumor mutational load and neoantigens have been associated with responses to immune checkpoint therapies in patients (pts) with melanoma and lung cancer. We designed a clinical trial (NCT02113657) in advanced PCa to determine whether the induction of antitumor responses by IPI correlate with T cell responses to PCa neoantigens. **Methods:** All advanced PCa pts enrolled into this study had sufficient DNA/RNA from tumor tissue obtained prior to receiving IPI (3 mg/kg every 21 days for up to 4 doses) for whole-exosome sequencing (WES) and RNA-seq. **Results:** Twenty-one of 30 pts have been enrolled. Nine (43%) have received all 4 doses of IPI. IPI was discontinued prematurely in 9 pts (43%) due to drug-related toxicities and in 3 (14%) due to disease progression. All 3 of the latter had liver metastases. To date, tumors from 13 pts have been comprehensively analyzed by WES and RNA-seq. The median time from IPI #1 to the next systemic therapy for these pts was 24 weeks (IQR, 18.3 – 54.3). Responders (R) were defined as pts whose time to next systemic therapy was > 24 weeks. The median time to next systemic therapy for R (n = 7, 54%) is 55 weeks (IQR, 52.0 – 89.0; 2 pts with ongoing responses) versus 18 weeks (IQR, 10.5 – 23.0) for non-responders (NR; n = 6, 46%). In an analysis of all 13 pts, including those with liver metastases, tumor mutational load and frequency of expressed non-synonymous mutations were similar for R and NR pts. However, a subset analysis, excluding pts with liver metastases, revealed > 100 total mutations and/or > 10 expressed non-synonymous mutations in 7/7 R versus 1/4 NR. **Conclusions:** For advanced PCa pts without liver metastases, tumor mutational load may be associated with responses to IPI. Identification of immunodominant neoantigens may lead to the development of personalized vaccines to be combined with immune checkpoint therapies for the effective treatment of pts with PCa. Clinical trial information: NCT02113657.

5066 Poster Session (Board #140), Mon, 1:15 PM-4:45 PM

History of PSA screening on prostate cancer aggressiveness. *First Author: Jennifer Cullen, Center for Prostate Disease Research, Rockville, MD*

Background: In 2012, PSA screening for prostate cancer (CaP) detection was given a "Grade D" recommendation for all men by the USPSTF. Recent U.S. studies report declines in PSA screening with concomitant increases in advanced CaP at diagnosis. This study examined the association between PSA screening history and CaP aggressiveness in a racially diverse, military cohort with equal health care access. **Methods:** This retrospective cohort study evaluated CaP patients undergoing radical prostatectomy (RP) from 1994-2015 at Walter Reed National Military Medical Center. Whole-mounted prostatectomy specimens were classified using 2014 ISUP Gleason grading system. Excluding the diagnostic PSA, screening history was categorized as: ≥ 6 PSA's prior to CaP diagnosis (uppermost quartile), 1-5 (lower 3 quartiles), vs. no screening history. Multivariable logistic regression (MLR) was used to examine NCCN risk stratum (intermediate-high vs. low) and Gleason upgrade (GU) from biopsy to RP. Multivariable Cox proportional hazards (Cox PH) analyses were used to model time to biochemical recurrence (BCR). Multivariable models controlled for age at RP, race, family history and obesity (BMI $>$ 30 vs. $\leq$ 30 kg/m^2). The GU and BCR models also controlled for NCCN risk classification. **Results:** There were 1,772 eligible patients with a median follow-up and age at RP of 7.0 and 59.8 years, respectively. Prior to CaP diagnosis, 42% and 19% of men had 1-5 and $\geq$ 6 PSA's screenings, respectively. MLR showed greater odds of intermediate or high vs. low risk disease for PSA screening history of none vs. 1-5 (OR = 1.33, CI = 1.03-1.70, p = 0.028) but not for none vs. $\geq$ 6 (p = 0.44). MLR showed increased odds of GU for none vs. $\geq$ 6 (OR = 1.81, CI = 1.23-2.7, $p < 0.001$). Multivariable Cox PH models showed incrementally poorer BCR-free survival as screening history decreased ($HR_{None\ vs.\ \geq 6} = 2.27$, CI = 1.54-3.33, $p < 0.001$; $HR_{None\ vs.\ 1\text{-}5} = 1.49$, CI = 1.15-1.92, p = 0.002). **Conclusions:** In this RP cohort, higher risk stratum, increased GU, and poorer BCR-free survival were associated with no PSA screening history. BCR-free survival was incrementally worsened by less PSA screening. A complete absence of PSA screening may lead to more aggressive disease at presentation and poorer clinical outcomes.

Serum androgens and survival in metastatic castration resistant prostate cancer (mCRPC) patients treated with docetaxel and prednisone: Results from CALGB 90401 (Alliance). *First Author: Charles J. Ryan, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Higher baseline androgens have been previously shown to be associated with an improved overall survival (OS) in mCRPC patients treated with the androgen synthesis inhibitors, ketoconazole or abiraterone. The purpose of this analysis was to determine whether baseline serum androgen levels (Testosterone (T), Androstenedione (A) and DHEA (D) are associated with OS in mCRPC patients treated with docetaxel-based chemotherapy. **Methods:** Data from 1,050 men treated on CALGB 90401 with docetaxel, prednisone and either bevacizumab or placebo were used. Eligibility required progressive mCRPC and no prior chemotherapy. Pre-treatment serum assays for T, A and D were performed via tandem Liquid Chromatography-Mass Spectrometry (LC-MS/MS) at NMS labs. The proportional hazards model was used to assess the prognostic significance of T, A, and D in predicting OS adjusting for known prognostic factors. **Results:** Median values for T, A, and, D were 1.00, 13.00 and 8.12, ng/dL respectively.Values above the median were defined as low, above as high. Median OS for low vs high levels was 22.7 and 23.1 month for T, 22.4 and 21.7 month for A and 21.8 and 24.0 month for D, respectively, all NS. In multivariable analysis adjusting for 10 known prognostic values and prior keto use in mCRPC (Halabi JCO 2014), A (p-value = 0.013) levels were associated with OS. The HR for A was = 0.99 (95% CI = 0.98-0.99). **Conclusions:** In multivariate analysis, baseline androstenedione levels are prognostic factors for OS in mCRPC patients receiving chemotherapy. Low or undetectable levels of other androgens are associated with shorter OS, consistent with prior results in androgen synthesis inhibitor treated pts in both the chemotherapy naive and post chemotherapy settings. This relationship may reflect more aggressive tumor biology that evolves in an extreme androgen deprived milieu. Clinical trial information: NCT00110214.

Translating prostate cancer working group (PCWG) criteria into a quantitative progression biomarker in metastatic castration resistant prostate cancer (mCRPC). *First Author: Aseem Anand, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: mCRPC is a bone dominant lethal disease. A validated endpoint in mCRPC trials is bone scan progression, which is semi-quantitative and rely on the appearance of new lesions as proposed by the PCWG. The validated automated bone scan index (BSI) quantifies the bone tumor burden as the fraction of total skeletal weight. To build on the current definition of disease progression, we sought to compare the association of time to progression with overall survival (OS) using PCWG criteria and BSI increase. **Methods:** mCRPC patients (pts) enrolled on trials of agents targeting androgen-receptor (AR) were assessed. Pts were required to have a raw bone scan image for BSI analysis concurrent with disease assessments. The EXINI automated computing platform generated the BSI values. Thresholds for the absolute and relative increase in BSI from 1st follow-up ($\leq$12 weeks) were explored for the time to BSI progression. The association with survival time was computed for each threshold defined time to BSI progression. Kendall's Tau, derived from the Clayton copula, was used to associate time to BSI progression with survival time, where both endpoints may be censored. **Results:** A total of 257 pts were assessed, of whom 169 had raw bone scans images needed for the BSI analysis. 90 pts (53%) met progression by PCWG criteria, the association between the time to PCWG progression and OS was 0.52. The association between time to BSI progression and OS was comparable to the PCWG progression when the absolute increase in BSI was 0.6 or more (table below). **Conclusions:** Progression in bone can be expressed as a single quantitative metric that describes the increase in total disease burden while retaining the same association that PCWG has with OS. These data represent the first steps to a quantitative expression of bone disease progression as a clinical trials endpoint.

		Proportion progressed	OS correlation
Absolute BSI increase			
	0.2	0.58	0.34
	0.4	0.47	0.41
	0.6	0.41	0.51
	0.8	0.36	0.52
	1.0	0.29	0.52
Relative BSI Increase			
	30%	0.53	0.25
	60%	0.39	0.29
	90%	0.31	0.41
	120%	0.26	0.49
	150%	0.23	0.50

Validation of cAMP phosphodiesterase-4D7 (PDE4D7) for its independent contribution to risk stratification in a prostate cancer patient cohort with longitudinal biological outcomes. *First Author: Jos Rijntjes, Philips Research Europe, Eindhoven, Netherlands*

Background: In this study we present the retrospective validation of the prognostic prostate cancer biomarker PDE4D7 in predicting longitudinal biological outcomes in a historical cohort of radical prostatectomy patients. **Methods:** Biopsy punches from 550 patients were collected from a representative tumor area of FFPE surgical resections. RNA was extracted and PDE4D7 quantified by one-step RT-qPCR. PDE4D7 scores were calculated by normalization of PDE4D7 to the averaged expression of four reference genes. The independent prognostic value of the PDE4D7 scores were evaluated using uni- and multivariate Cox proportional hazard regression. Multivariate analyses were adjusted for clinical prognostic variables. Post-surgical outcomes tested were: PSA relapse, start of salvage treatment, progression to metastases, overall and prostate cancer specific mortality. Logistic regression was used to create a combined prognostic model of PDE4D7 with clinical risk and tested in outcome prediction. **Results:** The PDE4D7 score was significantly associated with time to PSA failure after prostatectomy (HR 0.53; 95% CI 0.41-0.67 for each unit increase; $p < 1.0E\text{-}04$). After adjustment for pathology Gleason, pT stage, surgical margin status, and seminal vesicle invasion the HR was 0.55 (95% CI 0.43-0.72; $p < 1.0E\text{-}04$). Patients with a high PDE4D7 score that were clinically classified as intermediate to high risk of progression were re-classified into a group with an average progression risk less than the average cohort risk of clinically very low risk patients. The maximum benefit, compared to Gleason score, was observed in the clinically intermediate favorable risk group. Combining clinical risk with PDE4D7 scores improved the overall risk stratification. **Conclusions:** The PDE4D7 score has potential to provide independent risk information and, in particular, to re-stratify patients with clinical intermediate to high risk characteristics to a very low risk profile.

5070 Poster Session (Board #144), Mon, 1:15 PM-4:45 PM

Baseline CTC subtype to predict outcomes on mCRPC patients (pts) receiving enzalutamide (E) compared to abiraterone (A). *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prior response to A or E does not predict sensitivity to E following A or A following E. The detection of AR-V7 predicts insensitivity to either drug, but identifies only a portion of non-responders. We previously identified 15 CTC subtypes based on unique phenotypic features in mCRPC pts, each with unique biology and different degree of likelihood of predicting resistance to either drug. Here we explored the relationship between individual subtypes and sensitivity to A vs. E, but not both. **Methods:** 107 pre-treatment blood samples from mCRPC pts starting A (n = 47) or E (n = 60) as a 1st or 2nd line of Tx were analyzed for CTCs utilizing the Epic Sciences platform. Samples were assayed for CTC subtypes based upon 15 pre-defined phenotypic CTC classifiers (Type A-O). Treatment outcomes were assessed by serial PSA changes and landmarked percent time of therapy progression on radiographs, and overall survival following either A or E. Cell type prevalence was also analyzed in relation to clinical outcomes, and subsets of the CTC subtypes subject to single cell NGS to ascertain genomic drivers common to each subtype. **Results:** CTCs were identified in 94% (101/107) of pt samples. One, cell Type K, found in 25% (27/107) of pts, was associated with a statistically significant inferior outcomes on E for all measures. Whereas similar outcomes were seen between K+ & K- pts treated with A. The distinct features of Cell Type K include a large nucleus, high nuclear entropy and high Nuclear/cytoplasmic AR terminal ratio; and a unique genomic profile enriched for cell cycle and DNA repair alterations relative to other CTC subtypes. **Conclusions:** The presence of specific CTC subtypes in pre-Rx phlebotomy samples associated with outcomes on A or E. A CTC subtype (Cell Type K) helped to identify pts with poor outcomes on E but not A vs. those without the cell type. Further biologic interrogation of K cells and ongoing clincial validation of the CTC subtype is planned.

Pt outcomes on E by baseline Cell K status.

Cell K Status	% of Pts by status	% of Pts w/>50% PSA decline	% of Pts w/ >6 mo Time on Tx	% of Pts w/ >6 mo rPFS	% of Pts w/ >1 y OS
K+ (n=14)	23%	29%	43%	43%	29%
K- (n=46)	77%	63%	74%	74%	71%

5071 Poster Session (Board #145), Mon, 1:15 PM-4:45 PM

Phase 1-2 study of progesterone receptor (PR) inhibition with extended-release (ER) onapristone (ONA) alone or in combination with abiraterone (AA) in patients (pts) with castration-resistant prostate cancer (CRPC) incorporating plasma DNA analysis to define androgen receptor (AR) status. *First Author: Anuradha Jayaram, Institute of Cancer Research and The Royal Marsden NHS Trust Foundation, Sutton, United Kingdom*

Background: An urgent need exists for new therapies after progression (PD) onAA and enzalutamide (ENZ). Increased PR expression or progesterone-activating AR mutations have been associated with resistance to AR targeting. We aimed to test ONA, a type I PR antagonist with clinical activity in PR^{pos} cancers, in AA/enz-resistant CRPC. In a prospectively defined exploratory analysis, we aimed to report outcome by plasma *AR* status (*pAR*). **Methods:** This was a multi-institution, open label phase I/II clinical trial in pts progressing after ENZ/AA. Pts were first treated with single agent (SA) ONA using a randomised dose escalation design. ONA at 2 doses was then combined with AA (1000mg od with pred 5mg bid) in pts progressing on AA. The primary end-points were safety, pharmacokinetics (PK) and anti-tumor activity split by p*AR*. Archival and metastatic biopsies were collected when possible and tested for PR status. p*AR* was studied using previous methods (Romanel STM 2015). **Results:** 21 pts received SA ONA (5 = 10mg/ 5 = 20mg/ 4 = 30mg/ 4 = 40mg /3 = 50mg BID) and 15 pts received ONA-AA combination (5 = 30mg ONA BID, 10 = 50mg ONA BID). There were not DLTs or significant LFT abnormalities and no G3/4 adverse events (AE), no treatment discontinuations due to AEs and no SAEs considered related to ONA. PK in SA ONA observed active plasma concentrations and no interaction with AA. Of 32 evaluated pts 15 had a 2105T > A (p.L702H) or 2632A > G (p.T878A) AR mutation detected in plasma pre-treatment and 1 had AR copy number gain. PSA declines were not observed with SA ONA but in 2 pts with combination (-30%, -7%) who were AR normal. The rPFS on SA ONA was 2.8 months for AR normal and 2.6 for AR aberrant (Hazard ratio (HR) 1.41; 95% CI, 0.62-3.72; P 0.48) and on combination was 4.4 months for AR normal (8/15) and 2.2 for AR aberrant (7/15) (HR 6.08; 95% CI, 6.32-221.9; P < 0.001). **Conclusions:** ONA is safe in CRPC as SA and in combination with AA. There was no difference in rPFS by p*AR* status for SA ONA but on the combination with AA, pts who were plasma *AR* normal had a significantly longer rPFS. Clinical trial information: NCT02049190.

5072 Poster Session (Board #146), Mon, 1:15 PM-4:45 PM

Indentification of a CTC-based gene expression signature predicting resistance to abiraterone and enzalutamide in mCRPC. *First Author: Todd Matthew Morgan, University of Michigan, Ann Arbor, MI*

Background: Circulating tumor cell (CTC)-based detection of AR-V7 has been shown to be one potential marker for predicting response to 2nd generation androgen receptor (AR) therapies. However, the apparent rarity of AR-V7 positivity is indicative of the importance of other drivers of resistance in this setting. We sought to utilize a multiplex gene expression platform for assessing CTCs in order to determine other predictive biomarkers of response. **Methods:** Whole blood (~5mL) was obtained from 37 patients with mCRPC starting enzalutamide (n=16) or abiraterone (n=21). CTCs were isolated using anti-EpCAM-conjugated magnetic beads. Following cell lysis, mRNA was extracted followed by multiplex qRT-PCR for 92 prostate cancer-related genes. Samples were considered CTC-positive based on a previously established set of epithelial markers. We identified genes associated with PSA and radioclinical progression free survival (PFS) using Cox regression analysis. Muli-gene models were tested using ROC analysis. **Results:** We identified 20 patients (54%) with detectable CTCs, and patients were followed for a median of 10 months (IQR 3.9-19.4 months). Seven genes were associated with both PSA PFS and radioclinical PFS in the Cox analyses (Table). Combing the 7 genes into a single model gave AUC values of 0.88 for PSA PFS and 0.89 for radioclinical PFS. In comparison, the AR-V7-only model resulted in AUC values of 0.65 and 0.66. **Conclusions:** We identified seven prostate cancer-related genes that can be determined from CTCs and appear to predict short time to progression in men with mCRPC being treated with 2nd generation hormonal therapies. While this is a small cohort and prospective validation is needed, these findings highlight the potential role for this approach in helping guide therapy choice.

	PSA PFS			Radioclinical PFS		
Gene	HR	95% CI	p Value	HR	95% CI	p Value

Development and external validation of a novel risk score to identify insignificant prostate cancer. *First Author: Lorenzo Dutto, Klinik für Urologie, Kinderurologie und Urologische Onkologie, Prostatazentrum Nordwest, St. Antonius-Hospital, Gronau, Germany*

Background: Active surveillance is increasingly used for insignificant prostate cancer (PCa). In order to identify suitable patients, risk scores have been developed which use pre-operative factors. We evaluated the accuracy of 9 separate tools developed to identify patients harbouring insignificant PCa in 2613 patients who underwent radical prostatectomy for Gleason 3+3 PCa. We have developed and validated a novel risk score to correctly identify insignificant PCa for use in unscreened patient cohorts using non-dichotomised clinical predictors. **Methods:** 2799 patients who would have been candidates for AS (Gleason score 6 only) patients underwent robotic radical prostatectomy between 2006 and 2016 at a tertiary referral center. The volume and grade of tumour in the resected prostate was analysed. Insignificant PCa was defined as Gleason 3+3 only, index tumour volume <1.3 cm3 , total tumour volume <2.5 cm3 (updated ERSPC definition). 2613 patients were included in the final analysis. We computed the accuracy (specificity, sensitivity and area under the curve (AUC) of the receiver operator characteristic) of 9 predictive tools. Multivariate logistic regression with elastic net regularisation was used to develop a novel tool to predict insignificant prostate cancer using age at diagnosis, baseline PSA, TRUS volume, clinical T-stage, number of positive cores and percentage of positive cores as predictors. This tool was validated in an external cohort of 441 unscreened patients undergoing surgery for Gleason 6 PCa. **Results:** All of the predefined tools rated poorly as predictors of insignificant disease as none of them reached the required AUC threshold of 0.7. The new tool performed well in training and validation cohorts. **Conclusions:** Pre-existing predictive tools to identify indolent PCa have a poor predictive value when applied to an unscreened cohort of patients. Our novel tool shows good predictive power for insignificant PCa in this population in training and validation cohorts. The inherent selection bias due to analysis of a surgical cohort is acknowledged.

	Training data	Validation data
N-Total	2799	441
N-insignificant PCa	1045	65
AUC (95% CI)	0.756 (0.737- 0.774)	0.757 (0.699- 0.815)

5074 Poster Session (Board #148), Mon, 1:15 PM-4:45 PM

Association of risk of clinical recurrence (CR) and prostate cancer death (PCD) with a 17-gene genomic prostate score (GPS) value <20. *First Author: Phillip G. Febbo, Genomic Health, Redwood City, CA*

Background: Over-treatment of localized prostate cancer (PC) can result from over-estimation of a patient's risk of CR and PCD. GPS (scale 0-100) has been validated to predict adverse pathology, biochemical recurrence, metastasis, and PCD and provides a more accurate overall assessment of patient risk than clinical risk factors alone. A recent validation study found that no patients with AUA Low- or Intermediate-risk disease and a GPS of <20 developed PC metastases or PCD. Here, 2 large longitudinal PC cohorts were analyzed to estimate the risk of CR and PCD for GPS <or >20 units. **Methods:** Data from Klein et al. European Urology (EU) 2014 and Cullen et al. EU 2014 were analyzed to establish the risk of CR and PCD associated with a pre-established GPS cut-point of 20. Patients were divided based on the value of GPS (≤20, >20). Cox regression analyses accounted for cohort sampling weights. Since GPS was developed using Klein et al, standardized hazard ratios (std HR, HR for 1 SD change in the covariate) for GPS and CR and PCD survival curves for the 2 groups were estimated correcting for regression to the mean (RM). **Results:** Of the 402 patients in Cullen et al. (median follow up 5.2 years), only 5 patients developed metastases; all 5 had GPS >20. For Klein et al., of 426 patients with a median follow up of 6.6 years, there were 109 CR (metastasis and local recurrence) and 39 PCD; only one patient with events had a GPS <20. Overall 28% of patients had GPS <20. GPS was a significant predictor for both CR (std HR 2.50 (95%CI 1.99, 3.15, p <0.001, RM-corrected std HR 2.16, FDR <0.1%) and PCD (std HR 2.90 (95% CI 2.06,4.06, p<0.001, RM-corrected std HR 1.96, FDR <0.1%) after adjustment for AUA group. Men with intermediate risk prostate cancer and a GPS score of < 20 have a 2.6% and 0.7% 10-year RM-corrected risk of CR and PCD, respectively (Table 1). **Conclusions:** GPS strongly predicts risk of CR and PCD in men with AUA Low- or Intermediate-risk PC. Patients with a GPS score <20 have a very low risk of CR or PCD and should be considered for AS.

Estimated 10-year RM-corrected risk of CR PCD.

AUA Risk Group	GPS Group	CR risk	PCD Risk
Low	≤ 20	1.8%	0.5%
	> 20	4.3%	1.0%
Intermediate	≤ 20	2.6%	0.7%
	> 20	10.9%	3.1%
High	≤ 20	6.0%	2.1%
	> 20	21.2%	7.8%

5075 Poster Session (Board #149), Mon, 1:15 PM-4:45 PM

PSA doubling time (PSADT) and proximal PSA value predict metastasis-free survival (MFS) in men with biochemically recurrent prostate cancer (BRPC) after radical prostatectomy (RP). *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: We previously reported a relationship between PSADT and MFS in BRPC post RP (Pound 1999; Freedland 2007; Antonarakis 2012). In men with PSADT<12 months, who are at high risk of lethal PCa, we sought to identify a PSA cutpoint (proximal PSA; PP) that indicates the imminent emergence of metastasis (M+). In this report we combined Center for Prostate Disease Research and Johns Hopkins (CPDR/JHU) databases to investigate the association of the PP value on MFS in men with BRPC and PSADT <12 mos. **Methods:** In the CPDR/JHU RP database (31,296), 513 men with BCR (>0.2ng/ml) with PSADT <12 mos who received no adjuvant/salvage ADT/RT were prospectively followed until radiological evidence of M+ are included in this analysis. All patients were evaluated yearly with >1 PSA and scans at regular intervals until M+. Associations with MFS were compared using logrank test and Cox regression. The PP is the most recent value >6 months prior to M+/censor. **Results:** M+ occurred in 218 of 513 patients with BRPC (median follow up 9 years). Risk of M+ increased successively for PSADT 6.0-7.5, 4.5-6, 3.0-4.5, and <3.0 months, adjusted for pT stage and Gleason score. PP ≥10ng/ml significantly increased risk of M+ in pts with PSADT <12 mos, regardless of PSADT subgroup, hazard ratio=2.95, p<.0001. Median MFS was 4.0 years at PP >10ng/ml vs 20 years at PP <10ng/ml. Table 1 shows median MFS and 3, 5, and 7 year MFS rates in subgroups with PSADT <3 and 3.01-6 months representing the highest risk groups. **Conclusions:** In men with PSADT<12 months, PSADT subgroups <7.5 months and PP >10ng/ml are independent predictors of MFS, adjusted for pT stage and Gleason score. PP ≥10ng/ml further define risk of M+ in BRPC with PSADT<12 months. These data can assist physicians in patient counseling and clinical trial design.

	PSADT < 3 mos			PSADT 3.01-6.0 mos

5076 Poster Session (Board #150), Mon, 1:15 PM-4:45 PM

Changes in CTC burden and prevalence of specific CTC subtypes in mCRPC patients (pts) receiving alpharadin (Ra-223) as single agent or in combination with other therapuetics (Tx). *First Author: Ryan Vance Dittamore, Epic Sciences, Inc., San Diego, CA*

Background: Ra-223 prolongs life in mCRPC pts with symptomatic osseous metastasis with inconsistent effects on PSA. Survival times are prolonged further when combined with Abi/Enza. Data from preclinical studies suggest that Ra-223 may sensitize tumors to DDR agents and/or biologic therapies. But predictive biomarkers of benefit to each or both combinationso are lacking. We studied CTC counts and the prevelance of specific CTC subtypes in patients before and following Ra-223 therapy, both as a single agent and in combination, to identify biomarkers of sensitivity and treatement efficacy, and effects of Ra-223 on tumor biology. **Methods:** Pre and ~4 week post RA-223 therapy blood samples were collected from 35 pts (2 samples each) given as a single agent (n = 20 pts) or in combination with other therapies (n = 15 pts, 9 w/ Enza, 5 w/ Abi, 1 w/ Taxane). Samples were processed and CTCs analyzed using the Epic Sciences platform. Total CTC count and the prevalence of specific CTC phenotypes present pre and post Rx were identified utilizing high content digital pathology and associated with therapy type and post-treatment change. **Results:** CTC declines were observed in 55% (11/20) and 60% (9/15) of pts treated with single agent and combination respectively. In Ra-223 alone pts, a novel CTC subtype (high N/C ratio, high nuclear area) was identified at baseline 11/20 samples (med = 33% of CTCs). Which was no longer detected in 10 (90%) of the pts treated. This contrasts with a second novel CTC subtype present at baseline in 4 pts (med CTC = 9%) that increased to 9 cases (med CTC = 18%) at follow-up. **Conclusions:** A subset of pts demonstrate post-therapy CTC declines following Ra-223 alone or in combination. A novel CTC subtype resolved by RA-223 in conjunction with total CTC kinetics may indicate pt benefit from Ra-223. A novel emergent CTC subtype has also been identified in pts already receiving Ra-223. Single CTC sequencing and protein analysys of these CTC subtypes are ongoing, and may help describe tumor evolution and sensitization to novel therapuetics.

5077 Poster Session (Board #151), Mon, 1:15 PM-4:45 PM

Neoadjuvant randomized trial of degarelix (Deg) ± cyclophosphamide/GVAX (Cy/GVAX) in men with high-risk prostate cancer (PCa) undergoing radical prostatectomy (RP). *First Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: GVAX-Prostate is a GM-CSF–secreting allogeneic cellular vaccine, whose immunogenicity may be enhanced by androgen ablation as well as low-dose Cy. We conducted a neoadjuvant immunologic study comparing Deg vs. Cy/GVAX→Deg. **Methods:** Men with high-risk PCa (T1c–3b N0 M0, Gleason 7–10) were randomized 1:1 to Deg(240 mg SQ) vs. Cy(200 mg/m^2 IV)/GVAX(2.5×10^8 PC3 cells, 1.6×10^8 LNCaP cells) given 2 wk before Deg; all pts then had RP 2 wk after Deg. CD8+ T cell and Treg densities in the primary tumor were quantified by IHC (cells/mm^2). Clinical endpoints were time-to-PSA-relapse, time-to-next-therapy, and time-to-metastasis. The study was powered (α = 0.05, β = 0.18) to show a 2-fold increase in mean CD8+ density with Cy/GVAX→Deg (Arm B) vs. Deg (Arm A). **Results:** 28 men were enrolled (Arm A = 15, Arm B = 13). A concurrent control group (N = 20) who did not receive neoadjuvant therapy provided untreated RP tumor samples. Baseline variables were balanced across study arms: 64% had Gleason ≥8, 56% were pT3b, 18% were pN1. There were nonsignificant increases in CD8+ and Treg densities in Arm B vs. A, and statistically significant increases in CD8+ and Treg densities in both arms (A, B) compared to group C (TABLE). CD8+ and Treg densities were strongly correlated. Outcomes were numerically better in Arm B vs A with respect to time-to-PSA-relapse (HR 0.42, 95%CI 0.13–1.38, *P*= 0.15) and time-to-next-therapy (HR 0.43, 95%CI 0.13–1.39, *P*= 0.16), although not statistically significant. **Conclusions:** Intratumoral immune infiltrates were marginally augmented by Cy/GVAX→Deg vs. Deg alone, while CD8+ and Treg densities were significantly greater in both study arms vs. control, supporting the immunogenic effects of androgen ablation. CD8+ / Treg ratios were remarkably consistent across groups. Clinical trial information: NCT01696877.

	Arm A (Deg) N = 15	Arm B (Cy/GVAX→Deg) N = 13	Control (C) N = 20	*P*
CD8+ T cell density (mean, 95%CI)	205 (121–289)	263 (129–397)	96 (72–120)	0.35 (A vs B) < 0.01 (B vs C) 0.03 (A vs C)
Treg density (mean, 95%CI)	59 (34–85)	78 (48–107)	29 (21–36)	0.18 (A vs B) < 0.01 (B vs C) 0.02 (A vs C)
CD8+ / Treg ratio (mean, 95%CI)	4.0% (2.7–5.3%)	3.9% (2.2–5.7%)	3.7% (2.9–4.6%)	0.66 (A vs B) 0.87 (B vs C) 0.68 (A vs C)

5078 Poster Session (Board #152), Mon, 1:15 PM-4:45 PM

A secondary analysis of PSA response in NRG Oncology/RTOG 9902: A phase III trial of adjuvant chemotherapy with androgen suppression and radiation for high-risk prostate cancer (CaP). *First Author: Stephen Andrew Mihalcik, Harvard Radiation Oncology Residency Program, Massachusetts General Hospital, Boston, MA*

Background: RTOG 9902 was a randomized controlled trial of the addition of adjuvant chemotherapy (CT; paclitaxel, oral etoposide, and estramustine x4 cycles) to 24 mo of androgen suppression (AS) and radiation (RT) for patients (pts) with high-risk CaP., beginning with an initial 4 mo of AS; RT began after 2 mo. 9902 accrued 397 pts and closed early due to excess toxicity. At a median follow-up of 9.2 years, there was no benefit to CT, but it is hypothesized that a subset analysis by post-RT PSA identifies pts that benefit from treatment intensification with CT. **Methods:** Post-RT PSA status was dichotomized at $>$ 0.2 ng/mL within 1 mo of RT. Landmark analysis redefined starting times for disease-free survival (DFS), time to distant metastasis (TDM) and overall survival (OS) at 16 weeks post-RT (36 weeks post-randomization) when CT was planned to complete. Pts were excluded if they did not get RT or assigned CT, or experienced DFS events/lost to follow-up $<$ 36 wks post-randomization. Hazard ratios (HR), 95% confidence intervals (CI), and PSA-by-treatment interaction were estimated by Cox or competing-risks regression. **Results:** 333 pts were analyzed: 190 without and 143 with CT. 37% of pts had a post-RT PSA $\leq$0.2, 34% $>$ 0.2, and 29% no recorded PSA in the defined interval. CT was associated with improved DFS for pts with PSA $>$ 0.2 (HR 0.59, 0.38-0.91), but not for those with PSA $\leq$0.2 (HR 0.94, 0.60-1.46; interaction p = 0.13). This association, for those with PSA $>$ 0.2, persisted in those pts who received the full course of CT and trended in the same direction for pts receiving 1-3 cycles. CT was associated with a trend toward improved TDM in the PSA $>$ 0.2 group (HR 0.56, 0.23-1.35) and not in the PSA$\leq$0.2 group (HR 1.31, 0.36-4.70), based on 32 pts with metastases. OS did not show the same pattern (PSA $>$ 0.2: HR 0.98, 0.55-1.77; PSA$\leq$0.2: HR 0.57, 0.29-1.13). **Conclusions:** This analysis suggests that men with high-risk CaP and suboptimal response to AS+RT, as identified by post-RT PSA $>$ 0.2, may benefit from adjuvant CT. Prospective trials using contemporary CT (e.g. docetaxel) will help optimize treatment for these men. NRG-GU002, recently activated, is addressing this issue.

5079 Poster Session (Board #153), Mon, 1:15 PM-4:45 PM

Long-term results of a prospective phase II study of androgen deprivation therapy, external radiation, cs-131 brachytherapy, and adjuvant docetaxel in high-risk prostate cancer. *First Author: Stephanie Rice, University of Maryland Department of Radiation Oncology, Baltimore, MD*

Background: We report the long-term results of a prospective, Phase II study of 2 years androgen deprivation therapy (ADT), 45 Gy bone marrow sparing pelvic radiation (BMS-PR), Cs-131 brachytherapy boost (85 Gy), and 4 cycles of adjuvant docetaxel (75 mg/m2 q21d + prednisone) in high risk, localized prostate cancer. **Methods:** From2006-2014,38 patients were enrolled. Acute hematologic as well as acute and chronic gastrointestinal (GI) and genitourinary (GU) toxicities were scored based on the CTCAE v3.0 criteria. Biochemical recurrence was defined as a nadir + 2 rise in PSA. Actuarial freedom from PSA failure (bNED) and overall survival (OS) were calculated using SPSS v24. Median Gleason score was 8 (74% Gleason 8-10). Median PSA was 11.2 (range 2.8-96). **Results:** A total of 38 patients were enrolled on the trial. Median age was 62 years (range 45-82). 82% of patients completed all protocol specified treatments, while 84% completed all 4 cycles of docetaxel. After a median follow up of 44 mo (range 3.4-118), the 5-year bNED rate was 86% while 5-year OS was 80%. Acute grade $\geq$ 2 GI and GU toxicity rates were 12.5% and 21.9%, respectively. Chronic grade $\geq$ 2 GI and GU toxicity rates were 3.1% and 3.1%, respectively. 25.6% (n = 10) patients receiving docetaxel developed grade 4 hematologic toxicity. There were no grade 5 toxicities. **Conclusions:** We found this aggressive multi-modal approach to be feasible, safe, well-tolerated, and effective. It does not appear that BMS-PR decreases hematologic toxicity. Cs-131, with its 9.7 day half-life, does not appear to increase acute or late toxicity. These data build upon the ASCENDE-RT and RTOG 0521 trials that demonstrate the added benefits of brachytherapy boost and adjuvant docetaxel, respectively, in high-risk prostate cancer.

5080 Poster Session (Board #154), Mon, 1:15 PM-4:45 PM

Identification of low prostate-specific antigen, high Gleason prostate cancer as a unique hormone-resistant entity with poor survival: A contemporary analysis of 640,000 patients. *First Author: David Dewei Yang, Harvard-MIT Division of Health Sciences and Technology, Harvard Medical School, Boston, MA*

Background: The clinical implications of a low prostate-specific antigen (PSA) in high-grade prostate cancer are unclear. We examined the prognostic and predictive value of a low PSA in high-grade prostate cancer. **Methods:** We identified 642,975 patients in the National Cancer Database (n = 491,505) and Surveillance, Epidemiology, and End Results program (n = 151,470) with localized or locally advanced prostate cancer from 2004-2013. Patients were stratified by Gleason score (8-10 vs. $\leq$7) and PSA ($\leq$2.5, 2.6-4.0, 4.1-10.0, 10.1-20.0, and $>$ 20.0 ng/mL) for analyses. Multivariable Fine-Gray competing risks and Cox regressions were used to analyze prostate-cancer specific mortality (PCSM) and all-cause mortality (ACM), respectively. **Results:** 5.6% of Gleason 8-10 tumors were diagnosed with PSA $\leq$2.5 ng/mL. Among Gleason 8-10 disease using PSA 4.1-10.0 ng/mL as referent, PCSM was U-shaped with respect to PSA, with adjusted hazard ratio (AHR) of 1.75 (95% CI 1.05-2.92, P = 0.032) for PSA $\leq$2.5 ng/mL vs. 1.31, 0.88, and 1.60 for PSA 2.6-4.0, 10.1-20.0, and $>$ 20.0 ng/mL. In contrast, PCSM was linear for Gleason $\leq$7 disease with AHR of 0.32 (95% CI 0.10-1.00, P = 0.050) for PSA $\leq$2.5 ng/mL vs. 1.13, 1.69, and 3.22 for PSA 2.6-4.0, 10.1-20.0, and $>$ 20.0 ng/mL ($P_{Gleason*PSA\ interaction} < 0.001$). Gleason 8-10 disease with PSA $\leq$2.5 ng/mL had a much higher risk of PCSM than standard NCCN high-risk disease (AHR 1.92, 95% CI 1.18-3.14, P = 0.009; 47-month PCSM 14.0% vs. 10.5%). For Gleason 8-10 tumors treated with definitive radiotherapy, androgen deprivation therapy (ADT) was associated with decreased ACM for PSA $>$ 2.5 ng/mL (AHR 0.87, 95% CI 0.81-0.94, P $<$ 0.001) but trended toward increased ACM for PSA $\leq$2.5ng/mL (AHR 1.27, 95% CI 0.89-1.81, P = 0.194; $P_{ADT*PSA\ interaction} = 0.026$). **Conclusions:** Low PSA, high-grade prostate cancer appears to be a unique hormone-resistant entity with a high risk of PCSM that responds poorly to standard treatment. Further molecular classification and trials are urgently needed to develop biological insight into this entity and establish new treatment paradigms, potentially including chemotherapy or novel systemic agents.

5081 Poster Session (Board #155), Mon, 1:15 PM-4:45 PM

Investigation of mechanisms of resistance to ipilimumab therapy with a pre-surgical trial in patients with high-risk, localized prostate cancer. *First Author: Jianjun Gao, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anti-CTLA-4 therapy ipilimumab (BMS) has led to clinical benefit in patients with metastatic melanoma. However, in multiple clinical trials in patients with prostate cancer, ipilimumab has not demonstrated significant clinical benefit. To identify potential immune inhibitory pathways responsible for resistance to ipilimumab therapy, we evaluated tumor samples from a pre-surgical clinical trial and performed correlative laboratory studies. **Methods:** We carried out a pre-surgical clinical trial with androgen deprivation therapy (ADT), (leuprolide acetate, Tap Pharmaceuticals) plus ipilimumab in patients with localized, high-risk prostate cancer. Each patient received one injection of leuprolide (22.5 mg) on week 0 and ipilimumab (10 mg/kg) on weeks 1 and 4. Patients then underwent surgery at week 8. Tumor tissues were collected at baseline and then at surgery for flow cytometry, IHC, multiplex immunofluorescence, and gene profiling analyses. In vitro studies were carried out for functional analysis. **Results:** Sixteen patients completed treatment with ipilimumab plus ADT and surgery. We observed a significant increase of immune cells including T cells and macrophages into prostate tumors after ipilimumab therapy, similar to data observed in ipilimumab-treated melanoma samples. However, compared to melanoma tumors, we found higher expression of PD-L1 and VISTA inhibitory molecules on CD68+ macrophages in prostate tumors. Interestingly, PD-L1 and VISTA were expressed on distinct subset of CD68+ macrophages, with high expression of CD163, suggesting an M2 subtype. In vitro studies demonstrated that engagement of PD-L1 and/or VISTA pathways inhibited T cell responses. Coculture with monocytes resulted in suppression of T cell function, which can be reversed with anti-VISTA blocking antibody. **Conclusions:** These data suggest that evolving compensatory inhibitory pathways including PD-L1 and VISTA may mediate resistance of prostate cancer to ipilimumab therapy. Concurrent blockade of other immune checkpoints such as PD1/PD-L1 and/or VISTA may be necessary to provide significant clinical benefits for patients with prostate cancer. Clinical trial information: NCT01194271.

5082 Poster Session (Board #156), Mon, 1:15 PM-4:45 PM

Survival impact of initial local therapy selection for men under 60 with high risk prostate cancer. *First Author: Adeel Kaiser, University of Maryland School of Medicine, Baltimore, MD*

Background: The impact of initial local therapy selection on survival for high risk prostate cancer (PCa) patients remains uncertain. We sought to assess this effect, while limiting competing causes of death, through the examination of a younger PCa patient cohort within the National Cancer Database. **Methods:** We evaluated the overall survival (OS) of men under 60 with high risk PCa receiving either radiation therapy (RT) or radical prostatectomy (RP). All men in this age group were treated between 2004 and 2013, harbored cN0M0 disease, and presented with Gleason Scores (GS) of 8 to 10. The RT group included patients who received external beam radiation (EBRT) alone or EBRT in combination with brachytherapy (BT). Overall survival and covariates were evaluated using multivariable Cox regression analysis. **Results:** A total of 16,944 patients met inclusion criteria of which 12,155 underwent RP and 4,789 received RT as initial therapy. 82.5% of RT patients received hormonal therapy, and the median dose was 77.4 Gy. In the RP group, 17.2% of patients received postoperative radiation, and 87% of these cases received a dose exceeding 64.80 Gy. The RP group had a higher proportion of cases with Charlson-Deyo comorbidity score $>$ 0 (15.2% v. 11.2%, $p < 0.000001$). At a median follow-up of 50 months (0 - 131 months), RP was associated with improved OS in comparison to RT (hazard ratio = 0.52; 95% CI (0.47, 0.58); $p < 0.000001$). The estimated 8-year OS ($\pm$1 standard error of the estimate) was 85.1$\pm$0.7% and 74.9$\pm$0.7%, after RP and RT, respectively. This benefit remained present when adjusting for age, year of treatment, race, comorbidity score, Gleason score, T stage, hormonal therapy, chemotherapy, form of radiation, PSA, or insurance status. **Conclusions:** Compared to RT, initial treatment of men under 60 with high risk PCa with RP results in a large, statistically significant improvement in overall survival that remains consistent over time and remains significant in a multivariable model adjusting for known prognostic variables. These results are limited by the retrospective nature of the database analysis, and the lack of cancer specific survival information.

5084 Poster Session (Board #158), Mon, 1:15 PM-4:45 PM

The accuracy of multiparametric magnetic resonance imaging (mpMRI) using PI-RADS v2 in disease upgrading on re-biopsy among patients with low-risk prostate cancer (PCa) on active surveillance (AS): A Brazilian perspective. *First Author: PÃoblio C. C. Viana, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

Background: The current selection criteria to AS is critical and it becomes even more relevant in Latin America, given the higher proportion of high risk cancers. The objective of this study is to analyze the accuracy of mpMRI using PI-RADS v2 in predicting the risk of upgrading on re-biopsy (UR) in men with low-risk PCa on AS. **Methods:** In this Institutional Review Board approved prospective study, patients with low-grade PCa selected for AS at our institution underwent mpMRI at least 6 weeks after the baseline 12-core random prostate biopsy (BSB), from March 2014 to March 2016. One blinded abdominal radiologist evaluated the exams regarding presence of dominant lesion and assigned the PI-RADS v2 score. MRI-target transrectal ultrasound-guided re-biopsies were performed in all patients within 6-12 months after the BSB. Standardized 12-core biopsy was performed and additional cores were taken from suspicious areas on mpMRI. **Results:** One hundred and nine patients were included, 93 (85.3%) patients had a dominant lesion on MRI. mpMRI were classified as PI-RADS 1, 2 or 3 in 67 (61.5%) patients, and as PI-RADS 4 or 5 in 42 (38.5%) patients. UR occurred in 42 (38.5%) patients. Out of these, 39 (92.8%) had radical prostatectomy, 6 (15.4%) T2a, 24 (61.5%) T2b, and 9 (23.1%) T3a. The diagnostic performance of mpMRI for PCa upgrading after re-biopsy was summarized in table 1. Patients assigned as PI-RADS 4 or 5 presented a significantly higher risk for UR compared with patients with PI-RADS 1, 2 or 3 (73.8% vs 16.4%, $p < 0.001$). Logistic regression analyses demonstrated that PI-RADS 4 or 5 remained a significant predictor of UR (OR: 37.366, $p < 0.0001$). **Conclusions:** We demonstrated in our population that mpMRI using PI-RADS v2 is a significant predictor for upgrading on re-biopsy in patients on AS and could be used to guide TRUS biopsy, increasing the accuracy of current clinical criteria for AS.

Sensitivity	0.761 (0.612; 0.874)
Specificity	0.889 (0.784; 0.954)
Positive predictive value	0.833 (0.686; 0.930)
Negative predictive value	0.836 (0.725; 0.915)
Accuracy	0.835 (0.752; 0.899)

5085 Poster Session (Board #159), Mon, 1:15 PM-4:45 PM

Prostate cancer (PCa) in 696 hypogonadal men with and without long-term testosterone therapy (TTh): Results from a controlled registry study. *First Author: Ahmad Haider, Bremerhaven, Germany*

Background: There is no evidence that TTh in men with hypogonadism increases PCa incidence or severity. A Canadian group recently found that long-term TTh decreased the risk of PCa diagnosis (Wallis et al., Lancet Diab Endocrinol 2016; 4:498). We assessed incidence and severity of PCa in hypogonadal men on long-term TTh (T-group) in comparison to an untreated hypogonadal control group (CTRL). **Methods:** 400 men with testosterone $\leq$350 ng/dL and symptoms received testosterone undecanoate 1000 mg every 3 months for up to 10 years. 296 hypogonadal men (57-74) opted against TTh. Median follow-up: 8 years. Total observation time covered more than 5,000 patient-years. Prostate volume (PV), PSA, weight and C-reactive protein (CRP) were measured and digital rectal examination/transrectal ultrasound performed before treatment initiation and then every 6-12 months. Biopsies were performed when indicated according to EAU guidelines. **Results:** In the T-group, PV increased slightly but significantly by 2.41 mL ($p < 0.0001$), PSA by 0.22 (NS). In CTRL, PV decreased slightly but significantly by -1.20 mL ($p < 0.005$), PSA by -0.38 ($p < 0.0001$). Weight dropped by 18.23% in the T-group and increased by 1.78% in CTRL, CRP decreased significantly in the T-group and remained unchanged in CTRL. In the T-group, 9 men (2.3%) were diagnosed with PCa. In CTRL, 15 (5.1%) were diagnosed with PCa. The incidence per 10,000 years was 29 in the T-group and 102 in CTRL. The mean baseline age of PCa patients was 65 years in the T-group and 65.5 in CTRL. Prostatectomy was performed in all men. In the T-group, all but 1 patient had a Gleason score $\leq$6, and all a predominant Gleason score of 3. Tumor grade was G2 in all 9 (100%), tumor stage T2a in 7 (78%) and T2b in 2 (22%) patients. In CTRL, Gleason score was $>$ 6 in all 15 patients. 4 men had a predominant Gleason score of 3, 10 had 4, and 1 had 5. Tumor grade was G2 in 7 (46.7%) and G3 in 8 (53.3%) patients, tumor stage T2b in 1 (6.7%), T2c in 1 (6.7%), T3a in 1 (6.7%), T3b in 7 (46.7%) and T3c in 6 (50%) patients. **Conclusions:** In hypogonadal men, TTh may decrease PCa incidence compared to CTRL. PCa was less severe in the T-group. Weight loss and reduced inflammation by TTh may have contributed to our findings.

TPS5086 Poster Session (Board #160a), Mon, 1:15 PM-4:45 PM

A randomized phase II trial of abiraterone, olaparib or abiraterone + olaparib in patients with metastatic castration-resistant prostate cancer with DNA repair defects. *First Author: Zachery Reichert, University of Michigan, Ann Arbor, MI*

Background: Approximately 20% of patients with metastatic castration-resistant prostate cancer (mCRPC) harbor mutations in genes encoding DNA repair proteins (e.g. ATM, BRCA1, BRCA2, PALB2, RAD51, CHEK2, FANCA). These mutations impact base excision repair and alternative end-joining, which rely on the activity of poly(ADP-ribose) polymerase (PARP). Olaparib (olap) inhibits PARP and showed activity in a post hoc analysis in mCRPC patients with DNA repair defects (DRD). In a subgroup analysis of the NCI 9012 trial evaluating abiraterone (abi) +/- veliparib (a PARP inhibitor), patients with DRD in both treatment groups had a $>$ 80% prostate-specific antigen (PSA) response rate and prolonged progression free survival (PFS) (13.8 mos vs. 7.8 mos; P = 0.01). Preclinical data suggests interactions between androgen signaling and PARP activity. These observations provide the rationale to evaluate the efficacy of olap, abi or the combination in patients with DRD. **Methods:** This is a prospective, randomized, open-label phase 2 clinical trial with a primary endpoint of objective PFS (radiographic + clinical). Secondary endpoints: objective disease and PSA response rates. Analysis of tumor specimens, circulating tumor cells/DNA will be performed. Eligible patients with progressive mCRPC, no prior mCRPC therapy with tumor loss of ATM, BRCA1 or BRCA2 (based on known germline loss, prior CLIA certified tumor analysis or new metastatic biopsy) will be stratified by germline vs. somatic mutational status and randomized 1:1:1 to abi (1000 mg daily) + prednisone (5 mg bid), olap (300 mg daily) or olap + abi + prednisone (same doses). Patients in single agent arms may cross over to opposite single agent therapy at progression. An exploratory cohort of patients with DNA repair defects besides ATM, BRCA1, BRCA2 may receive olap. Statistical analysis will provide median, 12-month, and 24-month product-limit estimates of PFS by treatment arm. The study is recruiting 60 randomized patients at sites in the US. The trial is coordinated by the Prostate Cancer Clinical Trials Consortium, LLC and funded by AstraZeneca. Clinical trial information: NCT03012321.

TPS5087 **Poster Session (Board #160b), Mon, 1:15 PM-4:45 PM**

Trial of rucaparib in prostate indications 3 (TRITON3): An international, multicenter, randomized, open-label phase 3 study of rucaparib vs physician's choice of therapy for patients (Pts) with metastatic castration-resistant prostate cancer (mCRPC) associated with homologous recombination deficiency (HRD). *First Author: Charles J. Ryan, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Pts with mCRPC often initially receive androgen receptor-targeted therapy (eg, abiraterone or enzalutamide), but they almost always progress. Poly(ADP-ribose) polymerase (PARP) inhibitors (eg, olaparib) have demonstrated clinical activity in pts with mCRPC with a deleterious mutation in a homologous recombination (HR) DNA repair gene; 14 of 16 evaluable pts with mCRPC and a tumor alteration in an HR gene, including *BRCA1*, *BRCA2*, and *ATM*, responded to olaparib (Mateo et al. *N Engl J Med*. 2015;373:1697-708). The PARP inhibitor rucaparib is approved in the US for treatment of pts with ovarian carcinoma that harbors a deleterious *BRCA1* or *BRCA2* mutation (germline and/or somatic) who have received ≥2 chemotherapies. These data support investigating rucaparib as a treatment option in pts with mCRPC with HRD. **Methods:** TRITON3 (NCT02975934)is a phase 3 study evaluating rucaparib (600 mg BID) vs physician's choice (abiraterone, enzalutamide, or docetaxel) in pts with mCRPC who have a deleterious germline or somatic mutation in *BRCA1*, *BRCA2*, or *ATM* as determined by local and/or central testing. All pts must have progressed on abiraterone or enzalutamide in the mCRPC setting; pts who received prior chemotherapy for mCRPC or PARP inhibitor treatment are excluded. Pts will be randomized 2:1 to rucaparib or physician's choice of comparator therapy; pts randomized to physician's choice may cross over to rucaparib on radiographic progression confirmed by independent radiology review (IRR). The primary endpoint is IRR-confirmed radiographic progression-free survival (modified RECIST version 1.1/PCWG3 criteria). Secondary objectives include overall survival, objective response rate, duration of response, clinical benefit rate, pt-reported outcomes, and safety. Pretreatment blood samples will be collected from all pts to enable development of a plasma-based companion diagnostic to identify pts who may benefit from rucaparib treatment. Pts (≈400) will be enrolled at > 100 sites worldwide. Clinical trial information: NCT02975934.

TPS5088 **Poster Session (Board #161a), Mon, 1:15 PM-4:45 PM**

A phase 1/1b multicenter, open-label, dose escalation and dose expansion study to evaluate the safety, pharmacokinetics, immunogenicity, and antitumor activity of MEDI3726 in patients with metastatic, castration-resistant prostate cancer who have received prior treatment with abiraterone or enzalutamide. *First Author: Mark T. Fleming, Virginia Oncology Associates, Norfolk, VA*

Background: Therapeutic advances have recently been achieved for patients with metastatic, castration-resistant prostate cancer (mCRPC) due to abiraterone acetate (ABI) and enzalutamide (ENZ). However, virtually all patients with mCRPC eventually progress in their disease, and further treatment options are limited. Prostate-specific membrane antigen (PSMA) is highly expressed in nearly all prostate cancers, and its expression is highest in mCRPC. MEDI3726 is an antibody-drug conjugate composed of anti-PSMA antibody derived from J591, site-specifically conjugated to the cytotoxic, DNA cross-linking, pyrrolobenzodiazepine dimer. MEDI3726 has demonstrated potent and specific in vitro and in vivo antitumor activity in human prostate cancer-derived preclinical models with different expression levels of PSMA. **Methods:** This is a first-in-human, phase 1/1b, multicenter, open-label, dose escalation and dose expansion study in patients who have received prior treatment with ABI or ENZ, with or without prior taxane-based chemotherapy in the mCRPC setting (NCT02991911). The primary objectives are to assess safety and tolerability, describe dose-limiting toxicities, and determine the maximum tolerated dose or maximum administered dose of MEDI3726. The secondary objectives are to evaluate MEDI3726 for its antitumor activity (based on a composite response according to RECIST Version 1.1, a reduction in prostate-specific antigen level of 50% or more compared to baseline, or a conversion in the circulating tumor cell count [defined as a reduction from ≥5 cells/7.5 mL blood to < 5 cells/7.5 mL blood]), safety and tolerability in combination with ENZ, pharmacokinetics alone and in combination with ENZ, and immunogenicity. Recruitment is ongoing for this study, which has an estimated total target enrollment of 224 patients. Clinical trial information: NCT02991911.

TPS5089 **Poster Session (Board #161b), Mon, 1:15 PM-4:45 PM**

Phase 1b/2 keynote-365 trial: Pembrolizumab (pembro) combination therapy in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Evan Y. Yu, Seattle Cancer Care Alliance, Seattle, WA*

Background: Approved treatments for mCRPC (eg, enzalutamide and docetaxel) may increase programmed death ligand 1 (PD-L1) expression and facilitate neoantigen release. In phase 1b and 1/2 trials, pembro, an anti–PD-1 antibody, has produced antitumor responses in previously treated mCRPC as monotherapy and in combination with enzalutamide. Olaparib, a PARP inhibitor, has shown activity in mCRPC with DNA-repair defects. The nonrandomized, multicohort, open-label KEYNOTE-365 study (NCT02861573) will evaluate the safety and efficacy of pembro with olaparib (cohort A), docetaxel + prednisone (cohort B), or enzalutamide (cohort C) in mCRPC. **Methods:** Cohort allocation depends upon prior treatment: cohort A requires prior docetaxel (treatment with 1 other chemotherapy and ≤2 second-generation hormonal manipulations is allowed); cohort B requires prior abiraterone acetate or enzalutamide (but not both); cohort C requires prior abiraterone acetate. Additional eligibility criteria include confirmed prostate adenocarcinoma, disease progression (PD) ≤6 months before screening, ongoing androgen deprivation (serum testosterone < 50 ng/dL), and provision of nonirradiated tumor sample. Pembro 200 mg will be given every 3 weeks (Q3W) with either olaparib 400 mg twice daily (cohort A), docetaxel 75 mg/m^2 Q3W + prednisone 5 mg twice daily (cohort B), or enzalutamide 160 mg once daily (cohort C). Pembro treatment will continue for up to 35 cycles or until PD or unacceptable adverse events (AEs). Patients in cohort B may receive a maximum of 10 cycles of docetaxel + prednisone. Patients who discontinue 1 of 2 drugs in a combination because of a treatment-related AE may continue to receive the other drug until PD. Response will be evaluated by prostate-specific antigen (PSA) levels Q3W and by imaging Q9W for the first year and Q12W thereafter. Primary end points are safety and PSA response rate (decline of ≥50% from baseline twice ≥3 weeks apart). Secondary end points include time to PSA progression, progression-free survival, overall survival, and overall response rate. Enrollment will continue until 70 patients are enrolled for each cohort. Clinical trial information: NCT02861573.

TPS5090 **Poster Session (Board #162a), Mon, 1:15 PM-4:45 PM**

A phase III trial comparing atezolizumab with enzalutamide vs enzalutamide alone in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Thomas Powles, Barts Cancer Institute, London, United Kingdom*

Background: In the past decade, several therapies have been approved for patients (pts) with mCRPC, including the androgen receptor (AR) antagonist enzalutamide (enza) and the androgen synthesis inhibitor abiraterone acetate (abi). Despite these advances, most pts experience disease progression and there are inadequate data to guide the sequencing of agents to optimize outcomes. Pts with mCRPC who progress on enza have increased circulating PD-L1/PD-L2–positive dendritic cells compared with enza-naive pts or pts who are still responding to treatment (Bishop et al. *Oncotarget*. 2014). In two recent studies, PSA and radiographic responses were observed in mCRPC pts treated with a PD-L1/PD-1 pathway inhibitor with or without enza (Graff et al. *Oncotarget*. 2016; Hansen et al. *Ann Oncol*. 2016). Atezolizumab (atezo) is an anti–PD-L1 monoclonal antibody that inhibits the interaction between PD-L1 and its receptors, PD-1 and B7.1, enhancing T-cell responses and improving anti-tumor activity. Taken together, this suggests that the combination of atezo and enza may provide an effective treatment option for mCRPC pts. **Methods:** A Phase III randomized, multicenter, clinical trial (NCT03016312) is being conducted to evaluate the efficacy and safety of atezo with enza compared with enza alone in mCRPC pts who have received prior abi treatment and have progressed on, are ineligible for, or have refused a taxane regimen. Eligibility criteria include mCRPC or locally advanced, incurable CRPC and ECOG PS 0-1. Exclusion criteria include CNS metastasis, autoimmune disease, history of seizures, prior immunotherapy and prior treatment with enza or any other newer AR antagonists. Pts will be randomized 1:1 to receive atezo 1200 mg q3w and enza 160 mg qd or enza alone. The primary endpoint is OS, and secondary endpoints include PSA response rate, rPFS, ORR and safety. Exploratory biomarkers associated with responses to atezo and enza will be evaluated in tumor tissue collected at baseline and progression. Approximately 550 pts will be enrolled at 150 sites globally. Clinical trial information: NCT03016312.

TPS5091 Poster Session (Board #162b), Mon, 1:15 PM-4:45 PM

PROfound: A randomized Phase III trial evaluating olaparib in patients with metastatic castration-resistant prostate cancer and a deleterious homologous recombination DNA repair aberration. *First Author: Johann S. De Bono, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: The median overall survival for patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) is short. Available agents may offer limited therapeutic benefit, but no molecularly stratified treatment has yet been approved for this heterogeneous disease. A sizable percentage of pts with mCRPC has loss of function aberrations in genes involved in homologous recombination repair (HRR) in tumor tissue, such as *BRCA1/2* and *ATM*. These aberrations can confer sensitivity to poly(ADP-ribose) polymerase (PARP) inhibition. A Phase II study indicated that the oral PARP inhibitor olaparib (Lynparza) had antitumor activity in 33% of mCRPC pts who had progressed after new hormonal agent (NHA) treatment and chemotherapy, with a strikingly higher composite response rate in pts with a deleterious HRR gene aberration (HRRa) (88%; 14/16) vs pts without a HRRa (6%; 2/33) (Mateo *et al.*2015). The PROfound study evaluates olaparib efficacy and safety versus physician's choice of either abiraterone acetate or enzalutamide, in pts with mCRPC and a HRRa (NCT02987543). **Methods:** To be eligible for this multinational, open-label, Phase III study, mCRPC pts must have progressed on prior NHA treatment and have a tumor HRRa in one of 15 genes, as confirmed by an HRR Assay (Foundation Medicine, Inc.). Cohort A (n = 240 approx) includes pts with mutations in *BRCA1*, *BRCA2* or *ATM*, while pts with a mutation in 12 other HRR genes will be assigned to Cohort B (n = 100 approx). Pts will be randomized (2:1) to olaparib tablets (300 mg orally bid) or physician's choice of either enzalutamide (160 mg orally od) or abiraterone acetate (1000 mg orally od with 5 mg bid prednisone) and treatment continued until radiographic progression (as assessed by blinded independent central review) or lack of treatment tolerability. The primary endpoint of radiographic progression-free survival (rPFS) will be assessed in Cohort A using RECIST 1.1 (soft tissue) and PCWG3 (bone) criteria. Key secondary efficacy endpoints include confirmed objective response rate, time to pain progression, overall survival (all Cohort A) and rPFS (both cohorts combined). Clinical trial information: NCT02987543.

TPS5092 Poster Session (Board #163a), Mon, 1:15 PM-4:45 PM

ARASENS phase 3 trial of ODM-201 in men with metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Matthew Raymond Smith, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Androgen deprivation therapy (ADT) ± docetaxel is recommended first-line therapy for mHSPC, but most patients progress to castration-resistant PC (CRPC). BAY-1841788 (ODM-201) is an investigational oral androgen receptor (AR) antagonist that has a unique chemical structure designed to block the growth of cancer cells through binding to the AR with high affinity and inhibiting the receptor function. In preclinical studies, ODM-201 and its main circulating metabolite are active also in known AR mutants (eg, W742L, F877L), and have been found to have negligible blood-brain barrier penetration. In the phase 1 ARAFOR and phase 1/2 ARADES trials, ODM-201 had antitumor activity and was well tolerated in men with mCRPC (Massard et al. *Eur Urol.* 2016;69:834–840; Fizazi et al. *Lancet Oncol.* 2014;15:975–985). Given this promising activity in mCRPC, the ARASENS trial is evaluating ODM-201 plus standard ADT + docetaxel in men with metastatic disease (mHSPC). **Methods:** This international, randomized, double-blind, placebo-controlled, phase 3 trial (NCT02799602) is being conducted in 23 countries. ~1300 men with newly diagnosed mHSPC will be randomized 1:1 to either ODM-201 600 mg twice daily (2×300 mg tablets) orally with food or placebo, both with ADT + docetaxel (6 cycles after randomization), and stratified by extent of disease and alkaline phosphatase levels. Key inclusion criteria are histologically or cytologically confirmed PC with documented metastases, started ADT ± first-generation anti-androgen therapy ≤12 weeks before randomization, and Eastern Cooperative Oncology Group performance status 0 or 1. The primary objective is to show superior overall survival with ODM-201 vs placebo, both with ADT + docetaxel. Secondary end points include time to CRPC, initiation of subsequent anticancer therapy, symptomatic skeletal event-free survival (SSE-FS), time to first SSE, initiation of opioid use, pain progression, and worsening of physical symptoms, all measured at 12-week intervals. Safety will be assessed by adverse events. The trial is open for enrollment; first patient first visit was in November 2016 and > 10 sites are open for recruitment and enrolling patients. Clinical trial information: NCT02799602.

TPS5093 Poster Session (Board #163b), Mon, 1:15 PM-4:45 PM

Phase I dose-escalation study of fractionated-dose ^{177}Lu-PSMA-617 for progressive metastatic castration resistant prostate cancer (mCRPC). *First Author: Scott T. Tagawa, Sandra and Edward Meyer Cancer Center, New York, NY*

Background: PC is a radiosensitive disease. PSMA is selectively overexpressed in advanced PC with upregulation by androgen receptor (AR) pathway dysregulation; limited expression exists in other organs. A series of sequential studies of radiolabeled anti-PSMA antibody J591 revealed 1) targeting and safety [Bander 2003]; 2) safety and prelim efficacy [Milowsky 2004, Bander 2005]; 3) efficacy and initial dose-response [Tagawa 2013]; 4) dose-fractionation allows higher doses, ability to combine with docetaxel, confirmation of dose-response (PSA and overall survival) [ASCO 2010, 2014, 2016]; 5) predictable, reversible myelosuppression is dose-limiting [Tagawa 2013]. Small molecule PSMA inhibitor ligands can be successfully radiolabeled and are widely used for imaging and treatment in Europe. ^{177}Lu-PSMA-617 is the most commonly used, but experience is mostly anecdotal/retrospective and no formal dose-escalation studies have been performed. **Methods:** Men with progressive mCRPC following at least 1 potent AR-targeted agent (e.g. abi/enza) and docetaxel (or unfit/refuse chemo) without limit of # prior therapies provided adequate organ function will undergo imaging with ^{68}Ga-PSMA-HBED-CC PET/CT followed by escalating fractionated doses of ^{177}Lu-PSMA-617. Cohort 1 = 3.7 GBq x2 two weeks apart up to 11.1 GBq x2 in a 3+3 dose-escalation study. Dose-limiting toxicity (DLT) is defined as attributable grade 4 heme toxicity or grade 3/4 non-heme toxicity. Planned cohort expansion will occur at recommended phase 2 dose (RP2D) in a 2-stage design. The primary endpoint is determination of DLT and RP2D. Secondary endpoints include toxicity, PSA decline rate, RECIST response, PFS, rPFS, OS. Correlatives include baseline/follow up PSMA imaging, whole body distribution of ^{177}Lu-PSMA-617, CTC count (CellSearch) changes, tissue and circulating genomic assessment of DNA repair pathways, patient reported outcomes (FACT-P and BPI-SF). Clinical trial information: NCT03042468.

TPS5094 Poster Session (Board #164a), Mon, 1:15 PM-4:45 PM

A phase II randomized trial of observation versus stereotactic ablative radiation for oligometastatic prostate cancer (ORIOLE). *First Author: Ryan Phillips, Department of Radiation Oncology and Molecular Radiation Sciences, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: ORIOLE is a randomized, non-blinded Phase II interventional study evaluating the safety and efficacy of SBRT in biochemically recurrent, oligometastatic, hormone-sensitive prostate cancer at 3 centers in the US. Patients will be stratified by clinical characteristics and randomized 2:1 to SBRT or observation. The primary clinical endpoint is progression at 6 months defined by PSA increase, radiologic or clinical evidence, ADT initiation, or death from any cause. Secondary endpoints include local control at 6 months, SBRT-associated toxicity and quality of life, and ADT-free survival. Imaging and laboratory correlates will characterize, in isolation, the effects of SBRT on oligometastatic disease. **Methods:** Eligible patients are hormone-sensitive, have undergone prior definitive treatment and recurred with 1-3 asymptomatic bone or soft tissue metastases diagnosed within 6 months, PSA doubling time (PSADT) < 15 months, ECOG performance status ≤ 2, and normal organ and marrow function. Minimization will be used to balance assignment by primary intervention, prior ADT, and PSADT. Accrual of 54 patients provides 85% power to detect a decrease in progression rate from 80% to 40% with type I error = 0.05 using one-sided Fisher's exact test. Hazard ratios and Kaplan-Meier estimates of progression free survival, ADT free survival, and time to locoregional and distant progression will be calculated based on intention-to-treat. Local control will be assessed using RECIST 1.1 criteria. Withdrawal prior to 6 months will be counted as progression. Adverse events will be summarized and quality of life pre- and post-SBRT will be measured by Brief Pain Inventory. The investigational targeted imaging agent ^{18}F-DCFPyL will be compared to bone scan and CT for identifying oligometastases before SBRT and monitoring disease response following SBRT. Biological alterations induced by SBRT will be investigated using circulating tumor cell analysis, deep sequencing of circulating tumor DNA, and T-cell repertoire profiling. A hereditary cancer assay will inform efforts to advance personalized screening and therapy. Clinical trial information: NCT02680587.

TPS5095 Poster Session (Board #164b), Mon, 1:15 PM-4:45 PM

Abiraterone +/- cabazitaxel in defining complete response in prostatectomy (ACDC-RP) trial. *First Author: Anthony M. Joshua, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Given recent advances in the management of de novo metastatic hormone-sensitive prostate cancer with both docetaxel and abiraterone, as well as evidence of significant activity of cabazitaxel in the post-abiraterone castrate-resistant setting, we hypothesized that the addition of cabazitaxel to neoadjuvant abiraterone will improve pathological complete response rates by overcoming mechanisms of resistance in localized high-risk prostate cancer. Aim: To determine the relative efficacy of the addition of cabazitaxel to abiraterone in the neoadjuvant treatment of prostate cancer to achieve a complete response. **Methods:** Open label, randomized, 2-arm multi-centre, phase 2 clinical trial. Primary endpoint: Pathological complete response rate (pCR). Secondary endpoints: surgical outcomes (positive margins, extracapsular extension, seminal vesicle or nodal involvement), pharmacodynamic markers in residual tumour (apoptosis, androgen receptor expression, localization, and signaling), biomarkers (intra-prostatic androgen levels), and safety. Design: Study participants will be randomized in a 1:1 ratio to receive either: Arm A: Abiraterone (1000 mg/day), prednisone (5 mg b.i.d.), leuprolide (22.5 mg s.c. every 3 months), and cabazitaxel (25 mg/m^2 starting at week 2, with 6 mg pegfilgrastim 24 h following cabazitaxel) or Arm B: Abiraterone (1000 mg/day), prednisone (5 mg b.i.d.) and leuprolide (22.5 mg s.c. every 3 months). Assessments will take place biweekly for the first 12 weeks, then monthly until the prostatectomy (scheduled for 24 weeks following start of treatment). Target accrual is 88 participants within 36 months. Study is powered to detect a 15% difference with 85% power, assuming a one-sided type 1 error rate of 20%. A 6 patient safety run-in is included. As of Jan 2017, 1 site is open in Canada, with 4 additional Canadian sites and 1 site in Australia pending. To date, 4 participants are randomized and undergoing treatment. ACDC-RP is an investigator-initiated trial led by the Princess Margaret Urology Trials Group with funding from Ontario Institute for Cancer Research (OICR) and in-kind contributions from Janssen and Sanofi. Clinical trial information: NCT02543255.

TPS5096 Poster Session (Board #165a), Mon, 1:15 PM-4:45 PM

Randomised phase III trial of enzalutamide in androgen deprivation therapy (ADT) with radiation therapy for clinically localised, high risk, or node-positive prostate cancer: ENZARAD (ANZUP 1303). *First Author: Scott Williams, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Adjuvant ADT with an LHRH analog (LHRHA) given before, during and after radiotherapy (RT) is standard of care for high risk localised prostate cancer (PC). Enzalutamide is more effective in metastatic disease than conventional non-steroidal anti-androgens (NSAA). We hypothesize that addition of enzalutamide to adjuvant ADT and RT will improve outcomes. The aim is to determine the efficacy of enzalutamide compared with NSAA as part of adjuvant ADT with LHRHA in men planned for RT for localized high risk or node-positive PC. **Methods:** DESIGN: Open label, randomised, phase 3 trial including ANZ, USA, UK, Ireland and Europe. ENDPOINTS: OS (primary), cause-specific survival, PSA PFS, clinical PFS, time to subsequent hormonal therapy, time to castration-resistant disease (PCWG2 criteria), metastasis free survival, adverse events and HRQOL. Tertiary objectives: identification of prognostic/predictive biomarkers from archival tumour tissue and 4 serial fasting bloods. 800 target participants with 5.5 yrs minimum follow-up. 80% power to detect 33% reduction in the hazard of death assuming 5-year survival rate of 76% amongst controls. TREATMENT: Participants are randomised 1:1 to enzalutamide 160mg daily for 24 months versus conventional NSAA for 6 months. All participants receive LHRHA for 24 months and RT starting after week 16. RT delivered as 78Gy in 39 Fx or 46Gy in 23 Fx plus brachytherapy (nodal RT optional for N0, mandatory for N1). ASSESSMENTS: Baseline, then every 8 weeks until year 2, then 3-4 monthly until year 5, 6-monthly until year 7, then annually. CT/MRI and bone scan at baseline, PSA progression, 6 monthly until re-initiation of ADT, when PCWG2 criteria for CRPC are met and then 3 monthly until evidence of metastases. As of 1st February 2017, 55 of 67 sites open with 398 patients recruited. EORTC sites expected to open from Quarter 1 2017. ENZARAD is an investigator-initiated cooperative group trial led by ANZUP Cancer Trials Group with funds and product from Astellas. ANZUP is supported by Cancer Australia and previously CI NSW. ClinicalTrials.gov: NCT02446444, ANZCTR: ACTRN12614000126617 Clinical trial information: NCT02446444.

TPS5097 Poster Session (Board #165b), Mon, 1:15 PM-4:45 PM

A randomized study of enzalutamide in patients with localized prostate cancer undergoing active surveillance (ENACT). *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Prostate cancer (PC) patients (pts) who select active surveillance (AS) are a heterogeneous population with varying risks for disease progression. Studies have estimated that approximately 31–42% of pts electing AS have experienced disease progression (pathological or therapeutic) over 1.8 and 2.3 years. There is no evidence-based pharmacological intervention which has effectively lessened this progression event. Pharmacological intervention with enzalutamide (ENZ), an androgen receptor inhibitor approved for treatment of metastatic castration-resistant PC, may lessen this progression. The aims of this study are to evaluate the efficacy of ENZ versus AS alone for delaying time to progression in pts with clinically localized PC undergoing AS. This study examines the effects of ENZ on progression in a subset of pts with low- or intermediate-risk PC who would otherwise elect an AS protocol. **Methods:** This is a multicenter, randomized, open-label study (NCT02799745). Eligibility criteria include histologically confirmed prostate adenocarcinoma within 6 months of screening, low or intermediate risk PC (T1c−T2c, prostate-specific antigen [PSA] $<$ 20, N0, M0, Gleason score $\leq$7 [3+4 pattern only]), Eastern Cooperative Oncology Group status $\leq$2 and estimated life expectancy $>$ 5 years. Exclusion criteria include any prior PC intervention. Pts will be randomized to receive open-label oral ENZ 160 mg/day once daily or to AS during the 1-year study treatment period. After the first year, all pts will be followed for one additional year with no other intervention. All pts will undergo prostate biopsy at 1 and 2 years. The primary end point is time to PC progression (pathological or therapeutic). Secondary end points include safety, incidence of negative biopsies for cancer at 1 and 2 years, percentage of cancer positive cores at 1 and 2 years, time to PSA progression, incidence of secondary rise in serum PSA, and quality-of-life questionnaires. Exploratory end points include biomarker assessment and genomic analysis. Study enrolment commenced in June 2016, with study completion expected in March 2019. Planned total enrolment is 222 pts from ~60 United States/Canadian sites. Clinical trial information: NCT02799745.

5500 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

LION: Lymphadenectomy in ovarian neoplasms—A prospective randomized AGO study group led gynecologic cancer intergroup trial. *First Author: Philipp Harter, AGO and Kliniken Essen Mitte, Essen, Germany*

Background: So far, there is no level-1 evidence regarding the role of systematic pelvic and para-aortic lymphadenectomy (LNE) in patients with advanced ovarian cancer (AOC) with macroscopic complete resection und clinically negative lymph nodes (LN). Therefore, surgical management regarding LNE worldwide is very heterogeneous. **Methods:** Prospective randomized trial including patients with newly diagnosed AOC FIGO IIB-IV with macroscopic complete resection and pre- and intra-operatively clinical negative LN were randomized intra-operatively to LNE versus no-LNE. All centers had to qualify regarding surgical skills before participation in this trial. The primary endpoint was overall survival. **Results:** 647 patients were randomized between 12/08 and 1/12 to LNE (n=323) or no-LNE (n=324). The median number of removed LN in patients randomized to LNE was 57 (pelvic 35 and para-aortic22). Post-op platinum-taxane based chemotherapy was applied in 85% of the patients in the no-LNE arm and 80% in the LNE arm. Microscopic metastases were diagnosed in 56% of the pts in the LNE arm. Median OS in the no-LNE arm was 69 months and 66 months in the LNE arm (HR 1.06, 95%CI 0.83-1.34, p=0.65) and the median PFS was 26 months in both arms (HR 1.11, 95%CI 0.92-1.34 p=0.30). Surgery in the LNE arm was 64 minutes longer (means: 352 vs 288 min), resulted in a higher median blood loss (650 vs 500 ml), and a higher transfusion rate (67% vs 59%). Furthermore, serious post-operative complications occurred more frequently in the LNE arm (e.g. rate of re-laparotomies 12.1% vs 5.9% [p=0.006], hospital re-admittance rate 8.0% vs 3.1% [p=0.006] and deaths within 60 days after surgery 3.1 vs 0.9% [p=0.049]). **Conclusions:** Systematic pelvic and para-aortic LNE in patients with AOC with both intra-abdominal complete resection and clinically negative LN neither improve overall nor progression-free survival despite detecting (and removing) sub-clinical retroperitoneal lymph node metastases in 56% of the patients. Our data indicate that systematic LNE of clinical negative LN in patients with AOC and complete resection should be omitted to reduce post-operative morbidity and mortality. Clinical trial information: NCT00712218.

5501 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

Randomized controlled phase III study evaluating the impact of secondary cytoreductive surgery in recurrent ovarian cancer: AGO DESKTOP III/ENGOT ov20. *First Author: Andreas Du Bois, AGO and Kliniken Essen Mitte, Essen, Germany*

Background: The role of secondary cytoreductive surgery in recurrent ovarian cancer (OC) has not been defined by level-1 evidence. **Methods:** Pts with OC and 1st relapse after 6+ mos platin-free interval (TFIp) were eligible if they presented with a positive AGO-score (PS ECOG 0, ascites ≤500 ml, and complete resection at initial surgery) and were randomized to 2^{nd}-line chemotherapy alone vs cytoreductive surgery followed by chemo. Chemo regimens were selected according to the institutional standard. We report here results of the predetermined interim analysis. **Results:** 407pts were randomized 2010-2014. The TFIp exceeded 12 mos in 75% and 76% pts in both arms. 8.9% of 203 pts were operated despite of randomization to the no-surgery arm, whereas 6.9% of 204 pts in the surgery arm did not undergo operation. Complete resection was achieved in 67% of pts; 87% and 88% received a platinum-containing 2^{nd}-line therapy. Median PFS was 14 mos without and 19.6 mos with surgery (HR: 0.66, 95%CI 0.52-0.83, p<0.001). Median time to start of first subsequent therapy (TFST) was 21 vs 13.9 mos in favor of the surgery arm (HR 0.61, 95%CI 0.48-0.77, p=p<0.001). PFS-2 between 1^{st} and 2nd relapse equaled or even exceeded PFS-1 before 1^{st}relapse in 26% after surgery and only 16% without-surgery. Analysis of the primary endpoint OS is kept blinded due to immaturity and will be evaluated after extended follow-up (the observed pooled unblinded 2-YSR was 83% instead of the initially in the protocol assumed 55-66%). 60d mortality rates were 0 and 0.5% in the surgery and no-surgery arm. Re-laparatomies were performed in 7 pts (3.5%) in the surgery arm.With the exception of myelosuppression which occurred more frequently in the no-surgery arm no further significant differences were observed with respect to grade 3+ acute adverse events. **Conclusions:** Surgery in pts with 1st relapse of OC after a TFIp of 6+ mos and selected by a positive AGO-Score resulted in a clinically meaningful increase of PFS and TFST with acceptable treatment burden. Until final OS data will definitively define the role of secondary cytoreductive surgery it should at least be considered as valuable option in pts with a positive AGO-Score. Clinical trial information: NCT01166737.

5502 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

Final results of the international randomized PORTEC-3 trial of adjuvant chemotherapy and radiation therapy (RT) versus RT alone for women with high-risk endometrial cancer. *First Author: Stephanie M. De Boer, Department of Radiation Oncology, Leiden University Medical Center, Leiden, Netherlands*

Background: Women with high-risk endometrial cancer (HREC) are at increased risk of distant metastasis and endometrial cancer-related death. The randomized PORTEC-3 intergroup trial was initiated to investigate the benefit of adjuvant chemotherapy during and after radiotherapy (CTRT) versus pelvic radiotherapy (RT) alone for women with HREC. **Methods:** Women with HREC (FIGO stage I grade 3 with deep myometrial invasion and/or LVSI; stage II or III; or serous/clear cell histology) were randomly allocated (1:1) to RT (48.6 Gy in 1.8 Gy fractions) or CTRT (two cycles of cisplatin 50 mg/m² in week 1 and 4 of RT, followed by four cycles of carboplatin AUC5 and paclitaxel 175 mg/m² at 3-week intervals) with stratification for participating center, lymphadenectomy, stage, and histological type. The co-primary endpoints were overall survival (OS) and failure-free survival (FFS). The Kaplan-Meier method, log-rank test and Cox regression analysis were used for final analysis according to intention-to-treat. PORTEC-3 is registered with ISRCTN (ISRCTN14387080) and ClinicalTrials.gov (NCT00411138). **Results:** 686 women were included between 2006 and 2013. 13 patients with early informed consent withdrawal and 13 ineligible patients were excluded, leaving 660 patients in the analysis with a median follow up time of 60.2 months (IQR 47.1 – 72.9): 330 CTRT and 330 RT. Three- and five-year overall survival rates for CTRT vs. RT were 84.7% versus 83.7%, and 81.9% versus 76.6%, HR 0.78 [0.55-1.10], p = 0.16. Three- and five-year FFS rates were 83.5% (CTRT) versus 74.6% (RT) and 79.5% versus 70.8%, HR 0.68 [0.50-0.92], p = 0.014. Patients with stage III EC had lower 5-year FFS (69.6% vs 79.5% for stage I-II, p = 0.00124) and greatest absolute benefit of CTRT: 5-year FFS for stage III was 75.4% for CTRT vs 63.4% for RT, p = 0.0292. **Conclusions:** Adjuvant chemotherapy given during and after pelvic radiotherapy for treatment of HREC significantly improved 5-year FFS, with absolute and relative risk reductions of 9% and 30%, respectively, compared with RT alone. There was a non-significant 5% higher 5-year OS with CTRT; follow-up will continue to evaluate long-term OS. Clinical trial information: NCT00411138.

5503 **Oral Abstract Session, Fri, 3:00 PM-6:00 PM**

A randomized phase III trial of docetaxel plus cisplatin or paclitaxel plus carboplatin compared with doxorubicin plus cisplatin as adjuvant chemotherapy for endometrial cancer at high risk of recurrence: Japanese Gynecologic Oncology Group study (JGOG2043). *First Author: Hiroyuki Nomura, Keio University School of Medicine, Tokyo, Japan*

Background: The superiority of chemotherapy regimens employing a taxane plus a platinum agent over standard therapy with doxorubicin plus cisplatin (AP) was recently demonstrated for advanced or recurrent endometrial cancer. This multicenter phase III trial evaluated the clinical benefit of taxane plus platinum agent regimens as adjuvant chemotherapy compared with AP for endometrial cancer patients at high risk of recurrence after surgery. **Methods:** Endometrial cancer patients having a high risk of recurrence and postoperative residual disease < 2 cm were randomly assigned (1:1:1) with stratification by FIGO stage and histologic grade to receive 6 cycles of doxorubicin (60 mg/m^2) plus cisplatin (50 mg/m^2) on day 1 (AP), docetaxel (70 mg/m^2) plus cisplatin (60 mg/m^2) on day 1 (DP) or paclitaxel (180 mg/m^2) plus carboplatin (AUC 6.0 mg/mL x minute) on day 1 (TC) every 3 weeks as adjuvant chemotherapy. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS), adverse events, and tolerability. **Results:** From November 2006 to January 2011, 788 patients were enrolled from 118 institutions in Japan and were eligible for evaluation. The proportion of patients receiving 6 cycles was 80% for AP, 83% for DP, and 76% for TC, and tolerability of the regimens showed no significant difference. After a median follow-up period of 7.0 years, there was no statistical difference of PFS (P=0.1246) or OS (P=0.6734) among the 3 groups. The 5-year PFS rate was 74.9% for AP, 80.9% for DP, and 74.7% for TC, while the 5-year OS rates were 84.3%, 89.3%, and 88.4%, respectively. **Conclusions:** There was no significant difference of survival among patients receiving AP, DP, or TC as adjuvant chemotherapy for endometrial cancer. Since each regimen showed adequate tolerability, taxane plus platinum agent regimens may be a reasonable alternative to AP. Clinical trial information: UMIN000000522.

5504 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

An open-label, multicohort, phase I/II study of nivolumab in patients with virus-associated tumors (CheckMate 358): Efficacy and safety in recurrent or metastatic (R/M) cervical, vaginal, and vulvar cancers. *First Author: Antoine Hollebecque, Gustave Roussy Cancer Institute, Villejuif, France*

Background: Treatment options for cervical, vaginal, and vulvar (GYN) cancers are limited after first-line therapy. Human papillomavirus (HPV) infection is associated with squamous cell carcinomas of the cervix (≥90%) and vulva/vagina (40–70%), and may elicit an immune reaction. Programmed death (PD)-1 and its major ligand PD-L1 are expressed in GYN cancers and inhibit immune responses. Nivolumab disrupts PD-1–mediated signaling, restoring antitumor immunity. **Methods:** In CheckMate 358 (NCT02488759), an ongoing multicohort study of 5 virus-associated cancers, PD-L1–unselected adults with R/M GYN cancers, ECOG PS 0–1, and ≤2 prior systemic therapies for R/M disease were eligible to receive nivolumab 240 mg every 2 weeks until progression or unacceptable toxicity. Primary endpoints were objective response rate (ORR) and safety; secondary endpoints were duration of response (DoR), progression-free survival (PFS), and overall survival (OS). **Results:** Of 24 treated patients (pts), 19 had cervical and 5 had vaginal or vulvar cancer; median age was 51 y. At a median follow-up of 31 wks (range: 6–38), ORR was 20.8% (Table), and disease control rate (ORR + SD) was 70.8%. All responses were in pts with cervical cancer (ORR, 26.3%) and were observed regardless of PD-L1 or HPV status or number of prior R/M therapies. Median PFS was 5.5 mo (95% CI: 3.5, NR); median OS was NR. **Conclusions:** Nivolumab demonstrated encouraging clinical activity in pts with cervical cancer and a manageable safety profile in virus-associated GYN cancers, supporting further evaluation in these pts. Updated clinical and biomarker data to be presented. Clinical trial information: NCT02488759.

Response and safety.

5505 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

A randomized phase III trial of cisplatin and tumor volume directed irradiation followed by carboplatin and paclitaxel vs. carboplatin and paclitaxel for optimally debulked, advanced endometrial carcinoma. *First Author: Daniela Matei, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Patients with stage III/IVA uterine cancer (UC) carry high risk of systemic and local recurrence. Chemotherapy was shown to reduce systemic recurrence, however the risk of local failure remains high. **Methods:** The primary endpoint of this open label, randomized phase III trial was to determine if treatment with cisplatin and volume-directed radiation followed by carboplatin and paclitaxel for 4 cycles (C-RT, experimental arm) reduces the rate of recurrence or death (i.e., increases recurrence-free survival, RFS) when compared to carboplatin and paclitaxel for 6 cycles (CT, control arm) in patients with stages III-IVA (<2 cm residual disease) or FIGO 2009 stage I/II serous or clear cell UC and positive cytology. Secondary objectives were assessment of overall survival (OS), acute and late toxicities, and quality of life. A 28.5% reduction in the rate of recurrence or death was considered significant. Treatment randomization and analysis were stratified by gross residual tumor and age. **Results:** Between 6/2009 and 7/2014, 813 patients were enrolled and randomized (407 C-RT and 406-CT). Of those, 733 were eligible (344 C-RT and 360 CT), and 680 received the trial intervention (333 C-RT and 347 CT). Median follow up is 47 months. Patients characteristics were balanced between arms. There were 201 (58%) > grd 3 toxicity events in the C-RT arm and 227 (63%) in the CT arm. The most common > grd 3 events were myelosupression (40% vs. 52%), gastrointestinal (13% vs. 4%), metabolic (15% vs. 19%), neurological (7% vs. 6%), infectious (4% vs. 5%). Treatment hazard ratio for RFS was 0.9 (C-RT vs. CT; CI 0.74 to 1.10). C-RT reduced the incidence of vaginal (3% vs. 7%, HR = 0.36, CI 0.16 to 0.82), pelvic and paraaortic recurrences (10% vs. 21%, HR=0.43, CI 02.8 to 0.66) compared to CT, but distant recurrences were more common with C-RT vs. CT (28% vs. 21%, HR 1.36, CI 1 to 1.86). The analysis is premature for OS comparison. **Conclusions:** Although C-RT reduced the rate of local recurrence compared to CT; the combined modality regimen did not increase RFS in optimally debulked, stage III/IVA UC. Clinical trial information: NCT00942357.

5506 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Overall survival results of ICON6: A trial of chemotherapy and cediranib in relapsed ovarian cancer. *First Author: Jonathan A. Ledermann, University College London Cancer Institute, London, United Kingdom*

Background: ICON6 is a three-arm double-blind, placebo-controlled phase 3 trial of cediranib in platinum-sensitive relapsed ovarian cancer (NCT00532194). The primary analysis (Ledermann et al Lancet 2016) showed a significant ($p < 0.0001$), 2.3 month extension in progression-free survival (PFS) using cediranib with chemotherapy and as maintenance compared to chemotherapy and placebo. We present the final overall survival (OS) results. **Methods:** The trial was originally designed to recruit 2000 patients with OS as the primary endpoint. AstraZeneca discontinued cediranib development in Sep 2011, leading to an unplanned redesign prior to analysis. The sample size was reduced and primary outcome became PFS, comparing two arms, placebo (A) to cediranib given with chemotherapy and as maintenance (C). In arm B cediranib was given with chemotherapy followed by placebo maintenance. Analysis of PFS was performed on a sample size of 456 patients receiving a 20mg dose of cediranib. At the primary analysis, 52% patients had died; this mature OS analysis was performed after 85% patients died. **Results:** The OS analysis was performed at a median 25.6 months follow up; 102/118 (86%) died in A and 140/164 (85%) in C. In A the median survival was 19.9 months (95% CI: 17.4, 26.5) and in C 27.3 months (24.8, 33.0). Using the logrank test the Hazard Ratio estimate was 0.85 (0.66, 1.10) in favour of cediranib ($p = 0.21$). Evidence of non-proportionality of the survival curves was observed ($p = 0.0029$), so we measured the Restricted Mean Survival Time as an alternative to the median. Over 6 years, there was a 4.8 month (-0.1, 9.8) increase in time to death in C compared to A, from 29.4 to 34.2 months. The mean for arm B (32.0 months) was consistent with a benefit of increased use of cediranib. **Conclusions:** Cediranib has demonstrated a significant effect in increasing PFS. The mature survival analysis (85%) shows an improvement in median OS of 7.4 months, and an incremental benefit with increased cediranib use. The previously published significant PFS benefit coupled with the increase in OS highlights the potential value of cediranib in platinum-sensitive recurrent ovarian cancer. Further exploration of cediranib in this setting is underway. Clinical trial information: NCT00532194.

5507 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Health-related quality of life (HRQOL) and patient-centered outcomes with maintenance olaparib compared with placebo following chemotherapy in patients with germline (g) BRCA-mutated (m) platinum-sensitive relapsed serous ovarian cancer (PSR SOC): SOLO2 phase III trial. *First Author: Michael Friedlander, UNSW Clinical School, Prince of Wales Hospital, Randwick, Australia*

Background: The median PFS after chemotherapy in PSR SOC is less than 6 months in many patients. In SOLO2 (ENGOT Ov-21; NCT01874353), maintenance olaparib (O) given after response to chemotherapy resulted in a significant improvement in PFS vs placebo (P) in patients with g*BRCA*m PSR SOC (hazard ratio [HR] 0.30, 95% CI 0.22, 0.41; $P<0.0001$; median 19.1 vs 5.5 months; 63% data maturity; Pujade-Lauraine *et al*. SGO 2017). Our *a priori* hypothesis was that maintenance therapy with O would not negatively impact HRQOL compared with P and would be associated with additional patient-centered benefits to support the prolongation of PFS, the primary endpoint of SOLO2. **Methods:** HRQOL was evaluated by the Functional Assessment of Cancer Therapy-Ovarian Trial Outcome Index (FACT-O TOI) in all 295 patients. This measures functional and physical well-being and symptoms, including adverse events. Change from baseline in FACT-O TOI score during the first 12 months was the primary HRQOL analysis (mixed model repeated measures). Secondary planned analyses included duration of 'good quality of life' by time without symptoms of disease or toxicity (TWiST) and quality-adjusted PFS (QAPFS; a single measure of PFS and HRQOL outcomes). **Results:** There was no significant detrimental effect of O vs P on HRQOL analyzed by change from baseline in TOI score (–3.1 vs –2.9, respectively, difference (O minus P) –0.2; 95% CI –2.4, 2.1; $P=0.88$). There was a significant improvement for patients on maintenance O in TWiST (13.5 vs 7.2 months, difference 6.3; 95% CI 2.9, 8.6; $P<0.001$) and QAPFS (mean 14.0 vs 7.3 months for O and P, respectively, difference 6.7; 95% CI 5.0, 8.5; $P<0.0001$). **Conclusions:** Maintenance O did not detrimentally impact HRQOL relative to P. The significant improvement in PFS with O was associated with additional patient-centered benefits, including a longer duration without symptoms of disease or treatment toxicity and longer QAPFS. Clinical trial information: NCT01874353.

5508 Oral Abstract Session, Fri, 3:00 PM-6:00 PM

Phase II randomized trial of neoadjuvant (NA) chemotherapy (CT) with or without bevacizumab (Bev) in advanced epithelial ovarian cancer (EOC)þ (GEICO 1205/NOVA TRIAL). *First Author: Yolanda Garcia Garcia, Hospital Parc Tauli Sabadell, Sabadell, Spain*

Background: First line carboplatin(C)-paclitaxel(P) and Bev has proved to be an active combination after primary debulking surgery and improve overall survival in sub-optimal resected advanced EOC patients (pts). However, the role of Bev in the NA setting has not been well defined yet. **Methods:** We performed a phase II randomized open label multicentric study in pts with high grade serous or endometrioid EOC, FIGO stage III-IV, ECOG 0-2, considered unresectable in whom NA CT and interval debulking surgery (IDS) were planned. Main exclusion criteria were intestinal occlusion and contraindication for Bev. Pts were randomized to 4 courses of triweekly C AUC 6 and P 175 mg/m2 iv alone or with at least 3 courses of Bev 15 mg/kg i.v. every 3w in experimental arm. The primary endpoint was complete macroscopic response (CMR) rate at IDS. Secondary objectives were safety, surgical feasibility, optimal surgery rate (OSR), RECIST 1.1 and CA-125 GCIG response rate. Sample collection for translational research was taken at diagnosis and IDS. After surgery pts in both arms completed 3 additional cycles of CT and Bev, followed by maintenance Bev up to 15 mo. **Results:** Sixty-eight out of seventy-one evaluable pts. Clinical pts characteristics were well balanced, median age 60.0 y.o and a 33.8% stage IV. No differences in CMR were found at IDS (2/33 Control and 2/35 Bev). Bev arm was favoured in rate of surgical feasibility (66.7 vs 88.6%, p = 0.029), while no differences were found in OSR (63.6 vs 65.7%, p = 0.858) and in number of pts considered unresectable at time of IDS (2 vs 0). Median time from IDS to restarting Bev was 7.1 w. Median PFS was 20.3 mo in both arms, 20.13 mo in control arm and 20.36 mo in Bev arm, HR: 1.14 (IC 95%, 0.656 - 1.994). There were lower rates of serious adverse events (grade 3-4) in Bev arm (69.7 vs 42.9%, p = 0.026). 8 pts presented AE of special interest in Bev arm (3G2 proteinuria, 1G2/1G3 hypertension, 1G3 entero-vaginal fistulae, 1G3 entero-cutaneous fistulae, 1G3 deep venous thrombosis, 1G2 bleeding, 1G1 surgical dehiscence). **Conclusions:** NACT with Bevacizumab was feasible and improved the surgical outcomes at IDS in pts initially considered unresectable. Clinical trial information: 2012-003883-31.

5509 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

A novel genomic rearrangement signature to predict poor survival among women with high grade serous ovarian cancer. *First Author: Robert Tyler Hillman, MD Anderson Cancer Center, Houston, TX*

Background: Resistance to platinum-based chemotherapy is a major cause of disease progression and mortality among women with high grade serous ovarian cancer (HGSOC). It is not known whether patterns of genomic rearrangement are predictive of clinical outcome in HGSOC. **Methods:** This was a retrospective cohort analysis of whole genome sequences from 80 HGSOC tumors. Genomic rearrangements were identified and categorized by size and type (inversion, duplication, deletion, or translocation). Non-negative matrix factorization was then used to extract rearrangement signatures. Wilcoxon rank-sum test was used for comparison of continuous variables. Univariate and multivariate analyses were performed using Cox proportional hazards models. **Results:** A rearrangement signature characterized by 10 kilobase to 10 megabase duplications and deletions was identified. The median overall survival (OS) was 22.5 months (95% CI, 20.1 to 33.5 months) in the Sig-High group versus 46.0 months (95% CI, 27.7 to 80.6 months) in the Sig-Low group (hazard ratio, 2.13; 95% CI, 1.27 to 3.55; P=0.004). Exploration of clinical variables showed a significantly higher median signature contribution in platinum-resistant disease than platinum-sensitive disease (20.0% vs 9.1%, p=0.007). Multivariate analysis showed a hazard ratio for death of 2.1 associated with the Sig-High group (Table). Validation of this signature was performed using HGSOC copy number data from the Cancer Genome Atlas. In this cohort, the median OS was 38.8 months (95% CI, 36.7 to 44.5 months) in the Sig-High group versus 49.5 months (95% CI, 45.2 to 56.3 months) in the Sig-Low group (hazard ratio, 1.44; 95% CI, 1.14 to 1.82; P=0.024). **Conclusions:** A genomic rearrangement signature is associated with chemoresistance and poor prognosis in HGSOC. Prediction of poor survival outcomes could allow early identification of women who may be candidates for clinical trials.

Multivariate model of OS.

	Hazard Ratio	95% Confidence Interval	p value
Age at Diagnosis	1.01	0.98-1.04	0.53
Initial Stage	0.55	0.25-1.24	0.15
Optimal Tumor Debulking	0.87	0.49-1.53	0.62
Germline BRCA1/2 Mutation	0.80	0.37-1.72	0.57
Rearrangement Signature Group	2.10	1.19-3.70	0.01

5510 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Is the mesenchymal transition subtype more responsive to dose dense taxane chemotherapy combined with carboplatin (ddTC) than to conventional taxane and carboplatin chemotherapy (TC) in high grade serous ovarian carcinoma? A survey of Japanese Gynecology Oncology Group study (JGOG3016A1). *First Author: Ryusuke Murakami, Department of Gynecology and Obstetrics, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Background: High-grade serous ovarian cancer (HSOC) was divided into four transcriptome subtypes (i.e. Mesenchymal, Immunoreactive, Proliferative, and Differentiated). We established a new pathological classification based on these transcriptome subtypes: Mesenchymal Transition (MT) type, Immune Reactive (IR) type, Solid and Proliferative (SP) type and Papillo-Glandular (PG) type (PMID: 26993207). The MT type has the worst prognosis. We discovered the Mesenchymal transcriptome subtype might be sensitive to taxane chemotherapy. Therefore, we hypothesized that the MT type, which represents the Mesenchymal transcriptome subtype, may respond better to dose dense taxane combined with carboplatin (ddTC) rather than to conventional taxane and carboplatin (TC). **Methods:** We collected 207 HSOC slides registered in the Japanese Gynecology Oncology Group 3016 (JGOG3016) study. Two of the authors, R.M. and I.K., classified the samples into the four pathological subtypes (n=201). We categorized the patients into two groups based on the treatment they received: ddTC (n=95) or TC (n=106). Progression free survival (PFS) was compared between the two groups for each pathological subtype. **Results:** Among the MT patients, the ddTC group had a significantly better PFS than the TC group (n= 30 vs 42, median survival: 1.8 vs 1.2 years, p=0.01). Among the SP patients, the ddTC group had better PFS than the TC group, even though the difference was not statistically significant (n=22 vs 27, median survival: 3.2 vs 1.4 years, p=0.08). In contrast, among the IR patients, the two groups showed no significant difference in PFS (n=16 vs 16, median survival: 5.2 vs 5.8 years, p=0.64). The PG patients also showed no significant difference in PFS between the two groups (n=27 vs 21, median survival: 1.5 and 1.7 years, p=0.64). **Conclusions:** The HSOC of MT type is more responsive to ddTC than to TC. This new pathological classification reflecting HSOC transcriptome subtypes leads to individualization of chemotherapy treatments.

5511 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Evaluation of BRCA1/2 and homologous recombination defects in ovarian cancer and impact on clinical outcomes. *First Author: Melinda S. Yates, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Recent studies show that germline or somatic BRCA1/2 mutations and homologous recombination (HR) defects can be used to predict response to PARP inhibitors in recurrent ovarian cancer. However, the impact of defects in BRCA1/2 and HR genes on overall clinical outcomes are not yet defined for patients undergoing neoadjuvant chemotherapy (NACT) versus upfront surgical debulking (USD). **Methods:** Previously untreated ovarian cancer patients were prospectively enrolled under approved IRB protocol. Germline and tumor BRCA1/2 mutation testing and methylation were analyzed when sufficient tumor and blood was available. Mutation in 21 additional hereditary cancer genes (including HR genes) was also evaluated. Tumor HR defects were scored on LOH, telomeric allelic imbalance, and large-scale state transitions (as previously described). Presence of germline or somatic BRCA1/2 mutations, BRCA1 methylation, HR score $\geq$42, or germline mutation in other HR genes were defined together as HRD positive. **Results:** Of 299 enrolled patients, 129 (43%) received USD and 170 (57%) received NACT. Patients receiving USD had better outcomes compared to NACT, including overall survival (OS, 65.8 vs 45.2 months, p = 0.0003) and event free survival (EFS, 24.8 vs 15.6 months, $p < 0.0001$). In the overall cohort, EFS was significantly longer for HRD positive patients vs HRD negative (20.5 vs 16.3 months, p = 0.0268). Patients with somatic and germline BRCA1/2 mutations had longer OS vs BRCA1/2 negative (65.3 vs 46.1 months, p = 0.0403). Overall outcomes were worse in NACT compared to USD, but impact of BRCA1/2 mutations and HR defects was stronger in this group. NACT patients with any HR defect had longer EFS (19.7 vs 14.5 months, p = 0.0247). NACT patients with BRCA1/2 germline mutations had longer OS (65.3 vs 38.3 months, p = 0.0230). NACT patients with BRCA1/2 germline mutation had longer EFS (22.6 vs 14.6 months, p = 0.0047). OS and EFS in USD patients were significantly changed based on only debulking status; mutation or HR status did not have a statistically significant effect. **Conclusions:** While HR defects and BRCA1/2 mutations influence overall outcomes for ovarian cancer patients, the impact is stronger in NACT compared to USD.

5512 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Comprehensive genomic profiling (CGP) with loss of heterozygosity (LOH) to identify therapeutically relevant subsets of ovarian cancer (OC). *First Author: Julia Andrea Elvin, Foudation Medicine, Inc., Cambridge, MA*

Background: Defective homologous recombination DNA repair (HRD) is associated with high grade serous (OC-S) histology, longer survival, and platinum (Pt) or PARP inhibitor (PARPi) sensitivity. HRD causes LOH, a pattern of allelic imbalance detectable by CGP. *BRCA*wt OC-S can have LOH and respond to PARPi, while non-serous (OC-NS) or difficult to classify (OC-NOS) OC are often less responsive to Pt-based therapy. Integrating multiple genomic features derived from CGP may define other therapeutically relevant subsets. **Methods:** DNA from FFPE tumor tissue obtained during clinical care for 4114 advanced OC was analyzed for all classes of genomic alterations (GA) by hybrid-capture, next-generation sequencing of up to 315 genes. Tumor subtype counts were OC-S, n = 2770; OC-NOS, n = 807; OC-NS, n = 537 (mucinous, clear cell, endometrioid, neuroendocrine, carcinosarcomas, and low grade serous). Algorithms evaluated microsatellite instability (MSI), tumor mutation burden (TMB; TMB-H $\geq$ 10 muts/Mb), and LOH (LOH-H $\geq$ 14, LOH-L $<$ 14). **Results:** 706/4114 (17.2%) OC had $\geq$1 deleterious *BRCA* GA, OC-S (18.7%) more so than OC-NS (4.4%). Median LOH score for OC-S was significantly higher than OC-NS (12.8 vs. 5.8, $p < 0.05$). *BRCAmut* OC-S and OC-NS were similarly LOH-H (86% and 75%), unlike *BRCAwt* OC-S (38.4%) or OC-NS (18%). Regardless of LOH, similar co-occurrence of *MYC* (26.9%) and/or NF1 (19%) GA was seen in *BRCAmut* OC. *BRCAwt* LOH-L OC commonly had *CCNE1* (19.7%), *KRAS* (19%), *PIK3CA* (16.2%), *AKT2* (7.4%), *ERBB2* (4.7%), or *BRAF*(3.3%) GA. Frequency of TMB-H was 2.5% and MSI-H 1%. Correlation of GA with treatment, clinical histories and outcomes for some patients will be presented. **Conclusions:** *BRCAmut* or OC-S are commonly LOH-H; ~1 in 5 *BRCAwt* OC-NS, including carcinosarcomas and mucinous, are also LOH-H. Genes co-mutated in late stage LOH-H OC may be linked to treatment resistance. CGP of this large OC cohort reveals molecular, rather than histologic, patient subsets that may benefit from PARPi (46.2% *BRCA*mut or LOH-H), targeted therapy ($>$ 50% *BRCA*wt LOH-L, excluding *TP53*) or immunotherapy (3.5% TMB-H or MSI-H), providing more support for insurance coverage and integration into OC clinical trials.

Pembrolizumab in patients (pts) with PD-L1–positive (PD-L1$^+$) advanced ovarian cancer: Updated analysis of KEYNOTE-028. *First Author: Andrea Varga, Institut Gustave Roussy, Villejuif, France*

Background: Overexpression of the PD-1 ligand PD-L1 has been demonstrated in ovarian cancer and may hinder an effective antitumor immune response. A preliminary analysis of the ovarian cancer cohort of the KEYNOTE-028 study (NCT02054806) suggested that the PD-1 inhibitor pembrolizumab has promising antitumor activity in pts with PD-L1$^+$advanced ovarian cancer. An updated analysis of the ovarian cancer cohort based on 15.5 months of follow-up is presented. **Methods:** Key eligibility criteria for the ovarian cohort of this nonrandomized, multicohort phase Ib trial were advanced ovarian epithelial, fallopian tube, or primary peritoneal carcinoma; failure of prior therapy; PD-L1 positivity defined as membranous staining on $\geq$1% of tumor and associated inflammatory cells or positive staining in stroma; and ECOG PS 0/1. Pembrolizumab (10 mg/kg every 2 wk) was given for $\leq$2 y or until confirmed progression/unacceptable toxicity. Response was assessed per RECIST v1.1 by investigators every 8 wk for the first 6 mo and every 12 wk thereafter. Primary end points were safety, tolerability, and confirmed ORR. **Results:** 26 pts (median age, 57.5 y) were enrolled; 61.5% were white, 38.5% received $\geq$5 therapies for recurrent/metastatic disease, and 53.8% received prior neoadjuvant/adjuvant therapies. As of the October 10, 2016, data cutoff, the median follow-up duration was 15.5 mo (range, 2.4-30.8 mo). 1 pt had a complete response and 2 had partial responses; 6 pts had stable disease as best response. ORR was 11.5% (95% CI, 2.4%-30.2%). Tumor reduction was observed in 6/26 (23.1%); all 3 patients who responded completed 2 years of treatment. Median duration of response was not reached (range, 24.9+ to 26.5+ mo). Median (95% CI) PFS and OS were 1.9 mo (1.8-3.2 mo) and 13.1 mo (6.7-17.5 mo) respectively. Treatment-related AEs occurred in 73.1% of pts, and the most common were arthralgia (19.2%), nausea (15.4%), pruritus (15.4%), rash (11.5%), and diarrhea (11.5%). 1 patient had a grade 3 drug-related adverse event (transaminase increased). **Conclusions:** With 15.5 mo of follow-up, pembrolizumab continued to be well tolerated and demonstrated durable antitumor activity in pts with advanced ovarian cancer. Clinical trial information: NCT02054806.

5514 Poster Discussion Session; Displayed in Poster Session (Board #336), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Pembrolizumab for previously treated advanced cervical squamous cell cancer: Preliminary results from the phase 2 KEYNOTE-158 study. *First Author: Jan H.M. Schellens, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: In the phase 1b KEYNOTE-028 study, pembrolizumab showed promising activity as monotherapy in patients with advanced cervical cancers that expressed PD-L1. As part of the ongoing, multicohort, phase 2 KEYNOTE-158 study (NCT02628067), we assessed the antitumor activity of pembrolizumab in a larger cohort of patients with previously treated, advanced cervical squamous cell cancer who were enrolled without regard to tumor PD-L1 or other tumor biomarker expression. **Methods:** Key eligibility criteria for this cohort included age $\geq$18 years, histologically or cytologically confirmed advanced cervical squamous cell cancer, progression on or intolerance to $\geq$1 line of standard therapy, ECOG PS 0 or 1, and provision of a tumor sample for biomarker analysis. Patients received pembrolizumab 200 mg Q3W for 2 years or until progression, intolerable toxicity, or physician or patient decision. Clinically stable patients with progression could remain on treatment until progression was confirmed on subsequent assessment. Tumor imaging was performed every 9 weeks for the first 12 months and every 12 weeks thereafter. PD-L1 positivity was evaluated retrospectively by IHC and was defined as a combined positive score $\geq$1%. Primary end point was ORR assessed per RECIST v1.1 by independent central radiologic review. Planned enrollment is ~100 patients. This efficacy analysis includes patients who had $\geq$18 weeks of follow-up as of Oct 19, 2016. **Results:** Among the first 47 patients with advanced cervical cancer who enrolled, ORR was 17% (95% CI, 8%-31%), with 3 confirmed and 5 unconfirmed responses. 41 (87%) patients had PD-L1–positive tumors, and ORR was independent of PD-L1 status. Among the 15 patients who had $\geq$27 weeks of follow-up, ORR was 27% (95% CI 8%-55%), with 3 confirmed responses and 1 unconfirmed response. Safety and updated efficacy data for 83 patients with $\geq$27 weeks of follow-up will be available for presentation. **Conclusions:** Preliminary data from KEYNOTE-158 suggest that pembrolizumab has promising antitumor activity in patients with previously treated advanced cervical squamous cell cancer. The observed ORR with pembrolizumab appears to increase with longer follow-up. Clinical trial information: NCT02628067.

Aromatase inhibitor maintenance therapy in high grade advanced ovarian cancer to delay first recurrence. *First Author: Alexandra Maria Knipprath-Mészáros, Gynecological Cancer Centre, University Hospital Basel, Basel, Switzerland*

Background: Ovarian cancer (OC) is mostly diagnosed as G3 serous advanced stage disease with survival of only 20% in 5 years. Maintenance therapy after 1st line chemotherapy is increasingly used, particularly with Bevacizumab or PARP inhibitors. However, the effect of antihormonal treatment in breast cancer but also in relapsed gynecological cancers has been shown. Also in low grade OC, data are highly supportive of antihormonal treatment. In a previous study of ours, also high grade serous cancers express high amounts of estrogen receptor (ER). The aim of this study was to analyze whether a maintenance antihormonal therapy in advanced OC adds a benefit in relation to the time of recurrence. **Methods:** All newly diagnosed G3 FIGO III/IV OC cases at our Hospital were assessed prospectively for ER expression. Patients with positive ER status ($>$ 10%) were treated as maintenance therapy with Letrozol 2.5mg 1x/d or not. Progression free survival was recorded and analyzed according to Kaplan-Meier. Patients with macroscopic residual disease post surgery receiving Bevacizumab maintenance treatment were also included. **Results:** We identified 51 patients with G3 serous OC FIGO III/IV expressing ER. Hereby, 24 patients received and 27 patients did not receive Letrozol after adjuvant chemotherapy. Time to progression ranged from 4 to 121 months. The use of Letrozol was associated with a significant prolonged progression free interval. After 12 months, only 65% of women in the control group vs 84% in the Letrozol group were progression-free. After 24 months, the effect was even stronger (46% in the control group vs 74% with Letrozol ($p = 0.02$)). Within the subgroup of patients with residual disease treated with Bevacizumab a similar effect was seen with 41% of patients progression free after 12 months vs 89% when taking Letrozol in addition to Bevacizumab. **Conclusions:** The use of Letrozol as a maintenance therapy after the 1st line treatment in G3 advanced stage serous OC patients was associated with a longer recurrence free interval in our cohort. These findings warrant a randomized controlled trial comparing all existing maintenance regimen as this might have a major influence on cost development in OC treatment.

Evaluating the cost-effectiveness of current FDA-approved PARP inhibitors for the treatment of recurrent ovarian cancer. *First Author: Juliet Elizabeth Wolford, University of California, Irvine, Orange, CA*

Background: Unlike approved IV administered therapies, Medicare is under no obligation to cover prescription medicines. We sought to evaluate the cost-effectiveness of the two FDA-approved orally administered PARP inhibitors (PARPi), olaparib and rucaparib. **Methods:** A Markov model was created in TreeAge Pro 2015 with nodes in the chain allowing patients to transition through response, hematological complications, non-hematological complications, progression, and death. Separately, the PARP inhibitors were compared with IV administered drugs approved for recurrent ovarian cancers including platinum-based, non-platinum, and bevacizumab-based regimens. Toxicity and mean PFS rates for the different agents were obtained from registration trial data. Costs of IV chemotherapy, managing toxicities, infusions, and supportive care were estimated using 2015 Medicare data. Incremental cost-effectiveness ratios (ICER) were calculated and survival was reported in quality adjusted life months. **Results:** Platinum-based combinations were the most cost-effective at $1,672/PFS mo as compared to non-platinum agents ($6,688/mo), bevacizumab-containing regimens ($12,482/mo), olaparib ($13,3731/mo), and rucaparib ($14,034/mo). Considering a cost of $114,478 for olaparib and $137,068 for rucaparib prior to progression, costs associated with PARPi were 7.1 to 8.3X more than platinum combinations. To better compare the registration trial data to PARPi data, probability was adjusted to 2nd line for rucaparib, revealing it's ICERs' of per month of life added to be $26,997 for bevacizumab, $17,757 for non-platinum, and $79,585 for platinums. Using the adjusted-to-2nd-line probabilities for olaparib, exhibited ICERs were $16,549 for bevacizumab, $25,637 for non-platinums and $72,083 for platinums. **Conclusions:** The high costs of PARPi were not balanced by costs of infusion and managing toxicities of IV drugs typically associated with lower response rates and shorter PFS in the recurrent space. Balancing incremental clinical benefit with novel therapies remains problematic and could widen disparities among those with limited access to care.

Efficacy of niraparib on progression-free survival (PFS) in patients (pts) with recurrent ovarian cancer (OC) with partial response (PR) to the last platinum-based chemotherapy. *First Author: Mansoor Raza Mirza, Nordic Society of Gynecologic Oncology (NSGO) and Rigshospitalet–Copenhagen University Hospital, Copenhagen, Denmark*

Background: Therapeutic paradigms for recurrent OC vary by geography. Maintenance following response to platinum-based chemotherapy (Plat) is standard in Europe, whereas in the US maintenance is considered following complete response (CR) vs treatment for partial response (PR). Niraparib is a highly selective PARP 1/2 inhibitor (PARPi). In preclinical studies it concentrates in the tumor relative to plasma, delivering > 90% durable PARP inhibition and antitumor effects. Niraparib demonstrated significantly longer PFS vs placebo (P) in pts with recurrent OC following a CR or PR to Plat in the randomized, controlled, double-blind phase 3 ENGOT-OV16/NOVA trial. **Methods:** Pts with recurrent OC, no prior PARPi use, ≥2 prior courses of Plat, and response to most recent Plat were eligible. Pts were assigned to 1 of 2 cohorts on the basis of g*BRCA* testing (g*BRCA*mut or non-g*BRCA*mut) and randomized 2:1 within each cohort to niraparib 300 mg or P qd until progressive disease (PD). Randomization occurred up to 8 weeks after last dose of the most recent Plat. Pts were stratified by time to progression after penultimate Plat (6 to < 12 months or ≥12 months), prior use of bevacizumab (yes/no), and response to most recent Plat (CR or PR). PFS was measured from time of randomization to death or earliest PD as assessed by independent review committee. **Results:** 49% of pts (niraparib: 67/138; P: 32/65) in the g*BRCA*mut and ~49% of pts (niraparib: 117/234 [50%]; P: 56/116 [48%]) in the non-g*BRCA*mut cohorts entered NOVA with a PR following their most recent Plat. At time of unblinding, 30 (45%) niraparib and 23 (72%) P pts in the g*BRCA*mut and 65 (56%) niraparib and 45 (80%) P pts in the non-g*BRCA*mut cohorts had PFS events. PFS hazard ratios (95% CI) were 0.24 (0.131–0.441) in g*BRCA*mut and 0.35 (0.230–0.532) in non-g*BRCA*mut cohorts for pts who had a PR to their most recent platinum regimen. This compared favorably to the overall NOVA study results, where PFS hazard ratios (95% CI) were 0.27 (0.173–0.410) in g*BRCA*mut and 0.45 (0.338–0.607) in non-g*BRCA*mut cohorts. **Conclusions:** Niraparib treatment provided significant benefit to pts with recurrent OC who achieved a PR following Plat. Clinical trial information: NCT01847274.

5518 Poster Discussion Session; Displayed in Poster Session (Board #340), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Adverse events (AEs) with maintenance olaparib tablets in patients (pts) with *BRCA*-mutated (*BRCA*m) platinum-sensitive relapsed serous ovarian cancer (PSR SOC): Phase III SOLO2 trial. *First Author: Jonathan A. Ledermann, University College London Cancer Institute, London, United Kingdom*

Background: In the SOLO2 trial (ENGOT Ov-21; NCT01874353), maintenance therapy with the PARP inhibitor olaparib significantly improved PFS vs placebo (PBO) in *BRCA*m PSR SOC pts (HR 0.30, 95% CI 0.22–0.41, *P*<0.0001; median 19.1 vs 5.5 months) and was well tolerated (Pujade-Lauraine *et al*, SGO 2017). We analyzed AEs in SOLO2, the first study in PSR SOC to use the olaparib tablet formulation. **Methods:** Pts with *BRCA*m PSR SOC, who were in response to platinum chemotherapy, were treated with olaparib (300 mg bid; tablets; n=195) or PBO (n=99) until progression. AEs were graded by CTCAE v4.0. **Results:** The most common AEs with olaparib – nausea, fatigue/asthenia, anemia, and vomiting – were largely grade 1–2, though anemia was the most common grade ≥3 AE. AEs of fatigue/asthenia, vomiting and nausea generally improved as treatment continued, though fatigue/asthenia and anemia could last for several months (table). Most AEs were manageable by supportive treatment, dose interruptions (olaparib, 45%; PBO, 18%) and dose reductions (olaparib, 25%; PBO, 3%). Discontinuation of olaparib due to AEs was minimal (11%); anemia and neutropenia were the only AEs leading to discontinuation of olaparib in >one pt. **Conclusions:** Most AEs experienced by pts receiving olaparib tablets in SOLO2 were low grade and manageable. Initial nausea, vomiting and fatigue generally improved with ongoing treatment. The majority of AEs first occurred within the first three months of treatment. AEs causing treatment discontinuation were rare and mainly hematological. Clinical trial information: NCT01874353.

A phase 3 trial of hyperthermic intraperitoneal chemotherapy (HIPEC) for ovarian cancer. *First Author: Willemien Van Driel, Center for Gynecologic Oncology, Amsterdam, Netherlands*

Background: Cytoreductive surgery and systemic therapy are essential for newly diagnosed ovarian cancer. We conducted a multicenter phase 3 trial to study whether the addition of intraperitoneal chemotherapy under hyperthermic conditions (HIPEC) to interval cytoreductive surgery would improve outcome among patients receiving neo-adjuvant chemotherapy for stage III epithelial ovarian cancer. **Methods:** We randomly assigned patients who showed at least stable disease after three cycles of carboplatin (area under the curve 6) and paclitaxel (175 mg/m^2) to receive interval cytoreductive surgery with or without HIPEC using cisplatin (100 mg/m^2). Randomization was performed per-operatively and eligible patients had no residual mass greater than 2.5 mm. Three additional cycles of carboplatin and paclitaxel were given post-operatively. The primary endpoint was recurrence-free survival. Overall survival, toxicity, and quality-of-life were key secondary endpoints. **Results:** A total of 245 patients were randomly assigned to one of the two treatment strategies. In an intention-to-treat analysis, interval cytoreductive surgery with HIPEC was associated with longer recurrence-free survival than interval cytoreductive surgery alone (15 vs. 11 months, respectively; hazard ratio [HR], 0.65; 95% confidence interval [CI], 0.49 to 0.86; P=0.003). At the time of analysis, 49% of patients were alive, with a significant improvement in overall survival favoring HIPEC (48 vs. 34 months; HR, 0.64; 95% CI, 0.45 to 0.91, P=0.01). The number of patients with grade 3-4 adverse events was similar in both treatment arms (28% vs. 24%, p=0.61). Quality-of-life analysis will follow. **Conclusions:** The addition of HIPEC to interval cytoreductive surgery is well tolerated and improves recurrence free and overall survival in patients with stage III epithelial ovarian cancer. Clinical trial information: NCT00426257.

Randomized trial of hyperthermic intraperitoneal chemotherapy (HIPEC) in women with primary advanced peritoneal, ovarian, and tubal cancer. *First Author: Myong Cheol Lim, National Cancer Center, Seoul, Republic of Korea*

Background: Cytoreductive surgery followed by taxane and platinum-based chemotherapy is standard treatment for advanced ovarian cancer. We compared results of randomly allocated HIPEC in primary advanced epithelial ovarian cancer who have optimal cytoreductive surgery in this prospective randomized multicenter trial. The study endpoint is to evaluate progression free survival (PFS) and overall survival (OS). **Methods:** 184 patients staged III and IV were randomly allocated to trial arm (HIPEC, cisplatin 75 mg/m^2, 90 min) or control arm (no HIPEC), intraoperatively based on residual tumor (size $<$1cm) from July 2010 to January 2016. The groups were well balanced according to the age, body mass index, performance status, stage, histology, serum CA125 level, and use of neoadjuvant chemotherapy (NAC) at study entry. **Results:** 184 pts (HIPEC, 92; control, 92) were included in this preplanned analysis. No mortality after surgery $\pm$ HIPEC was identified in both groups. Postoperative outcomes including extent of surgery, estimated blood loss, residual tumor, and hospitalization day were not different between both group, except operation time (487 vs. 404 min, $p<0.001$) due to HIPEC procedure. The most common adverse event was anemia: 67.4% in HIPEC and 50% in control group (p=0.025). The other toxicity common in HIPEC group is the elevation of creatinine (15.2% vs. 4.3%, p=0.026). There were no differences between both groups for transfusion (35.9 vs. 29.3, p=0.432), neutropenia (19.6 vs. 10.9%, p=0.151), and thrombocytopenia (9.8 vs. 3.3%, p=0.136). Two-year PFS was 43.2% and 43.5% and 5-year PFS was 20.9% and 16.0% in HIPEC and control group, respectively (p=0.569). Five-year OS was 51.0% and 49.4% in HIPEC and control group, respectively (p=0.574). In women who received NAC, the median PFS for HIPEC and control group were 20 and 19 months, respectively (log-rank test, p = 0.137) and the median OS for HIPEC and control group were 54 and 51 months, respectively (log-rank test, p = 0.407). In the subgroup with NAC, 2-year PFS was 37.2% in HIPEC group and 29.5% in control group and 5-year OS was 47.9% in HIPEC group and 27.7% in control group. After 20 months in PFS and 30 months in OS, two survival curves in women who received NAC showed the trend of gradual distinction, favoring HIPEC group. **Conclusions:** No mortality was identified and postoperative morbidities were not statistically different between two groups except anemia and creatinine elevation in HIPEC group. The survival analysis did not show the statistical superiority of the HIPEC arm. More follow-up is required to confirm the impact of HIPEC on long-term survival outcome in ovarian cancer, especially in NAC group. Clinical trial information: NCT01091636.

5521 Poster Discussion Session; Displayed in Poster Session (Board #343), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

The prognostic value of tumor residuals indicated by surgeon, by radiology or an integrated approach by surgeons' assessment and pre-chemotherapy CT-scan in patients with advanced ovarian cancer: An exploratory analysis of the AGO Study led Intergroup trial AGO-OVAR 12. *First Author: Florian Heitz, Department of Gynecologic Oncology, Kliniken Essen-Mitte, Essen, Germany*

Background: Post-OP TR is a strong prognostic factor in AOC; the best prognosis is observed after complete resection (TR0). TR assessment is performed at the end of the surgery and may be exposed to personal bias. Pre-Chemo CT may improve post-OP assessment, however, it may also be prone to findings by post-OP tumor re-growth, tissue repair or scarring. **Methods:** Pts with FIGO IIB-IV AOC recruited into the double-blind randomized frontline AGO-OVAR12 trial were scheduled for baseline CT before the 1st chemo cycle. SA and RA of TR were compared. Additionally, a measurement of TR integrating both approaches were assessed (IA). For this IA information of surgical and path reports were reviewed by two of the authors. **Results:** 1355 pts had complete data for all 3 assessment methods. Of 689 pts with TR0 in SA, 497 (72%) and 539 (78%) had also TR0 pre-Chemo (RA and IA), but showed TR$>$0 in 192 (28%) and 150 pts (22%), respectively. Pts with SA defined TR0 had a similar median PFS of 27.6 mos compared to TR0 defined by RA (27.8 mos) and IA (28.9 mos). Pts with concordant TR0 (SA/ IA and SA/ RA) had a median PFS of 28.9 mos. In contrast, pts with discordant SA TR0 - RA TR$>$0 or SA TR0 - IA TR$>$0 showed inferior median PFS of 19.2 mos (HR: 1.89, 95%CI: 1.48-2.40; $p<0.0001$) and 16.9 mos (HR: 2.02, 95% CI: 1.57- 2.59; $p<0.0001$), respectively. Pts with concordant TR$>$0 had an even lower median PFS of 13.5 (SA and IA) and 12.9 mos (SA and RA). PFS of the experimental therapy or placebo dependent if SA, RA or IA were used, will be presented. **Conclusions:** Pre-Chemo CT provides information separating the group of pts with post-OP TR0 in pts with TR0 and pts with TR$>$ 0 pre-Chemo. The latter group showed PFS values in between those with surgically assessed post-OP TR0 and those with post-OP TR$>$ 0, forming a third prognostic group. Detailed analysis should evaluate to what extend tumor biology, surgical bias, or imperfect imaging contribute to the discrepancies. Integrating all this may lead to better definition of prognostic groups and the need for specific treatment strategies.

Phase II clinical and molecular trial of oral ENMD-2076 in clear cell ovarian cancer (CCOC): A study of the Princess Margaret phase II consortium. *First Author: Stephanie Lheureux, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: CCOC is a rare chemoresistant subtype of OC. ENMD-2076 is an oral multi-target kinase inhibitor with antiangiogenic/antiproliferative profile; selective activity against the mitotic kinase Aurora A and VEGFRs, FGFRs. **Methods:** This is a multi-center Phase II study of ENMD-2076 in pts with recurrent CCOC and prior platinum. Primary endpoints were ORR and 6-m PFS rate. Correlative analyses include ARID1A, PTEN expression by IHC and genome sequencing by custom capture library of 555 genes. **Results:** Completed study enrolled 40 pts – 37 evaluable, median age of 54 (39-78). 12 pts (31%) received prior radiation and 24 (62%), 11 (28%), 4 (10%) had 1, 2 or 3 lines of chemotherapy. Archival tissue was available for 36/37 pts. Best response was PR for 2 pts (1 unconfirmed), SD for 25 (68%) and PD for 10 (26%) pts. Median PFS was 3.7 months (m) (95%CI: 3.4-4.4). ENMD was well tolerated with main related AE: hypertension (21 pts - 8 G3), nausea (18 pts -1 G3) and diarrhea (17 pts - 4 G3). By IHC, median PFS (95%CI) in ARID1A loss (19 pts) was 4.1m (3.5-10.3) vs 3.6m (1.7-3.9) in ARID1A positive (17 pts) (p = 0.024). Whilst, by IHC, PTEN was loss in 20 pts; intact in 10 and heterogeneous in 6 pts; no difference in PFS was observed. By PI3KCA mutation status, median PFS (95% CI) in wild-type (WT) (12 pts) was 5m (3.4-19.3) vs 3.7m (167-4.4) in mutated group (20 pts) (p = 0.038). Molecular profiling showed variants in PI3KCA (27%), ARID1A (26%), TP53 (7%), BRIP1 (7%), ATM (11%), BRCA1 (5%), BRCA2 (3%), RAD50 (3%), PABL2 (1%), RAD51C (1%), FANCA (1%), CTNNB1 (3%).The patient with the longest treatment duration (22m) was PTEN WT, diploid PTEN, putative bi-allelic inactivation of ARID1A. **Conclusions:** The PFS at 6 months was 20% for the evaluable patients, 31% in ARID1A loss and 12% in ARID1A positive patients. Loss of ARID1A, a known negative prognostic factor, was correlated with better PFS on ENMD-2076. Additional molecular profiling of the baseline biopsy material is underway. Clinical trial information: NCT01914510.

Stage I ovarian immature teratomas: Is there a role for chemotherapy? *First Author: John K. Chan, Palo Alto Medical Foundation, San Francisco, CA*

Background: To determine the impact of chemotherapy on survival of patients with stage I ovarian immature teratomas. **Methods:** Data obtained from the National Cancer Database from 2004-2013. Kaplan-Meier methods and multivariate Cox regression models were used for statistical analyses. **Results:** Of 888 patients (median age 24 years), 76%, 7%, 15%, 3% were stages I, II, III, and IV, respectively. 27%, 28%, 38%, and 8% had grades 1, 2, 3 and 4. The predominant racial group was White (50%) and remainder Black (19%), Hispanic (16%), Asian (6%) and other (9%). 64% had fertility sparing surgery and 55% received chemotherapy. For all patients, 5 year survival was over 90%. Chemotherapy did not change the 5 year survival for stage I or stage II disease (p = 0.35 and p = 0.69, respectively). However, chemotherapy improved 5 year survival from 59% to 76% in stages III-IV ($p < 0.01$). When controlling for other factors, older age (HR 3.2, $p < 0.01$), stages II and III-IV (HR 6.0, $p < 0.01$; HR 10.6, $p < 0.01$) and grades 3-4 (HR 15.3, $p < 0.01$) had worse survival. In a subset analysis of stage I patients chemotherapy did not improve 5 year survival of those with stage I grade 1 (p = 0.75) but chemotherapy did improved the survival of those with stage I grade 2 disease from 85% to 99% (p = 0.04). **Conclusions:** The overall survival of patients with immature teratomas is excellent. In patients with stage I grade 2 or higher disease chemotherapy was associated with an improved overall survival.

Phase II study of cabozantinib (cabo) in patients (pts) with recurrent/metastatic endometrial cancer (EC): A study of the Princess Margaret, Chicago, and California phase II consortia. *First Author: Neesha C. Dhani, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Recurrent/metastatic EC has a poor prognosis with no standard 2ndline therapy. Cabo is a multi-targeted kinase inhibitor of MET, VEGFR, TIE2, AXL & KIT, relevant in epithelial-stromal cross-talk. The role of MET/HGF in aggressive EC biology, where transient benefit of VEGF-targeting is due to MET/HGF, TIE2 & AXL, provides rationale for MET targeting in EC. **Methods:** PHL86 (NCI#9322/NCT01935934) is a multi-centre, phase II trial of cabo (60mg oral daily dose) in pts with EC recurring within a year of adjuvant chemotherapy (ctx), or with progression after 1 line of ctx for metastatic disease. Experimental (E) cohort was stratified by histology (serous (SER) vs endometroid (END)) in a Simon two-stage design for co-primary endpoints of response rate ($>$ 30%) & 12-week progression-free-survival (PFS) ($>$ 55%). Activity was defined as $>$ 7 partial responses (PRs) or $>$ 15 instances of 12 wk-PFS in 36 pts. Pts with rare histology EC were treated in a parallel exploratory (Ex) cohort. **Results:** From May 2013 to Nov 2016, 102 pts (E: 71; Ex: 31) have been treated with cabo after prior radiation (59) and/or ctx (no. lines: 1 (77); 2(22)). Cabo was well tolerated with common toxicities of fatigue, nausea, diarrhea & hand-foot syndrome. Most frequent Grade 3/4 toxicity was hypertension (32/101 pts). Fistula/perforation occurred in 4 of 71 SER/END pts & 4 of 31 Ex pts; no risk factors were identified. In 33 END pts, 6 PRs & 24 instances of $>$ 12-wk PFS were observed; median PFS is 4.8 mths (95% CI: 4.4 – 6.4) with estimated 6-mth PFS of 43% (95% CI: 27 to 59%). In 34 SER pts, 4 PRs & 20 instances of $>$ 12-wk PFS were observed; median PFS is 4.0 mths (95% CI: 2.7 – 4.7) with estimated 6-mth PFS of 30% (95% CI: 15 to 46%). 4 pts have had PFS $>$ 12 mths, 1 SER pt remains on study after 25mths. Mutational analysis demonstrated presence of KRAS with PTEN or PIK3CA mutations in 9 (SER/END) pts, of whom 8/9 pts met 12-wk PFS endpoint, with a median PFS 5.9 mth (4.1 to 15.4). **Conclusions:** Cabo has single agent activity in END and SER EC with durable disease control. Concurrent mutation in KRAS/PTEN/PIK3CA may enrich for response. The current data support further evaluation of cabo in EC. Clinical trial information: NCT01935934.

5525 Poster Session (Board #347), Sat, 1:15 PM-4:45 PM

Association of T cell responses after vaccination with HPV16 long peptides for late stage cervical cancer with prolonged survival. *First Author: Winald R. Gerritsen, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

Background: Therapeutic vaccination with HPV type 16 synthetic long peptides (HPV16-SLP) results in T cell–mediated regression of HPV16-induced premalignant lesions but fails to install effective immunity in patients with advanced HPV16-positive cervical cancer. We showed that HPV16-SLP vaccination in mice and in patients with advanced cervical cancer patients fosters robust HPV16-specific T cell responses, when combined with chemotherapy (Welters et al. Sci. Transl. Med., 2016). **Methods:** We have now completed a chemo-immunotherapy study in 70 patients with late stage HPV16+ cervical cancer (clinical trials.gov NCT02128126). Three HPV16-SLP vaccine doses were given 2 weeks after the second, third and fourth cycle of standard chemotherapy (carboplatin, AUC 6; paclitaxel 175 mg/ m^2). Cohorts of 12 patients each were vaccinated with each of 4 dose levels (20, 40, 100 and 300 μg/ per peptide) of 13 overlapping HPV16 synthetic long peptides (HPV16-SLP) together covering the length of the 2 E6 and E7 proteins. Two additional cohorts of 6 patients each were vaccinated with the most promising doses of 40 and 100 μg/ peptide. **Results:** Robust vaccine-induced HPV16-specific T cell responses as assessed by interferon-γ Elispot were observed and were sustained until at least 30 days after the 6th cycle of chemotherapy. In addition the chemotherapy augmented recall responses to microbial antigens. Such robust T cell responses were not noted in previous trials when similar patients were vaccinated without timing of vaccination during chemotherapy. A marked and significant positive correlation was observed between the strength of the vaccine-induced immune response and overall survival. No such correlation was observed between the strength of the T cell response against common recall antigens and survival. In addition a remarkably high proportion of patients survived beyond 2 years after the start of therapy. **Conclusions:** The results suggest that survival duration is directly related to the strength of the vaccine-induced HPV16-specific T cell response and is not due to generally better immuno-competence. Clinical trial information: NCT 02128126.

5526 Poster Session (Board #348), Sat, 1:15 PM-4:45 PM

A phase I study of sequential ipilimumab in the definitive treatment of node positive cervical cancer: GOG 9929. *First Author: Jyoti Mayadev, University of California, Davis, Sacramento, CA*

Background: The outcome of lymph node positive (LN) cervical cancer (CC) with chemoradiation (CRT) is dismal, especially with involved para-aortic nodes (PAN). The anti-CTLA-4 immune checkpoint inhibitor ipilimumab (ipi) holds promise. We report the safety, tolerability, and efficacy in this GOG phase I study examining sequential ipi after CRT for CC. **Methods:** Patients (pts) with LN CC were treated with 6 weekly doses of cisplatin (40 mg/m2) and extended field radiation (RT). 2-6 weeks after RT, if there was no progression of disease, sequential ipi was given at the following dose levels: dose level 1: 3mg/kg, level 2: 10mg/kg, and an expansion cohort of 10mg/kg. The primary endpoints (endpts) were the maximum tolerated dose (MTD), and dose-limiting toxicities (DLT) of adjuvant ipi. Secondary endpt included the 1-yr disease free survival (DFS). Translational endpts included the effect of CRT on enumeration and subsets of T-cells, and CTLA4, PD-1 and ICOS expression. **Results:** 34 pts were enrolled, and 19 pts are evaluable for the endpts: 14 pts went off study to reasons unrelated to the study drug, 1 pt continues in her DLT evaluable period. Of the evaluable pts, all had pelvic LN, with 25% PAN. All pts completed CRT, 90% had 4 cycles of ipi, and the other 10% had 2 cycles of ipi. The ipi MTD was 10 mg/kg. There were 3 pts (16%) with acute grade 3 toxicity (lipase, ↓ANC, rash) which self-resolved. Most of the acute toxicities were grade 1-2 GI distress, rash, endocrinopathies. There were no minor or major RT quality deviations. With a median follow up of 12 months, there were no major late toxicities reported, with a 1-year DFS of 74%. There was no difference in CD4$^+$- and CD8$^+$- T cell levels nor CTLA-4 expression with sequential ipi. CRT itself increased ICOS and PD-1 expression. **Conclusions:** This study is the first to describe the safety of immunotherapy sequencing with definitive CRT in CC. Our data suggests that immunotherapy is tolerable and shows possible activity in this population with a historical dismal prognosis with standard therapy. CRT increased ICOS and PD-1 expression which was sustained with ipi, illustrative of immune modulation targets for future clinical trials and radio-immunotherapy combinations. Clinical trial information: NCT01711515.

5527 Poster Session (Board #349), Sat, 1:15 PM-4:45 PM

A randomized phase III trial of cisplatin with or without S-1 in patients with FIGO IVB, recurrent, or persistent cervical cancer: An Asian study. *First Author: Soyi Lim, Department of Obstetrics and Gynecology, Gachonuniversity Gil Medical Center, Incheon, Republic of Korea*

Background: A combination of S-1, an oral fluoropyrimidine, plus cisplatin has been used for advanced gastric cancer in Asia and EU, and lung cancer in Japan. It also evaluated in advanced or recurrent cervical cancer in a phase II setting. We conducted a randomized phase III trial to compare the efficacy and safety of S-1 plus cisplatin with those of cisplatin alone in recurrent or persistent after treatment and FIGO IVB cervical cancer patients. **Methods:** Stage IVB, recurrent or persistent cervical cancer patients aged ≥ 20 years, ECOG PS 0–1 and adequate organ function were randomly assigned (1:1) to receive S-1 (80–120 mg daily, according to BSA, day 1–14) plus cisplatin (50 mg/m^2 on day 1) (study group) or cisplatin alone (50 mg/m^2 on day 1) (control group) every 3 weeks. Treatment was continued until disease progression. In all, 360 patients (at least 296 events) with a hazard ratio (HR) for death of 0.72 were required for a two-sided alpha of 5% and power of 80% under 2 years of recruitment and 1.5 years of follow-up. Stratification factors included recurrence in previously irradiated field, previous platinum-based therapy, and institution. Primary endpoint was OS based on intent-to-treat principle, and secondary endpoints were PFS, overall response rate (ORR), and safety. **Results:** In all, 375 patients were assigned to the study (n = 189) and control (n = 186) groups. Rate of previous platinum-based therapy was 64%. The median survival time was 21.9 and 19.5 months (95% CI, 18.6–25.8 and 17.0–24.3) with the use of unstratified log-rank test in the study and control groups, respectively (log-rank P = 0.125; HR, 0.84; 95% CI, 0.67–1.05). Significant increases in median PFS (7.3 vs. 4.9 months; log-rank P $<$ 0.001; HR, 0.62) and ORR (43.8 vs. 20.1%, P $<$ 0.001) were observed in the study group. Adverse events (grade≥3) were frequent in the study group (80.9 vs. 41.7%) with neutropenia (52.7%), anemia (34.6%), and leukopenia (32.4%) being the most common events. **Conclusions:** Compared with cisplatin alone, S-1 plus cisplatin did not significantly improve OS but increased ORR, prolonged PFS, and had tolerable safety of patients with stage IVB, recurrent or persistent cervical cancer. Clinical trial information: NCT00770874.

5528 Poster Session (Board #350), Sat, 1:15 PM-4:45 PM

The neoantigen landscape and immune regulators in cervical cancer. *First Author: Jason Roszik, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Human papillomaviruses (HPVs) play a major role in development of cervical cancer, and HPV oncoproteins are being targeted by immunotherapies. Although these treatments show promising results in the clinic, many patients do not benefit or the durability is limited. **Methods:** To explore the landscape of neoantigens in cervix cancer, we predicted all possible mutated neopeptides using exome and RNA sequencing data of a large number of tumors in two independent data sets (n = 194 and 79), and analyzed whether mutation and neoantigen load correlate with expression of genes involved in antigen presentation, infiltrating immune cell type markers, and HPV oncoprotein-associated genes. Normal tissue expression analyses were also performed using data from the Genotype-Tissue Expression project (n = 8,555). **Results:** We found that potentially immunogenic and targetable neoantigens can be predicted for almost all cervix tumors, including recurrent neoantigens from mutations of known oncogenic driver genes (KRAS G12D, MAPK1 E322K, PIK3CA E545K, PIK3CA E542K, ERBB2 S310F, and ERBB3 V104M). Furthermore, we found that expression of HPV-associated "master regulator" genes is associated with mutation, neoantigen, and HPV load, and also with expression of several important markers in the immune microenvironment. Notably, the OVOL1 master regulator positively correlated with mutation and neoantigen load, and also with PD-L1 and TGFB1 expressions. Furthermore, ENO1 overexpression in cervical cancer was associated with high HPV load, and ENO1 level also positively correlated with PD-L1 and TGFB1 expressions, suggesting that it may be a potential target in cervical cancer. **Conclusions:** For most of the cervix tumors we report predicted neoantigens, and we also identified recurrent neopeptides derived from mutations in known oncogenes. We have also identified statistically significant associations between neoantigen availability, antigen presentation, cytotoxic T-cell function, suppressive mechanisms, and expression of HPV master regulators to help guide immunotherapies of cervical cancer.

5529 Poster Session (Board #351), Sat, 1:15 PM-4:45 PM

Functional and oncologic outcomes of radical trachelectomy in early-stage cervical cancer: A prospective multicentric cohort of 61 patients. *First Author: Vincent Balaya, Hopital Européen Georges Pompidou, Paris, France*

Background: The aim of this study was to assess the post-operative morbidity of patients who have undergone a radical trachelectomy for early-stage cervical cancer and the oncologic outcomes. **Methods:** We retrospectively analyzed the data of two prospective trials on sentinel node biopsy for cervical cancer (SENTICOL I & II). Patients underwent a radical trachelectomy for early-stage cervical cancer between January 2005 and March 2012 from 8 French oncologic centers. **Results:** A total of 61 patients have undergone a radical trachelectomy: 41 patients by laparoscopic-assisted vaginal way, 7 patients by total laparoscopic way, 11 patients by total vaginal way and 2 patients by laparotomy. The median age was 33 years (range = 22-68 years). 88.5 % of patients had a stage IB1 disease. There were 63.9% of epidermoid carcinoma and 34.4 % of adenocarcinoma. Eighteen patients (29.5%) had only a sentinel lymph node biopsy and 43 patients (70.5%) had an additional pelvic lymphadenectomy. The median follow-up was 46 months (range = 0-85 months). Twenty patients (32.8%) had a urinary complication. There were 12 cases of urinary infections (19.6%), 6 cases of dysuria (9.8%), 3 cases of urinary incontinence (4.9%), and one case of ureteral fistula (1.6%). Nine patients had a major neurologic complication (14.7%): the genito-femoral nerve was injured in 4 cases (6.5%) and the obturator nerve was injured in 5 cases (8.2%). Sixteen patients (26.2%) presented a lymphovascular complication. There were 12 cases of limb lymphedema (19.7%) and 5 cases of pelvic lymphocyst (8.2%). During the follow-up, 3 patients (4.9%) had a local recurrence and two patients died : one from a breast cancer and one from a liver metastasis. **Conclusions:** The radical trachelectomy is a feasible and safe alternative option for young patient with a early-stage cervical cancer in order to preserve their fertility. See table.

Post-operative complications.

Postoperative complications	
Clavien I	19 (31,1%)

Genito-femoral nerve	4 (6,5%)

5530 Poster Session (Board #352), Sat, 1:15 PM-4:45 PM

3D HDR intracavitary brachytherapy combined with complementary applicator-guided external beam radiotherapy for 338 patients with stage IIB-IIIB uterine cervical cancer: A single-center phase II prospective study with long-term follow-up. *First Author: Jin Yi Lang, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China*

Background: For uterine cervical cancer (UCC) patients with asymmetric parametric lesions, 3D HDR-intracavitary brachytherapy (HDR-ICBT) could not cover all the lesions, resulting in residual lesion and treatment failure. To settle this problem, a novel treatment modal of 3D HDR-ICBT combined with complementary applicator-guided external beam radiotherapy (EBRT) was used for UCC patients with stage IIB-IIIB in present study. **Methods:** Between June 2010 and June 2015, 338 patients with locally advanced cervical cancer (International Federation of Gynecology and Obstetrics stage IIB-IIIB) were treated with concurrent chemoradiotherapy. Imaged guided IMRT was used for external beam radiotherapy, 45Gy/25f. The chemotherapy was weekly cisplatin (40mg/m2). Four fractions of 3D HDR-ICBT combined with complementary applicator-guided external beam radiotherapy were used. The prescribed dose for HR-CTV and IR-CTV was 7Gy (D90) and 5Gy (D90). Dose constraints for organs at risk were D2cc $<$70 Gy for rectum, and D2cc$<$90 Gy for bladder in terms of equivalent total dose in 2 Gy fractions as GEC-ESTRO recommendations. **Results:** Median follow-up was 64 months (11–71 months). The D_{90} of GTV, HR-CTV, and IR-CTV in all cases were 93.4 (85.1-107.8) Gy, 86.4 (79.9-91.3) Gy and 72.3 (70.8-75.2) Gy, respectively. The $D2_{CC}$ of bladder, rectum and sigmoid were 74.3Gy、65.5Gy and 64.1Gy, respectively. 5-year LRC, DFS, and OS was 90.8%, 84.1% and 80.8%, respectively. Treatment was well tolerated. The grade $\geq$3 genitourinary and gastrointestinal acute and late toxicities were 2.1% and 5.2%, respectively. **Conclusions:** The combination of HDR-ICBT with an applicator-guided IMRT is feasible for uterine cervical cancer patients with asymmetric parametric lesions. Further study is needed to determine whether this treatment modal could be used to replace the invasive interstitial brachytherapy (ISBT) in the cases of locally advanced cervical cancer where HR-CTV coverage cannot be obtained with ICBT.

5531 Poster Session (Board #353), Sat, 1:15 PM-4:45 PM

Treatment and outcomes of small cell neuroendocrine carcinoma of the cervix (SCCC). *First Author: Brooke Schlappe, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Extrapulmonary small cell carcinoma is rare. SCCC represent 2% of cervical cancers and can portend a poor prognosis. Treatment standardization is challenging given its rarity. We describe management of limited stage (LS; disease could be encompassed within one radiation port) at a large tertiary referral center and the characteristics and outcomes in a cohort of patients (pts) with LS and extensive stage (ES) SCCC. **Methods:** Pts with SCCC diagnosed from 1/1990-1/2016 were identified following IRB approval. Clinicopathologic, treatment, and follow-up data were recorded. Descriptive statistics were provided. Median PFS/OS or PFS/OS rate were estimated using Kaplan-Meier method. **Results:** 39 pts were identified, 29 with LS. Select characteristics are shown in table. Tumor molecular profiling revealed *MYC* amplifications, *TP53* mutations, *PIK3CA* mutation among the small subset of pts who had this performed. LS SCCC was treated with whole pelvic radiation therapy (RT) (4500-5040cGy) and concurrent IV cisplatin ($60mg/m^2$) on day 1 and etoposide ($120mg/m^2$) on days 1, 3, and 5 during RT and days 1-3 post RT to complete a total of 4 cycles. 26 pts, all had LS, underwent initial surgical management. No pt had prophylactic cranial RT. 3 pts (8%), all had LS, developed brain metastases. Median follow-up was 59.5 months (1.9-234.1). Median PFS (95%CI) for LS pts was 39.2 months (15.1-not estimable) vs 2.9 months (0.9-4.6) for ES. Median OS(95%CI) was 31.8 months (16.3-56.0) for the whole cohort, 52.8 months (31.8-not estimable) for LS and 5.9 months(1.8-16.3) for ES. **Conclusions:** In the LS SCCC cohort treated with concurrent cisplatin/etoposide chemo/RT and outback cis/etoposide +/- post initial radical hysterectomy the 5-year PFS (95%CI) was 37.5% (19.2-55.9%). Clinicopathologic characteristics and risk factors for SCCC appear distinct to cervical cancers and lung small cell cancers. Further investigation of molecular alterations and treatment of this rare tumor is needed to improve pt outcomes.

Characteristics	Median (range) or n (%)
Age (years)	39 (24-85)
Smoking history	11 (28%)
Lymphovascular invasion +	20 (80%)
Stage	
I	18 (46%)
II/III	13 (33%)
IV	8 (21%)

5532 Poster Session (Board #354), Sat, 1:15 PM-4:45 PM

A randomized phase II evaluation of weekly gemcitabine plus pazopanib versus weekly gemictabine alone in the treatment of persistent or recurrent epithelial ovarian, fallopian tube or primary peritoneal carcinoma. *First Author: Linda R. Duska, University of Virginia Health System, Charlottesville, VA*

Background: Inhibition of angiogenesis is a valuable treatment strategy for ovarian cancer. Pazopanib (paz) is a potent angiogenic small molecular inhibitor of the tyrosine kinases VEGRF-1, -2, -3, PDGFR, c-kit and has shown activity as a single agent in ovarian cancer. We designed a trial to assess the benefit of adding paz to gemcitabine (gem) in patients with recurrent, advanced ovarian cancer. **Methods:** An open-label, randomized, multi-site, phase 2 trial was conducted (NCT01610206) including patients with platinum resistant or sensitive ovarian cancer with up to 3 prior lines of chemotherapy, and measurable or evaluable disease. Patients were randomly assigned (1:1) to receive weekly gem 1000 mg/m^2 with or without paz 800 mg QD and stratified according to platinum sensitivity and number of prior lines (1 vs 2 or 3). The primary endpoint was PFS. Intent-to-treat was defined as all eligible patients who receive any protocol treatment with analysis based on randomized arm. **Results:** As of 3/2017, we randomized 148 and treated 146 patients (target sample size 148 eligible patients who receive any protocol treatment). 75 (46 platinum resistant, 61%) were randomly assigned to receive gem/paz and 71 (41 platinum resistant, 58%) to receive gem only. 110 patients (75%) had received 2 or 3 prior lines. There were no unexpected toxicities or deaths. Adverse events were more common in the gem/paz group. The most common grade 3–4 AEs (gem/paz vs gem) were: neutropenia (25 [33%] vs 15 [21%]), fatigue (7 [10%] vs 1 [2%]), hypertension (11 [15%] vs 1 [1%]), elevated alanine aminotransferase (8 [11%] vs 0), thrombocytopenia (9 [12%] vs 12[3%]) and anemia (7 [9%] vs 2 [3%]). There were 2 GI perforations in the paz arm. Median time on therapy was 12 weeks (range 1-55 weeks). Of the 138 patients off study to date, 30 (22%) were for AE's (23 on gem/paz arm). **Conclusions:** The gem/paz combination is tolerable in this population, with patients tolerating multiple cycles with manageable toxicity. Median follow-up and PFS data will be presented after 122 events (progression or death) have occurred per protocol (currently 117 events). Clinical trial information: NCT01610206.

5533 Poster Session (Board #355), Sat, 1:15 PM-4:45 PM

Clinically significant long-term maintenance treatment with olaparib in patients (pts) with platinum-sensitive relapsed serous ovarian cancer (PSR SOC). *First Author: Charlie Gourley, University of Edinburgh Cancer Research UK Centre, MRC IGMM, Edinburgh, United Kingdom*

Background: In Study 19 (NCT00753545), a RCT in 265 pts with PSR SOC, the oral PARP inhibitor olaparib significantly improved progression-free survival (PFS) vs placebo (PBO), with the greatest benefit seen in pts with a *BRCA1/2* mutation (*BRCA*m); an interim overall survival (OS) analysis suggested an advantage for olaparib-treated pts (DCO: Sep 30, 2015; Ledermann *et al*, 2016). We report a planned final analysis of the long-term benefit of olaparib in pts with PSR SOC in Study 19. **Methods:** Pts who had received ≥2 prior regimens of platinum-based chemotherapy and were in response to their most recent regimen received olaparib (400 mg bid; capsules) or PBO until disease progression. Retrospective germline or tumor testing resulted in a known *BRCA*m status for 254/265 pts (96%). **Results:** At final DCO (May 9, 2016) median OS follow-up was 78.0 months. A long-term treatment benefit and the final hazard ratio (HR) for OS vs PBO (unadjusted for crossover: 13% of PBO pts – full analysis set [FAS]; 23% of PBO pts – *BRCA*m subgroup) is shown (Table). Details of *BRCA*wt pts on treatment for ≥6 years will be presented. No new safety signals or changes in olaparib tolerability profile were seen. **Conclusions:** The Study 19 final analysis shows that olaparib provides clinically significant, long-term treatment benefit in pts with PSR SOC. A durable benefit was seen in ≥10% of *BRCA*m and *BRCA*wt pts, who continued to receive and benefit from olaparib for ≥6 years–unprecedented in the relapsed ovarian cancer setting. Olaparib is well tolerated in this pt population and the analysis suggests olaparib confers an OS benefit in *BRCA*m pts. Clinical trial information: NCT00753545.

OS maturity, %	FAS 79		*BRCA*m 73		*BRCA*wt 86	
N	Olaparib 136	PBO 129	Olaparib 74	PBO 62	Olaparib 57	PBO 61
Pts on treatment at final DCO, n (%)	14 (10.3)	1 (0.8)	7 (9.5)	1 (1.6)	7 (12.3)	0
Pts on treatment for ≥6 years, n (%)	15 (11.0)	1 (0.8)	8 (10.8)	1 (1.6)	7 (12.3)	0
OS events, n (%)	98 (72.1)	112 (86.8)	49 (66.2)	50 (80.6)	45 (78.9)	57 (93.4)
Median OS, months	29.8	27.8	34.9	30.2	24.5	26.6

Nominal *P* value*	0.021		0.021		0.397	

* *P* value not considered statistically significant due to multiple testing.

5534 Poster Session (Board #356), Sat, 1:15 PM-4:45 PM

Long-term benefit of niraparib treatment of recurrent ovarian cancer (OC). *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: Current therapies for recurrent OC include chemotherapy (C) or bevacizumab (B) in combination with C followed by continuous B, which showed improved progression-free survival (PFS) compared with C followed by placebo (P) over 3.4 months (GOG-0213) or 4.0 months (OCEANS). Potential impact of B on effectiveness of subsequent therapies has not been described. Niraparib (N) is a highly selective PARP 1/2 inhibitor (PARPi). In preclinical studies, N concentrates in the tumor; N showed significantly longer PFS vs P in patients (pts) with recurrent OC following complete/partial response (CR/PR) to platinum based chemotherapy (Plat) in the randomized, controlled, double-blind phase 3 ENGOT-OV16/NOVA trial. We report the long term effect of treatment with N and its impact on subsequent therapy. **Methods:** Eligibility for NOVA included recurrent OC, fallopian tube or peritoneal cancer, no prior PARPi use, and completion of ≥2 prior courses of Plat, with a CR or PR following the most recent Plat. Pts were enrolled into g*BRCA*mut or non-g*BRCA*mut cohorts based on BRCA mutation test results and randomized 2:1 to receive N 300 mg qd or P until progression of disease or death (PD). Tumors were tested for homologous recombination deficiency (HRD). Estimated probability of PD in each cohort at 12, 18 and 24 months post randomization, representing ~18, 24 and 30 months post chemotherapy initiation, was determined; the difference between PFS2 and PFS (PFS2-PFS) was evaluated in all randomized pts. **Results:** 203 pts were randomized in the g*BRCA*mut cohort. Of 350 pts randomized in the non-g*BRCA*mut cohort, 162 had HRD+ and 134 HRD− tumors. Estimated probability (product-limit method) of PFS at 12, 18 and 24 months was greater in the niraparib arm than in the placebo arm in each cohort and subgroup at each time interval. Probabilities (95% CI) at 24 months for niraparib vs control were 0.42 (0.30, 0.55) vs 0.16 (0.07, 0.28) (gBRCAmut) and 0.27 (0.19, 0.35) vs 0.12 (0.06, 0.21) (non-gBRCAmut). PFS2-PFS was similar in the 2 treatment arms in the combined cohorts (HR 1.02, 95% CI 0.765, 1.349). **Conclusions:** Niraparib provided long term benefit in pts with recurrent OC irrespective of g*BRCA*mut or HRD status, and no decrement in the benefit of subsequent therapy was observed. Clinical trial information: NCT01847274.

5535 Poster Session (Board #357), Sat, 1:15 PM-4:45 PM

Overall survival and updated progression-free survival results from a randomized phase 2 trial comparing the combination of olaparib and cediranib against olaparib alone in recurrent platinum-sensitive ovarian cancer. *First Author: Joyce F. Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: We previously reported that the combination of cediranib (ced) and olaparib (olap) improved progression-free survival (PFS) and overall response rates (ORR) in women with recurrent platinum-sensitive (plat-sens) high-grade serous (HGS) or BRCA-related ovarian cancer (OvCa) (NCT 01116648). We conducted an updated PFS and overall survival (OS) analysis. **Methods:** Patients (pts) across 9 centers were randomized 1:1 in this Ph 2 open label study to Olap (olap 400 mg capsules BID) or Ced/Olap (olap 200 mg capsules BID; ced 30 mg daily), stratified by BRCA status and prior anti-angiogenic therapy. Eligibility included pts with recurrent plat-sens HGS or BRCA-related OvCa. Pts had measurable disease by RECIST 1.1, PS 0 or 1, and the ability to take POs. No prior anti-angiogenics in the recurrent setting or prior PARP inhibitor was allowed. PFS was defined as time from randomization to radiographic progression or death. OS was defined as time from randomization to death. **Results:** Pts were enrolled from Oct 2011 to Jun 2013: 46 to Olap, 44 to Ced/Olap. 48 pts were known BRCA carriers (25 Olap; 23 Ced/Olap). As of Dec 21, 2016, 67 pts had a PFS event, and 52 pts had an OS event. Updated median PFS was 8.2 mos for Olap and 16.5 mos for Ced/Olap (HR 0.50, 95% CI 0.30-0.83, p=0.007). Median OS was 33.3 mos for Olap and 44.2 mos for Ced/Olap (HR 0.64, 95% CI 0.36-1.11, p=0.11). Within known germline BRCA mut carriers, updated PFS was 16.5 vs 16.4 mos (HR 0.75, p=0.42), and OS was 40.1 vs 44.2 mos (HR 0.79, p=0.55) for Olap and Ced/Olap, respectively. In pts without known germline BRCA mut, updated PFS was 5.7 vs 23.7 mos (HR 0.32, p=0.002), and OS was 23.0 vs 37.8 mos (HR 0.48, p=0.074). **Conclusions:** Updated PFS results consistently demonstrated that Ced/Olap significantly extended PFS compared to Olap in the overall population of women with plat-sens OvCa. In this Phase 2 study not powered to detect OS diferences, there was a trend towards OS improvement with Ced/Olap, particularly in pts without a known germline BRCA mutation. Results from ongoing studies of this oral combination in OvCa are of clinical interest. Clinical trial information: NCT 01116648.

5536 Poster Session (Board #358), Sat, 1:15 PM-4:45 PM

A randomized phase II study assessing an optimized schedule of oregovomab (O) anti-CA125 vaccination with carboplatin paclitaxel (CP) relative to CP alone in front-line treatment of optimally cytoreduced stage III/IV ovarian cancer (EOC). *First Author: Gabriella Ferrandina, Catholic University of Rome, Rome, Italy*

Background: In a phase II study of vaccination schedule in front-line combinatorial treatment of EOC (Braly JIT 2009), simultaneous day infusion dramatically enhanced the magnitude of induced immunity relative to a one week delayed schedule & other schedules historically evaluated. The current study is exploring the clinical & biological effects of the optimized 4 vaccine schedule relative to CP alone. **Methods:** Stage III/IV EOC patients (pts) optimally debulked to <1cm residual disease with CA125 >2x ULN were randomized to CP+O (cycle 1,3,5, & C5 +12 weeks) vs CP and followed for clinical outcomes and immune reponse. A total of at least 80 evaluable pts were required for 80% power to detect a difference of 45% vs 15% for a primary comparative analysis of induced CA125 specific T cell immunity using an IFN-γ ELISpot. Clinical evaluations and safety were considered secondary endpoints. **Results:** 97 pts (47 OV+SOC & 50 SOC) were accrued at 13 centers in US & Italy. Analysis of immune markers and long term clinical outcomes is ongoing. The median duration of follow up at time of this analysis was 26 months (m). There was no difference in safety outcomes between the treatment groups. Grade 3-4 toxicity was observed in 24 (52%) CP+O vs 28 (58%) C-P pts. Toxicities were typical of standard IV C-P chemotherapy. K-M Analysis of recurrence free survival (RFS) showed median RFS not estimable for CP+O [95% CI: 21.3, NE] vs 15.4 m [10.9,19.3] for CP (p=0.0009 log rank). In the interim analysis of survival (OS), 4 deaths have been observed in CP+O vs 16 in CP (log rank p=0.0025). Cox proportional hazard analysis finds consistent results across centers, and no imbalance in identified risk factors explanatory for the emerging outcome **Conclusions:** This study suggests simultaneous day vaccination with O on alternate cycles of front line CP leverages CP associated temporal change in the tumor microenvironment permitting an immune treatment effect to enhance the outcomes achievable with CP alone. This observation will be further characterized in ongoing translational studies and confirmed in a future phase III study. Clinical trial information: NCT01616303.

5537 Poster Session (Board #359), Sat, 1:15 PM-4:45 PM

Effect of adoption of neoadjuvant chemotherapy for advanced ovarian cancer on all-cause mortality. *First Author: Alexander Melamed, Massachusetts General Hospital, Boston, MA*

Background: Use of neoadjuvant chemotherapy followed by surgery for advanced epithelial ovarian cancer is controversial in the United States. **Methods:** Use of neoadjuvant chemotherapy for stage IIIC and IV ovarian cancer has increased gradually in the United States since 2007, but rates of adoption vary by region. Between 2011 and 2012, use of neoadjuvant chemotherapy increased by 27% in the New England and East South Central regions, but remained unchanged in three control regions (South Atlantic, West North Central, and East North Central regions). Employing prospectively collected data from Commission on Cancer-accredited cancer programs in the United States, we used this discontinuity in treatment approach to assess the causal impact of neoadjuvant chemotherapy on all-cause mortality in a quasi-experimental fuzzy regression discontinuity design. Kaplan-Meier curves and proportional hazard models were estimated to compare mortality differences between rapidly-adopting regions and controls. We also conducted a cross-sectional analysis of the relationship between regional use of neoadjuvant chemotherapy and survival. **Results:** We identified 1,156 women treated for advanced epithelial ovarian cancer during 2011 and 2012 in the two rapidly-adopting regions and 4,878 women in the three control regions. In the rapidly-adopting regions, patients treated in 2012 compared with 2011 had a mortality hazard ratio (HR) of 0.81 (95%CI=0.71-0.94) after adjusting for mortality time trends, while no difference was observed in control regions (HR=1.02, 95%CI=0.93-1.12). Compared with control regions, we observed larger declines in 90-day surgical mortality (7.0% to 4.0% versus 5.0 to 4.3%, p=0.01) and in the proportion of women not receiving surgery and chemotherapy (20.0% to 17.4% versus 19.0 to 19.5%, p=0.04) in rapidly adopting regions. Cross-sectional analysis confirmed that treatment in regions with greater use of neoadjuvant chemotherapy was associated was lower mortality (p=0.001). **Conclusions:** Adoption of neoadjuvant chemotherapy for advanced epithelial ovarian cancer in New England and East South Central regions led to a sizable reduction in mortality within three years after diagnosis.

5538 Poster Session (Board #360), Sat, 1:15 PM-4:45 PM

Efficacy and long-term safety with bevacizumab included in neoadjuvant and adjuvant therapies in patients with advanced ovarian cancer: Results of the ANTHALYA trial. *First Author: Florence Joly, GINECO and Regional Centre Control Against Cancer Francois Baclesse, Caen, France*

Background: ANTHALYA showed that neoadjuvant Bevacizumab (B) added to Carboplatin and Paclitaxel (CP) was well tolerated and achieved encouraging complete resection rates at IDS (58.6%) in unresectable FIGO stage IIIC/IV ovarian, tubal or peritoneal adenocarcinoma (EJC 2017;70: 133–42). We report response rates, PFS and long-term safety. **Methods:** Patients (pts) in ANTHALYA were randomized 2:1 to 4 cycles (c) of neoadjuvant CP ±3 c of B (15 mg/kg), IDS for eligible patients, then 1 c of CP + 3 c CPB + 21 c of B. Response and progression were evaluated by RECIST 1.1 using CT scan and CA-125. Circulating tumor cell counts (CTC) were evaluated at baseline, c2 and IDS. **Results:** 95 pts were treated in CP (n=37) or BCP (n=58) groups (mean study duration were 16.1 months [mo] and 16.9 mo, respectively). 80 pts (CP: 81% / BCP: 88%) had a CA-125 response (50% reduction in CA-125 level) before IDS. Objective response rates were 65% (62% CP / 67% BCP) before IDS (28 days after c4), 46% at c8 (46% CP/ 47% BCP) and 19% at c26 (19% CP/ 19% BCP). 24 (64.9%) CP pts and 26 (44.8%) BCP pts progressed during follow up (median PFS 21.2 mo [95%CI: 14.5, 26.7] and 23.5 mo [18.5, 30.6], respectively). Median PFS was respectively: 25.8 mo (21.0, 30.0) and 17.1 mo (13.5, 22.2) for pts with/without complete resection at IDS; 21.0 mo (15.0, 25.4) and 25.8 mo (18.5, 27.2) for pts with/without baseline CTCs (n=29 / 59); 21.8 mo (17.5, 27.1) and 22.2 mo (15.3, 38.0) for pts with FIGO IIIC and IV tumors. 36 pts did not receive adjuvant therapy within the study (21 were unresectable for IDS), 59 pts (57% CP / 66% BCP) received it. Of those, 34 pts (52% CP / 61% BCP) had Grade ≥3 adverse events including neutropenia (29% CP / 34% BCP), HBP (10% CP / 8% BCP), proteinuria (10% CP / 0% BCP), deep venous thrombosis (5% CP / 3% BCP), pulmonary embolism (0% CP / 8% BCP). **Conclusions:** Neoadjuvant BCP followed by IDS and adjuvant BCP achieves high response rates and extended PFS with an acceptable toxicity in this specific population of pts with FIGO stage IIIC/IV ovarian, tubal or peritoneal adenocarcinoma not eligible for primary debulking surgery. IDS outcome and CTC counts should be further explored as long term prognostic factors. Clinical trial information: NCT01739218.

5540 Poster Session (Board #362), Sat, 1:15 PM-4:45 PM

Trends in the receipt of guideline care and survival for women with ovarian cancer. *First Author: Joan Warren, National Cancer Institute, Bethesda, MD*

Background: Guideline care has been found to improve survival for women with ovarian cancer, yet many women do not receive appropriate care. We assessed trends in the receipt of guideline care and 2-year cause-specific survival for women diagnosed with ovarian cancer. **Methods:** This retrospective cohort analysis used National Cancer Institute's Patterns of Care studies data for women diagnosed with primary ovarian cancer in 2002 and 2011 (weighted n=6867). Data included patient characteristics, type of treatment, and provider characteristics. We used logistic regression to evaluate the association of year of diagnosis with receipt of guideline surgery, multiagent chemotherapy, or both. Two-year cause-specific survival, 2002-2013, was assessed using SEER data. **Results:** Forty-six percent of women received stage-appropriate surgery, unchanged from 2002 to 2011. The percent of women seeing a gynecologic oncologist (GO) 2002 to 2011 increased from 43% to 77%, 53.6% of women who saw a GO received stage-appropriate surgery. The percent of women with Stages IC-IV cancer who received both stage-appropriate surgery and multiagent chemotherapy increased significantly from 31% in 2002 to 38% in 2011. From 2002 to 2011, 2-year cause-specific ovarian cancer survival did not improve for Stages I/II cancers, with slight improvement for Stages III/IV cancers. **Conclusions:** There has been modest improvement in the receipt of guideline care for women with ovarian cancer, 2002-2011. However, current treatment falls far short of clinical recommendations and may explain limited improvement in 2-year cause-specific survival. There has been a marked increase in the percent of women consulting a GO and seeing a GO increased the chances of receiving guideline care. However many women who consulted a GO did not receive guideline care. There needs to be a better understanding of the decision-making process about treatment during the consultation with GOs and other factors precluding receipt of guideline care.

5541 Poster Session (Board #363), Sat, 1:15 PM-4:45 PM

A multicenter phase II study of the efficacy and safety of quisinostat (an HDAC inhibitor) in combination with paclitaxel and carboplatin chemotherapy (CT) in patients (pts) with recurrent platinum resistant high grade serous epithelial ovarian, primarily peritoneal or fallopian tube carcinoma cancer (OC). *First Author: Sergei Tjulandin, N. N. Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Quisinostat is an orally bioavailable potent pan-histone deacetylase inhibitor. Combinations of HDAC inhibitors with paclitaxel or cisplatin demonstrate promising results in preclinical models with cisplatin and paclitaxel resistant OC. In phase Ib study the dosage of Quisinostat in combination of paclitaxel and carboplatin recommended for the phase II study was 12 mg. We report results of the phase II study of Quisinostat in combination with paclitaxel and carboplatin in pts with recurrent platinum resistantOC. **Methods:** the main inclusion criteria was tumor progression observed not less than 1 month and no more than 6 months after completion of the planned number of cycles of 1st line platinum/paclitaxel based CT. Quisinostat was administered at dose 12 mg p.o. each 3 week cycle on Days 1, 3, 5, 7, 9, 11 with of paclitaxel (175 mg/m^2) and carboplatin (AUC5) on Day 7 of each cycle, for 2nd line. Pts received up to 6 cycles. The primary efficacy endpoint is the objective response rate (ORR) verified by the ICR. The secondary endpoints include safety, progression free survival (PFS) and overall survival. The study design implies the use of the two-stage Simon model: 29 patients who underwent treatment would provide 80% power for hypothesis testing in order to frequency of the ORR 30% (α = 0.05). **Results:** 31 pts were enrolled (30 pts evaluated). Median age was 57 years. Twenty one pts (67.7%) received all 6 cycles of therapy. ORR was 50.0% (15 pts). Median duration of response was 5 months (4.2-5.7). Median PFS - 6 months (95%CI 4.4-7.6). Any SAE were seen in 16.1% pts, AE of grade 3 and 4 – in 71% and 48.4% pts temporarily discontinued therapy due to AE. Dose reduction of CT due to AE was performed in 22.6% pts. The most common adverse events were neutropenia – 67,7%, nausea – 61.3%, weakness – 29%, thrombocytopenia – 22.6%, neuropathy – 19.4%, vomiting – 19.4%. **Conclusions:** Quisinostat in combination with paclitaxel and carboplatin in pts with recurrent platinum resistant ovarian cancer showed high efficacy and good tolerability Clinical trial information: NCT02948075.

5543 Poster Session (Board #365), Sat, 1:15 PM-4:45 PM

CD8$^+$ TILs in early stage epithelial ovarian cancer: A GEICO study. *First Author: Ignacio Romero, Clinical Area of Gynecologic Oncology, Instituto Valenciano de Oncología (IVO), Valencia, Spain*

Background: The extent of tumor infiltrating lymphocytes (TILs) has emerged as a potential clinical useful biomarker in epithelial ovarian cancer (OC); however differences in TILs among OC histological types have not been extensively analysed. **Methods:** From a prospective early stage (I-II) GEICO registry of 1151 cases, 573 were sent for central pathology review. Complete analysis for classification of OC correctly identified 488 cases. Histological typing was performed according to morphological features and the expression of WT1, p53, p16, estrogen receptor (ER), progesterone receptor, and napsin A. The expression of mismatch repair (MMR) proteins MLH1, PMS2, MSH2 and MSH6 was performed in all tumors. The absolute number of stromal and intraepithelial CD8$^+$ TILs per 0.6 mm^2 TMA core was quantified and correlated with pathological features. **Results:** The series included 127 high-grade serous carcinomas (HGSC) (26%), 22 low-grade serous carcinomas (LGSOC) (4.5%), 165 endometrioid carcinomas (EC) (33.8%), 124 clear cell carcinomas (CCC) (2.4%), and 50 mucinous carcinomas (MC) (10.2%). The mean of intraepithelial CD8$^+$ TILs was higher in HGSG (48.7) than in all other histological types (LGSG: 16.3; EC: 27.1; MC: 7.0; and CCC 10.3; $p<0.0001$). In the stromal component, the mean of CD8$^+$TILs was also higher in HGSG (31.1) than in EC, MC and CCC (15.8, 8.0 and 12.7, respectively; $p<0.0001$). The mean of intraepithelial CD8$^+$ TILs was significantly higher in RE-positive (71.9) than in RE-negative (34.8) HGSC (p=0.002). In the complete series, 33 (6.6%) OCs showed absent expression of at least 1 MMR protein, and the mean of intraepithelial CD8$^+$ TILs was significantly higher in these OCs (57.0) than in those with preserved expression of all MMR proteins (23.6; p=0.0035). MMR protein deficiency was observed in 27 (16%) ECs, and these tumours had significantly higher mean of both intraepithelial (60.4 vs. 20.7 p=0.003) and stromal CD8+ TILs (26.6 *vs.* 13.8, p= 0.046). No significant differences in TILs were observed among EC of different histological grades. **Conclusions:** The extent of CD8$^+$TILs significantly correlates with the histological type and MMR status in OCs, being HGSCs and EC with MMR deficiency those OCs with higher CD8$^+$TILs.

5544 Poster Session (Board #366), Sat, 1:15 PM-4:45 PM

Management of platinum-sensitive recurrent ovarian cancer (PSROC) in the era of biologics: Can ASCO's net health benefits (NHB) inform our decisions? *First Author: Jonathan Foote, Division of Gynecologic Oncology, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: The ASCO value framework allows assessment of novel cancer therapies based on NHB. We assessed novel biologic therapies in the management of PSROC. **Methods:** ASCO's revised value framework NHBs were constructed for key therapies based on randomized clinical trials for PSROC. BRCA-germline and HRD status were included. Additionally, patient-centered NHB calculations were weighted based on results from a prospective patient preferences study (n=54) and compared to ASCO-based NHB. **Results:** ASCO-centered NHB calculations were: platinum + taxane-based chemotherapy (ICON4) = 35; carboplatin + liposomal doxorubicin (CALYPSO) = 22; platinum-based chemotherapy + bevacizumab (OCEANS = 35; GOG 213 = 26). NHB scores based on germline-BRCA alterations were maintenance niraparib (NOVA) = 50 and maintenance olaparib (Study 19) = 62; wild-type BRCA, maintenance niraparib = 36 and maintenance olaparib = 33; and HRD-positive status, maintenance niraparib = 42. Patients valued clinical benefit as the most important component of NHB. Patients valued OS as the most important component of clinical benefit, followed by response rate (RR), then PFS. Patient-weighted NHB were significantly lower than ASCO-weighted scores (mean NHB 37.8 versus 23.5; p=0.009) due to decreased preference for PFS compared to other clinical benefit measures (Table). **Conclusions:** NHB scores for treatment of PSROC were highest in women with germline-BRCA and HRD tumor alterations who were treated with maintenance PARPi. Our data suggest that a patient-centered NHBs can be used to inform treatment decisions.

NHB of platinum-sensitive treatment options in the era of biologics.

Regimens		ASCO NHB	Patient-weighted NHB	P value
Platinum-based chemotherapy + taxane (ICON4)		35	27	0.009
Carbo + liposomal doxorubicin (CALYPSO)		22	17	
Platinum-based chemotherapy + bevacizumab	*OCEANS*	35	20	
	GOG 213	26	15	
Maintenance olaparib	*gBRCA*	62	38	
(Study 19)	*wBRCA*	33	20	
Maintenance niraparib	*gBRCA*	50	30	
(NOVA)	*wBRCA*	36	21	
	wBRCA HRD+	42	24	

NHB = Net Health Benefit (based on PFS); gBRCA = germline BRCA alteration; wBRCA = wild-type germline BRCA; HRD = homologous recombination deficiency

5545 Poster Session (Board #367), Sat, 1:15 PM-4:45 PM

Somatic mutations in homologous recombination pathway genes in ovarian cancer. *First Author: Carol Aghajanian, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: 15% of patients with OC have a germline *BRCA 1 / 2* mut & 6% of OC have a somatic *BRCA 1/2* mut. Inhibitors of poly ADP ribose polymerase (PARPi) are approved in this setting. Data is evolving as to activity of PARPi in *BRCA* wild type OC with somatic homologous recombination (HR) gene deficiency. We sought to determine the prevalence of somatic alterations in HR genes in an unselected cohort of epithelial OC of any histologic type. **Methods:** From 03/2014-10/2016 patients consented to an IRB approved protocol for tumor-normal sequencing, via a custom next-generation sequencing panel (MSK-IMPACT) with return of results for tumor mut only. Muts in 14 HR genes (*ATM, BARD1, BRCA1, BRCA2, BRIP1, CHEK1, CHEK2, FANCA, MRE11, NBN, PALB2, PTEN, RAD51D, RAD51C)* and *p53*were assessed. Statistics were analyzed using GraphPad Prism v. 6. **Results:** 260 tumors were sequenced; 156 (60%) high grade serous (HGS), 34 (13%) low grade serous (LGS), 34 (13%) clear cell, 10 (4%) mucinous, 8 (3%) endometrioid, 18 (7%) mixed/other histology. 151 (97%) of HGS and 24 (23%) of the remaining tumors harbored *p53* mut. 48 (18%) somatic HR mut were identified. (Table 1) 26 HGS (17%) tumors and 22 (21%) of the remaining tumors harbored a HR gene mut (HGS vs other histology, p=0.4). Notably, 8 (24%) of clear cell cancers demonstrated HR gene muts (vs HGS, p=0.3). 18 (38%) of the identified muts in the overall cohort were in *BRCA 1/2*. There were no somatic HR gene muts identified in the mucinous OC, which were characterized by frequent *p53* (90%) and *KRAS*(60%) muts. **Conclusions:** In this cohort of OC, 17% of tumors harbor somatic HR gene muts. The prevalence of HR somatic muts was similar in HGS vs other histologies, with the exception of mucinous OC. *BRCA1/2* muts predominated, however 60% of identified muts were in other genes. Accrual is ongoing to increase histologic cohort sizes. Broad HR gene somatic mutational profiling may identify a wider cohort of OC patients with potential to benefit from PARPi therapy.

5546 Poster Session (Board #368), Sat, 1:15 PM-4:45 PM

***BRCA*-like classification in ovarian cancer: Results from the AGO-TR1-trial.** *First Author: Lisa Katharina Richters, Center for Hereditary Breast and Ovarian Cancer and Center for Integrated Oncology (CIO), Medical Faculty, University Hospital Cologne, Cologne, Germany*

Background: *BRCA* associated cancers show a distinct pattern of genomic gains and losses that is associated with impaired repair of DNA double-strand breaks via homologous recombination (HR). We investigated whether *BRCA1*- and *BRCA2*-like classifiers could predict *BRCA1* and *BRCA2* mutation status in ovarian cancer. In addition, we explored whether promoter hypermethylation or mutations in other genes involved in DNA repair associate with a *BRCA*-like profile in ovarian cancer. **Methods:** The AGO-TR1 cohort study (NCT02222883) enrolled 525 consecutive patients with primary (PR) and platinum sensitive relapsed (RE) ovarian cancer to perform paired mutational analysis of germline and tumor tissue. We performed mutation panel sequencing, *BRCA1* promoter hypermethylation and low-coverage whole genome sequencing to classify samples as *BRCA1*-like or *BRCA2*-like in 298 ovarian cancer samples (PR: n = 159, RE: n = 139). **Results:** A *BRCA*-like profile was observed in 58.1% of the samples without germline or somatic mutation in *BRCA1/2* (n = 179; *BRCA1*-like: n = 26, *BRCA2*-like: n = 23, *BRCA1*- and *2*-like: n = 55). There was no significant difference between PR- and RE-cases (54.5% vs 61.3%). 64 of 70 *BRCA1* germline mutation carriers could be identified by the *BRCA1*-like classifier (sensitivity: 0.91). The *BRCA2*-like classifier identified *BRCA2* germline mutation carrier with a sensitivity of 0.71 (17 of 24). The complementary use of both classifiers led to the detection of 22 of 25 somatic mutations in *BRCA1* (16/16) or *-2* (6/9). Remarkably, 12 of 13 tumor samples from germline *RAD51C* mutation carriers were recognized by the *BRCA1*-like classifier (sensitivity: 0.92). No correlation of *PALB2* mutation status (n = 7) with *BRCA*-like profile was observed. Of 28 tumor samples with a *BRCA1* promoter hypermethylation 26 had a *BRCA1*-like profile (sensitivity: 0.93). **Conclusions:** A high number of ovarian cancer cases display a *BRCA*-like profile. Mutations (germline and somatic) in *BRCA1, BRCA2, RAD51C* as well as *BRCA1* hypermethylation strongly associate with a *BRCA*-like profile and can explain 146 of 212 cases. Future studies will investigate whether the classifiers identify patients who benefit from HR-deficiency directed approaches beyond the *BRCA* mutation status. Clinical trial information: NCT02222883.

5547 Poster Session (Board #369), Sat, 1:15 PM-4:45 PM

Mirvetuximab soravtansine (IMGN853), a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), in platinum-resistant epithelial ovarian cancer (EOC) patients (pts): Activity and safety analyses in phase I pooled expansion cohorts. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: The early clinical evaluation of mirvetuximab soravtansine (IMGN853), an ADC that comprises a FRα-binding antibody linked to the tubulin-disrupting maytansinoid DM4, has revealed encouraging signs of activity in pts with ovarian cancer. A pooled analysis of safety and efficacy was performed including individuals with platinum-resistant EOC, enrolled across three expansion cohorts of an ongoing phase I trial (NCT01609556), who met the eligibility criteria for the pivotal phase III study of IMGN853 (FORWARD I; NCT02631876). **Methods:** Pts were administered IMGN853 intravenously once every 3 weeks at 6 mg/kg using adjusted ideal body weight dosing. Responses were assessed according to RECIST 1.1 and adverse events (AEs) evaluated by CTCAE v4.0. **Results:** A total of 37 EOC pts treated as part of the three phase I expansion cohorts (pooled population; n = 113) met the FORWARD I enrollment criteria of moderate to high tumor FRα levels (≥ 50% of cells with ≥ 2+ FRα expression) and 1-3 prior lines of therapy. In this group of pts with platinum-resistant disease, confirmed objective tumor responses were observed in 17 individuals (1 complete response [CR] and 16 partial responses [PR]) for an overall response rate (ORR) of 46% (95% CI, 29.5, 63.1) and a median PFS of 6.7 months (95% CI, 4.1, 9.0). The safety profile of the pooled population was consistent with that previously reported (ASCO Annual Meeting, 2016) with the most common AEs being diarrhea, fatigue, nausea, and blurred vision; these were low grade and readily managed. **Conclusions:** IMGN853 continues to be characterized by favorable tolerability and encouraging activity in pts with platinum-resistant EOC. In particular, both the ORR (46%) and PFS (6.7 months) achieved in this group of pts are superior to outcomes typically seen with established single-agent chemotherapy within the setting of primary platinum resistance. Overall, these analyses provide continued, robust support for the patient eligibility strategy employed in the phase III evaluation of IMGN853. Clinical trial information: NCT01609556.

5548 Poster Session (Board #370), Sat, 1:15 PM-4:45 PM

A phase 1b/2 study of napabucasin with weekly paclitaxel in advanced, previously treated platinum resistant ovarian cancer. *First Author: Carlos Becerra, Texas Oncology, Dallas, TX*

Background: Napabucasin is a first-in-class cancer stemness inhibitor, identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al PNAS 112 (6):1839, 2015). Napabucasin has shown potent synergistic preclinical anti-tumor activity with paclitaxel (PTX). In a phase Ib dose escalation study in patients (pts) with advanced solid tumors, napabucasin plus weekly PTX was well tolerated. A phase II expansion cohort was opened for patients with platinum resistant ovarian cancer. **Methods:** Pts with advanced ovarian cancer who had disease progression either during or in the 6 months following platinum-based systemic therapy were enrolled. napabucasin was administered orally at a starting dose of 240, 480, or 500 mg twice daily with PTX 80 mg/m2 IV weekly on 3 of every 4 weeks. AEs were evaluated using CTCAE v4.03 and objective assessments were performed per RECIST 1.1 every 8 weeks. **Results:** A total of 98 pts were enrolled. The average number of prior lines of systemic treatment was 3.5, including prior taxane-based therapy in 100% of patients. Treatment was well tolerated. Related grade 3 adverse events occurring ≥ 5% of pts included diarrhea (12.2%) and vomiting (5.1%). Among pts who received RECIST evaluation (n = 76), the disease control rate (DCR, proportion with SD at 8 weeks + PR + CR) was 65%, and the objective response rate (ORR, PR+CR) was 20%, with complete response in 3 pts (4%). In all patients (ITT, n = 98), the median progression-free survival (mPFS) was 3.0 months and median overall survival (mOS) was 9.3 months. **Conclusions:** Clinical safety and encouraging signs of anti-cancer activity, including three complete responses, were observed in pts with pre-treated platinum resistant ovarian cancer who received treatment with napabucasin plus weekly PTX. Further clinical evaluation in controlled trials is warranted. Clinical trial information: NCT01325441.

5549 Poster Session (Board #371), Sat, 1:15 PM-4:45 PM

Shared decision-making in ovarian cancer. *First Author: Lari B. Wenzel, University of California, Irvine, Irvine, CA*

Background: The value of shared decision-making in ovarian cancer is relatively unexplored. The goal of this study was to test a new decision aid, Patient Centered Outcome Aid (PCOA), that facilitates shared decision-making and helps ovarian cancer patients assimilate information and identify quality of life (QOL), toxicity and survival trade-offs between IP/IV therapy and IV therapy alone, based on their preferences and personal clinical characteristics. **Methods:** Participants were randomized to either PCOA (N=64) or usual care (N=59). Patient characteristics, QOL and shared decision-making data were collected at baseline and treatment initiation. Primary outcomes included satisfaction with treatment decision and decisional regret. Comparisons were made using t-tests and multivariate methods, adjusting for patient covariates. Multivariate linear models were used to investigate predictors of the primary outcomes. **Results:** Although satisfaction and decisional regret did not differ significantly by arm at any time point, the majority of PCOA patients indicated that the aid helped them understand treatment options and side effects. Notably, low shared decision-making and low QOL, were significant predictors of low satisfaction at treatment initiation (multiple r=0.76), six months (multiple r=0.48) and nine months (r=0.58). They were also significant predictors of decisional regret (multiple r=0.48 and 0.36 at 6 and 9 months). Patient covariates including age, stage, treatment and neoadjuvant status were not associated with differences in satisfaction or decisional regret. **Conclusions:** There were no clinically meaningful differences in satisfaction with the treatment decision, or decisional regret between the study arms. The absence of a difference may reflect the high degree of shared decision-making in both arms and greater disease severity in PCOA patients, who were more likely to report low baseline QOL and declining QOL over time. Both shared decision-making and quality of life were robust, independent predictors of satisfaction with the treatment decision over time. This implies that women who perceive themselves as less engaged in the decision process, and report poor QOL may benefit from a decision aid, in addition to physician counseling. Clinical trial information: NCT02259699.

5550 Poster Session (Board #372), Sat, 1:15 PM-4:45 PM

Bevacizumab, eribulin, and oxaliplatin in patients with platinum-resistant ovarian carcinomas: A phase II study with biomarker analysis. *First Author: Masashi Takano, Department of Obstetrics and Gynecology, National Defense Medical College Hospital, Tokorozawa, Japan*

Background: Eribulin is a candidate for paclitaxel-refractory breast cancers, and Bevacizumab (B) is known to enhance efficacy of anti-cancer agents in ovarian cancers. A phase II study to evaluate weekly administration of B with eribulin and oxaliplatin (EriOX) in patients with platinum-resistant and refractory ovarian carcinomas (PR-ROC) was performed. **Methods:** Eligible patients were as follows: (a) ECOG PS = 0~2 (b) histologically confirmed epithelial ovarian cancer (c) diagnosed as platinum-resistant ovarian cancer (d) written informed consent. Patients were treated with weekly-B-EriOX consisting of B (2mg/kg), eribulin (1mg/m^2) and oxaliplatin (30mg/m^2), three weeks on and on week off, q4weeks. The study was conducted using two-stage design of Simon (type I error = 0.05, power = 0.9, true response rate = 25%). Biomarker analyses including serum VEGF, BNP, p53, IL-6, and Her-2 were also conducted. **Results:** A total of 34 patients were enrolled in the present study: 13 cases in the first-stage, and additional 21 cases in the second-stage. There were 3 responders ($\geqq$2) in the first-stage, and the protocol was proceeded to the second-stage. Median age of the patient was 58.5 years (range: 35-76), and median number of previous regimen was 4 (range: 2-9). Overall, two patients (6%) had a complete response (CR), 8 patients (24%) had a partial remission (PR) and 16 patients (47%) had a stable disease (SD). The response rate and clinical benefit rate (CR+PR+SD) were 29% and 76%, respectively. Median progression-free survival was 4 months (range: 1-27+). Hematological adverse effects (AE) with grade 3/4 were observed in 4 patients (11%). Non-hematological AE greater than grade2 was observed in one case: hypo albuminemia and edema, which were manageable and tolerable. As there were 10 responders ($\geqq$6), the protocol was considered for additional investigation. The Patients with elevated serum mutated p53 / IL-6 showed lower response and worse prognoses. **Conclusions:** Weekly B and EriOX administration was considered for additional investigation for patients with PR-ROC. Serum mutated p53 protein and/or IL-6 could be biomarkers in PR-ROC patients treated with weekly B and EriOX.

5551 Poster Session (Board #373), Sat, 1:15 PM-4:45 PM

***BRCA1/2* reversion mutations revealed in breast and gynecologic cancers sequenced during routine clinical care using tissue or liquid biopsy.** *First Author: Paul Mayor, Roswell Park Cancer Institute, Buffalo, NY*

Background: Tumors with genomic alteration (GA) of *BRCA1* or *BRCA2* (*BRCA*) may be more sensitive to platinum (Pt) therapies and PARP inhibitors (PARPi). However, secondary reversion mutations (revGA) can arise that may restore *BRCA* function and underlie reduced sensitivity to Pt compounds or PARPi. **Methods:** DNA extracted from FFPE tumor tissue or blood samples obtained during routine clinical care for patients with predominantly relapsed, refractory or metastatic breast cancer (10967) or ovarian/peritoneal cancer (8352) was analyzed by hybrid-capture, next-generation sequencing for all classes of GA: base substitutions, indels, rearrangements, and copy number changes. RevGA were any GA that could restore the reading frame if in cis with a nonsense or frameshift (fs) GA. **Results:** 1900/19329 (9.8% $\pm$ 0.4%) tumors had $\geq$1 deleterious *BRCA* GA. 38 samples harbored potential revGA in *BRCA1* (16) or *BRCA2* (22): breast carcinoma (Ca) (21), ovarian or peritoneal serous Ca (10), ovarian or peritoneal adenocarcinoma (3), and ovarian epithelial Ca NOS (4). 35/38 sequenced samples were metastases. All potential revGA were somatic and fell into 3 classes: overlapping indel (21), compensatory fs (6), and missense mutation (11). One case harbored both an overlapping indel and a missense mutation with potential to revert a nonsense alteration. For 6 patients, testing of multiple tissue samples reveals the acquisition of revGA over time. RevGA are generally observed at allele frequencies lower than the deleterious GA they may revert. Clinical histories for patients with reversion mutations will be presented. **Conclusions:** Genomic profiling of breast and gynecological carcinomas, using either tissue or liquid biopsies, reveals potential revGA that may restore some level of *BRCA* function. RevGA, although rare, can be acquired during the course of treatment. We identified potentially compensatory missense, fs and indel mutations with CGP. Comparison of allele frequencies suggests that revGA often arise as subclones. The acquisition of a revGA over time can be observed through testing of multiple samples, either tissue or liquid biopsy.

5552 Poster Session (Board #374), Sat, 1:15 PM-4:45 PM

Prognostic impact of neo-adjuvant vs adjuvant vs neo-adjuvant plus adjuvant chemotherapy in advanced ovarian cancer: Analysis of National Cancer Database. *First Author: Suresh Mukkamala, Easton Hospital, Easton, PA*

Background: Patients (Pts) with advanced ovarian cancer (OvCa) are usually treated with primary debulking (deb) surgery (Sx) followed by adjuvant (adj) chemotherapy (CRx). Recently neo-adjuvant (neo-adj) CRx is increasingly being used to reduce the bulk of the tumor. Hence, we analyzed for any prognostic impact of neo-adj vs adj vs neo-adj plus adj CRx along with deb Sx in the management of advanced OvCa. **Methods:** Only Stage III and IV Pts in National Cancer Data Base (NCDB) from 2006-2014, who underwent deb Sx without bowel resection (1), with bowel resection (2) and with bowel and bladder resection (3) were analyzed. Group (gp) A Pts had neo-adj CRx, gp B had adj CRx and gp C Pts had neo-adj plus adj CRx. The Pearson Chi square testing was used to evaluate the survival between gp A vs B vs C. **Results:** A total of 20910 Pts in stage III and 7483 Pts in stage 4 were included. Stage III Pts had a better 5 year (yr) survival in gp B compared to gp A and C, in all Pts who underwent Sx 1, 2 and 3 (Table 1). Stage IV Pts had a better 5 yr survival in gp C compared to gp A and B who underwent Sx 1 and 2, and gp B had a better 5 yr survival in Pts who underwent Sx 3 (Table 1). Overall survival was worse for all stages in Pts with neo-adj (gp A) than gp Band C. **Conclusions:** Deb Sx followed by adj CRx had better survival than in gp A or C. This may be secondary to less bulkier disease in the beginning in gp B than those in gp A or C requiring neo-adj CRx for the later. Pts survival also improved after addition of adj CRx following deb Sx compared to no adj CRx. A prospective multicenter randomized trial between each group may further validate the true benefits of neo-adj CRx in advanced OvCa.

1- 5 yr survival for gp A (neo-adj) vs gp B (adj) vs gp C (neo-adj plus adj) based on type of deb Sx.

		5 yr survival in % for gp A vs gp B vs gp C			
Type of deb Sx	No. of Pts	gp A(neo-adj)	gp B (adj)	gp C (neo-adj plus adj)	P value
			Stage III		
Sx 1	11,666	41.6 %	52.7 %	47.8 %	<0.001
Sx 2	8523	43.4 %	51.4 %	46.4 %	<0.001
Sx 3	721	41.7 %	53.5 %	52.4 %	0.383
			Stage IV		
Sx 1	3973	39.2 %	38.6 %	46.1 %	0.001
Sx 2	3178	36.4 %	39.8 %	42.6 %	0.186
Sx 3	332	26.5 %	47.3 %	41.2 %	0.064

Sx 1- deb Sx without bowel resection, Sx 2- deb Sx with bowel resection, Sx 3- deb Sx with bowel and bladder resection.

5553 Poster Session (Board #375), Sat, 1:15 PM-4:45 PM

Safety findings from FORWARD II: A Phase 1b study evaluating the folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC) mirvetuximab soravtansine (IMGN853) in combination with bevacizumab, carboplatin, pegylated liposomal doxorubicin (PLD), or pembrolizumab in patients (pts) with ovarian cancer. *First Author: David M. O'Malley, The Ohio State University College of Medicine, Columbus, OH*

Background: FORWARD II is a phase 1b study of the FRα-targeting ADC, mirvetuximab soravtansine (IMGN853), in combination with bevacizumab (BEV), carboplatin, PLD, or pembrolizumab in adults with FRα-positive EOC, primary peritoneal, or fallopian tube tumors (NCT02606305). **Methods:** The escalation stage of this trial evaluated the safety and tolerability of IMGN853 as part of 4 combination regimens: IMGN853 + BEV; + carboplatin; + PLD; and + pembrolizumab. IMGN853 was administered in combination on Day 1 of a 21 (BEV or carboplatin) or 28-day cycle (PLD). Pembrolizumab escalation is continuing. The starting dose of IMGN853 was 5 mg/kg (adjusted ideal body weight, AIBW), one level lower than the recommended single agent phase 2 dose (RP2D; 6 mg/kg AIBW) defined in a first-in-human study (NCT01609556). Adverse events (AEs) were evaluated by CTCAE v4.0. **Results:** 46 pts enrolled in the first 3 cohorts. IMGN853 was escalated from 5 to 6 mg/kg. Carboplatin and PLD dosing were escalated from AUC4 to AUC5 and 30 to 40 mg/m^2, respectively; BEV dosing remained constant at 15 mg/kg. Diarrhea, nausea, and fatigue were common across cohorts (all grades; 33-57%) and mostly low grade (i.e. $\leq$ 2), consistent with the IMGN853 safety profile from the earlier phase I monotherapy study. AEs of interest related to the combination agents were seen in each arm. For example, grade 1/2 proteinuria (36%) and grade 3 hypertension (21%) were only observed in the BEV combination. Thrombocytopenia (44%) and neutropenia (39%), grades 1-3, occurred most frequently in the carboplatin arm. Grade 3 anemia and vomiting (each 14%), as well as low grade ($\leq$ 2) constipation (43%), were seen in the PLD cohort. **Conclusions:** The RP2D dose of IMGN853 was readily combined with the highest doses (as per protocol) of BEV, carboplatin, and PLD. The AE profiles for these combinations were manageable and as expected based on known profiles of each agent; importantly, no new safety signals were identified. Updated data from all 4 combination regimens will be presented. Clinical trial information: NCT02606305.

5554 Poster Session (Board #376), Sat, 1:15 PM-4:45 PM

Two prognostic populations of ovarian cancer patients defined by CA125 modeled kinetic parameter KELIM (AGO-OVAR 7 & 9; ICON 7 AGO/GINECO/MRC CTU/GCIG trials). *First Author: Benoit You, Institut de Cancérologie des Hospices Civils de Lyon (IC-HCL), CITOHL, Lyon, France*

Background: Longitudinal CA125 kinetics during treatment can be assessed by mathematical models. The modeled CA125 elimination parameter KELIM (with 3-4 timepoints) was an early prognostic factor in CALYPSO (Gynecol Oncol 2013). Validating the prognostic value of KELIM in phase 3 trial datasets with different 1st line treatments was warranted. **Methods:** Data from AGO-OVAR 9 (training set: carboplatin-paclitaxel (CP) +/- gemcitabine; n=1742); AGO-OVAR 7 (validation set: CP +/- topotecan; n=1308); and ICON 7 trials (validation set: CP +/- bevacizumab; n=1528) were analyzed. CA125 profiles were fit to nonlinear mixed effect equations, and KELIM estimated in all patients at 100 days. KELIM prognostic value was tested regarding PFS and OS against other prognostic factors (stage; pathology; grade; arms; GCIG CA125 criteria; Oza groups in ICON 7) using univariate/multivariate tests. **Results:** KELIM (≤ or > median 0.0598) had reproducible independent prognostic value for PFS (AGO 9: HR = 0.60 [0.53-0.69]; AGO 7: HR = 0.58 [0.40-0.83]; ICON-7: HR=0.65 [0.44-0.96]) and for OS (AGO 9: HR = 0.55 [0.47-0.64]; AGO 7: HR = 0.55 [0.35-0.86]; ICON-7: HR=0.49 [0.41-0.57]) by multivariate tests. Other significant factors for PFS & OS: stage IV in AGO7 & 9 (HR=6.0 to 8.3) and ICON 7 poor progn group (PFS HR=2.24 PFS; OS HR=2.22 [1.9-2.6]). KELIM prognostic value was independent on regimen arms (Table), maintained within ICON7 progn groups (best OS gain with bevac if poor progn & unfav KELIM), and better than GCIG CA125 (inconsistent progn value). **Conclusions:** The reproducible & independent early prognostic value of KELIM regarding PFS and OS is validated. Easily calculable online, it early discriminates 2 ovarian cancer populations for PFS & OS whatever treatments, and is a new reference prognostic factor.

		PFS (months)		OS (months)	
	Treatment	Favorable KELIM > 0.059	Unfavorable KELIM ≤ 0.059	Favorable KELIM > 0.059	Unfavorable KELIM ≤ 0.059
AGO/OVAR 9	CP	25.6	11.4	59.5	36.6
	CP + Gemcitabine	21.9	11.2	NR, >70	38.7
AGO/OVAR 7	CP	28.3	12.8	NR, > 60	45.5
	CP + topotecan	19.5	10.2	NR, > 60	31.6

5555 Poster Session (Board #377), Sat, 1:15 PM-4:45 PM

Cell-free tumor DNA in peri-operative blood samples from advanced high-grade serous ovarian cancer patients with and without complete resection. *First Author: Florian Heitz, Department of Gynecologic Oncology, Kliniken Essen-Mitte, Essen, Germany*

Background: Surgical outcome is an important prognostic factor in advanced high-grade serous ovarian cancer (HGOC). Intra-operative determination of residual disease may be prone to subjective bias. **Methods:** We prospectively collected and analyzed tumor tissue and plasma from 21 pts with FIGO IIIC-IV HGOC. All tumor specimen showed loss of TP53 in immunohistochemistry. Tumor DNA from tissue and peri-operative cell-free DNA at baseline (BL) and at d(ays) 1, d4 and d10 were subjected to comprehensive hybrid-capture based next-generation sequencing (NEO New Oncology GmbH, Cologne, Germany). **Results:** The initial cohort comprised 10 pts without (TR>0) and 11 pts with complete resection TR0, with a total of 43 somatic genomic alterations. *TP53* was mutated in 20/21 (95.2%) of tissue samples and in 15/21 (71.4%) corresponding plasma samples at BL. Therefore, *TP53* mutations were used as a molecular marker of circulating tumor DNA levels post-surgery. In the remaining 5 BL cases the *TP53* mutations were either not present in plasma (N= 3) or rested below the detection limit (N= 2). In d1, d4 and d10 post-surgical samples, the sample specific *TP53* mutations were detected in 12 out of 15, 10 out of 14 and in 7 out of 13 cases, respectively. *TP53*variant allele frequency (VAF) did not differ among TR0 and TR>0 at BL (mean= 1.91 versus 1.73, Mann-Whitney test p = 0.86) whereas it was significantly lower for TR0 at d1 (mean= 0.06 versus 2,06; p value= 0.002), d4 (mean= 0.07 versus 1.8; p= 0.04) and d10 (mean VAF= 0 versus 1.04; p= 0.008). Five out of 9 TR>0 cases showed at least one increase in VAF between d0 and any additional time-point. In 8 out of 9 mutations remained detectable at d10 (VAF: 0.076 – 3.26). By contrast, TR0 cases showed consistent reduction in VAF throughout the follow-up period which maximized at d10. **Conclusions:** Liquid biopsycan efficiently detect somatic mutations in the cfDNA of pts with HGOC following debulking surgery. Variation of the *TP53* VAF in sequential post-surgical samples appears to be restricted to TR>0 cases, whereas in TR0 pts VAF progressively decreases. Liquid biopsy may hold promise as a tool for the objective determination of residual disease after debulking surgery.

5556 Poster Session (Board #378), Sat, 1:15 PM-4:45 PM

A phase II clinical trial of metformin as a cancer stem cell targeting agent in stage IIc/III/IV ovarian, fallopian tube, and primary peritoneal cancer. *First Author: Ronald J. Buckanovich, Department of Internal Medicine, University of Michigan, Ann Arbor, MI*

Background: Epidemiologic and preclinical studies suggest that Metformin has antitumor effects which may be due to an impact on cancer stem-like cells (CSC). We present a phase II trial of metformin administered in combination with chemotherapy for patients with advanced stage epithelial ovarian cancer (EOC). Primary endpoints were 18 month progression free survival (PFS) and CSC number in Metformin treated tumors. **Methods:** Thirty-eight patients with confirmed stage IIC(n=1)/III(n=25)/IV(n=12) EOC were treated with either neoadjuvant metformin followed primary debulking surgery and adjuvant Metformin+chemotherapy, or neo-adjuvant metformin+chemotherapy, followed by interval debulking and adjuvant chemotherapy+Metformin. Patients were evaluated for side effects, PFS and overall survival (OS). Metformin treated tumors were evaluated for the presence of CSC via FACS and sphere assays. **Results:** Thirty-two patients (84%) completed at least six cycles of metformin+chemotherapy. Metformin was well tolerated with only one grade III/IV treatment-related adverse event (3%) noted. Common adverse effects were diarrhea (18%) and nausea (16%). Eighteen month PFS was 65.4% (95% confidence interval 47.9-78.3), Median PFS was 21.7 months (CI-17-26.7). Estimated three year OS was 73.5% (CI-54.7-84.3) with median OS not reached after a media follow-up of 33 months. Finally, tumors treated with metformin were noted to have a 3-fold decrease in ALDH+ CSC at baseline, increased sensitivity to Cisplatin in vitro, and a reduced ability to amplify ALDH+ CSC with passage in vitro. **Conclusions:** This is the first prospective study of Metformin in EOC patients. Translational studies confirm an impact of metformin on CSC. Metformin was well tolerated and outcome results were favorable, supporting the use of Metformin in phase-III studies. Clinical trial information: NCT01579812.

5557 Poster Session (Board #379), Sat, 1:15 PM-4:45 PM

Comparison of patient reported symptom burden in patients with ovarian cancer undergoing primary vs. interval tumor reductive surgery. *First Author: Larissa Meyer, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patient-reported outcomes (PROs) are important in comparative effectiveness research. We compared symptom burden and functional recovery in pts undergoing primary cytoreductive surgery (PCS) or neo-adjuvant chemotherapy (NACT) and interval cytoreductive surgery (ICS) within an enhanced recovery after surgery program (ERAS). **Methods:** Perioperative PROs were measured for women with ovarian cancer undergoing PCS or ICS using the MD Anderson Symptom Inventory- Ovarian Cancer, a 27-item validated tool which was administered preoperatively, daily in hospital, and at least weekly for 8 weeks post-op. Mixed-effect modeling was performed. **Results:** 108 pts (45 PCS, 63 ICS) participated. There was no difference in median age, Charlson comorbidity index, ASA status, history of chronic opioid use, length of stay or readmission rate. At pre-op baseline assessment, the mean pain score was higher in the PCS group (3.8 vs. 1.8, p = .0005). ICS pts had a lower median surgical complexity score (4.0 vs. 2.0, p = .03), and shorter median surgical time (260 min vs. 223 min, p = .05). During hospitalization, pts undergoing PCS reported significantly more bloating, urinary urgency, distress, sadness and mood disturbance. Women who received NACT had a significantly higher symptom burden of neuropathy, leg cramps and memory disturbances. There was no difference in pain, fatigue, drowsiness, nausea, or emesis within the first 5 days postoperatively. While there was no significant differences in the physical interference composite score, (walking, work, activity), those who underwent ICS had improved affective interference scores (mood, relations, enjoyment of life). **Conclusions:** Within an ERAS program, there were few significant differences in surgery related symptoms related to physical recovery between pts undergoing PCS or ICS. The differences in overall symptom burden suggest that disease related symptoms (pain, bloating, urinary urgency) and emotional symptoms may be related to recent diagnosis and higher tumor burden in pts undergoing PCS while the increased numbness, leg cramps and memory issues reflect chemo-related effects in the ICS cohort.

5558 Poster Session (Board #380), Sat, 1:15 PM-4:45 PM

Panitumumab in platinum-sensitive epithelial ovarian cancer patients with KRAS wild-type: The PROVE-study, a phase II randomized multicenter study of the North-Eastern German Society of Gynaecologic Oncology. *First Author: Radoslav Chekerov, NOGGO and Department of Gynecology, Campus Virchow-Klinikum, Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: For ovarian cancer (OC) patients with platinum-sensitive recurrence the addition of new biologic agents to chemotherapy may improve survival. Panitumumab is a fully human monoclonal antibody specific to the epidermal growth factor receptor (EGFR). The purpose of this trial was to investigate the therapeutic efficacy of panitumumab in the combination with carboplatin-based chemotherapy in relation to the respective standard combination in patients with a KRAS wildtype with platinum-sensitive recurrent ovarian cancer (NCT01388621). **Methods:** Major eligibility criteria were pretreated platinum-sensitive epithelial ovarian/ fallopian/ peritoneal cancer and no more than 2 prior treatments for this disease. Only patients with measurable disease or elevated CA125 and with KRAS wild type were eligible. Patients were treated with Carboplatin AUC4/Gemcitabine 1000 mg/m^2 or Carboplatin AUC5/PLD 40 mg/m^2 and randomized to panitumumab 6 mg/kg day 1 and day 15, every 3 or 4 weeks. Tumor assessment was performed at baseline and at every third cycle according to CT-scan and CA-125 criteria. **Results:** In this multi-institutional phase II trial 102 patients were randomized and 96 enrolled for the final analysis. Progression-free survival in the intention-to-treat population (N=96) was 9.5 vs. 10.7 months (HR 0.829, 95%CI of 8.5-11.6 months vs 8.5-13.1 months) for the experimental vs. standard arm, p=0.45. Data of overall survival are not jet evaluable. The most common treatment related grade 3+ toxicities included hematologic toxicity (54%), skin reactions (18%) and gastrointestinal events (16%). **Conclusions:** The addition of panitumumab to platinum-based chemotherapy for recurrent ovarian cancer does not influence efficacy and progression-free survival in platinum sensitive patients, while no new additional toxicity aspects for panitumumab were evaluated. Clinical trial information: NCT01388621.

5559 Poster Session (Board #381), Sat, 1:15 PM-4:45 PM

ENGAGE: Evaluation of a streamlined oncologist-led *BRCA* mutation (*BRCA*m) testing and counselling model for patients with ovarian cancer. *First Author: Nicoletta Colombo, University of Milano-Bicocca and Istituto Europeo di Oncologia, Milan, Italy*

Background: Short *BRCA*m testing turnaround times (TAT) are crucial to making timely treatment decisions for patients (pts) with ovarian cancer. ENGAGE (NCT02406235; D0816R00006) evaluated a streamlined, oncologist-led germline *BRCA*m testing model, piloted by the Institute of Cancer Research and the Royal Marsden Hospital, London, UK. Results presented are from the final analysis (data cut-off: 30 Sep 2016). **Methods:** This prospective, observational study enrolled pts with ovarian cancer across sites in the US (n = 11), Italy (n = 8) and Spain (n = 7). Oncologists and nurses at participating sites were trained on genetic counselling techniques relating to *BRCA*m testing. Primary endpoints were *BRCA*m testing TAT (time from initial counselling to the provision of test results or post-*BRCA*m test counselling [whichever occurred latest]); pts' satisfaction with the oncogenetic testing model, evaluated using pre- and post-*BRCA*m testing surveys; and clinicians' opinion on the value of this new testing pathway, evaluated using a post-*BRCA*m testing survey. **Results:** For the 700 evaluable pts enrolled (US = 317; EU = 383), pre-*BRCA*m testing counselling was carried out by either an oncologist (40.7%) or clinical staff (nurse or research coordinator; 59.3%) in the US, and only by oncologists in the EU. The median overall TAT was 9.1 weeks (all pts), with 12.0 weeks in Spain, 20.4 weeks in Italy (17.4 weeks EU median) and 4.1 weeks in the US. The differences were mainly due to the time from *BRCA*m testing to obtaining the test results. Satisfaction with the overall counselling was high amongst pts, with a mean dimension score rating of 3.8/4 (where 4.0 = highest satisfaction). 93.6% of pts were happy to have received genetic testing as part of an existing oncologist appointment, and more than 80% of oncologists were satisfied with the screening process, agreeing that it was an efficient use of their time. **Conclusions:** The ENGAGE study results show that a streamlined oncologist-led *BRCA*m testing model can offer reduced TAT and high levels of satisfaction amongst pts and clinicians. The success of this model is enhanced by access to a *BRCA*m testing facility, from which results can be obtained quickly. Clinical trial information: NCT02406235; D0816R00006.

5560 Poster Session (Board #382), Sat, 1:15 PM-4:45 PM

The successful phase 3 niraparib ENGOT-OV16/NOVA trial included a substantial number of patients with platinum resistant ovarian cancer (OC). *First Author: Jose Maria Del Campo, Grupo Español de Investigación en Cáncer de Ovario (GEICO) and Vall d'Hebrón University Hospital, Barcelona, Spain*

Background: Niraparib is a highly selective poly (ADP-ribose) polymerase (PARP) 1/2 inhibitor (PARPi); in preclinical studies, it concentrates in the tumor relative to plasma to deliver durable, near complete PARP inhibition and persistent antitumor effects.Niraparib demonstrated significantly longer progression free survival (PFS) vs placebo in patients (pts) with recurrent OC who were randomized following a complete response (CR) or partial response (PR) to platinum based chemotherapy in the controlled, double-blind phase 3 ENGOT-OV16/NOVA trial. To more fully characterize the NOVA trial population, we assessed platinum resistance status, defined as a duration of response to platinum $<$ 6 months to the most recent (ultimate) platinum regimen. Analysis was limited to pts in the placebo arm, as inclusion of pts receiving active treatment (niraparib) would have confounded the ability to determine duration of response to platinum alone. **Methods:** Pts with recurrent OC, no prior PARPi use, $\geq$2 prior courses of platinum based chemotherapy, and CR or PR to the most recent platinum based chemotherapy were eligible. Pts were assigned to one of two cohorts based on g*BRCA* testing (g*BRCA*mut or non-g*BRCA*mut) and randomized 2:1 within each cohort to niraparib 300 mg or placebo qd until progressive disease (PD). Randomization occurred up to 8 weeks following the last dose of the most recent platinum based chemotherapy. PFS was measured from time of randomization to death or earliest PD as assessed by independent review committee. Estimated probability of pts having disease progression in each cohort and pooled across cohorts 6 months after the last dose of their most recent platinum therapy was calculated using the Kaplan-Meier methodology. **Results:** 181 pts were randomized to placebo (65 g*BRCA*mut and 116 non-g*BRCA*mut). Platinum resistance rate estimates for the g*BRCA*mut, non-g*BRCA*mut, and pooled cohorts were 42%, 53%, and 49%, respectively. **Conclusions:** Approximately half of the pts in the NOVA study, where niraparib treatment met its primary endpoint of prolonging PFS following a response to platinum, had developed platinum resistance to their last line of chemotherapy. Clinical trial information: NCT01847274.

A platinum-resistant subtype of high-grade serous ovarian cancer identified by a network of somatic mutations. *First Author: John P. Shen, University of California San Diego Moores Cancer Center San Diego School of Medicine, La Jolla, CA*

Background: High-grade serous ovarian carcinoma (HGS-OvCa) is a heterogeneous entity with a widely variable clinical course even among patients of the same stage and histological subtype. Although most patients will achieve remission with platinum-based chemotherapy, ~20% will display primary platinum resistance. Currently no biomarker exists to identify these platinum resistant patients. **Methods:** We have recently developed a method called Network-based Stratification (NBS), which combines genome-scale somatic mutation profiles with genetic interaction networks and performs unsupervised clustering of patients into subtypes. **Results:** Using NBS HGSOC patients were stratified into subtype, in both TCGA (n = 330) and the ICGC (n = 92) a high-risk (HR) subtype consisting of ~20% of the patients was identified (see table). Propagated mutation scores of the HR tumors from TCGA and ICGC cohorts we remarkably correlated (Pearson r^2 = 0.94, $p < 0.001$), relative to the correlation between HR and standard risk subtypes within TGCA cohort (r^2 = 0.18). We then identified molecularly matched cell line models for *in vitro* study, finding that HR cell lines (Kuramochi, Ovkate, OAW28, 59M) were significantly more resistant to cisplatin relative standard risk cell lines (COV318, TYK-NU, OVCAR4), (IC_{50} 14.4 vs. 3.3 μM, $p < 0.0001$). There was no significant difference in sensitivity to paclitaxel. A genome-wide knockout screen using CRISPR-Cas9 has identified several candidate genes mediating this observed platinum resistance. **Conclusions:** NBS can be used to identify a molecularly distinct subtype of HGSOC characterized by poor patient survival and primary platinum resistance.

TCGA Cohort (Nature 2011).

subtype	median OS (months)	HR vs. SR I	n (% of cohort)
High-Risk (HR)	32	2.17	64 (19%)
Standard Risk I	55	–	231 (70%)
Standard Risk II	60	0.66	14 (4.2%)
Standard Risk III	not-yet-reached	0.4 log rank p = 1.6 e-5	21 (6.4%)

ICGC Cohort (Nature 2015)

subtype	OS (months)	HR vs. SR I	n (% of cohort)
High-Risk (HR)	25.2	2.15 *	20 (22%)
Standard Risk I	45.6	–	63 (68%)
Standard Risk II	not-yet-reached	0.98 log rank p = 2.0 e-4	10 (11%)

5562 Poster Session (Board #384), Sat, 1:15 PM-4:45 PM

Ki67 as a prognostic factor in low grade serous ovarian cancer (LGSOC): A retrospective analysis of the Tumor Bank Ovarian Cancer (TOC). *First Author: Jalid Sehouli, AGO and Charité Campus Virchow-Klinikum, Berlin, Germany*

Background: LGSOC is a rare and distinct entity characterized by younger age, lower response to chemotherapy and better clinical outcome. Aim of this study was to evaluate the impact of Ki67, estrogen and progesterone receptors (ER and PR) on platinum response and survival in primary LGSOC patients. **Methods:** 80 primary LGSOC patients with available FFPEs were identified within TOC. The histology was confirmed at a second histological evaluation. For Ki67 analysis conventional immunohistochemical staining was performed with the Mib-1 clone on Ventana. Slides were explored with a light microscope camera. A representative field for Ki-67 evaluation was selected, in case of heterogeneous staining a hot spot was chosen. The software classified detected cells into non-tumor, negative and positive cells. When necessary, a correction of tumor and non-tumor areas was performed by an experienced pathologist. The counted cells ranged between 175 and 2398. Overall the method allows a precise, continuous and standardized means to quantify Ki-67. ER and PR status was determined on scanned IHC TMA slides. ER and PR positive tumors were defined if the percentage of stained tumor cells was at least 10%. Statistical analysis was performed using IBM SPSS Statistics. **Results:** Median age at diagnosis was 56 years (range: 20-81), 81.3% of patients presented in advanced stage and 96.3% received platinum based chemotherapy. Ki67 median value was 5.09 (IQR: 1.56-10.5). 93.1% and 47.9% of the patients showed ER and PR positive tumors, respectively. Median overall survival (OS) was 45.5 months (range: 0.1-182.8). Our analysis showed that platinum free interval (PFI) was significant longer in patients with lower Ki67 ($p = 0.006$). Higher proliferation rates were significant associated with poorer progression free ($p = 0.011$, HR = 1.039, 95%CI: 1.009-1.070) and OS rates ($p = 0.001$, HR = 1.059, 95%CI: 1.025-1.095). No differences in clinical outcome were seen in patients with different ER and PR status. **Conclusions:** This is the first study showing that higher Ki67 values correlate with shorter PFI and poorer survival rates in LGSOC, underlying the heterogeneous character of this disease.

5563 Poster Session (Board #385), Sat, 1:15 PM-4:45 PM

Should MMMT of the endometrium/ovary be treated with anthracycline instead of taxane based chemotherapy? *First Author: Viola A. Heinzelmann-Schwarz, University Hospital Basel, Basel, Switzerland*

Background: Carcinosarcomas of endometrial (MMMT-E) and ovarian (MMMT-O) origin are rare biphasic tumors, associated with poor prognosis and thought to be epithelial in origin. In view of this, there has been a shift towards carboplatin and paclitaxel rather than anthracycline based chemotherapy regimens which were used when they were treated as "sarcomas". The purpose of this large retrospective study is to determine whether this change in chemotherapy is associated with better outcomes. **Methods:** Firstly, clinicopathological features of patients with all stages of MMMT-E (n=103) and -O (n=17) were compared to patients with adenocarcinoma of the endometrium (n=172) and ovary (n=189) in a case-controlled study. Clinicopathological characteristics, FIGO stage, first-line regimens and patient outcomes were analyzed. Secondly, primary tumor specimens of high grade serous ovarian cancers (HGSOC, n=1290) and MMMT-O (n=450) from an independent cohort were analyzed using immunohistochemistry and next generation sequencing to predict response to chemotherapeutic agents. **Results:** MMMT have a poor prognosis, however, there was a plateau in survival of MMMT-E after 2.5 years in patients with FIGO stage I/II disease, with no recurrence/cancer deaths observed beyond this. There was a statistically significant worse relapse-free survival in patients with MMMT-E treated with carboplatin and paclitaxel compared to carboplatin and anthracyclines ($p=0.0011$). In the second independent prospective cohort comparing HGSOC versus MMMT-O, both were driven predominantly by p53 mutations. MMMT-O expressed statistically more commonly PI3KCA and KRAS ($p=0.015$ and 0.018), respectively. Of particular interest, both HGSOC and MMMT-O showed a higher percentage of probability of responding to a combination of carboplatin/anthracyclins (71.2 vs. 73.9%) than carboplatin/taxanes (58.4 vs 39.4%). **Conclusions:** Patients with MMMT-E and stage I/II have an excellent prognosis if there is no recurrence by 2.5 years. Platinum/anthracyclines regimens appear to be associated with a better outcome than platinum/taxane in MMMT-E and MMMT-O. This could be tested in an international prospective randomized controlled trial.

5564 Poster Session (Board #386), Sat, 1:15 PM-4:45 PM

A re-analysis of the prostate, lung, colorectal, and ovarian (PLCO) cancer screening trial accounting for ovarian cancer (OVCA) heterogeneity. *First Author: Sarah Madhu Temkin, Virginia Commonwealth University, Richmond, VA*

Background: A mortality benefit from screening for OVCA has not been demonstrated, but screening efficacy could differ for histologic subtypes. We re-analyzed PLCO evaluating whether OVCA detection and outcomes were affected by the heterogeneous biologic behavior of this disease. **Methods:** Type 2 tumors (moderately/poorly differentiated serous and adenocarcinoma) were compared to all other tumor (OT) types (low grade serous and endometrioid, clear cell, other, low malignancy potential) (LMP). We examined differences in the distribution of tumor types and stage by study arm and method of diagnosis [screen detected (SD) and interval detected (ID) (i.e. assigned to screening but diagnosed between screening tests)]. Stage distribution and survival were analyzed. **Results:** Among the entire PLCO population, 531 women were diagnosed with OVCA during the study; 282 (53%) in the screening arm and 249 (47%) in the usual care arm. Of the tumors able to be characterized (n=408; 77%), 74% (n=300) were Type 2 and 26% OT (n=108). In the screening arm, 70% of tumors diagnosed were Type 2 compared to 78% in usual care ($p=0.07$). Overall, survival was significantly better for OT tumors compared to Type 2 tumors ($p<0.01$) but there was no difference in survival by study arm for either tumor type separately (Type 2: $p=0.50$; OT: $p=0.23$). Within the screening arm, 30% of Type 2 tumors were SD compared to 54% of OT tumors ($p=0.02$) (see Table). Only 15% of Type 2 SD tumors were Stage I/II, compared to 82% of SD OT tumors ($p<0.01$). Stage at diagnosis was similar among Type 2 patients whether they were SD or ID ($p=0.56$) and there was no difference in survival ($p=0.56$). **Conclusions:** A significant difference in tumor types by study arm was not observed. However, within the screening arm, Type 2 tumors were less likely to be SD or Stage I/II compared to OT tumors. Survival for Type 2 tumors was similar regardless of method of diagnosis.

Ovarian tumor types by diagnosis method.

	Type 2 N (%)	OT N (%)	p-value
Usual Care	144 (48)	41 (38)	0.07
Screening	156 (52)	67 (62)	
• Never screened	15 (9.6)	8 (11.9)	<0.01
• Post-screening	70 (44.9)	17 (25.4)	
• Interval	25 (16.0)	6 (9.0)	
• Screen Detected	46 (29.5)	36 (53.7)	

5565 Poster Session (Board #387), Sat, 1:15 PM-4:45 PM

Are symptoms of ovarian cancer evident: A retrospective analysis of claims data to determine prior symptoms to diagnosis. *First Author: Denise Manon Langabeer, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are no standard of care screening methods for ovarian cancer. Over sixty percent (60%) of ovarian cancer cases are found at Stage III and IV, which ultimately impacts a woman's survival rate. The purpose of this study is to determine if specific symptoms are evident prior to diagnosis of ovarian cancer. **Methods:** A retrospective analysis of health insurance claims between 2008 through 2013 from a commercial payer was performed based on the following eligibility criteria: 1) women diagnosed with ovarian cancer, 2) at the time of diagnosis, 24 years of age or older, 3) enrolled in healthcare plan for a period of 24 months or more prior to diagnosis, and 4) resident in the state of Texas. Symptoms were identified based on ICD-9 diagnosis codes and categorized specific to pain, abdominal and pelvis, digestive, and bladder and were evaluated at minimum of six months prior to diagnosis. ICD9 codes are used for this analysis as the data is limited to years before the change to ICD10. **Results:** Baseline data of 3,641 women diagnosed with ovarian cancer were identified and were associated with 927,528 claims specific to the symptoms. The age of women diagnosed with cancer ranged between 24 and 88 (mean=52; SD: 0.1833). Nearly 70% of women were treated for one or more symptoms prior to diagnosis. The symptoms women experienced the most were associated with abdomen and pelvis at 60%. Pain, digestive, and bladder ranged between 20% and 30%. **Conclusions:** This research is intended to further explore whether symptoms are evident in women diagnosed with this disease, and if so, how long and how frequent did the symptoms occur prior to diagnosis. Additionally, a review of combination of symptoms is explored. This research is intended to provide a better understanding of the disease as well as support that women may need to be referred to an oncologist earlier for further evaluation should reoccurring symptoms present.

5566 Poster Session (Board #388), Sat, 1:15 PM-4:45 PM

Circulating free DNA and circulating tumor cells as new serum biomarkers in advanced ovarian cancer. *First Author: Jeronimo Martinez Garcia, Hospital Clinico Universitario Virgen de la Arrixaca, Murcia, Spain*

Background: Circulating free DNA (cfDNA) and circulating tumor cells (CTC) are new biomarkers for malignant tumors. Its role on ovarian epithelial cancer (OEC) is not yet well stablished. We analyze its role on advanced OEC compared with CA125 and HE4. **Methods:** Multicentric prospective observational study from November 2013 until February 2017, with OEC patients group (OECG), benign ovarian tumors group (BENIGNG) and health subjects control group (HEALTHG). CTCs were analysed by the CellSearch method and cfDNA by ALU-sequences-based quantitative PCR using two primers (115 and 247 bp); cfDNA integrity was calculated by ALU247/ ALU115 ratio. Samples were obtained before treatment (M0), after primary peritoneal surgery (M1), after one cycle of chemotherapy (M2), before (M3) and after interval surgery (M4). This study was approved on May 2013 by the corresponding Central Research Independent Ethics Committee. **Results:** We analyzed 102 subjects from all 3 groups (81 OECG, 14 BENIGNG y 7 HEALTHG); 68% were high grade serous subtype; most frequent staging was IIIC (58%). Within the follow-up (FU) period (average 14 months: min 0, max. 35) 36% relapses and 23% deaths were reported. CTCs were positive on 23% of OECG. In HEALTHG no positive were seen and only 1/14 in the BENIGNG group. Monitoring of cfDNA at the treatment points shows significant differences between M0 and M4 (p = 0.02). No differences were seen in the other determinations. cfDNA-ALU115 was 1.40178 ng / mcL (95% CI 1.18066-1.62290) in the OECG, 0.66383 (95% CI 0.44832-0.87935) in BENIGNG and 0.59923 in HEALTHG (95% CI, 0.14449-1.05397). The difference was significant between OECG and BENIGNG (P = 0.017) and near the significance between OECG and HEALTHG (p = 0.69). cfDNA integrity in OECG and HEALTHG was significantly different (P = .012). The area under the curve of Ca125, HE4, CTC, cfDNA and CFDNA integrity was 0.490, 0.526, 0.621, 0.587 and 0.450 respectively. New generation sequencing of circulating TP53 is ongoing. **Conclusions:** CTC and cfDNA are new biomarkers that might have an important role in the diagnosis and monitoring of OEC.

5567 Poster Session (Board #389), Sat, 1:15 PM-4:45 PM

Prognostic implications of lymph node metastasis in advanced ovarian cancer: Analysis of National Cancer Database. *First Author: Sukamal Saha, Easton Hospital, Easton, PA*

Background: During debulking surgery (Surg) for advanced ovarian cancer (OvCa), lymph node (LN) sampling are not routinely performed. Hence, prognostic implications of LN involvement following debulking surg and chemotherapy (ChemoRx) were analyzed from National Cancer Database (NCDB). **Methods:** Only Stage III and Stage IV patients (pts) from 2004 –2014 NCDB pts undergoing Debulking surg. and ChemoRx were included. Group A included pts with debulking surg without bowel resection; Group B with major bowel resection and Group C with bowel and bladder resection. Pts were further subdivided according to the use of 1) NeoAdjuvant (NeoAdj) 2) Adjuvant (Adj) and 3) Neo Adj and Adj ChemoRx. Survival analysis was done based on -ve or +ve LN status. using Pearson Chi Square testing. **Results:** Out of 10,737 Stage III and 3,102 Stage IV pts, there were 6828 Group A, 6413 Group B and 598 Group C pts. Five year overall survival (OS) for all pts in Stage III with LN-ve vs LN +ve was 59.9% vs 53.9% and Stage IV was 48.7% vs 41.2%. In Group A, B, and C, the 5 yr OS was better in LN – ve than LN +ve pts (Table1). The OS for both LN –ve and LN +ve groups were better in Adjuvant chemoRx in all 3 groups. OS was slightly better in Stage III vs Stage IV pts. **Conclusions:** Even though LN dissection are not routinely done during debulking surg, overall pts with LN metastasis do worse than LN –ve pts irrespective of the timing of ChemoRx. Hence, LN sampling during debulking surg should be strongly considered as it may provide important prognostic information.

Five year overall survival by LN +ve vs -ve.

		Stage 3 (n=10737)			
Surg (n)	**LN Status**	**NeoAdj (%)**	**Adj (%)**	**NeoAdj and Adj (%)**	**p value**
Grp A	LN-ve	46.0%	63.0%	57.8%	<0.001
5492	LN +ve	46.8%	58.8%	42.0%	<0.001
Grp B	LN-ve	50.4%	60.0%	45.0%	<0.001
4824	LN +ve	41.2%	51.8%	48.9%	0.051
Grp C	LN-ve	75.0%	63.9%	37.5%	0.249
421	LN +ve	27.3%	55.0%	33.3%	0.075
			Stage 4 (n=3102)		
Grp A	LN-ve	44.8%	45.5%	54.1%	0.232
1336	LN +ve	33.1%	42.4%	42.4%	0.150
Grp B	LN-ve	42.1%	50.0%	54.0%	0.334
1589	LN +ve	33.3%	42.4%	35.8%	0.083
Grp C	LN-ve	40.0%	57.1%	42.9%	0.618
177	LN +ve	30.0%	51.1%	33.3%	0.298

Group A = debulking without bowel resection; Group B = debulking with major bowel resection and Group C =debulking with bowel and bladder resection

5568 Poster Session (Board #390), Sat, 1:15 PM-4:45 PM

Phase I study of the safety and activity of formulated IL-12 plasmid administered intraperitoneally in combination with neoadjuvant chemotherapy in patients with newly diagnosed advanced stage ovarian cancer. *First Author: Premal H. Thaker, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: This study evaluated weekly intraperitoneal (IP) GEN-1, an IL-12 plasmid formulated with polyethyleneglycol-polyethyleneimine cholesterol lipopolymer, with intravenous (IV) weekly taxane (T) and carboplatinum (C) every 3 weeks in epithelial ovarian, fallopian tube or primary peritoneal cancer (EOC) patients undergoing neoadjuvant therapy (NAC). The primary objective was to evaluate the tolerability and safety of GEN-1 with NAC. Secondary objectives included objective clinical response and pathological response at interval debulking surgery (IDB). **Methods:** Newly diagnosed advanced stage EOC patients being treated with NAC were eligible. The trial utilized a 3+3 design with GEN-1 IP dose levels of 36 mg/m^2, 47 mg/m^2, 61 mg/m^2, and 79 mg/m^2 weekly for 8 treatments with concurrent IV T/C. Dose-limiting toxicity (DLT) was based on the first 4 doses of GEN-1 administered. **Results:** To date, 13 patients have been treated on-study with 12 patients receiving all 8 treatments of IP GEN-1 with no DLTs. The most common related toxicities were Gr 1 nausea, vomiting, abdominal pain and fatigue. One patient experienced Gr 2 fevers associated with GEN-1 but responded to acetaminophen and fluids. One patient did not undergo IDB while on-study due to a cancer related pulmonary embolism and severe deconditioning. This patient has since improved and will have IDB. **Conclusions:** Adding GEN-1 to neoadjuvant T/C is safe and appears to be active in EOC patients. We are reporting the interim findings; final results with translational data to be presented. Clinical trial information: NCT02480374.

Response		**Total n**	**36 mg/m^2**	**47 mg/m^2**	**61 mg/m^2**	**79 mg/m^2**

5569 Poster Session (Board #391), Sat, 1:15 PM-4:45 PM

Impact of genomic heterogeneity on PI3K/AKT/mTOR inhibitors (PAMi) efficacy in gynecologic cancer (GYN) patients (pts). *First Author: Victor Rodriguez Freixinos, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Aberrant PI3K/AKT/mTOR activation is common in GYN. Predictive biomarkers to PAMi in GYN have yet to be identified. **Methods:** Advanced GYN pts with available genomic data, treated with PAMi in phase I/II clinical trials were selected. Mutation (mut) allele fractions (MAFs) were corrected for tumor purity and defined as clonal (cl) ($\geq$ 0.4) or subclonal (scl) ($<$ 0.4). PAMi efficacy: (i) time to progression (TTP); (ii) clinical benefit rate (CBR: complete/partial response or stable disease $>$ 4 months [m]); and (iii) ratio TTP on PAMi/ TTP on non-standard chemotherapy pre- or post-PAMi (PAMi/nsChemo TTP). **Results:** From 2010 to 2016, 264 GYN pts (152 ovarian(OC); 75 endometrial(EC); 37 cervical(CC)) had genomic analysis; 50 pts (24 OC [11 PIK3CA mut, 5 KRAS mut], 15 EC [6 PIK3CA mut, 5 PTEN mut, 4 KRAS mut], and 11 CC [9 PIK3CA mut, 3 KRAS mut]) received PAMi (17 pan-PI3K/mTOR or AKT inh, 17 α-PI3K inh, 16 PAMi targeted combos). PAMi therapy was matched (MA) to PIK3CA/ PTEN mut in 30 pts (60%). Median age was 57 years (30-70); median number of prior lines was 2 (1-6) and 34 pts (68%) received nsChemo. Efficacy of PAMi: (i) median TTP (3.27 m [95% CI 2.1-4.4] with trend for longer TTP in OC compared to others [3.93 vs. 2.1 m, HR 0.57; p = 0.08], without differences according to MA status [p = 0.26] or regimen [p = 0.5]); (ii) CBR (42% [95% CI 27-58%], without differences according to tumor type [p = 0.47], MA status [p = 1] or regimen [p = 0.86]); and (iii) TTP PAMi/ nsChemo $\geq$ 1.3 (42% [95% CI 24-63%], without differences according to tumor type [p = 0.53], MA status [p = 0.23] or regimen [p = 0.41]). Partial responses were seen in 5 pts (4 PIK3CA mut on single agent PAMi; 1 KRAS mut on PI3K + MEK inh). Of 4 KRAS mut pts, none had CBR with single agent PAMi. PIK3CA mut were cl in 63% of OC, 17% of EC and 40% of CC. Clonal exon 20 PIK3CA mut were more frequent in OC (p = 0.03). We found longer TTP for cl PIK3CA events (4.0 vs. 1.5 m in scl, HR 5.1, p = 0.006) and a trend for exon 20 events (4.4 vs. 1.4 m in exon 9, HR 1.7, p = 0.25). **Conclusions:** Regardless of PIK3CA/PTEN mut status, PAMi confer CBR in almost 40% of GYN pts. Functionality and clonality of PIK3CA mut impact on TTP and interact with tumor type. Coexisting KRAS mut may drive resistance to single agent PAMi.

5570 Poster Session (Board #392), Sat, 1:15 PM-4:45 PM

Neoadjuvant BEP regimen in the treatment of extensively advanced yolk sac tumor: A single institutional experience. *First Author: Gong-Yi Zhang, Department of Gynecological Oncology, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Due to the highly aggressive biological behavior and early intra-abdominal spread potential of ovarian yolk sac tumor (YST), a considerable proportion of patients were inoperalbe at initial diagnosis. The aim of this study was to investigate the role of neoadjuvant chemotherapy (NACT) in this cohort of patients. **Methods:** Between July 1982 and December 2015, 58 patients diagnosed as YSTs were initially treated at Cancer Hospital of China Academy of Medical Science (CAMS), among which 18 were evaluated to be inoperable and received NACT. They were either too debilitated by the disease (ECOG ps≥2) to undergo a major surgery, or were with too extensively disseminated lesions to be optimally debulked. Massive ascites, pleural effusion, dyspnea, neoplastic fever, hypoproteinemia, or electrolyte disturbance were also common in these 18 patients. This cohort of patients was retrospectively reviewed. **Results:** One or 2 cycles of BEP regimens were prescribed to the majority of patients preoperatively. At the completion of NACT, all the 18 patients had ECOG ps≤1 . Seventeen of them (94.4%) exhibited clinical partial tumor regression and 1(5.6%) had clinical stable disease. Pathological complete tumor regression was observed in 2 (11.1%) patients, whereas the remaining 16(88.9%) had nearly complete pathological response. All these 18 patients were rendered operable at the completion of NACT, yielding a resection rate of 100%. Seventeen patients (94.4%) were cytoreduced to no macroscopic residual disease, 1 (5.6%) patient was cyto-reduced to macroscopic residual disease ≤2 cm. No major surgical complications occurred in our series. After a median follow-up of 83.5 months, 17 patients were free of recurrence. Five-year DFS and OS were both 94.4%. Fertility-sparing surgery was carried out in all the 17 patients with fertility desire, and 5 infants were delivered in 6 patients who attempted conception. **Conclusions:** One or 2 cycles of NACT followed by early cyto-reductive surgery offers a chance for cure in patients with extensively advanced YSTs. It allows for a more through and safe cyto-reductive surgery, improves survival outcomes, and helps pave the way for fertility-sparing surgery.

5571 Poster Session (Board #393), Sat, 1:15 PM-4:45 PM

Evaluating the repertoire of immune checkpoint markers expressed on peripheral and ascites CD8$^+$ T cells in ovarian cancer. *First Author: Stephanie Gaillard, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Understanding the immune checkpoint marker repertoire can facilitate development of therapeutic strategies to improve efficacy of immune-based therapies. We used a novel high-dimensional flow cytometry panel to determine co-expression patterns of immune checkpoint markers and effector function of CD8+ T cells from peripheral blood and ascites of patients newly diagnosed with ovarian cancer. **Methods:** Peripheral blood and ascites samples were collected from patients with epithelial ovarian cancer (n=8). Cells isolated from peripheral blood and ascites were used for immune profiling by multiparameter flow cytometry of 5 inhibitory receptors (PD-1, LAG-3, TIM-3, TIGIT, and BTLA) on CD8+ T cells, along with 4 functional parameters (production of each of the following: TNF-α, IFN-γ, IL-2, and upregulation of CD107a). A complementary multiplex analysis on plasma and ascites fluid was performed to quantify 14 soluble checkpoint markers. **Results:** The concentrations of soluble PD-1, TIM-3, LAG-3, CTLA-4, BTLA, IDO, and CD137 were increased in ascites fluid compared to plasma from patients with ovarian cancer. Ascites CD8+ T cells co-express higher levels of inhibitory receptors than peripheral CD8+ T cells. In total, CD8+ T cells in ascites retained the ability to produce effector functions at levels similar to peripheral blood. However, IFN-γ production was retained in PD-1 only expressing CD8+ T cells and decreased in CD8+ T cells co-expressing multiple receptors. **Conclusions:** High-dimensional flow cytometry allowed for the phenotypic and functional characterization of CD8+ T cells from ovarian cancer patients. The profile of receptor co-expression was distinct in peripheral blood compared to ascites. Collectively, our study suggests that co-expression of factors beyond PD-1 influences CD8+ T cell activity. Thus blocking PD-1 and PD-L1 alone may not be sufficient for CD8+ T cells expressing multiple inhibitory receptors.

5572 Poster Session (Board #394), Sat, 1:15 PM-4:45 PM

A phase I dose-escalation study of intraperitoneal (IP) cisplatin, IV/IP paclitaxel, IV bevacizumab, and oral olaparib for newly diagnosed adenxal carcinoma. *First Author: Jason A. Konner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: IP cisplatin (Cis) plus IV/IP paclitaxel (Tax) is a standard therapy for optimally debulked adnexal cancer. We previously demonstrated the feasibility of combining bevacizumab (Bev) with this IV/IP regimen. In this study IP Cis, IV/IP Tax, and IV Bev are combined with olaparib (Ola) as front-line therapy. **Methods:** Patients with newly diagnosed adnexal (ovarian, fallopian tube, or primary peritoneal) carcinoma, acceptable organ function, and KPS ≥ 70% are eligible. Patients receive 6 cycles of chemotherapy plus Bev: Tax 135 mg/m^2 IV over 3 hours on Day 1, Bev 15 mg/kg IV on Day 1 (starting cycle 2), Cis 75 mg/m^2 IP on Day 2, Tax 60 mg/m^2 IP on Day 8. Bev is continued every 3 weeks for 21 treatments after chemotherapy is complete. In addition, Ola is given at escalating doses (50/100/200mg tabs BID) on Days 2-8 during cycles 1-6, and then 300mg BID Daily during cycles 7-22. The primary objective is to evaluate the MTD and safety/tolerability of Ola when combined with IP Cis, IV Bev and IV/IP Tax using a 3+3 dose escalation scheme. **Results:** Seventeen women have been treated [median age 57 (47-73)]: 8 in cohort 1 (50mg), 3 in cohort 2 (100mg) and 6 in cohort 3 (200mg). Thirteen (76%) completed all 6 cycles of IV/IP cis/tax; 2 (12%) experienced IP port malfunction (both were removed and replaced); 2 (12%) switched from IP Cis to IV carboplatin due to nephrotoxicity (via ATN and/or OCT-2 inhibition). Grade 3/4 toxicities have included: neutropenia (50%), hyperglycemia (12.5%), leukopenia (12.5%), anemia (18.8%), fatigue (12.5%), and lymphopenia (31.3%). There were 2 occurrences of related grade 3 small bowel obstructions (12.5%), during cycles 2 and 7, respectively. There were no perforations or fistulae. Maintenance therapy with Bev + Ola was generally well tolerated. **Conclusions:** The addition of Ola to this IV/IP regimen appears to be feasible. Ola may increase the risk of creatinine elevation and myelotoxicity. The MTD of intermittent dosing of Ola tabs concurrent with chemotherapy appears to be 200mg BID, while maintenance bev + full-dose ola at 300mg BID continuous appears feasible following IV/IP. Updated results will be presented. Clinical trial information: NCT02121990.

5573 Poster Session (Board #395), Sat, 1:15 PM-4:45 PM

Phase I study to evaluate the tolerability, pharmacokinetics (PK) and pharmacodynamic (PD) of PM01183 (Lurbinectedin) in combination with olaparib in patients with advanced solid tumors. *First Author: Andres Poveda, Clinical Area of Gynecologic Oncology, Instituto Valenciano de Oncología (IVO), Valencia, Spain*

Background: PM01183 (Lurbinectedin) is a new anticancer drug that exerts antitumor activity through inhibition of trans-activated transcription and modulation of tumor microenvironment and is highly active in platinum resistant ovarian cancer. (Poveda A et al. ASCO 2014.abstr #5505). Olaparib (AZD2281, KU-0059436) is a polyadenosine 5'diphosphoribose (poly [ADP ribose]) polymerase (PARP) inhibitor of PARP-1,-2 and-3 with proven antitumoral activity in homologous recombination deficient tumors. The combination of PM01183 and Olaparib has shown synergistic activity in cell-lines, independent of *BRCA* mutation status. **Methods:** This phase I study evaluates the safety, PK and PD of PM1183 in combination with short course of Olaparib tablet formulation [days (d) 1-5] a cycle of 21 d, through a 3+3 dose escalation design (NCT02684318**)** Patients with advanced or metastatic solid tumors without established standard therapeutic alternatives were selected. Primary endpoints: safety (MTD, DLT and RP2D). Secondary endpoints: PK and PD (western blot analysis of RAD51 and p-gH2AX) profiles at 0h,4.5h, 6.5h and 24h at first cycle of treatment. **Results:** 20 patients were enrolled from Nov 2015 to Sep 2016 (15 ovarian, 5 endometrial) to 5 dose levels. 19/20 were evaluable for toxicity. Two dose limiting toxicities (DLTs) (both grade 4 neutropenia ≥ 4 days) occurred at the highest dose level (PM01183 2 mg/m2 iv d1 + Olaparib 250 mg [BID] oral on d 1-5. Grade 3 toxicities occurred in 30% of patients, including grade 3 neutropenia (6%) and grade 3 asthenia (10%). PK data are available from 19 patients. Median of PM01183 total clearance (11.0 L/h) is the same as when PM01183 is given as single agent. Clearance of Olaparib (7 L/h) is consistent with results reported elsewhere (5.1 – 8.6 L/h). PD: An overall increase of RAD51 and p-gH2AX was observed, being particularly evident in 56% of patients. **Conclusions:** The Recommended Dose for Phase II (RP2D) was PM01183 1,5 mg/m2 iv d1 + Olaparib 250 mg BID on d 1-5. This combination is feasible and without evidence of drug-drug interactions. A phase-II study at RP2D is ongoing. Clinical trial information: NCT02684318.

5574 Poster Session (Board #396), Sat, 1:15 PM-4:45 PM

Incidence of secondary myelodysplastic syndrome and acute myeloid leukemia in patients with ovarian and breast cancer in real-world setting in the U.S. *First Author: Nicole Fulcher, Truven Health Analytics, an IBM Company, Cambridge, MA*

Background: Limited real-world data are available on cancer patients withsecondary malignancies such as myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) caused by use of certain chemotherapeutic agents that interfere with DNA. This study assessedthe incidence of secondary MDS and AML in patients (pts) with ovarian cancer (OC) or breast cancer (BC), including subcohorts tested for *BRCA* mutations and those exposed to DNA damaging therapy. **Methods:** Adult females with OC or BC between 1/1/2000 and 6/30/2014 (first observed diagnosis of OC or BC = index date) were identified from the MarketScan Commercial and Medicare claims databases. Patients had ≥12 months of pre- and ≥1 month of post-index continuous health plan enrollment. The incidence of MDS and AML (per 1000 person-years [PY]) was assessed using ICD-9 codes over a variable-length post-index period for each cancer cohort and separately for pts with *BRCA* testing and those exposed to DNA damaging therapy. **Results:** The study identified 23,862 OC pts (mean [SD] follow-up: 35.8 [31.4] months), and 281,473 BC pts (mean [SD] follow-up: 46.0 [37.2] months). Among OC pts, 10.9% had *BRCA* testing (OC-*BRCA*) and 56.6% had exposure to DNA damaging therapy (OC-DNA); 12.9% of BC pts were *BRCA* tested (BC-*BRCA*) and 28.1% had exposure to DNA damaging therapy (BC-DNA). The incidence of MDS and AML expressed as cases per 1,000 PY in the OC cohort was 0.51 (0.2%) and 0.39 (0.1%); in OC-*BRCA* pts, 0.62 and 0.25; and in OC-DNA pts, 0.68 and 0.41. In the BC cohort, the incidence of MDS and AML was 0.33 (0.1%) and 0.19 (0.1%); in BC-*BRCA* pts, 0.07 and 0.15; and in BC-DNA pts, 0.60 and 0.50. **Conclusions:** In addition to providing background rates in OC and BC pts, these data suggest that the incidence of MDS and AML in OC and BC pts was higher in patient subcohorts exposed to DNA damaging agents than in the overall cohort.

5575 Poster Session (Board #397), Sat, 1:15 PM-4:45 PM

Predictors of stopping chemotherapy early and short survival in patients with potentially platinum sensitive (PPS) recurrent ovarian cancer (ROC) who have had ≥3 lines of prior chemotherapy: The GCIG symptom benefit study (SBS). *First Author: Felicia Roncolato, Macarthur Cancer Therapy Centre, Sydney, Australia*

Background: PPS ROC is defined by a platinum free interval > 6 months. Women starting ≥3 lines of chemotherapy for PPS ROC are however a heterogeneous group with variable response to chemotherapy and OS. We sought to identify baseline characteristics (health related quality of life [HRQL] and clinical features) that were associated with stopping chemotherapy early and shorter OS to improve patient selection for palliative chemotherapy. **Methods:** 378 women with PPS ROC starting ≥3 lines chemotherapy enrolled in GCIG SBS. HRQL was assessed with EORTC QLQ-C30/QLQ-OV28. Associations with stopping chemotherapy early (by 8 weeks) were assessed with logistic regression. Associations with OS were assessed with Cox proportional hazards regression. Variables significant in univariable analysis ($p < 0.05$) were included as candidates for multivariable analyses using backward elimination to select those independently significant at $p < 0.05$. **Results:** Median age was 64 years. The line of chemotherapy was third in 40%, fourth in 29%, and ≥ fifth in 31%. Chemotherapy was stopped early in 45/378 (12%) and their median OS was 3.4 months. Poor physical function (PF) and global health status (GHS) at baseline were significant univariable predictors of stopping chemotherapy early ($p < 0.008$); PF remained significant in a multivariable model adjusting for clinical factors (haemoglobin [Hb], ascites, abdominal cramps, neutrophil: lymphocyte≥5, platelets, log CA125); p = 0.03. Median OS in the whole group was 16.6 months. PF, role function, GHS and abdominal/GI symptoms were significant univariable predictors of OS ($p < 0.001$); PF and GHS remained significant predictors of OS in multivariable models including Hb, ascites, neutrophil: lymphocyte≥5, platelets, log CA125, ECOG and BMI ($p < 0.007$). **Conclusions:** In women with PPS ROC ≥3 lines chemotherapy, baseline PF and GHS are independent significant predictors of stopping chemotherapy early and short OS. HRQOL is easily measured, prognostic and may improve clinical trial stratification, patient-doctor communication and support clinical decision making. Clinical trial information: 12607000603415.

5576 Poster Session (Board #398), Sat, 1:15 PM-4:45 PM

Homologous recombination deficiency and platinum rechallenge in platinum-resistant ovarian cancer patients. *First Author: Alexandre Andre B. A. Da Costa, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Ovarian carcinomas show homologous recombination deficiency (HRD) in up to 50% of cases and in 15 to 20% of cases occur due to germline *BRCA1* or *BRCA2* mutations. *BRCA* mutated tumors are more sensitive to PARP inhibitors and platinum based chemotherapy. The objective of this study was to characterize a cohort of ovarian cancer patients regarding HRD and to evaluate the impact of these scores in prolonged platinum sensitivity. **Methods:** Thirty one ovarian cancer patients with platinum resistant recurrence reexposed to platinum based chemotherapy were selected. Paraffin embedded tumor samples from 14 patients were analyzed using ONCOSCAN assay (Affymetrix) to evaluate HRD scores. The association of the scores with response rate to platinum rechallenge, overall survival and clinical pathologic factors was evaluated. **Results:** From the cohort of 31 patients, 15 samples from 14 patients were analyzed for genomic alterations. Median scores were 19.5 for TAI, 12.5 for cnLOH+L, 26.0 for LST and 6.3 for HRD. High scores were found in 10 out of 14 (for cnLOH+L score) and 9 out of 14 (for LST score) patients. Seven of the 14 patients analyzed analyzed for genomic alterations had response, which suggested homologous recombination deficiency. No significant differences were observed between response rates for high versus low scores. Numerically, cnLOH+L, LST and HDR scores were higher in patients with response to treatment compared to those without response. Median overall survival was 13.4 months from the beginning of platinum rechallenge and no difference in survival according to scores was observed. Among the clinical pathologic factors, family history of breast or ovarian cancer or personal history of breast cancer was associated to higher response rate to platinum rechallenge. **Conclusions:** In conclusion,HRD scores showed to be potential markers of response to platinum rechallenge in the platinum resistant setting. Further studies are necessary to clarify the best cutoffs for each score, the impact of tumor heterogeneity and the analysis of tumor samples in the moment of treatment. Positive family history of cancer is a clinical factor predictvie of platinum rechallenge response.

5577 Poster Session (Board #399), Sat, 1:15 PM-4:45 PM

Open label phase II clinical trial of orteronel (TAK-700) in metastatic or advanced non-resectable granulosa cell ovarian tumors: The Greko II study. *First Author: Jesús García-Donas, Centro Integral Oncológico Clara Campal, Madrid, Spain*

Background: Granulosa-cell tumors (GCT) of the ovary are a rare entity characterized by presenting a punctual mutation at the FOXL2 gene 402C→G (C134W). Such mutation leads to a disregulation and overstimulation of the steroidogenic pathway and, ultimately, hormone overproduction. A prior trial by our group (GREKO I trial-GETHI 2011-03; NCT01584297) showed promising activity of ketoconazole, a CYP17 inhibitor used to control steroidogenesis in several conditions. Thus, we aimed to assess the activity of Orteronel (TAK700), a selective inhibitor of 17, 20-lyase, in GCT. **Methods:** An open-label phase II single arm clinical trial was designed for women with metastatic or locally advanced non-resectable GCT who harbored the somatic mutation FOXL2 402C→G (C134W) and who had not received prior treatment with any CYP17 inhibitor. Treatment consisted on Orteronel 300mg BID, given orally, continuously in a 28-day treatment cycle. The primary objective was clinical benefit rate; secondary objectives were response rate, progression free and overall survival, assessment of the impact of Orteronel in reducing hormonal overproduction and toxicity. Sample size calculation was based on a two stage Simon´s design. A power of 80% was set to differentiate between a 5% and a 25% clinical benefit rate. 20% of losses had been assumed thus 20 patients were scheduled to be enrolled. **Results:** Since 30/06/2014 to 11/01/2017 10 patients have been included in 9 participating institutions members of Spanish Group for Research in Orphan and Unfrequent Tumors (GETHI). Due to a low recrutiment rate the study was terminated early. Median PFS was 3 months 95%CI (0-12) with 3 patients achieving disease stabilization longer than 12 months. 2 patients remain on treatment after 16 and 14 months. Clinical benefit rate (CR + PR + SD) was 50%, 95%CI (19%-81%). Seven patients have progressed and 2 have died. Only 6 suspected unresected adverse reactions (SUSARs) have been communicated so far (chest pain, fever, febrile neutropenia, eosinophila, neutropenia and anemia). **Conclusions:** Orteronel achieved a significant clinical benefit in advanced GCT with an favorable toxicity profile. Clinical trial information: NCT02101684.

5578 Poster Session (Board #400), Sat, 1:15 PM-4:45 PM

Impact of beta blocker medication on survival outcome of ovarian cancer: A nationwide population-based cohort study. *First Author: Jeong-Yeol Park, Department of Obstetrics and Gynecology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea*

Background: In experimental studies, adrenergic hormones are involved in tumorigenesis of ovarian cancer and its progression. We investigated the impact of beta adrenergic blocker on survival outcome of ovarian cancer since few studies have investigated its relevance. **Methods:** Data of Korean National Health Insurance Service was analyzed (n = 866). We analyzed the impact of beta blocker on survival outcome of ovarian cancer according to the duration on medication and age groups of patients. Cox proportional hazards regression was used to analyze hazard ratios (HR) for all-cause mortality with 95% confidence intervals (CI) adjusting for confounding factors. **Results:** Median years of follow-up was 5.98 and 6.71 for non-users and users, respectively. Among the 866 patients, 206 (23.8%) were users and 660 (76.2%) were non-users. In total, there was no survival difference between the 2 groups. But, when patietns were grouped according to the duration of medication, patients with longer duration of medication ($\geq$1 year) showed better survival outcome (adjusted HR 0.305 [95% CI: 0.187-0.500], $P < 0.001$). Also, beta blocker use in patients with > 60 years showed better survival compared to younger patients (adjusted HR 0.579 [95% CI: 0.408-0.822], $P = 0.002$). In patients with > 60 years, medication longer than 720 days was associated with better survival outcome (adjusted HR 0.267 [95% CI: 0.140-0.511], $P < 0.001$). Both selective and non-selective beta blocker showed identical survival benefit in these settings without difference between each other. **Conclusions:** Beta blocker medication was associated with favorable survival outcome in ovarian cancer, especially when used in older patients and in long term duration.

5579 Poster Session (Board #401), Sat, 1:15 PM-4:45 PM

Racial disparities in ovarian cancer survival in New York state. *First Author: Sarah Madhu Temkin, Virginia Commonwealth University, Richmond, VA*

Background: Disparities between black and white patients are well documented in gynecologic cancers but information on the contributions of social factors and medical comorbidities is sparse. We examined differences in outcomes amongst black and white women with ovarian cancer in New York State. **Methods:** Patients with incident ovarian cancer in the New York State Cancer Registry and the Statewide Planning and Research Cooperative System from 2006-2013 were included. Differences in social and demographic factors, comorbidities and tumor characteristics between black and white women were examined with bivariate analysis. Multivariable analyses were used to examine factors associated with specific treatments and survival. **Results:** Of 5969 patients, 87% were white and 13% black. Age, Hispanic ethnicity and median income were similar between groups. Black women were less likely to be married (27 vs 48%, $p < 0.01$); and less likely to be privately insured (20 vs 50%, $p < 0.01$). More black women had comorbidities by Charlson Comorbidity Index (CCI) (63 vs 51%, $p < 0.01$). Black women were more likely to have Stage IV disease and non-serous histology ($p < 0.01$). More black women were treated at academic medical centers (67 vs 50%, $p < 0.01$). Marital status, insurance, CCI, stage, histology and treatment site correlated to the type of treatment received ($p < 0.01$). Black women received different treatment and had higher odds of receiving no treatment 1.63 (1.24, 2.14); chemotherapy without surgery 1.26 (1.00, 1.59); lower odds of undergoing primary surgical management 0.71 (0.58, 0.86) or chemotherapy following surgery 0.79 (0.66, 0.96; and similar rates of neoadjuvant chemotherapy. The risk of 5 year mortality was 1.14 (1.02, 1.27) times higher for black women compared with whites. Marital status, CCI, stage and histology correlated with overall and disease specific survival among both black and white women ($p < 0.01$). **Conclusions:** Multiple factors, including race, are associated with receipt of treatment and survival in ovarian cancer. Treatment for ovarian cancer was significantly different amongst black women than white in New York State. Understanding modifiable influences on racial disparities is imperative to reducing race based differences in outcomes.

5580 Poster Session (Board #402), Sat, 1:15 PM-4:45 PM

INNOVATE: A phase II study of TTFields (200 kHz) concomitant with weekly paclitaxel for recurrent ovarian cancer—Updated safety and efficacy results. *First Author: Ignace Vergote, Universitaire Ziekenhuizen Leuven, Leuven, Belgium*

Background: TTFields are a non-invasive, regional antimitotic treatment modality, which have been approved for the treatment of recurrent and newly diagnosed glioblastoma by the FDA. TTFields act by delivering intermediate frequency alternating electric fields to the tumor, predominantly by disrupting the formation of the mitotic spindle during metaphase. INNOVATE was the first trial testing TTFields (200kHz) in ovarian cancer patients. **Methods:** Thirty-one recurrent, platinum-resistant, unresectable ovarian cancer patients were enrolled in the INNOVATE trial and treated with TTFields in combination with weekly paclitaxel. The primary endpoint was treatment emergent adverse events. Secondary endpoints included progression free-survival, overall survival and radiological response rate. **Results:** The median age was 60 (range – 45-77), most patients (77%) had serous histology. 52% had an ECOG score of 0. The median number of prior chemotherapy regimens was 4.1 (range 1-11). All patients were platinum-resistant, and 97% of patients received prior taxane-containing regimens. Ten (32%) patients suffered from serious adverse events (SAEs) during the study, none were related to TTFields. Of all reported SAEs, 31% were related to gastrointestinal disorders (ileus, jaundice and ascites) and 31% were respiratory events (dyspnea, pleural effusion and pulmonary embolism). Only one SAE which, related to the tumor, led to permanent discontinuation of the device. Most patients were reported to have mild-moderate, TTFields-related skin irritation, out of whom only two patients (6.4%) had severe-grade events. The median PFS was 8.9 months (95% CI 4.7, NA). Of the evaluable tumors, 25% had partial response and another 46.4% stable disease – a clinical benefit of 71.4%. Six patients (19.4%) had a CA 125 response, translating into a decrease of 50% or more in serum levels. The median OS was not reached. **Conclusions:** TTFields concomitant to weekly paclitaxel are tolerable and safe in heavily pre-treated platinum-resistant ovarian cancer ovarian cancer patients. These data support further clinical testing of TTFields with chemotherapy in ovarian cancer. Clinical trial information: NCT02244502.

5581 Poster Session (Board #403), Sat, 1:15 PM-4:45 PM

Immunologic and genomic characterization of high grade serous ovarian cancer (HGSOC) in patients (pts) treated with pembrolizumab (Pembro) in the phase II INSPIRE trial. *First Author: Ilaria Colombo, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Checkpoint inhibitors have shown to be effective in different tumors and are under investigation in HGSOC. **Methods:** INSPIRE (NCT02644369) is a prospective multi-cohort study investigating tumor genomic and immune landscapes in pts treated with Pembro at 200 mg IV Q3W. Patients underwent tumor biopsy pre, on-treatment and at progression for DNA/RNA sequence, immune-profile, and PD-L1 expression by immunohistochemistry (IHC). Serial blood samples for immunophenotyping were collected. Correlative data are available for 6 pts: 3 with shrinkage in target lesion and 3 with progressive disease (PD). **Results:** At interim analysis as of January 2017, 18 pts with HGSOC have been enrolled and 16 have platinum-resistant disease, with median 3 prior lines of treatment (range 1-7). Of 14 evaluable pts, best response by RECIST 1.1 was stable disease (SD) in 5 (36%) and PD in 9 (64%). Mean Tumor Proportion Score of PD-L1 by IHC (Qualtek) was 6.4% (range 0-30%). Grade 3/4 adverse events possibly related to Pembro were observed in 4/18 (22%) pts; none was fatal and the most common were fatigue and hyponatremia. Preliminary correlative data showed no significant change in CD4, CD8 and myeloid-derived suppressor cells in peripheral blood after Pembro treatment. Mean PD-1 expression on CD4 and CD8 T cells on baseline tumor tissue (measured as product of PD-1+ cells and the per cell expression of PD-1 [% of mean fluorescence intensity]) was significantly higher in pts with tumor shrinkage compared to pts with PD (CD4: 2658 vs 678, p = .02; CD8: 1999 vs 451, p = .048). Genomic analysis of baseline tumor tissue was available for 3 pts with tumor shrinkage and 2 with PD. Mean mutation burden was higher for pts with tumor shrinkage (2.38 vs 1.0 mutations/Mb covered). The pt with the longest SD in our cohort (6 months) had the highest mutation burden (2.72), including somatic POLE (c.6331-6C > G) and germline *BRCA2*mutations. **Conclusions:** In HGSOC, pts with higher PD-1 level on tumor CD4 and CD8 T cells and higher mutation burden at baseline may have a better outcome following treatment with Pembro. POLE mutation is rare in HGSOC but may correlate with checkpoint inhibitor activity. Clinical trial information: NCT02644369.

5582 Poster Session (Board #404), Sat, 1:15 PM-4:45 PM

Circulating tumor DNA analysis using targeted sequencing of 508 clinically actionable genes in patients with high grade serous ovarian cancer. *First Author: Anniina Färkkilä, University of Helsinki and Helsinki University Hospital, Helsinki, Finland*

Background: The prediction of tumor chemoresponse and treatment toxicity is crucial for optimal patient care in high grade serous ovarian cancer (HGSC). We employed a targeted sequencing panel of 508 clinically annotated cancer genes to screen for actionable genetic variants in tumor tissue and ctDNA of patients with advanced HGSC. **Methods:** Tumor tissue, and serial plasma samples at diagnosis and during primary therapy were obtained from five patients with FIGO Stage IIIc HGSC. All patients were surgically debulked and received standard carboplatin and paclitaxel chemotherapy. DNA isolated from tumor tissue and plasma was analyzed for genetic alterations by targeted deep-sequencing of 508 previously annotated cancer genes. Somatic variants were systematically reported for alterations related to drug sensitivity and treatment toxicity, and analyzed with respect to clinical parameters and primary therapy outcomes. **Results:** In tumor tissues, and the corresponding pre-treatment ctDNA, oncogenic mutations were detected at a median of 13.0 and 1.6 allelic frequencies, respectively. The mutation frequency was higher, and also more unique mutations were detected in ctDNA of patients presenting with high tumor spread. Interestingly, a de-novo ctDNA MAPK1 mutation was detected in a sample taken during chemotherapy with partial response, while, no new mutations emerged in a patient with complete response. Analysis of the pretreatment plasma ctDNA revealed profiles of low and high drug sensitivities consistent with the clinical course of the patients. In two patients, increased risk profiles for treatment toxicities were identified via e.g. GSTP1. Consistently, these two patients were forced to discontinue standard therapy. **Conclusions:** Panel-based targeted sequencing of ctDNA identified potentially actionable mutations, and reflected tumor heterogeneity of HGSC. Further, the ctDNA gene panel annotations showed concordance with the chemoresponse- and treatment toxicity profiles, suggesting that ctDNA gene panel maybe a feasible approach to individualize treatment of HGSC patients.

5583 Poster Session (Board #405), Sat, 1:15 PM-4:45 PM

Hedgehog inhibition impaired platinum response in high-grade serous ovarian cancer harboring high hedgehog ligand expression and mTOR pathway activation. *First Author: Gwo Yaw Ho, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Background: Elevated Glioma-associated Oncogene Homolog-1 (Gli1) protein expression is associated with Hedgehog (Hh) pathway activation in high-grade serous ovarian cancer (HGSOC). Inhibition of Hh signaling in Gli1-overexpressing HGSOC patient-derived xenograft (PDX) inhibited tumour growth, particularly in combination with chemotherapy. Early phase HGSOC clinical trials of vismodegib, a potent Hh inhibitor (SMO inhibitor), were disappointing. We identified a HGSOC PDX harboring both Indian Hh ligand-overexpression and bi-allelic deletion of *TSC1,* which latter event is reported to derepress the mTOR pathway, driving non-cannonical Gli1 expression. We explored the effect of vismodegib in combination with cisplatin or the mTOR inhibitor, everolimus, in this model. **Methods:** A cell-line was generated from the well-characterised PDX (identity confirmed by PDX-specific p53 mutation). *In vitro* response to vismodegib was assessed. qRT-PCR was performed to establish Hh-ligand and Gli1 expression with/without SMO inhibition. A PDX was generated from this cell-line and randomized to *in vivo* treatment with cisplatin, vismodegib, everolimus or vehicle alone, or vismodegib in combination with cisplatin or everolimus. **Results:** The HGSOC cell-line was sensitive to vismodegib *in vitro* (EC50 of 3.5μM) and qRT-PCR analysis revealed down-regulation of Hh-ligand and *Gli1* expression following *in vitro* SMO inhibition, confirming on-target vismodegib activity. *In vivo* treatment with vismodegib or everolimus alone did not result in reproducible *in vivo* efficacy. The combination of vismodegib + everolimus caused short-lived responses in 3 of 6 mice. Strikingly, *in vivo* treatment with vismodegib in combination with cisplatin impaired median survival (19 days) when compared with cisplatin treatment alone (43 days; p = 0.039) due to rapid tumour progression. **Conclusions:** Combining chemotherapy with Hh inhibition in Hh ligand-overexpressing HGSOC PDX with mTOR pathway activation may be detrimental. These findings highlight the importance of an in-depth understanding of tumour biology in order to effectively combine therapeutic approaches.

5584 Poster Session (Board #406), Sat, 1:15 PM-4:45 PM

Does treatment at a high volume center mitigate racial and ethnic disparities in ovarian cancer survival? *First Author: Renee A. Cowan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Population-based studies of women with advanced ovarian cancer report racial/ethnic disparities in access to high volume centers (HVCs), surgical outcomes after primary debulking surgery (PDS), and overall survival (OS). However, there is evidence that with equal utilization of expert ovarian cancer care, differences in survival dissipate. The objective of this study is to evaluate patients (pts) with advanced ovarian cancer who had PDS at a HVC to determine whether racial/ethnic disparities persist in surgical outcome and survival. **Methods:** With IRB approval, all pts with stages IIIB to IV high-grade ovarian cancer who underwent PDS from 1/2001-12/2013 were identified. Pts self-identified race/ethnicity as Non-Hispanic White (NHW), Non-Hispanic Black (NHB), Asian (A), or Hispanic (H) in the medical record. The main outcome measures were PDS $<$1cm residual and OS. A Cox proportional hazards model was used to compare OS by race/ethnicity. Pt and clinical factors, including age, income, BRCA status, BMI, ASA, grade, carcinomatosis, bulky abdominal disease, were adjusted for in the multivariate analysis. **Results:** 963 pts were identified: 851 NHW (88%); 43 A (4%), 34 H (4%), 28 NHB (3%), 7 Other (0.7%). Asian pts were younger at diagnosis ($p<0.0001$); there were no differences in other demographic or clinical characteristics among racial/ethnic groups. After adjusting for pt and clinical factors, the likelihood of PDS to residual $<$1cm was similar among NHB and H compared to NHW pts; Asian pts were more likely than NHW to have $>$1cm residual (OR 2.32, 95%CI 1.1-4.9, p=.03). Median OS was 55.1 mos (95%CI: 51.8-58.5) for the entire cohort. On both univariate and multivariate analysis, there was no disparity in OS among racial or ethnic groups (p=0.615). **Conclusions:** Racial and ethnic disparities in overall survival and surgical outcomes in women with advanced ovarian cancer can be reduced by treatment at a HVC. Additional research is needed to determine what factors are associated with receiving treatment at HVCs, and what interventions could increase the diversity of patients treated at HVCs.

5585 Poster Session (Board #407), Sat, 1:15 PM-4:45 PM

Clinical activity, safety and biomarker results from a phase Ia study of atezolizumab (atezo) in advanced/recurrent endometrial cancer (rEC). *First Author: Gini F. Fleming, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: The prognosis for patients (pts) with rEC remains poor, with a 5-y OS of 20%-26%. We report safety, clinical activity and biomarker data from a Phase Ia study of atezo (anti–PD-L1) monotherapy in rEC. **Methods:** Atezo 1200 mg or 15 mg/kg IV q3w was administered until toxicity or loss of clinical benefit. Pts were initially eligible based on PD-L1 status ($>$ 5% of tumor-infiltrating immune cells [IC; IC2/3], VENTANA SP142 IHC assay) and then enrolled regardless of PD-L1 status. Tumor-infiltrating lymphocytes (TILs) were assessed by H&E. The FoundationOne NGS panel was used for microsatellite instability (MSI) and tumor mutation load analyses. Confirmed ORR and PFS were assessed by RECIST v1.1. **Results:** As of March 31, 2016, 15 pts were evaluable for safety and efficacy (minimum follow-up, 11.2 mo). The median age was 61 y (range, 20-74 y), 53% were ECOG PS 1 and 93% had $\geq$ 2 prior systemic therapies; 10 (67%) pts had prior RT. Pts were MSI-H (1/15), MSS (7/15) or MSI unknown (7/15). EC subtypes were endometrioid (5/15), serous (5/15), ER+ leiomyosarcoma (1/15) or unknown (4/15). Five (33%) pts were IC2/3, and 10 (67%) pts were IC0/1. Seven (47%) pts had any related AE, mainly G1-2 (5 pts). No G4-5 related AEs occurred. Two pts had related SAEs (colitis; rash). ORR was 13% (2/15) by RECIST. Both pts achieved PR and were IC2/3. ORR for IC2/3 pts was 40% (2/5). One responder was MSS and heavily infiltrated with TILs (IC3, 70% TILs, 1.8 Mut/Mb, unknown subtype); the other responder was hypermutated, MSI-H and moderately infiltrated with TILs (IC2, 10% TILs, 237 Mut/Mb, endometrioid). DOR in the 2 responders was 7.3 and 8.1+ mo. mPFS was 1.7 mo (range, 0.6-11+ mo); mOS was 9.6 mo (range, 0.6-11.8+ mo). Of the remaining pts, 2 had SD, 9 had PD and 2 were non-evaluable. DCR (PR + SD) was 27%. A trend for higher PFS and OS was seen in IC2/3 vs IC0/1 pts. **Conclusions:** Atezo had a favorable safety profile in rEC, with durable clinical benefit in some pts. Clinical benefit appeared to increase with higher PD-L1 expression, suggesting a link between PD-L1 status and response. Hypermutation and/or high immune infiltration may be linked to response to PD-L1 blockade, and further evaluation is merited. Clinical trial information: NCT01375842.

5586 Poster Session (Board #408), Sat, 1:15 PM-4:45 PM

Activity of lurbinectedin (PM01183) as single agent and in combination in patients with endometrial cancer. *First Author: Martin David Forster, University College London Hospitals, London, United Kingdom*

Background: Lurbinectedin (L) is a new anticancer drug that blocks transactivated transcription, induces DNA double-strand breaks and modulates the tumor microenvironment. Advanced endometrial cancer (EC) is an unmet medical need. **Methods:** Activity in EC patients was reviewed in 3 trials: a phase IB study of lurbinectedin combined with doxorubicin (L+DOX), a phase I study of PM combined with paclitaxel (L+TAX) and a phase II single-agent basket trial (L). Baseline characteristics, safety and efficacy were analyzed. **Results:** 97 patients were evaluated: 34 (2 cohorts) with L+DOX, 11 with L+TAX and 52 with L. Median age was similar in the 3 studies. Endometrioid was the most frequent histology. Median (range) of prior chemotherapy lines for advanced disease was: L+DOX, 1(0-2); L+TAX, 2(1-3); L, 1(0-2). Responses were observed in the 3 studies (see table). Main adverse event was myelosuppression (grade 3-4 neutropenia/thrombocytopenia/febrile neutropenia: L+DOX Cohort A, 94%/26%/40%; L+DOX Cohort B, 79%/10%/16%; L+TAX, 54%/0%/0%; L, 33%/6%/6%). Non-hematological toxicity was mostly grade 1-2: fatigue, nausea and vomiting, and transaminase increase. **Conclusions:** Lurbinectedin is active as single agent and in combination in patients with advanced EC, with remarkable activity in terms of response rate, duration of response and PFS when combined with doxorubicin. Safety was acceptable in L+DOX Cohort B, L+TAX and L, and myelosuppression was well managed. Clinical trial information: NCT01970540.

5587 Poster Session (Board #409), Sat, 1:15 PM-4:45 PM

Exploratory phase II evaluation of cabozantinib in recurrent/metastatic uterine carcinosarcoma (CS): A study of the Princess Margaret, Chicago, and California phase II consortia. *First Author: Victoria Mandilaras, McGill University Health Centre, Montréal, ON, Canada*

Background: Carcinosarcoma (CS) is a rare ($<$ 5%) aggressive subtype of endometrial cancer (EC). Patients (pts) with progression on platinum-based chemotherapy (CTX) have limited options, there is no standard 2ndline treatment and median progression-free survival (PFS) is $<$ 2months (mt), 6-mt PFS less than 20%. Limited molecular data on CS aligns with epithelial EC, providing rationale for evaluating similar strategies such as targeting MET and angiogenesis. Cabozantinib (cabo) is multi-targeted tyrosine kinase inhibitor against MET, VEGFR, TIE2, RET, AXL and KIT. **Methods:** PHL-86 (NCI#9322/NCT01935934) is a multi-centre, non-randomized, phase II trial of cabo (60 mg oral daily dose on a 28-day cycle) in EC pts recurring within a year of adjuvant CTX or with progression after 1stline of CTX for metastatic disease. Pts with rare histology including CS, were enrolled in an exploratory cohort. Activity of interest for further evaluation was defined as 4 responses (either partial response [PR] or 12-wk PFS) out of 10 pts of a given histotype. CT scans were performed after cycle 3 and every 2 cycles thereafter. **Results:** From 2013 to 2016, 32 pts were treated in the exploratory cohort, 19 pts with CS. Median age was 66 years (range 25-75); prior treatment included CTX (17: 1 line, 6: 2 lines) and/or radiation (11). Fifteen pts were evaluable for response, with 1 PR (7%) and 8 pts with 12-wk PFS (53%). Median PFS was 3 mt (95% CI: 2.7 – 4.6) with estimated 6-mt PFS of 13% (2 to 33%). Toxicity evaluation is available for 19 pts. Common events were fatigue and GI upset. Most frequent $>$ Grade3 toxicities were hypertension (5), anemia (4), diarrhea (2). Four pts had GI fistula (2) or perforation (2). Mutation profiling in archival tissue showed *TP53* (73%), *PIK3CA* (40%), *KRAS* (27%), *PTEN*(13%) with $>$ 1 mutation present in 14/15 pts analyzed. The 1 pt with no somatic mutations had a PR (31% decrease) on cabo (PFS 6.7mt). **Conclusions:** Cabo in CS cohort met the predefined endpoint for further evaluation and compares favourably with other agents in this poor prognosis disease. Larger studies are required to define depth and durability of response and identify relevant biomarkers. Clinical trial information: NCT01935934.

5588 Poster Session (Board #410), Sat, 1:15 PM-4:45 PM

Utility of multi-gene panel testing with next generation sequencing in women with endometrial cancer. *First Author: Jing-Yi Chern, NYU Langone Medical Center, New York, NY*

Background: Lynch syndrome (LS) accounts for 2-6% of all endometrial cancers (EC), and women with a germline mutation in the mismatch repair (MMR) genes (*MLH1, MSH2, MSH6, and PMS2*) have an average lifetime risk of EC of 40%. As with breast and ovarian cancer syndromes, there are likely other genes implicated in the development of EC outside of the MMR genes. Multi-gene panel testing (MGPT) with next generation sequencing (NGS) allows for simultaneous analysis of numerous genes.We sought to evaluate the characteristics and incidence of gene mutations in women with newly diagnosed EC. **Methods:** We conducted a review of EC patients diagnosed from 6/2013 to 12/2016 who had MGPT at our institution. Demographics, family history, genetic testing results, and tumor characteristics were collected and analyzed using χ^2 tests. **Results:** Of the 129 patients who had MGPT, 13 (10%) had a mutation and only 5 (38%) were in patients $<$ 50 years old. The median age of EC diagnosis is 55 (31-100) years and median BMI = 27.5 (21-59). Majority were stage 1, 76 (59%) and grade 1, 50 (39%). Patients with additional primary cancers, breast or colon were not more likely to have a mutation. However, patients with a family history of gynecologic cancer were more likely to have a mutation identified, 10 (77%) mutation vs no mutation 34 (29%), p = 0.003. Among all patients tested, 8 (6%) had a mutation in LS genes, and 6 (5%) had mutations in other genes (*BRCA1, BRCA2, RAD51C, MUTYH, CHEK2*); 1 (0.8%) had both *MSH2* and *CHEK2* mutation. Three patients had prior testing for breast cancer; 2 were found to have a *BRCA1/ 2* mutation and the other was on Tamoxifen and *BRCA* negative. IHC was performed on 7 of 13 patients, and 5 (71%) had a loss of MMR protein expression. Variants of uncertain significance were noted in 35/129 (27%) of patients tested. **Conclusions:** Majority of EC patients with a mutation detected with NGS were $>$ age 50. We identified additional new mutations in non-LS genes including, *CHEK2, RAD51C*, and *MUYTH* with MGPT. These accounted for 29% of the mutations and would have not been not detected using classic LS gene testing. These genes are implicated in breast, ovary or colon cancer. MGPT testing is feasible and useful in identifying additional actionable gene mutations.

5589 Poster Session (Board #411), Sat, 1:15 PM-4:45 PM

Role of adjuvant chemoradiation in treatment of elderly women with advanced high-grade endometrial cancer: A SEER-Medicare analysis. *First Author: Hyo K. Park, Karmanos Cancer Institute, Detroit, MI*

Background: Use of combined adjuvant chemoradiation (CRT) in treatment of advanced stage endometrial cancer is increasing, but the survival benefit over chemotherapy (CT) or radiation therapy (RT) alone remains unclear. We examined adjuvant treatment patterns and survival associated with CRT for Stage III-IV high-grade endometrial cancer using a large population-based database. **Methods:** Women 66 years of age or older who underwent primary surgical treatment for Stage III-IV high-grade endometrial cancer between 2000-2011 were identified from the SEER-Medicare database. Demographic and clinical predictors for receipt of adjuvant CRT vs. CT or RT alone were examined using multinomial logistic regression. In addition, overall survival (OS) by adjuvant treatment type, histology (endometrioid vs. non-endometrioid), stage, and age group were examined using Kaplan-Meier estimates and Cox proportional hazards regression. **Results:** Of the 2,735 eligible women, 13.1% received CRT vs. 42.5% CT alone vs. 13.2% RT alone, and 31.1% received no adjuvant treatment. Hispanic ethnicity, carcinosarcoma, serous histology, and Stage IV disease were significant predictors of receiving CRT over CT alone. Increasing age group, non-Hispanic black race/ethnicity, endometrioid histology, having 3+ comorbidities at the time of surgery, and not being partnered were associated with receiving RT alone over CRT. For Stage III disease, those who received CT (HR 1.30; 95% CI 1.09-1.55) or RT alone (HR 1.34; 95% CI 1.09-1.64) had poorer 5-year OS compared to CRT. In a subgroup analysis, the relative survival benefit of CRT vs. CT was only significant for women $<$ 75 years of age and was more pronounced for endometrioid (HR 1.72; 95% CI 1.22-2.41) vs. non-endometrioid histology (HR 1.22; 95% CI 0.99-1.49). For Stage IV disease, there was no survival difference among those who received CT or RT only compared to CRT regardless of histologic subtypes. **Conclusions:** Adjuvant CRT was associated with improved OS in elderly women with Stage III high-grade endometrial cancer. This survival benefit was more pronounced for endometrioid histology and women $<$ 75 years of age.

5590 Poster Session (Board #412), Sat, 1:15 PM-4:45 PM

Association of delayed adjuvant therapy and overall survival in early stage endometrial cancer. *First Author: Leo Luo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The primary treatment for early stage endometrial cancer includes definitive surgical staging procedure followed by adjuvant therapy in women with high risk of recurrence. The optimal interval time between surgery and adjuvant therapy is unclear. **Methods:** 349,404 patients with primary uterine carcinoma diagnosed from 2004 and 2012 were extracted from National Cancer Database (NCDB). Study population was limited to patients with FIGO 2009 stage I and II endometrial cancer with endometroid, mucinous, clear cell, or serous histology. Adjuvant therapy included radiation therapy, chemotherapy, or a combination. A binary variable of interval time between surgery and adjuvant therapy ("early" vs. "delayed") was created by using the median time as a cutoff. Analysis of relationship between the interval time and overall survival was performed. **Results:** Final analysis included 118,373 early stage endometrial cancer patients who had definitive surgical treatment. Median age was 61 (interquartile range 55-69). 87,189 patients (74%) had stage IA disease, 21,573 (18%) patients had stage IB disease, and 9,611 (8%) patients had stage II disease. 28,824 (24%) patients received adjuvant therapy after surgery. The median time from surgery to adjuvant therapy was 1.6 months (interquartile range 1.3-2.2 months). Of the patients that received adjuvant therapy, 48% received intra-vaginal brachytherapy alone, 31% received pelvic external beam radiation, and 7% received a combination of chemotherapy and brachytherapy. There was a significant difference in overall survival in patients who received adjuvant therapy within 1.6 months from surgery and 1.6 months after surgery (Log-rank test, $p = 0.04$). Patients with advanced age, African-American or Hispanic race, and uninsured status or government-sponsored insurance were associated with delayed treatments. **Conclusions:** In this large retrospective review of early stage endometrial cancer patients, delayed time between surgery and adjuvant therapy is associated with worse overall survival. Further analysis will be performed to determine an optimal timing between surgery and adjuvant therapy.

5591 Poster Session (Board #413), Sat, 1:15 PM-4:45 PM

High-intermediate risk endometrial cancer: Can gene expression predict recurrence? *First Author: Cindy Tawfik, TL1 Predoctoral Trainee University of Alabama, Birmingham, AL*

Background: Studies have shown that adjuvant therapy increases progression free survival, but does not affect overall survival in patients with high-intermediate risk (H-IR) endometrial cancer (EMCA). Our objective was to develop a gene expression signature that may help identify H-IR EMCA patients with the highest risk of recurrence to help guide treatment strategies. **Methods:** Data was collected on all patients that met H-IR EMCA criteria diagnosed between 2000-2010 at UAB (n = 292). Of the patients that did not receive adjuvant treatment, 13 patients that recurred were matched to 13 patients that did not recur and original tumor was compared. Of those that recurred, 5 patients had original and recurrent tumor available for analysis. Gene expression data was collected using the Nanostring nCounter PanCancer Pathway 770 gene panel. Data was analyzed using nSolver Advanced Analysis Software. A fold change (FC) of $\geq \pm 2$ ($p < 0.05$) was used to identify genes with a significant expression difference. **Results:** Comparing the 13 patients that recurred to the 13 that did not, there were 5 genes with FC $\geq$ +2: BAIAP3, PLCB1, IL1R1, NOS3 and RAD50. There were 29 genes with FC $\geq$ -2; the top 3 genes with decreased expression (FC $\geq$ -10) were: BMP7, FGF18, WNT7A. Genes in the Cell Cycle (CC) pathway were significantly different in the patients that recurred ($p = 0.02$). There were 61 genes with FC $\geq$ +2 when comparing the original tumor to recurrent tumor; the top 3 genes with increased expression (FC $\geq$ 10) were: FGF18, CCND1, HIST1H3H ($p < 0.05$). There were 50 genes with FC $\geq$ -2; the top 3 genes with decreased expression (FC $\geq$ -1000) were: HOXA11, LEFTY2 and SFRP4. Wnt, Hedgehog, Chromatin Modification, DNA repair, TGF-β, MAPK, and CC pathways were significantly different in the recurrent samples compared to the original tumor ($p < 0.05$). **Conclusions:** Our data suggests that gene expression panels could better identify patients that warrant adjuvant treatment. The CC pathway, which is significantly different in the original tumor from those that recurred and those that did not, was further altered in the recurrent tumor samples. Additional studies are on-going to validate these findings and to further investigate DNA mutation differences in larger cohort of patients.

5592 Poster Session (Board #414), Sat, 1:15 PM-4:45 PM

Clinical activity of the selective DRD2 antagonist ONC201, an imipridone, in metastatic endometrial cancer (mEC). *First Author: Lorna Rodriguez-Rodriguez, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: mEC is a generally incurable, with limited therapeutic options. ONC201 is the founding member of the new class of compounds called imipridones that are orally active small molecules. ONC201 a specific antagonist of the G protein-coupled receptor DRD2 exerts antitumor activity via a series of established signaling pathways (dual inhibition ERK/AKT, integrated stress response). DRD2 expression is elevated in malignant versus normal endometrial tissue. Furthermore ONC201 has shown anti-cancer activity in preclinical models of EC. **Methods:** In a Phase I trial that included an expansion cohort, a total of 28 evaluable patients (pts) were treated with ONC201 at doses from 125mg every 3 weeks to 625 weekly. Five of these patients had advanced mEC. **Results:** The median age for the mEC patients was 60 years (56-72), the median number of prior treatments was 5 (3-6), 3 patients had prior radiation and all patients had prior surgery. One patient received 375mg ONC201 while the other 4 patients received 625mg ONC201, orally every 3 weeks. The median number of doses was 3 (2-14). Two of 5 patients exhibited regressions in individual metastatic lesions, however they did not qualify as overall objective responses by RECIST criteria. One of these two patients experienced stable disease for 42 weeks. There were no reported SAEs and no Grade > 1 AEs attributed to study drug. **Conclusions:** ONC201 is clinically active and well tolerated with oral administration in refractory mEC patients. Clinical trial information: NCT02250781.

5593 Poster Session (Board #415), Sat, 1:15 PM-4:45 PM

Assessment of a custom designed next generation DNA sequencing gene panel to profile endometrial cancers. *First Author: Eirwen M Miller, Montefiore Medical Center, Bronx, NY*

Background: Using whole genome sequencing (WGS), the Cancer Genome Atlas (TCGA) identified four genomic subtypes of endometrial cancer (EC) with survival differences. Limited clinical data is available in the TCGA dataset restricting correlation of WGS with clinical endpoints. We sought to determine if high depth target sequencing allows for genomic classification of EC and prediction of the tumor biology when clinical variables are known. **Methods:** Using a custom designed sequencing panel targeting the coding regions of 156 EC genes we analyzed 47 EC samples and matching normal controls. Variants were annotated for pathogenicity. Charts were reviewed for clinicopathologic data. Routine statistical analyses were applied. **Results:** Endometrioid (EEC) tumors had a significantly higher frequency of total and pathogenic SNVs than serous (USC). Pathogenic PTEN and PIK3CA SNVs were more common in EEC while pathogenic TP53 SNVs were more frequent in USC. The presence of pathogenic TP53 SNVs was significantly associated with disease recurrence/progression. A pathogenic SNV at PTEN locus chr10:89692904 was associated with grade 1 EEC. Six hypermutated specimens were identified with 99-272 SNVs (mean 185.8 v 8.7 in non-hypermutated samples). All 6 were grade 3 EEC, of which 4 patients are alive without clinical evidence of disease (mean follow up 35 months). NTRK3, LRP1B, SLIT2, APC, RAD50, PIK3R1, and JAK2 SNVs were more common in grade 3 EEC than the other histologies. **Conclusions:** Pathogenic variants in EC associated with PTEN, PIK3CA, and TP53 and the number of somatic variants, as identified by a targeted sequencing, can predict histologic features and clinical behavior. Targeted sequencing panels may be a useful tool to predict the clinical phenotype and guide individualized therapeutic intervention.

	EEC (n = 34)	USC (n = 13)	P value

5594 Poster Session (Board #416), Sat, 1:15 PM-4:45 PM

Evaluation of systemic and local immune responses in patients with endometrial cancer. *First Author: Martin Ore, Clinical Area of Gynecologic Oncology, Instituto Valenciano de Oncología (IVO), Valencia, Spain*

Background: Several studies suggest that systemic immune response (SIR) and local immune response (LIR) have independent roles in multiple types of cancer. In endometrial cancer (EC), the correlation between SIR and LIR and its prognostic value remains unclear. **Methods:** A total of 146 EC patients (stage I-IV) who had undergone surgery from 2009 to 2015, were identified from a prospective institutional database. Lymphocyte/monocyte ratio (LMR) to represent SIR was calculated from preoperative blood samples. The presence of intratumoral and peritumoral infiltrating lymphocytes (TILs) on hematoxylin and eosin-stained slides was considered as a surrogate of LIR. LMR and TILs were correlated to pathological findings and survival outcomes (overall survival: OS, disease free survival: DFS). **Results:** A LMR cutoff value of 4.4 for survival was determined based on receiver operating characteristic (ROC) curve analysis. LMR high was significantly associated with endometrioid histology (p=0.03), lower grade (G1-2; p=0.003), < 50% myometrial invasion (p=0.01) and I-II stage (p=0.02). TILs were correlated with MSI-high (p<0.005), but not with LMR (p=0.3). Low LMR was associated with worse 5-year OS rates (64.5% vs 93.9%; p<0.01) and presence of TILs with better 5-years OS rates (72% vs 27%; p=0.04). On multivariate analysis (table 1) LMR, histology, stage and grade remained independent prognostic factors for OS (p=0.01). Using the combination of LMR and TILs, four groups with decreasing 5-years OS rates were identified: LMR-high/TILs+ (100%) > LMR-high/no-TILs (87%) > LMR-low/TILs+ (71%) > LMR-low/no-TILs (61%). **Conclusions:** In our series of resected EC patients, SIR (defined by LMR) constituted an independent prognostic factor for OS and LIR for DFS. We did not find any correlation between SIR and LIR, but the combination of both higher SIR and LIR showed better OS.

Multivariate analysis.

OS	VARIABLE	*HR (95% CI)*	*P VALUE*
	LMR low vs. high	6.4 (1.3-30.6)	0.01
	Stage III-IV vs. I-II	4.8 (1.3-16.8)	0.01
	Endometrioid G3, serous vs. Endometrioid G1-2	9.9 (2.3-42.1)	<0.01
DFS	Stage III-IV vs. I-II	8.3 (2.3-29-6)	<0.01
	Endometrioid G3, serous vs. Endometrioid G1-2	10.4 (2.5-40)	<0.01
	TILs present vs. absent	0.1 (0.03-0.5)	<0.01

5596 Poster Session (Board #418), Sat, 1:15 PM-4:45 PM

Spectroscopy of blood samples for the diagnosis of endometrial cancer and classification of its different subtypes. *First Author: Maria Paraskevaidi, University of Central Lancashire, Preston, United Kingdom*

Background: Symptoms of endometrial cancer often appear in early stages, thus a diagnosis, based on microscopic histological examination of endometrial tissue, can be given relatively on time. However, this procedure interferes subjective interpretation allowing human error, while screening of the asymptomatic population is not widely performed because of the high cost of the available tests (e.g. transvaginal ultrasound) and the relative invasiveness [biopsy or dilation and curettage (D+C)]. Consequently, there is a widespread need to develop inexpensive, non-invasive techniques that would accurately diagnose endometrial cancer, as well as classify the different subtypes. Spectrochemical methods generate a signature fingerprint of biological material in the form of spectra. Unlike immunological methods, which detect only one molecule at a time, the spectra obtained from a clinical sample represent all the molecular constituents within that sample, including proteins, lipids and carbohydrates; this provides a holistic picture of the sample. Previous studies have confirmed spectroscopy's ability to diagnose gynecologic cancers in blood. **Methods:** Attenuated total reflection-Fourier transform infrared (ATR-FTIR) spectroscopy was used to analyse blood plasma and serum from 71 women with endometrial cancer and 18 age-matched healthy controls; classification algorithms were then applied to extract the underlying biological information. **Results:** Principal component analysis followed by support vector machine (PCA-SVM) diagnosed endometrial cancer with 100% accuracy in plasma and 95% in serum. Discrimination between the different subtypes [endometrioid adenocarcinoma (n = 43) vs carcinosarcoma (n = 14)] was achieved with 98.33% accuracy in both plasma and serum. The spectral regions responsible for discrimination were attributed to protein and lipid alterations. **Conclusions:** Our preliminary results suggest an accurate and objective diagnostic tool for endometrial cancer with blood testing, allowing therefore thoughts for a potential screening test in high risk populations. Future work will include higher number of normal cases and different subtypes and grades.

5597 Poster Session (Board #419), Sat, 1:15 PM-4:45 PM

Outcome of patients with advanced endometrial and cervical cancer treated in a phase 1 unit. *First Author: Rowan Miller, Department of Medical Oncology, University College London Hospital, London, United Kingdom*

Background: Patients (pts) with advanced endometrial (EC), cervical and vulval (CVC) cancer have limited therapeutic options and poor prognosis. Early phase trials may be a suitable option for pts with good performance status aided by molecular selection. We sought to determine the outcome of EC and CVC pts treated in a phase 1 unit. **Methods:** Medical records of pts with EC and CVC treated within an early phase trial between 2010 and 2016 were reviewed. Data comprised pt and tumor characteristics, prior therapy, trial therapy and outcome. **Results:** 38 pts, median age 59 years (21-74) with EC (19) or CVC (19) were identified. Median prior therapies for advanced disease: 1 (1-3). Histological subtypes: endometrioid (4), high grade serous (HGS 7), carcinosarcoma (CS 4), clear cell (1), and adenosquamous (3) for pts with EC; adenocarcinoma (5), squamous (11), clear cell (2) and neuroendocrine (1) for CVC pts. 20 pts (53%) had Next Generation Sequencing (NGS) using a targeted panel with actionable mutations identified in 10 (KRAS (4), PIK3CA (6) and EGFR (1)). Pts were allocated in order of priority to a trial (1) on the basis of NGS ('genomic' 8%), (2) within a 'tumor specific' expansion cohort (45%) or (3) a 'generic' study (47%). The overall response rate (ORR) was 21% with 34% stable disease (SD) and median progression free survival (PFS) and overall survival (OS) of 11 and 42 weeks respectively, with 10 pts still on study. Within the EC cohort ORR was 21% with 32% SD and PFS and OS of 9 and 38 weeks respectively. For the CVC cohort ORR was 21% with 37% SD and PFS and OS of 12 and 42 weeks respectively. Outcomes were better for the pts in the genomic and tumour specific groups. Both PFS and OS were longer with median PFS of 42, 32 and 8 weeks and OS of 91, not reached and 37 weeks for genomic, tumor specific and generic trials respectively. **Conclusions:** Early phase trials represent a good option for pts with advanced EC and CVC with meaningful clinical benefit observed even in this small cohort. Encouraging RR and PFS were observed in these pts with limited standard treatment options. This includes pts with difficult to treat histological subtypes such as HGS and CS EC and clear cell and adenocarcinoma CVC. NGS is feasible in real time and increasing use may benefit pts further.

5598 Poster Session (Board #420), Sat, 1:15 PM-4:45 PM

A phase Ib/II trial of lenvatinib (LEN) plus pembrolizumab (Pembro) in patients (Pts) with endometrial carcinoma. *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: LEN is a multikinase inhibitor of vascular endothelial growth factor (VEGF) receptor 1−3, fibroblast growth factor receptor 1−4, platelet-derived growth factor receptor α, RET, and KIT. Pembro, an antibody targeting programmed cell death protein 1 (PD-1), prevents T cell deactivation. In addition to its antiangiogenic effects, LEN may act in part by preventing VEGF-mediated immune suppression, suggesting combination with pembro could improve its activity. We report results in pts with endometrial carcinoma from a phase Ib/II trial of LEN + pembro. **Methods:** In this multicenter, open-label study, pts had confirmed metastatic endometrial cancer that progressed after approved therapy, measurable disease, and ECOG performance status ≤ 1. Pts received oral LEN 20 mg/day plus pembro 200 mg intravenously every 3 weeks. Tumor assessments were by the investigator. The primary phase II endpoint was objective response rate (ORR) based on immune-related RECIST (irRECIST). Secondary endpoints included progression-free survival (PFS), disease-control rate (DCR; complete response [CR] + partial response [PR] + stable disease [SD]), clinical-benefit rate (CBR; CR + PR + durable SD), and duration of response (DOR), all by irRECIST, and safety. **Results:** 23 Pts enrolled (phase II: 21; phase Ib: 2); median age was 64 years (range: 51−80); 87% were white; and all had ≥ 1 prior anticancer therapy. Confirmed ORR was 48% (all PR). Median PFS and DOR were not estimable (NE; see table). All pts had a treatment-emergent adverse event (TEAE). The most common TEAEs were hypertension, fatigue, arthralgia, diarrhea, and nausea. Toxicities were manageable with dose interruption and/or modification and no new safety signals were found. Updated data will be presented. **Conclusions:** Promising efficacy was observed in pts receiving LEN + pembro. In addition, toxicities were generally expected and manageable with dose modification. These results warrant further study of LEN + pembro in pts with endometrial carcinoma. Clinical trial information: NCT02501096.

Parameter	Pts (n = 23)	95% CI
ORR, n (%)	11 (48%)	27−69
DCR, n (%)	22 (96%)	78−100
CBR, n (%)	17 (74%)	52−90
Median PFS, months	NE	4.1−NE
Median DOR, months*	NE	2.6−NE

*For pts with CR or PR. CI, confidence interval.

5599 Poster Session (Board #421), Sat, 1:15 PM-4:45 PM

Prognostic importance of p16 status for women with vulvar squamous cell carcinoma (SCC) treated with radiotherapy. *First Author: Larissa Janeen Lee, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: To evaluate the association between p16 status and in-field recurrence (IFR), progression-free (PFS) and overall (OS) survival in patients with vulvar SCC treated with radiation (RT) with or without surgical resection. **Methods:** In a multi-institutional retrospective cohort study, we identified 105 women with vulvar SCC who received RT between 1985-2011. Immunostaining for p16 was performed on archival tumor tissue using the Leica Bond III staining platform. Histopathology and p16 stains were reviewed by pathologists with expertise in gynecologic cancer; the intensity and extent of p16 staining in tumor cells were classified as negative (focal, weak, patchy) or positive (moderate or strong diffuse linear positive). Actuarial estimates of PFS, OS and IFR were calculated using the Kaplan-Meier method and compared by the logrank test. Multivariable analysis (MVA) was performed using the Cox proportional hazards model. **Results:** Patients with p16-positive disease were significantly younger at diagnosis (median 67 vs. 77 years) and were more likely to be current smokers (51% vs. 0%) and to have received concurrent chemotherapy (68% vs. 47%, all $p<0.05$). FIGO stage distribution, RT intent and median RT doses were similar by p16 status. With a median follow-up of 61 months, 5-year PFS and OS rates were 35% and 40%, respectively. Women with p16-positive tumors had significantly better 5-year PFS and OS rates than those with p16-negative tumors (61% and 23%, $p<0.01$ and 64% and 29%, $p=0.01$, respectively). The 5-year IFR rate was also lower for those with p16-positive disease (17% vs. 65%, $p<0.01$). On univariate analysis, use of concurrent chemotherapy was not associated with PFS ($p=0.5$), OS ($p=0.3$) or IFR ($p=0.8$). On MVA adjusted for age and stage, p16 positivity was significantly associated with better PFS (HR 0.57, 95% CI 0.33-0.97) and lower IFR (HR 0.24, 95% CI 0.09-0.6). **Conclusions:** In a multi-institutional setting, women with p16-positive vulvar SCC treated with RT had a lower IFR rate and longer survival than those with p16-negative disease. The magnitude of prognostic importance of p16 status is similar to that seen in oropharyngeal, anal and cervical cancers treated with RT.

TPS5600 Poster Session (Board #422a), Sat, 1:15 PM-4:45 PM

Phase III randomized trial of image-guided bone marrow-sparing intensity modulated radiation therapy (IG-BMS-IMRT) for locoregionally advanced cervical cancer: The INTERTECC-3 trial. *First Author: Loren K. Mell, University of California San Diego Moores Cancer Center, La Jolla, CA*

Background: Cervical cancer is a leading cause of cancer death in women worldwide. Image-guided bone marrow-sparing intensity modulated radiation therapy (IG-BMS-IMRT) has shown potential to reduce acute toxicity of chemoradiotherapy and improve chemotherapy delivery in phase I and II trials (Mell LK, Sirák I, Wei L, et al. Bone Marrow-sparing IMRT With Concurrent Cisplatin For Stage IB-IVA Cervical Cancer: An International Multicenter Phase II Clinical Trial (INTERTECC-2). *Int J Radiat Oncol Biol Phys* 2017;97:536-545. Mell LK, Saenz CC, Yashar CM, et al. Phase I Trial of Bone Marrow Sparing IMRT With Concurrent Cisplatin and Gemcitabine in Stage IB-IVA Cervical Cancer (abstr.) *Int J Radiat Oncol Biol Phys* 2016; 96: S14.). **Methods:** INTERTECC-3 is a randomized phase III trial designed to test the effect of IG-BMS-IMRT on progression-free survival (PFS) for women with unresected FIGO stage IB-IVA cervical carcinoma (clinicaltrials.gov #NCT01554397). It presently involves centers in the U.S., Czech Republic, U.K., India, Japan, and China. Women are randomized 3:2 to either (A) IG-BMS-IMRT or (B) standard chemoradiation, with 6 cycles of concurrent cisplatin (40 mg/m^2) weekly in both arms. Secondary objectives are to compare overall survival, treatment-related toxicity, disease recurrence, quality of life, chemotherapy delivery, and radiation quality assurance. Planning objectives require maintaining pelvic marrow and active marrow mean doses < 27 Gy and < 28.5 Gy respectively. Correlative studies involve longitudinal collection of magnetic resonance restriction spectrum imaging and ^{18}F-fluorothydimine positron emission tomography scans to assess imaging biomarkers of treatment response in select patients. 415 women will be enrolled to determine if IG-BMS-IMRT improves the median PFS from 3.2 to 5.0 years with 80% power and alpha = 0.05. INTERTECC-3 opened in the U.S. and Czech Republic in 2016. To date, 17 patients have been randomized. The trial will be activated at additional international sites in late 2017 and 2018. We are seeking to recruit sites who wish to collaborate. Clinical trial information: NCT01554397.

TPS5601 Poster Session (Board #422b), Sat, 1:15 PM-4:45 PM

A randomized phase II study of chemoradiation and pembrolizumab for locally advanced cervical cancer. *First Author: Linda R. Duska, University of Virginia Health System, Charlottesville, VA*

Background: The standard of care for patients with LACC is concurrent chemoradiation therapy (CRT) with weekly cisplatin. Five-year disease overall survival after contemporary CRT for LACC is only 66%. Human Papillomavirus (HPV) DNA is detected in virtually all cervical cancers, and HPV specific CD4+ helper and CD8+ cytotoxic T cells are found in cervical tumors, indicating the inherent immunogenicity of these tumors. The failure of the immune system to eradicate HPV DNA integration is thought to be associated with the cancer cells' acquisition of mechanisms to avoid cytotoxic T cells, including, but not limited to, the expression of checkpoint inhibitory molecules such as PD-L1 and the recruitment of FoxP3+ immunosuppressive regulatory T cells. Low ratios of CD8+ T cells: regulatory T cells are associated with poor survival for cervical cancer patients, suggesting that strategies to enhance immune response would be effective. Additionally, in cervical cancer, PD-1 is expressed by the majority of infiltrating CD8+ T cells, suggesting that blocking of PD-1 could have therapeutic potential, inducing tumor-specific immunity in cervical cancer patients. We hypothesized that CRT may increase tumor responsiveness to anti-PD-1 therapy by enhancing antigen availability and disrupting immune-regulatory networks. However, it is unclear how treatment with cisplatin and/or ionizing radiation could influence the quality and quantity of the immune response. **Methods:** A randomized Phase II open-label multi-center study was designed in which 88 eligible subjects with LACC will be treated with standard CRT plus the PD-1 monoclonal antibody pembrolizumab. The primary objectives in the study are to estimate the safety and immune response to pembrolizumab given either sequentially or concurrently with CRT. Secondary objectives will evaluate the metabolic response and rates of distant metastases following treatment with pembrolizumab given sequentially or concurrently with CRT. The study design also affords the opportunity to characterize the effect of treatment on immune response pathways by estimating the effects of treatment on specific immune markers. Clinical trial information: NCT02635360.

TPS5602 Poster Session (Board #423a), Sat, 1:15 PM-4:45 PM

TRUST: Trial of radical upfront surgical therapy in advanced ovarian cancer (ENGOT ov33 / AGO-OVAR OP7). *First Author: Sven Mahner, Department for Gynecology and Obstetrics, University of Munich, Munich, Germany*

Background: Primary cytoreductive surgery (PDS) followed by chemotherapy has been considered as standard management for advanced ovarian cancer patients (pts) over decades. An alternative approach of interval debulking surgery (IDS) following neoadjuvant chemotherapy (NACT) was subsequently reported by two randomized phase III trials (EORTC-GCG, CHORUS). Owing to important limitations of these studies, especially regarding surgical quality, optimal timing of surgical therapy in advanced ovarian cancer is still unclear. **Methods:** TRUST is an international open, randomized, controlled multicenter trial investigating overall survival (OS; primary endpoint) after PDS vs NACT and subsequent IDS in pts with FIGO stage IIIB-IVB ovarian, tubal, and peritoneal carcinoma. Secondary objectives are safety of complete tumor resection, progression-free survival and quality of life (QoL) as well as surgical morbidity. In order to guarantee adequate surgical quality, participating centers need to fulfill specific quality assurance criteria (e.g. $\geq$50% complete resection rate in upfront surgery for FIGO IIIB-IV pts, $\geq$36 debulking-surgeries/year) and agree to independent audits by TRUST Quality committee delegates. A 1:1 randomization to PDS or NACT followed by IDS stratified by center and age-ECOG combination (ECOG 0 and age $\leq$65 years vs ECOG $>$ 0 or age $>$ 65 years) is performed. Pts in the PDS arm will undergo surgery followed by 6 cycles of platinum-based chemotherapy, whereas pts in the IDS arm will be treated with 3 cycles of NACT after histologic confirmation of the disease, followed by IDS and subsequently 3 cycles of platinum-based chemotherapy. Intention of surgery for both groups will be complete tumor resection as per guideline recommendations. Health related QoL will be assessed using the EORTC QLQ-C30, QLQ-OV28, and EQ-5D-3L questionnaires. For sample size planning, we considered a prolongation of median OS from 45 months in the IDS arm to 60 months in the PDS arm (HR 0.75) as clinically relevant. 380 events are needed to obtain a power of 80% in two-sided log-rank test with significance level of 0.05. The primary analysis will be done in the ITT-population of 686 randomized pts. By Feb 3 2017, 46 pts were randomized. Clinical trial information: NCT02828618.

TPS5603 Poster Session (Board #423b), Sat, 1:15 PM-4:45 PM

ARIEL4: An international, multicenter randomized phase 3 study of the PARP inhibitor rucaparib vs chemotherapy in germline or somatic *BRCA1*- or *BRCA2*-mutated, relapsed, high-grade ovarian carcinoma. *First Author: Amit M. Oza, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: In high-grade epithelial ovarian carcinoma (OC), ≈18% of patients (pts) have tumors with a germline *BRCA1* or *BRCA2* mutation; ≈7% have tumors with a somatic *BRCA1* or *BRCA2* mutation (Pennington et al. *Clin Cancer Res.* 2014;20:764-75). The poly(ADP-ribose) polymerase (PARP) inhibitor rucaparib is approved in the United States for treatment of pts with OC associated with a deleterious *BRCA1* or *BRCA2* mutation (germline and/or somatic) who have received ≥2 chemotherapies. Although PARP inhibitors have demonstrated clinical activity in OC in both treatment and maintenance settings, comparison to standard of care (SOC) has only been evaluated in the maintenance setting. Randomized studies are needed to assess the benefit-risk profile of PARP inhibitors vs current SOC as treatment for *BRCA1*- or *BRCA2*-mutated, relapsed, high-grade OC. **Methods:** ARIEL4 (NCT02855944) is evaluating rucaparib vs chemotherapy as treatment for pts with germline or somatic *BRCA1*- or *BRCA2*-mutated, relapsed, high-grade OC (regardless of histology) who have received ≥2 prior chemotherapy regimens. Approximately 345 pts will be randomized 2:1 to receive rucaparib (600 mg BID) (n = 230) or chemotherapy (n = 115) and stratified by progression-free interval after their most recent platinum regimen. Pts with platinum-resistant (progressive disease [PD] 1– < 6 mo after last platinum) or partially platinum-sensitive disease (PD 6– < 12 mo after last platinum) will be randomized to rucaparib or weekly paclitaxel; pts with platinum-sensitive disease (PD ≥12 mo after last platinum) will be randomized to rucaparib or platinum-based therapy (single-agent or doublet at the discretion of the investigator). Pts receiving chemotherapy have the option to cross over to rucaparib upon radiographic disease progression. The primary endpoint is progression-free survival. Secondary endpoints include investigator-assessed objective response rate (ORR) (RECIST version 1.1), ORR/CA-125 response, duration of response, overall survival, and pt-reported outcomes. Safety will be summarized descriptively using standard adverse event reporting. Clinical trial information: NCT02855944.

TPS5604 Poster Session (Board #424a), Sat, 1:15 PM-4:45 PM

Clinical trial in progress: A phase 3 study of maintenance bi-shRNA-furin/GM-CSF-expressing autologous tumor cell vaccine in women with stage IIIb-IV high-grade epithelial ovarian cancer. *First Author: Jonathan Oh, Texas Oncology, Dallas, TX*

Background: Vigil is an immuno-stimulatory autologous cellular therapy, which uses patient tumor cells transfected with a plasmid encoding genes for GM-CSF and furin (to down regulate TGFβ 1&2). In Phase I, systemic immune activation was demonstrated in the majority of patients using an IFNγ ELISPOT assay. A randomized Phase 2 assessment of Vigil maintenance therapy vs. observation in ovarian cancer demonstrated prolonged relapse free survival (RFS) (Oh J, Barve M, et al. Gynecologic Oncology, 2016; 143: 504–510.). Based on these observations, a Phase 3 study of maintenance Vigil therapy in patients with advanced ovarian cancer was initiated (NCT02346747). **Methods:** This is a multicenter, randomized, double-blind, placebo-controlled, Phase 3 study of maintenance Vigil in women with Stage IIIb,c or IV high-grade papillary serous/clear cell/ endometrioid ovarian, fallopian tube or primary peritoneal cancer. Patients will have a minimum of 4 and a maximum of 12 Vigil doses manufactured from tumor obtained at primary debulking surgery. Patients must achieve a complete clinical remission following primary surgery and chemotherapy before being randomized 1:1 to receive either monthly intradermal Vigil or placebo. Randomization is stratified by extent of surgical cytoreduction (complete/ microscopic vs. macroscopic residual disease) and neoadjuvant vs. adjuvant chemotherapy. The primary objective is to compare RFS of subjects randomized to Vigil vs. placebo, and the key secondary objective is overall survival (OS). The sample size calculation of 222 patients assumes 24 months for accrual and 36 months of follow-up with a median RFS of 19 months from randomization, in the control group. This provides 90% power to detect a hazard ratio (HR) of 0.6 favoring Vigil at the 0.05 level of significance. To date, 61 patients have been randomized and an additional 55 patients are receiving chemotherapy in anticipation of randomization. Tumor tissue is being obtained from approximately 20 patients per month at multiple sites across the U.S. At their last meeting in January, 2017 the independent DSMB recommended that the study continue without change. Clinical trial information: NCT02346747.

TPS5605 Poster Session (Board #424b), Sat, 1:15 PM-4:45 PM

PAOLA-1: An ENGOT/GCIG phase III trial of olaparib versus placebo combined with bevacizumab as maintenance treatment in patients with advanced ovarian cancer following first-line platinum-based chemotherapy plus bevacizumab. *First Author: Isabelle Laure Ray-Coquard, GINECO Group and Centre Léon Bérard, Lyon, France*

Background: Olaparib (Lynparza) is an oral PARP inhibitor indicated in the EU for the maintenance treatment of patients (pts) with platinum-sensitive relapsed *BRCA*-mutated high grade serous ovarian cancer (HGSOC). Bevacizumab is an anti-VEGF monoclonal antibody indicated in the EU in first line or relapse for the treatment of OC in combination with specific chemotherapeutic agents. Bevacizumab treatment is associated with increasing hypoxia-induced homologous recombination repair deficiencies in tumor cells, and is hypothesized to increase ovarian tumor sensitivity to olaparib. **Methods:** PAOLA-1 (ENGOT-ov25) is a randomized, placebo-controlled trial evaluating the efficacy and safety of olaparib (tablet formulation) in pts with advanced HGSOC receiving bevacizumab maintenance therapy. Eligible pts are those in complete or partial response following first-line platinum chemotherapy plus bevacizumab, and for whom bevacizumab maintenance therapy is planned. Approximately 762 European and 24 Japanese pts will be randomized 2:1 to olaparib 300 mg twice daily or placebo for up to 24 months. All pts will receive standard maintenance care of bevacizumab (15 mg/kg every three weeks) for up to 15 months. Primary objective: PFS1 according to RECIST 1.1 Secondary objectives: PFS2, OS, Safety, PRO/QoL, TFST, TSST All pts will undergo tumor *BRCA* testing prior to randomization. Central *BRCA* testing (tumor) will be performed in five screening platforms in France. Tumor *BRCA* test results have to be available within two months of sample provision. PFS will be evaluated using a log-rank test stratified by response to first-line treatment and *BRCA* mutation status. Treatment effect hazard ratio of 0.7 is expected and final PFS1 analysis will be performed after 372 events. The first pt from eight ENGOT groups plus Japan (10 participating countries) was randomized in July 2015. As of 31 January 2017, 549 pts have been randomized. The median period between the provision of a tumor sample and returned *BRCA* test result is 40 days. Accrual is expected to be complete before July 2017. Clinical trial information: NCT02477644.

TPS5606 Poster Session (Board #425a), Sat, 1:15 PM-4:45 PM

A phase 2 study to assess olaparib by homologous recombination deficiency status in patients with platinum-sensitive, relapsed, ovarian, fallopian tube, or primary peritoneal cancer. *First Author: Karen Anne Cadoo, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: The poly (ADP-ribose) polymerase (PARP) inhibitor olaparib is approved for treatment of patients (pts) with germline *BRCA* mutations (*BRCAm*) and advanced ovarian cancer (OC). *BRCA* mutations are genetic alterations leading to homologous recombination deficiency (HRD) and tumor susceptibility to DNA-damaging agents, including PARP inhibitors. Loss of genetic heterozygosity, telomeric-allelic imbalance, or large-scale state transitions may identify additional pts who could benefit from PARP inhibitor therapy. **Methods:** LIGHT is a non-randomized, open-label, phase 2 study to assess the efficacy and safety of olaparib in patient cohorts identified by different HRD genetic tests (NCT02983799). Patients will have platinum-sensitive (progression > 6 mo after the end of the last platinum-based chemotherapy), relapsed, high-grade epithelial ovarian, fallopian tube, or primary peritoneal cancer; ECOG performance status 0–1; and ≥2 prior lines of platinum-based chemotherapy for OC. Key exclusion criteria include prior PARP inhibitor treatment; concomitant use of potent CYP3A4/5 inhibitors or inducers; and symptomatic uncontrolled brain metastases. Patients will be enrolled into 4 cohorts of 30 pts each based upon *BRCAm* or tumor HRD status determined by genetic test results: germline *BRCAm*; somatic *BRCAm*; MyChoice HRD-positive and wildtype *BRCAm*; MyChoice HRD-negative and wildtype *BRCAm*. All pts will receive 300 mg olaparib tablets twice daily until disease progression (RECIST v1.1) or unacceptable toxicity. The primary endpoint is investigator-assessed objective response rate (ORR) according to RECIST v1.1 criteria. The maximum precision of the ORR is approximately ±18.7% for 30 pts. Secondary endpoints include duration of response, cancer antigen-125 response rate, disease control rate, progression-free survival, time to any progression, overall survival, and homologous recombination repair gene panel mutation status related to clinical outcome. Planned enrollment of 120 pts at sites in the United States was initiated in December 2016. Clinical trial information: NCT02983799.

TPS5607 Poster Session (Board #425b), Sat, 1:15 PM-4:45 PM

FORWARD I (GOG 3011): A randomized phase 3 study to evaluate the safety and efficacy of mirvetuximab soravtansine (IMGN853) versus chemotherapy in adults with folate receptor alpha (FRα)-positive, platinum-resistant epithelial ovarian cancer (EOC), primary peritoneal cancer, or primary fallopian tube cancer. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Elevated FRα expression is characteristic of a number of solid tumors, including EOC, thereby providing an attractive candidate for targeted therapeutic approaches. Mirvetuximab soravtansine is an antibody-drug conjugate (ADC), comprising a FRα-binding antibody linked to the tubulin-disrupting maytansinoid DM4, that has shown single agent clinical activity and a favorable safety profile in an ongoing, first-in-human phase 1 trial (NCT01609556). **Methods:** FORWARD I is a randomized phase 3 study designed to evaluate the efficacy of mirvetuximab soravtansine compared with that of standard-of-care chemotherapy in adult patients with platinum-resistant EOC, primary peritoneal cancer, or fallopian tube cancer. Confirmation of FRα positivity by immunohistochemistry (medium or high expression; ≥ 50% of cells with at least moderate staining intensity) and ≤ 3 prior lines of therapy are required for inclusion. A maximum of 333 patients are expected to be recruited. Patients will be randomized 2:1 to Arm 1 (intravenous mirvetuximab soravtansine at a dose of 6.0 mg/kg, calculated using adjusted ideal body weight, on Day 1 of a 21-day cycle) or Arm 2 (investigators' choice chemotherapy: paclitaxel, pegylated liposomal doxorubicin, or topotecan). The primary efficacy endpoint is progression-free survival (PFS; by blinded independent central review) and secondary endpoints include objective response rate, quality of life, overall survival, safety and tolerability, and duration of response. The first patient was enrolled in January 2017. Clinical trial information: NCT02631876.

TPS5608 Poster Session (Board #426a), Sat, 1:15 PM-4:45 PM

Phase II open-label randomized multi-centre study of neoadjuvant olaparib in patients (pts) with platinum sensitive (PS) relapsed high grade serous ovarian cancer (OC): The NEO trial. *First Author: Yada Kanjanapan, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Olaparib is a PARP inhibitor with clinical benefit in relapsed OC, especially in pts with germline *BRCA1/2* mutation (*gBRCA*). Study 19 (NCT00753545) found a progression free survival (PFS) gain from maintenance olaparib, post chemotherapy for PS relapse. Olaparib treatment in *gBRCA* OC pts relapsing post ≥ 3 prior chemotherapy regimens gave a response rate (RR) of 46% in the PS subgroup (Study 42; NCT01078662). Efficacy of olaparib may extend to OC with homologous recombination DNA repair pathway deficiency (HRD); susceptible to synthetic lethality from PARP inhibition. NEO [NCT02489006] is a window of opportunity study to assess tumor heterogeneity and the pharmacodynamic effects of olaparib given prior to surgery in PS OC, analyse the tumor genomic landscape pre and post olaparib, and assess for predictive biomarkers beyond *BRCA* mutation. **Methods:** This phase 2 study enrols pts with high grade serous OC, primary peritoneal or fallopian tube cancer with a progression free interval of ≥6 months and sensitive to their last line of platinum therapy. Pts must be suitable for secondary debulking surgery and agree to pre-operative tumour biopsy. All pts receive olaparib tablets 300mg po bid for 6 ± 2 weeks pre-surgery. Post-operatively, pts are randomised 1:1 to olaparib or 6 cycles of platinum-based chemotherapy followed by maintenance olaparib. The primary endpoint is the degree of PAR and PARP-1 inhibition in the blood and tumor following pre-operative olaparib in PS relapsed OC. Clinical efficacy is assessed by RR (RECIST 1.1), CA125, PFS and PFS2. Translational studies include next generation sequencing HRD panel to assess for somatic and germline mutations including RAD51B/C/D, PPM1D, FANCM, BRIP1, PALB2 and BARD1; evaluation of gene expression change in tumor tissue pre and post olaparib; assessment for resistance mechanisms and impact of heterogeneity. Circulating tumor DNA measured weekly pre-surgery is assessed for its prognostic value, alone and compared with CA125. The study will enrol 50-70 pts with estimated accrual of 3 pts/month across multiple sites, and opened at Princess Margaret Cancer Centre in 7/2016. Clinical trial information: NCT02489006.

TPS5609 Poster Session (Board #426b), Sat, 1:15 PM-4:45 PM

OCTOPUS: A randomised, multi-centre phase II umbrella trial of weekly paclitaxel+/- novel agents in platinum-resistant ovarian cancer—Vistusertib (AZD2014). *First Author: Susana N. Banerjee, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: There is an urgent need to improve outcomes for patients with platinum-resistant and refractory ovarian cancer (PROC). OCTOPUS is an umbrella phase II framework for testing whether the addition of novel targeted agents to weekly paclitaxel (wPxl) improves efficacy in PROC. The first agent to be evaluated is the dual mTORC1/mTORC2 inhibitor, vistusertib (AZD2014), as preclinical studies support targeting the PI3kinase/Akt/mTOR pathway in PROC and the combination of vistusertib and wPxl has shown promising preliminary activity in high grade serous ovarian cancer (HGS) patients in a phase I trial (Banerji et al poster discussion ESMO 2016). This is the first randomised trial of wPxl and a dual mTORC1/2 inhibitor in ovarian cancer. **Methods:** OCTOPUS is an investigator-initiated, randomised, double-blind, placebo-controlled, multicentre, phase II trial. 140 patients with PROC (histologically confirmed HGS) are randomised 1:1 to receive wPxl (80mg/m2 D1, D8, D15 of 28 day cycle) plus oral vistusertib (50mg BD) or placebo (D1-3, D8-10, D15-17). The primary endpoint is progression-free survival (PFS) based on combined RECIST v1.1/GCIG CA125 criteria. The study is designed to detect a 50% improvement in median PFS from 3.7 months on placebo to 5.55 months on the experimental arm with 90% power, at the 20% 1-sided level of statistical significance (or equivalently with 80% power at the 10% level of statistical significance) using a 3-outcome design. Secondary endpoints include response (based on RECIST 1.1 and GCIG CA125 criteria), overall survival, toxicity and quality of life. Patients whom received prior wPxl for PROC are not eligible. A mandatory pre-treatment biopsy (if technically feasible), archival tissue, and serial blood samples will be collected for translational research studies. 49 patients have been recruited. The study is part of the NIHR CRN Cancer/Astrazeneca Alliance, sponsored by NHS Greater Glasgow and Clyde/University of Glasgow and endorsed by Cancer Research UK (CRUKE/14/052). Clinical trial information: ISRCTN16426935.

TPS5610 Poster Session (Board #427a), Sat, 1:15 PM-4:45 PM

A phase II trial of enzalutamide in patients with androgen receptor positive (AR+) ovarian, primary peritoneal or fallopian tube cancer and one, two, or three prior therapies. *First Author: Rachel N. Grisham, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: Approximately 75% of women with epithelial ovarian cancer (OC) present with advanced disease. Most of these women will ultimately recur and require life-long treatment for their cancer. Well tolerated therapies for treatment in the recurrent setting are needed. The AR is expressed in greater than 60% of cases of OC and is more prevalent than the estrogen or progesterone receptor. All past clinical studies of AR inhibition in OC have focused on unselected populations of heavily pretreated women; however preclinical data suggests that AR expression decreases in OC cells with increasing lines of therapy. Enzalutamide is a small molecule androgen receptor-antagonist that is FDA approved for treatment of prostate cancer and is currently being investigated as treatment for breast and ovarian cancer. **Methods:** This is a phase II, single-institution trial of enzalutamide 160mg po QD in patients with AR+ ovarian, fallopian tube or primary peritoneal cancer. Eligible patients must be found to have greater than or equal to 5% AR staining by IHC on FFPE tumor tissue and been treated with only 1,2 or 3 prior cytotoxic therapies. Patients must have RECIST 1.1 defined measurable disease. Enrolled patients are treated with enzalutamide until progression of disease or unacceptable toxicity. The primary endpoint is to estimate the proportion of women who achieve a complete or partial response by RECIST 1.1 criteria or survive progression free for at least 6 months. Secondary objectives include the retrieval of optional tumor biopsies at time of progression to evaluate the effect of enzalutamide on AR expression and to observe the effect of enzalutamide on serum testosterone and estradiol levels. This study will enroll 58 patients at Memorial Sloan Kettering Cancer Center and its regional sites. The study utilizes a safety lead-in phase and a two-stage design. The first patient enrolled in April 2015. The safety lead-in phase has been completed. The prespecified activity goal for the first stage was met; second stage accrual began in October 2016. Thus far, 35 patients have initiated treatment. Clinical trial information: NCT01974765.

TPS5611 **Poster Session (Board #427b), Sat, 1:15 PM-4:45 PM**

Combination chemotherapy with nintedanib/placebo for patients with advanced or recurrent endometrial cancer: The NSGO ENGOT-EN1/FANDANGO trial. *First Author: Mansoor Raza Mirza, NSGO and Rigshospitalet Copenhagen University Hospital, Copenhagen, Denmark*

Background: Endometrial cancer (EC) patients with advanced and recurrent disease relapse despite treatment with combination chemotherapy and have a short progression-free survival (PFS). With the emerging clinical data on anti-angiogenic agents and with promising results of nintedanib in ovarian cancer, it is apparent to explore its role in EC. Nintedanib is a potent, orally available triple receptor tyrosine kinase inhibitor targeting VEGFR 1-3, PDGFR α/β, and FGFR 1-3. This placebo-controlled, multicenter, two-arm, phase 2 trial compares nintedanib versus placebo as concomitant and maintenance therapy in combination with chemotherapy in patients with advanced or recurrent EC. **Methods:** The primary objective of this trial is to evaluate efficacy of nintedanib against placebo in combination with chemotherapy, defined by PFS. Key eligibility criteria include: histologically confirmed EC, stage 3C 2 or 4 A & B or relapsed after adjuvant therapy for stage 1-3 disease; prior surgery; adjuvant chemotherapy; radiation therapy; hormonal therapy are permitted; measurable/non-measurable disease. 148 patients will be randomized 1:1 to receive nintedanib 200mg twice daily or placebo days 2-21 during chemotherapy (six cycles of Carboplatin (AUC5) and paclitaxel (175mg/m2) every 21 days) and continuously in maintenance phase. Nintedanib/placebo is continued until disease progression, unacceptable toxicity, or withdrawal. Secondary endpoints include PFS in sub-populations, PFS2, disease specific survival, time to first subsequent therapy, time to second subsequent therapy, overall survival, objective response, disease control rate, patient reported outcoms (assessed via EORTC QLQ-C30 and EORTC QLQ-EN24) and safety. Trial is enrolling patients. The following cooperative groups are participating: NSGO (DK, FIN, SWE, NOR), NOGGO (GER), BGOG (BEL), & GINECO (FRA). Clinical trial information: NCT02730416.

TPS5612 **Poster Session (Board #428a), Sat, 1:15 PM-4:45 PM**

Palbociclib versus placebo in combination with letrozole for patients with advanced or recurrent endometrial cancer: The NSGO ENGOT-EN3/PALEO trial. *First Author: Mansoor Raza Mirza, NSGO and Rigshospitalet Copenhagen University Hospital, Copenhagen, Denmark*

Background: Endometrial cancer (EC) patients with advanced or recurrent disease and endometrioid histology have a short progression-free survival (PFS). These malignancies are hormone dependent and endocrine therapy with aromatase inhibitors is well established. Palbociclib is an oral and selective inhibitor of cyclin-dependent kinases CDK4 and CDK6. Studies in breast cancer have demonstrated superiority of letrozole treatment in combination with palbociclib vs. letrozole monotherapy in oestrogen receptor positive (ER+) HER2- advanced disease. The combination is generally well tolerated with an acceptable toxicity profile. This multicenter, prospective, double-blind, placebo-controlled, randomized, phase II trial is evaluating the efficacy of letrozole when combined with palbociclib against letrozole-placebo combination therapy in women with ER+ advanced or recurrent EC. **Methods:** The primary objective of this trial is to demonstrate superiority of palbociclib against placebo in combination with letrozole, as defined by investigator-assessed progression-free survival (PFS). Key eligibility criteria include: histologically confirmed ER+ EC of endometrioid type; stage 4 or recurrent disease; prior surgery, adjuvant chemotherapy, radiation therapy, hormonal therapy (e.g. megestrol acetate) is permitted; measurable/evaluable disease according to RECIST 1.1. 78 patients will be randomized 1:1 to receive palbociclib 125mg daily or placebo on days 1-21 and letrozole 2.5mg daily on days 1-28 in a 28 days cycle until disease progression, unacceptable toxicity, or withdrawal. Secondary endpoints include PFS in sub-populations, overall response rate, disease control rate, PFS2, time to first subsequent therapy, time to second subsequent therapy, overall survival, safety & tolerability, patient reported outcomes (assessed via EORTC QLQ-C30 and EORTC QLQ-EN24) and PFS in patients with or without retinoblastoma protein-expressing tumors. The following cooperative groups are participating: NSGO (DK, FIN, NOR), MITO (ITA), GEICO (SPA) & NOGGO (GER). Clinical trial information: NCT02730429.

TPS5613 **Poster Session (Board #428b), Sat, 1:15 PM-4:45 PM**

Postoperative chemotherapy or no further treatment for patients with node-negative stage I-II intermediate or high risk endometrial cancer: The ENGOT-EN2/DGCG trial. *First Author: Mansoor Raza Mirza, The Finsen Centre, Ballerup, Denmark*

Background: Patients with medium and high-risk stage I and II endometrial cancers (EC) have, despite radical surgery, a high risk for progression. Adjuvant brachytherapy or EBRT is the traditional therapy for many decades although without impacting on survival. Several studies have failed to demonstrate superiority of adjuvant chemotherapy in unselected population with a high number of low-risk patients. It is of utmost importance to demonstrate efficacy of adjuvant combination chemotherapy in a randomized trial comparing to no further treatment in the medium and high-risk node negative stage I and stage II patients. **Methods:** The primary objective of this trial is to evaluate the effect on overall survival of carboplatin-paclitaxel combination chemotherapy against no further systemic treatment. Key eligibility criteria include: histologically confirmed EC, stage I grade 3 endometrioid adenocarcinoma or stage II endometrioid adenocarcinoma or stage I and II type 2 histology (clear cell, serous, squamous cell carcinoma, carcinosarcoma or undifferentiated carcinoma); prior surgery with pelvic lymphadenectomy or sentinel lymph node biopsy. Patients may receive vaginal brachytherapy in both arms. 240 patients are randomized to receive six courses of adjuvant carboplatin (AUC5) and paclitaxel (175mg/m2) combination on day one every 21 days or no further treatment (1:1 randomization). Primary endpoint is overall survival of endometrioid subgroup. Secondary endpoints include overall survival of whole study population, disease specific survival, progression-free survival, toxicity, compliance, Quality of Life (assessed via EORTC QLQ-C30 and EORTC QLQ-EN24), rate of isolated pelvic or distant relapses, as well as mixed relapses. Trial is enrolling patients. The following cooperative groups are participating: DGCG (DK), NSGO (DK, FIN, SWE), BGOG (BEL), MaNGO (ITA), MITO (ITA), GEICO (SPA), NOGGO (GER), CEEGOG (Czech), ISGO (ISR) & MDACC (USA). Clinical trial information: NCT01244789.

TPS5614 **Poster Session (Board #429a), Sat, 1:15 PM-4:45 PM**

A phase II trial of durvalumab (Medi 4736) in advanced endometrial cancer: PHAEDRA. *First Author: Yoland Catherine Antill, Cabrini Health, Brighton, Australia*

Background: Advanced endometrial cancer (EC) progressing after 1 or more lines of chemotherapy is an area of unmet need with objective tumour response rates to subsequent lines of chemotherapy of $\leq$20%. DNA mismatch repair (MMR) deficiency, seen in approximately 15% of EC, is associated with a high mutational load and in addition, up to 90% of ECs are reported to have PDL1/ PD1 expressions. These factors make immune check point inhibition an ideal target for treatment. **Methods:** DESIGN: Multicentre phase 2 trial in two cohorts. ELIGIBILITY: Advanced, unresectable endometrial cancer that is either MMR-proficient and progressing after 1-3 lines of chemotherapy, or MMR-deficient and progressing after 0-3 lines of chemotherapy. ENDPOINTS: Objective tumour response rate (OTRR) according to iRECIST (primary) and RECIST 1.1, disease control rates at 16 and 24 weeks, progression free survival, overall survival, duration of OTR and DC, adverse events, health related quality of life. Tertiary correlative objectives: Associations between immunologic (including PD-L1), DNA mismatch repair (MMR) and other genetic characteristics with clinical outcomes; and family history of cancer and referral to familial cancer services. INTERVENTION: Durvalumab 1500 mg intravenously every 28 days until disease progression or prohibitive toxicity. STATISTICS: Total of 70 participants in two cohorts (35 each) will have 90% power to distinguish a difference in observed OTRR of $\geq$20% versus $\leq$5% (uninteresting rate) using Simon's 2-stage minimax design with 10% type 1 error rate and allowing 10% ineligibility and missing data. Durvalumab will be considered worthy of pursuit if 4 or more OTR are observed in the first 32 participants in each cohort (OTRR $\geq$12.5%). BIOSPECIMENS: Tumour tissue and serial bloods (5 time points) will be collected for translational research. PHAEDRA is an investigator-initiated, cooperative-group trial led by ANZGOG, in collaboration with NHMRC Clinical Trials Centre, University of Sydney. Australian New Zealand Clinical Trials Registry: Clinical trial information: ACTRN12617000106336.

TPS5615 Poster Session (Board #429b), Sat, 1:15 PM-4:45 PM

Phase 2, two-group, two-stage, open-label study of avelumab in patients with microsatellite stable, microsatellite instable and *POLE*-mutated recurrent or persistent endometrial cancer. *First Author: Panagiotis A. Konstantinopoulos, Dana-Farber Cancer Institute, Boston, MA*

Background: The Cancer Genome Atlas project identified 2 groups of hypermutated endometrial cancers (ECs): an ultramutated group that harbored mutations in the exonuclease domain of polymerase e (*POLE*), and a hypermutated group with microsatellite instability (MSI), the majority of which harbored *MLH1* promoter methylation. We (Howitt, JAMA Onc 2015) and others have shown that *POLE* and MSI ECs are associated with higher number of predicted neoepitopes and tumor infiltrating lymphocytes, which is counterbalanced by overexpression of PD-1/PD-L1, suggesting that they may be excellent candidates for PD-1/PD-L1 blockade. Anti-PD-1 therapy has also demonstrated promising activity in mismatch repair deficient colorectal cancers and collectively in non-colorectal cancers (Le, NEJM 2015). **Methods:** This is an open-label, two-cohort, two-stage, phase 2 trial, of avelumab, a fully human IgG1 antibody directed against PD-L1, in two cohorts: i) a MSI/*POLE* cohort including ECs with immunohistochemical (IHC) complete loss of expression of at least one of the mismatch repair (MMR) proteins and/or documented mutation in the exonuclease domain of *POLE* and ii) a MSS cohort including ECs with normal IHC expression of all MMR proteins. Key eligibility criteria include measurable disease, no upper limit of prior therapies, and any EC histology. Co-primary objectives include objective response rate and rate of progression-free survival at 6 months. Avelumab is administered at 10 mg/kg as 1-hour IV infusion every 2 weeks until disease progression or unacceptable toxicity; therapy may continue at the investigator's discretion while awaiting radiologic confirmation of disease progression 4 weeks later. Maximum target enrollment is 70 patients (35 for each cohort). In the first stage, 16 patients will be enrolled in each cohort; if there are at least two objective responses or two patients progression-free at 6 months, accrual will continue to the second stage where 19 more patients will be enrolled for each cohort. Thus far, 16 patients have been enrolled, 13 on the MSS cohort and 3 on the MSI/*POLE* cohort. Clinical trial information: NCT02912572.

6000 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III randomized trial of chemotherapy with or without bevacizumab (B) in patients (pts) with recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN): Survival analysis of E1305, an ECOG-ACRIN Cancer Research Group trial. *First Author: Athanassios Argiris, Thomas Jefferson University, Philadelphia, PA*

Background: The addition of B, an anti-VEGF monoclonal antibody, to chemotherapy has improved outcomes in several solid tumors. Pemetrexed plus B showed promising efficacy in R/M SCCHN (Argiris et al. *JCO* 2011). E1305 was designed to evaluate the addition of B to a platinum doublet in R/M SCCHN. **Methods:** B-eligible pts with performance status 0-1, not having received chemotherapy for R/M SCCHN (prior chemotherapy for locally advanced disease allowed ≥ 4 months) and without factors predisposing to bleeding (history of bleeding due to SCCHN, anticoagulation, central cavitary lung metastasis, carotid invasion) were randomized to: A) one of 4 regimens (investigator's choice) given every 3 weeks: A1, cisplatin (C) 100 mg/m^2, 5-FU 1000 mg/m^2/day x 4 days; A2, carboplatin (Cb) AUC 6, 5-FU 1000 mg/m^2/day x 4 days; A3, C 75 mg/m^2, docetaxel (D) 75 mg/m^2; A4, Cb AUC 6, D 75 mg/m^2, or B) the same regimen (B1, B2, B3, B4) plus B 15 mg/Kg IV, every 3 weeks, until progression. Chemotherapy could be stopped after 6 cycles after maximum response. All pts received prophylactic antibiotics. The primary endpoint was overall survival (OS). Control median OS of 8.5 months (mo) was projected; the addition of B was hypothesized to increase median OS to 11.5 mo with a hazard ratio (HR) of 0.74. **Results:** 403 pts were randomized (200 in arm A; 203 in arm B). Baseline characteristics were well balanced. 38% in arm A/42% in arm B had an oropharyngeal primary; 87% received C or Cb plus D. With a median follow-up of 23.1 mo, median OS was 11 mo in arm A and 12.6 mo in arm B; HR 0.84 (95% CI 0.67-1.05), p = 0.13. The 1-, 2-, 3-, and 4-year OS were 46% vs 51%, 18% vs 26%, 8% vs 16%, 6% vs 13%, in arm A vs B, respectively. Median PFS was 4.4 mo in arm A and 6.1 mo in arm B (HR 0.71, 95% CI 0.58-0.87; p = 0.0012). Objective response rate was 25% in arm A vs 36% in arm B (p = 0.013). Grade 3-5 bleeding occurred in 3.5% in arm A vs 7.7% in arm B (p = 0.08). **Conclusions:** B added to a standard platinum doublet improved response rate and PFS but not OS in first-line treatment of R/M SCCHN. The control arm in this study performed better than expected. Clinical trial information: NCT00588770.

6001 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

LUX-head and neck 2: Randomized, double-blind, placebo-controlled, phase III trial of afatinib as adjuvant therapy after chemoradiation (CRT) in primary unresected, high/intermediate-risk, squamous cell cancer of the head and neck (HNSCC) patients (pts). *First Author: Barbara Burtness, Yale School of Medicine, New Haven, CT*

Background: Locally advanced HNSCC is treated curatively, but recurrence is common. In HNSCC, EGFR is richly expressed and EGFR inhibition is validated treatment (tx); the ErbB family blocker afatinib (A) showed efficacy in recurrent/metastatic disease. This Phase III trial assessed if A after definitive CRT improves disease-free survival (DFS). **Methods:** Eligible pts had complete response after CRT ≥66 Gy (or equivalent) with concurrent cisplatin or carboplatin but not prior EGFR inhibition, for HNSCC of oral cavity, hypopharynx, larynx, or oropharynx with >10 pack years (pk yrs) tobacco use. Pts were stratified by ECOG PS (0/1) and nodal stage (N0–2a/N2b–3), and randomized 2:1 to A 40 mg/d or placebo (P); tx continued for 18 m if tolerated, or until disease recurrence. The primary endpoint was DFS. **Results:** Of 669 pts planned, 617 were randomized; A 411, P 206. Median age was 58 yrs; 86% were male; 65% ECOG PS 0; most had smoked (A/P ex-smoker: 66/72%; current: 28/22%). Subsites (A/P) were: oropharynx 53/54%; hypopharynx 21/23%; larynx 18/12%; oral cavity 9/10%. The majority had T3 or 4 (A/P 70/68%) and N2 disease (67/63%). Accrual was halted for futility on independent DMC recommendation: at a pre-planned interim analysis (40% of DFS events), median DFS was A 43.4 m vs P not reached (NR; HR 1.13 [95% CI 0.81–1.57], p=0.48); the Table shows key subgroups. Median treatment duration was A 300.0 d, P 455.5 d. Recurrence was A 23%, P 23%. Dose reduction of A was required in 53% (mostly due to diarrhea, stomatitis). Tx was discontinued due to AEs in A 15%, P 4%. **Conclusions:** A after CRT did not improve DFS vs P. Subgroup analyses were underpowered to provide definitive conclusions. Harrington and Cohen contributed equally. Clinical trial information: NCT01345669.

6002 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A multicenter randomized controlled trial (RCT) of adjuvant chemotherapy (CT) in nasopharyngeal carcinoma (NPC) with residual plasma EBV DNA (EBV DNA) following primary radiotherapy (RT) or chemoradiation (CRT). *First Author: Anthony T. C. Chan, Department of Clinical Oncology, State Key Laboratory of Oncology in South China, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: The benefit of adjuvant CT in NPC is unclear. Post-RT EBV DNA predicts poor survival and may be a biomarker of subclinical residual disease. We conducted a biomarker driven RCT using post-RT EBV DNA to select high risk NPC patients (pts) for adjuvant CT while sparing low risk pts from unnecessary toxicity. **Methods:** Eligible pts had biopsy proven NPC of AJCC (6th Ed) stage IIB-IVB, detectable EBV DNA (> 0 copy/ml) at 6-8 weeks post-RT, no persistent locoregional disease or distant metastasis, ECOG 0 or 1, and adequate organ function. Pts were randomized with stratification for primary therapy (RT Vs CRT) and tumor stage (II/III Vs IV) to arm A (adjuvant cisplatin 40 mg/m2 and gemcitabine 1000 mg/m2, both given on D1+8 q3w x 6 cycles) or arm B (clinical follow-up). Primary endpoint was relapse free survival (RFS). With a hazard ratio (HR) of 2, 100 pts were required with a power of 0.8 and an alpha at 0.05. **Results:** From 9/2006 to 7/2015, 789 pts consented for EBV DNA screening, 218 (27.6%) pts had detectable EBV DNA, and 104 (13.2%) pts were randomized (arm A: 52; arm B: 52). The two arms were well balanced in baseline characteristics. 84.6% received prior neoadjuvant and/or concurrent CT and all received curative RT. Staging distribution: IIB 27.9%, III 37.5%, IVA 19.2%, IVB 15.4%. 8 pts refused adjuvant CT after randomization. Overall 69% and 50% completed 3 and 6 cycles of adjuvant CT respectively. After median follow up of 6.5 years (yr), the 3-yr and 5-yr survival outcomes were summarized in Table. **Conclusions:** In NPC pts who had residual EBV DNA after curative RT/CRT, adjuvant CT with cisplatin-gemcitabine did not improve survival. Clinical trial information: NCT00370890.

6003 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Impact of prophylactic human papillomavirus (HPV) vaccination on oral HPV infections among young adults in the U.S. *First Author: Maura L. Gillison, Ohio State University, Columbus, OH*

Background: The incidence of HPV-positive oropharyngeal cancers has risen in recent decades among US men. The potential impact of HPV vaccines on oral HPV infections has yet to be evaluated in efficacy-trials or surveillance studies. **Methods:** To evaluate the impact of prophylactic HPV vaccination on oral HPV infections in the US population, we conducted a cross-sectional study among men and women aged 18-33 years (n = 2,627) in the National Health and Nutrition Examination Survey, 2011-2014. We examined the effect of self-reported receipt of ≥1 vaccine dose on oral HPV infection (vaccine-types 16/18/6/11) prevalence among vaccinated vs. unvaccinated individuals. Additional outcomes included percent reduction in infection-prevalence among vaccinated individuals and population-level effectiveness of vaccination. Analyses accounted for the complex sampling design. Comparisons between vaccinated and unvaccinated individuals were conducted using binary logistic regression, with adjustment for age, gender, and race. Statistical significance was assessed using a quasi-score test. **Results:** During 2011-2014, 18.3% of the US population aged 18-33 years reported receipt of ≥1 HPV vaccine-dose prior to age 26 (29.2% in women and 6.9% in men; $P < 0.001$). The prevalence (population-weighted) of oral HPV16/18/6/11 infections was significantly reduced in vaccinated vs. unvaccinated individuals (0.11% vs. 1.61%; $P = 0.008$), corresponding to an estimated 88.2% (95%CI = 5.7%-98.5%) reduction in prevalence. Notably, oral HPV16/18/6/11 prevalence was significantly reduced in vaccinated vs. unvaccinated men (0.0% vs. 2.13%; $P = 0.007$). In contrast, prevalence for 33 non-vaccine HPV types was similar (3.98% vs. 4.74%; $P = 0.24$). Accounting for HPV vaccine-uptake, the population-level effectiveness of HPV vaccination on the burden of oral HPV16/18/6/11 infections was 17.0% overall, 25.0% in women and 6.9% in men. **Conclusions:** HPV vaccination substantially reduced vaccine-type oral HPV infection prevalence among young adults (ages 18-33 years) in the US population during 2011-2014. However, due to low vaccine uptake, population-level effectiveness was modest overall and particularly low in men.

6004 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Developing and validating a multivariable predictive biomarker for treatment selection for oropharyngeal squamous cell carcinoma: The PREDICTR-OPC study. *First Author: Hisham Mohamed Mehanna, University of Birmingham, Birmingham, United Kingdom*

Background: To date there are no validated predictive tests to inform treatment selection for patients with oropharyngeal cancer (OPC). Currently treatment is decided on disease resectability, clinician preference and patient choice. **Methods:** Objective To develop a predictive test to select treatment for advanced OPC. Participants Training cohort: 543 cases from 10 cancer centres. External validation cohort: 442 cases from 3 centres. Design Multivariable logistic regression of 8 clinical parameters and 10 biomarkers to develop biomarker-only and composite clinical/biomarker predictive models; subsequently validated on a separate cohort. Biomarkers scored by ≥2 'blinded' pathologists. Outcomes Primary: overall survival (OS). **Results:** 724 males, 261 females; Median follow-up =8.8 (6.86-10.47) years. More validation cases received surgery (53.5% vs 37.9%, p=0.001) and fewer received chemo/radiotherapy (42%vs67.5%; p=0.001) compared to training cohort. The biomarker-only model performed better than the clinical/biomarker one. The final OS model - comprising p16, high risk HPV DNA ISH, survivin and tumour infiltrating lymphocyte score (TILS)- was not only prognostic for OS, but importantly was predictive for surgery+/-adjuvant RT over CRT (3yr OS 63%, vs 42.5% respectively) in the High Risk group. Treatments were equally effective in the Low Risk group. The RFS model (p16, PLK1, survivin, TILS) was prognostic, but not predictive for treatment. Validation testing confirmed good calibration and concordance (C-index =0.73; 0.68-0.79). The OS model remained prognostic and predictive for surgical treatment in High Risk group (HR=0.51; 95%CI= 0.3-0.85, p=0.01). **Conclusions:** To our knowledge, this is the first-ever validated model for treatment selection in HNC. Clinicians can now recommend the treatment most likely to be effective on the basis of an easily-applied, relatively inexpensive panel of 4 biomarkers.

	OS Hazards Ratio (95% CI)	p - value	RFS Hazards Ratio (95% CI)	p - value	3 yr OS treated by SURG	3 yr OS treated by CRT
High risk (HR) group	0.51 (0.3-0.85)	0.01	0.83 (0.43-1.62)	0.58	63%	42.5%
Low risk group	0.85 (0.31-2.35)	0.76	0.87 (0.31-2.44)	0.79	89%	82%

6005 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Neoadjuvant chemotherapy followed by concurrent chemoradiotherapy versus concurrent chemoradiotherapy alone in locoregionally advanced nasopharyngeal carcinoma: A phase III multicentre randomised controlled trial. *First Author: Ming-Yuan Chen, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: The role of neoadjuvant chemotherapy (NACT) for locoregionally advanced nasopharyngeal carcinoma (NPC) is unclear. We aimed to evaluate the feasibility and efficacy of NACT followed by concurrent chemoradiotherapy (CCRT) versus CCRT alone in locoregionally advanced NPC. **Methods:** Patients with stage III-IVB (excluding T3N0-1) NPC were randomly assigned to receive NACT followed by CCRT (investigational arm) or CCRT alone (control arm). Both arms were treated with 80 mg/m^2 cisplatin every three weeks concurrently with radiotherapy. The investigational arm received cisplatin (80 mg/m^2 d1) and fluorouracil (800 mg/m^2 civ d1-5) every three weeks for two cycles before CCRT. The primary endpoint was disease-free survival (DFS) and distant metastasis-free survival (DMFS). Secondary endpoint was overall survival (OS). **Results:** 476 patients were randomly assigned to the investigational (n = 238) and control arms (n = 238). The investigational arm achieved higher 3-year DFS rate (82.0%, 95% CI = 0.77-0.87) than the control arm (74.1%, 95% CI = 0.68-0.80, P = 0.028). The 3-year DMFS rate was 86.0% for the investigational arm versus 82.0% for the control arm, with marginal statistical significance (P = 0.056). However, there were no statistically significant differences in OS or locoregional relapse-free survival (LRRFS) rates between two arms (OS: 88.2% vs 88.5%, P = 0.815; LRRFS: 94.3% vs 90.8%, P = 0.430). The most common grade 3–4 toxicity during NACT was neutropenia (16.0%). During CCRT, the investigational arm experienced statistically significantly more grade 3–4 toxicities (P < 0.001). **Conclusions:** NACT improved tumor control compared with CCRT alone in locoregionally advanced NPC, particularly at distant sites. However, there was no early gain in overall survival. Longer follow-up is needed to determine the eventual therapeutic efficacy. Clinical trial information: NCT00705627.

6006 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Concurrent chemoradiotherapy with 3-weekly versus weekly cisplatin in patients with locoregionally advanced nasopharyngeal carcinoma: A phase 3 multicentre randomised controlled trial (ChiCTR-TRC-12001979). *First Author: Hu Liang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: In intensity-modulated radiotherapy (IMRT) era, concurrent chemoradiotherapy (CCRT) with either every three week (ETW) or once a week (OAW) cisplatin is accepted practice for locoregionally advanced nasopharyngeal carcinoma (LANPC). However, ETW and OAW were never prospectively compared in phase 3 clinical trials. This study is to assess the efficacy and toxicity profiles of CCRT with ETW versus OAW schedule of cisplatin. **Methods:** We conducted an open-label phase 3 multicentre randomised controlled trial in an endemic area. Patients with stage II-IVB NPC were randomly assigned to receive either cisplatin 100 mg/m^2 every 3 weeks for 2 cycles or cisplatin 40 mg/m^2 weekly up to 6 cycles concurrently with IMRT. IMRT in both groups was given as 2.19-2.34 Gy per fraction with five daily fractions per week for 6-7 weeks to a total dose of 68-70 Gy to the primary tumor and 62-68 Gy to the involved neck area. The primary endpoint was failure-free survival. Intention-to-treat population was adopted for efficacy analyses. **Results:** Of the 526 eligible patients, 267 were assigned to OAW arm, and 259 to ETW arm. Two arms were well-balanced in all prognostic factors. No difference was observed in overall tumor response between OAW and ETW (99.6% vs 98.9%, P = 0.624). After a median follow-up of 17.5 months (range 1.6-64.1), estimated 2 year failure-free survival rate was 92% (95% CI 87.7-96.3) in OAW and 88.3% (95% CI 83.2-93.4) in ETW (hazard ratio 1.056, 95% CI 0.58-1.92). The grade 3 or 4 toxicities were similar between two arms, but leucopenia and thrombocytopenia were significantly higher in OAW compared with ETW (24.8% vs 15.9%, P = 0.015 and 5.2% vs 1.1%, P = 0.01, respectively). Stomatitis (35.2% vs 32.6%, P = 0.576), leucopenia and nausea/vomiting (11.2% vs 12.5%, P = 0.684) were the most commonly observed grade 3 or 4 toxicities during both OAW and ETW arms. **Conclusions:** Weekly regimen of cisplatin as CCRT shows similar treatment efficacy but increased toxic effect of leucopenia and thrombocytopenia compared with 3-weekly schedule in LANPC. Longer follow-up is needed to fully assess prognosis and late toxicities. Clinical trial information: ChiCTR-TRC-12001979.

6007 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III randomized trial comparing weekly versus three-weekly (W3W) cisplatin in patients receiving chemoradiation for locally advanced head and neck cancer. *First Author: Vanita Noronha, Tata Memorial Hospital, Mumbai, India*

Background: Chemoradiation (CRT) with cisplatin 100mg/m^2 given 3-weekly is the standard of care in locally advanced head and neck squamous cell cancer (HNSCC). Substituting low dose weekly cisplatin has pharmacological rationale due to lower toxicity and enhanced radiosensitization but has never been compared to 3-weekly cisplatin. **Methods:** Phase III non-inferiority trial (CTRI/2012/10/003062) in patients with Stage III or IV (non-metastatic) HNSCC planned for radical CRT. Pts were stratified for T-category, N-category and intent of therapy (adjuvant versus definitive) and centrally randomized 1:1 to cisplatin 30mg/m^2 weekly or 100mg/m^2 3-weekly concurrently with radiotherapy. Primary endpoint was locoregional control (LRC); secondary endpoints included toxicity, compliance, response, progression-free survival and overall survival. The upper boundary of non-inferiority margin was set at 15%, assuming LRC of 60% with power 80% and alpha 0.05. **Results:** 300 pts were randomized,150 to each arm; median age 44 years (range: 25-67), males 89%; 71% were smokeless tobacco users. 61% were T4, 71% > N2. 93% pts received CRT as adjuvant therapy for high-risk disease; indication was perinodal extension in 84%, close/ positive margins 8%. Median total treatment time was 86 days (IQR: 79-95). Median RT dose was 60 Gy (IQR 60-60 Gy) using shrinking field technique. In the weekly arm, 133 pts (88.7%) received > 6 cycles; 14 (9%) required dose reduction, median cumulative cisplatin dose 210 mg/m^2 (IQR 180-210). In the 3-weekly arm, 143 pts (95%) received > 2 cycles, median cumulative cisplatin dose 300 mg/m^2 (IQR 200-300); 12 (8%) required dose reduction. At a median follow up of 20 months (range: 1-49), locoregional relapses (LRR) occurred in 42.2% pts in the weekly arm and 29.6% pts in the 3-weekly arm, leading to an absolute difference in LRR of 12.7% (95%CI:1.89-23.41), p=0.035 by Gray's test, HR-1.58 (95% CI:1.02-2.46). Acute > grade 3 toxicity occurred in 85.3% pts in 3-weekly arm and 70.7% pts in weekly arm, p=0.002; 30.7% pts in the 3-weekly arm and 14% patients in the weekly arm required hospitalization for management of toxicity, p=0.001. **Conclusions:** 3-weekly cisplatin leads to 42% relative reduction in locoregional recurrence; it is superior to weekly cisplatin and should be the preferred regimen in CRT for HNSCC. Clinical trial information: CTRI/2012/10/003062.

6008 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Post-operative concurrent chemo-radiotherapy versus post-operative radiotherapy in high-risk cutaneous squamous cell carcinoma of the head and neck: A randomized phase III trial (Trans Tasman Radiation Oncology Group 05.01 Trial; POST study). *First Author: Sandro Virgilio Porceddu, University of Queensland, Brisbane, Australia*

Background: We report on the first multi-centre randomized phase III trial of post-operative radiotherapy (PORT) vs post-operative chemo-RT (CRT) in high-risk cutaneous squamous cell carcinoma of the head and neck (cSCCHN) (NCT00193895). **Methods:** The primary objective was to determine whether there was a freedom from loco-regional relapse (FLRR) difference between patients randomly assigned to 60-66Gy (6-6.5 weeks) with or without weekly carboplatin (AUC 2) following resection of gross disease. Patients were stratified to high-risk nodal (either extracapsular nodal extension, intra-parotid nodal disease of any size or number, cervical nodal disease with ≥2 nodes or largest node > 3cm) or high-risk primary (T3-T4 or in-transit metastases). Patients with both features were stratified to the high-risk nodal group. Secondary objectives included disease-free survival (DFS), overall survival (OS) and acute & late toxicity (CTCAE V3). **Results:** 321 patients were randomly assigned between 2005-2014, with 11 not commencing treatment protocol due to disease progression or withdrawal of consent. Of the 310 patients commencing treatment protocol (157 RT and 153 CRT), 230 (74%) had high-risk nodal, 70 (22%) high-risk primary and 10 (3%) both. Median follow up was 60 months, median RT dose was 60Gy and 85% randomised to CRT completed 6 cycles of carboplatin. The 2- & 5-year FLRR (95% CI) for the RT arm was 88% (83-93%)/83% (77-90%) and for CRT 89% (84-94%)/87% (81-93%) (HR 0.85; 95%CI [0.46-1.55]; p = 0.59). The 2- & 5 year DFS (95% CI) for the RT arm was 78% (72-85%)/67% (60-76%) and for CRT 83% (77-89%)/73% (66-81%) (HR 0.85; 95%CI [0.55-1.29]; p = 0.43). The 2- & 5 year OS (95% CI) for the RT arm was 88% (83-93%)/76% (69-84%) and for CRT 88% (83-94%)/79% (72-86%) (HR 0.95; 95%CI [0.58-1.57]; p = 0.84). 134 (43%) experienced Grade 3/4 skin toxicity; 49% RT, 37% CRT (p = 0.039). 12 (3.9%) experienced Grade 3/4 subcutaneous fibrosis; 2.5% RT, 5.2% CRT. **Conclusions:** While surgery and PORT provided excellent FLRR with acceptable toxicity, the addition of weekly carboplatin did not improve outcomes in high-risk cSCCHN. Clinical trial information: NCT00193895.

6009 Clinical Science Symposium, Tue, 8:00 AM-9:30 AM

Genomic determinants of response to pembrolizumab in head and neck squamous cell carcinoma (HNSCC). *First Author: Robert I. Haddad, Dana-Farber Cancer Institute, Boston, MA*

Background: Somatic mutational load (ML) is associated with response to anti CTLA-4 and PD-1/-L1 immunotherapies in select tumors, due to formation of neoepitopes not subject to central immune tolerance. Neoepitopes specific to HPV, EBV virus infection are also present in some HNSCC. An IFNγ gene expression profile (GEP) characteristic of tumor inflammation is also related to response to anti PD-1/-L1 therapy. This study evaluated relationships between ML and clinical outcome and independent predictive values of ML and GEP in patients with HNSCC treated with pembrolizumab. **Methods:** Whole exome sequencing (WES) and GEP were assessed in FFPE tumor specimens of patients with HNSCC (KEYNOTE 012; subsets of B1 [PD-L1$^+$, n = 34] and B2 [PD-L1$^+$/$^-$, n = 73] cohorts). ML, neoantigen load (NL), HPV/EBV status and clonality were assessed by standard WES analytical methods. GEP score is a weighted sum of normalized expression values of 18 genes. Statistical testing of ML and response, and ML and GEP relationship by HPV/EBV status was prespecified. **Results:** There were 73 patients identified as HPV$^-$ and EBV$^-$ (n = 25 in B1; n = 48 in B2). In HPV$^-$ and EBV$^-$ patients in B1 and B2 cohorts, respectively, associations between ML and objective response (OR) (P = 0.029 and 0.055; AUROC 0.89 and 0.63), and GEP and OR (P = 0.064 and 0.01; AUROC 0.82 and 0.74) were statistically significant. In combined cohorts of HPV$^-$ and EBV$^-$ patients, ML and GEP were significantly associated with OR (P = 0.009 and 0.002; AUROC 0.70 and 0.76, respectively). ML and GEP were only weakly correlated (r = 0.173). In a joint model, ML was significantly associated with response (p = 0.020) after adjusting for GEP (also significant, p = 0.006). NL and clonality weighted ML were also significantly associated with response (P = 0.026 and 0.006, respectively). In HPV$^+$ or EBV$^+$subjects, OR association was not significant for ML, possibly due to a dominance of viral vs somatic neoepitopes; GEP was significant, likely due to tumor inflammation. **Conclusions:** ML and GEP are independently predictive of response to pembrolizumab in HPV$^-$/EBV$^-$ patients with HNSCC; GEP was predictive regardless of viral status. ML and GEP may have utility in characterizing responses to anti PD-1 therapies and novel cancer regimens in HNSCC. Clinical trial information: NCT01848834.

6010 Clinical Science Symposium, Tue, 8:00 AM-9:30 AM

Epacadostat plus pembrolizumab in patients with SCCHN: Preliminary phase I/II results from ECHO-202/KEYNOTE-037. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Indoleamine 2,3-dioxygenase 1 (IDO1) is a tryptophan-catabolizing enzyme that induces immune tolerance by T-cell suppression. IDO1 overexpression has been associated with poor survival in SCCHN. Epacadostat (E) is a potent, selective oral IDO1 inhibitor. ECHO-202/KEYNOTE-037 is an open-label, phase I/II (P1/2) study evaluating E plus PD-1 inhibitor pembrolizumab (P) in multiple tumor types. We report preliminary P1/2 efficacy, safety, and tolerability findings in the SCCHN cohort as of a 29OCT2016 data cutoff. **Methods:** Eligible adult patients (pts) had metastatic SCCHN and received ≥1 prior chemotherapy regimen that included a platinum agent. Prior checkpoint inhibitor therapy (tx) was not permitted, and pts with carcinoma of the nasopharynx or salivary gland were excluded. In P1 dose escalation (3+3+3), pts received E (25, 50, 100, or 300 mg PO BID) + P (2 mg/kg or 200 mg IV Q3W); MTD was not exceeded. E (100 mg BID) + P (200 mg Q3W) dosing was selected for P2 cohort expansion. Response was assessed in RECIST 1.1 evaluable pts. **Results:** A total of38 pts (P1, n = 2; P2, n = 36) were evaluated. Median age was 63 years, 87% of pts were men, 95% were white, and 66% received prior cetuximab. Of 36 efficacy-evaluable pts, 81% (n = 29) received 1–2 prior lines of tx and 19% (n = 7) received ≥3 prior lines of tx. ORR (CR+PR) and DCR (CR+PR+SD) for pts with 1–2 prior tx were 34% (2 CR, 8 PR) and 62% (8 SD), respectively; for pts with ≥3 prior tx, ORR and DCR were 14% (1 PR) and 43% (2 SD). Response was observed regardless of HPV status. At data cutoff, 9/11 responses were ongoing (range, 1+ to 563+ days). PFS and biomarker analyses are ongoing. The most common TRAEs in all 38 pts were fatigue (24%), nausea (11%), and decreased weight (11%). Grade ≥3 TRAEs occurred in 11% of pts; only increased amylase and lipase (both asymptomatic) were grade ≥3 TRAEs that occurred in > 1 pt. TRAEs led to discontinuation in 1 pt (increased amylase and lipase). **Conclusions:** In pts with advanced SCCHN, E + P was generally well tolerated and associated with encouraging response rates, particularly in pts with 1–2 prior lines of tx. A phase III SCCHN study is planned. Clinical trial information: NCT02178722.

6011 Clinical Science Symposium, Tue, 8:00 AM-9:30 AM

Safety of pembrolizumab with chemoradiation (CRT) in locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). *First Author: Steven Francis Powell, Sanford Health, Sioux Falls, SD*

Background: Pembrolizumab (pembro) is a humanized monoclonal antibody that blocks the programmed death receptor-1 (PD-1) interaction with its ligands (PD-L1, PD-L2). While pembro is approved for platinum-refractory, recurrent/metastatic SCCHN, its role in definitive therapy for LA-SCCHN is not yet defined. Here we present the safety results of pembro with cisplatin-based CRT for patients (pts) with LA-SCCHN (NCT02586207). **Methods:** 27 pts with oropharyngeal (OP), hypopharyngeal (HP), and laryngeal (L) stage III-IVB SCCHN (any HPV status) eligible for cisplatin-based, definitive CRT were enrolled from November 2015 to August 2016 as part of a safety cohort. Pembro was given at a fixed dose of 200 mg IV 4-7 days prior to initiation of CRT and then every 3 weeks during CRT (2 concomitant doses) and then following CRT for 5 additional doses. CRT consisted of weekly cisplatin 40 mg/m2 IV x 6 doses (240 mg/m2 maximum) given concurrently with radiation at a dose of 2 Gy once daily for 35 fractions (total 70 Gy). Safety was determined by the occurrence of CRT or pembro dose-limiting adverse events (AEs) and immune-related AEs (irAEs). Efficacy was defined as complete response (CR) rate on imaging or with salvage surgery at 100 days post-CRT completion. **Results:** 20 (74%) pts with OP HPV+ and 7 (26%) pts with HPV- (4 L, 2 OP, 1 HP) tumors were enrolled. 21 (78%) completed all planned doses of pembro. 3 discontinued due to irAEs (G2 peripheral motor neuropathy, G3 AST elevation, G1 Lhermitte-like syndrome). 3 discontinued due to protocol reasons (early neck dissection -2 pts, prolonged hospitalization-1 pt). All pts completed the full radiation dose (70 Gy) without significant delay (defined as > 5 days). 23 (85%) received the goal target dose of cisplatin (≥200 mg/m2). There was one pt death due to concurrent illness, unrelated to treatment. The study has been reopened with expansion cohorts of 34 HPV+ pts and 23 HPV- pts to evaluate efficacy. **Conclusions:** Pembro in combination with weekly cisplatin-based CRT is safe and does not significantly impair radiation or chemotherapy dosing. Efficacy of this combination is being explored further in this study and through larger phase III clinical trials. Clinical trial information: NCT02586207.

6012 Clinical Science Symposium, Tue, 8:00 AM-9:30 AM

Neoadjuvant pembrolizumab in surgically resectable, locally advanced HPV negative head and neck squamous cell carcinoma (HNSCC). *First Author: Ravindra Uppaluri, Brigham and Women's Hospital and Dana-Farber Cancer Institute, Boston, MA*

Background: Pembrolizumab has efficacy in metastatic HNSCC. We hypothesized that treatment intensification in surgically resectable HPV-negative, Stage III/IV HNSCC with neoadjuvant plus post-operative adjuvant (POA) pembrolizumab would be safe and reduce 1-year locoregional recurrence/distant metastases (LRR/DM) from 35% (historical: Cooper and Bernier NEJM 2004) to 15%. **Methods:** Phase II trial where all eligible patients received 1 dose of pembrolizumab (200 mg) prior to surgery and only those with high-risk pathologic features (HRPF: extracapsular extension/positive margin) were given POA cisplatin and radiation followed by pembrolizumab. PD-L1 staining was assessed by immunohistochemistry (9A11 antibody). **Results:** The study continues to enroll. Characteristics of 21 enrolled patients (pts) were median age 59 (32-87) yrs, tobacco use 81% (17 pts), clinical T2 (n = 2), T3 (n = 1), T4 (n = 18), and cN0/1 (n = 8), cN2 (n = 13). Preliminary analyses revealed five important findings: 1) No serious study drug-related AEs or unexpected surgical delays/complications, 2) No LRR/DM events in the first 10 patients with $>$ 1-year follow-up after surgery 3) HRPF rate of 38% (95% CI: 18%-62%) (expected: 80%), 4) 43% of pts (95% CI: 22%-66%) with pathologic treatment response to neoadjuvant pembrolizumab (definition: tumor necrosis and/or giant cell/histiocytic reaction to keratinous debris in $>$ 10% of tumor area), and 5) 48% of pts (95% CI:26%-70%) with clinical-to-pathologic downstaging. Pathologic treatment effect (TE) in $\geq$ 70% of the resected tumor or lymph node tissue area occurred in 6/21 pts (29%). Baseline tumor biopsies were PD-L1 positive ($>$ 1% of tumor cells) in 11/19 (58%) evaluable samples and in 7/8 (88%) evaluable pathologic responders. A significant correlation existed between baseline PD-L1 expression on tumor cells and pathologic treatment effect in the tumor (correlation coefficient: 0.72 and p = 0.0005). **Conclusions:** Neoadjuvant and adjuvant pembrolizumab was safe and well tolerated. We observed several lines of evidence supporting an anti-tumor effect in these pts with a single dose of pre-operative pembrolizumab. Further evaluation of this strategy is warranted. Clinical trial information: NCT02296684.

6013 Poster Discussion Session; Displayed in Poster Session (Board #1), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

The role of PET for predicting nodal response in locally advanced (LA) head and neck squamous cell carcinoma (HNSCC) treated with chemoradiotherapy (CRT): Results of a prospective multicenter trial. *First Author: Sandra Schmitz, Department of Head and Neck Surgery, St-Luc Hospital, Catholic University of Louvain, Brussels, Belgium*

Background: Controversy about neck management after CRT in patients with LA HNSCC persists due to low accuracy of CT/MR to asses the neck. As already demonstrated (Mehanna, NEJM 374, 2016), PET is an alternative to planned neck dissection (ND) thanks to its high negative predictive value (NPV). However, no conclusion could be drawn for patients (pts) with equivocal response (e.g. suspicion of residual disease on CT/MR but negative PET) because pathologic confirmation was lacking. **Methods:** Multicenter, prospective, nonrandomized trial including pts with LA HNSCC of oral cavity, oro- hypopharynx, larynx, staged N1, N2, N3, treated with CRT and evaluated 12 weeks after CRT by overall assessment (OA): clinical examination (CE), PET and CT/MR. ND was performed in incomplete regional response based on at least 1 positive evaluation method. Pathologic analyses (HE and KI67) were performed on ND samples. Primary objective was to determine the NPV and accuracy of PET as a single examination in the post CRT nodal assessment. Primary outcome was 2-year regional recurrence free survival rate (RRFSR). **Results:** 264/318 pts included completed full treatment and had post CRT OA. Median follow up was 40 months. No ND was proposed in 119 patients because of a negative OA; 145 patients had ND. The presence of viable cells was reported in 27 ND (18.6%). Sensitivity, specificity, PPV, NPV, accuracy of OA were 90.0%, 49.6%, 18.6%, 97.5%, 54.2% vs 69.7%, 75.3.%, 28.8%, 94.6%, 74.6% for PET alone. Kappa coefficient was of 0.838, indicating an almost perfect agreement. In pts with negative OA, RRFSR was 61.3% vs. 56.6% in pts with positive OA and ND (p=0.45). Using post CRT assessment with PET alone, RRFSR in pts with negative PET was 63.0% vs. 48.8% in pts with positive PET (p=0.04). Using PET assessment alone, 65/145 ND (44.8%) could have been avoided without compromising RRFSR. **Conclusions:** NPV using PET alone is 94.6%. Post CRT evaluation using only PET would have resulted in considerably fewer ND without jeopardizing neck control. PET alone is more accurate and more discriminant for predicting pts outcome. Clinical trial information: NCT00634777.

Validation of the pathological classification of lymph node metastasis for head and neck tumors (HNSCC) according to the 8th edition of the TNM Classification of Malignant Tumors (8th TNM). *First Author: Antonio Lopez-Pousa, Hospital Sant Pau, Barcelona, Spain*

Background: Changes in 8th TNM edition are a specific staging for p16 +oropharyngeal carcinoma and the inclusion of extracapsular spread (ECS) in N extension. We evaluate the improvement in prognostic capacity from the inclusion of the ECS in HNSCC patients treated with a neck dissection (ND). **Methods:** Retrospective study based on prospectively collected information of 1188 HNSCC patients (oral cavity, HPV-oropharynx, hypopharynx, or larynx) diagnosed from 1990 to 2013, treated with unilateral or bilateral ND and a minimum fw-up of 2 years. We performed 1820 ND: 410 radical, 1410 selective ND; 683 patients (60.1%) had bilateral ND. Mean lymph nodes/patient: 32.6 (SD 19.9, 7-118). In 157 cases (13.8%) ND was performed after radiotherapy (RT, n =71) or chemoradiotherapy (CHRT, n = 86) with a median interval of 8.5 weeks (6-10). 596 patients (52.4%) had post-operative RT (n=525) or CHRT (n=71). Mean fw-up: 5.6 years (SD 4.9): 213 patients (18.7%) had local failure, 158 (13.9%) regional failure, 172 (15.14%) metastases. **Results:** 570 patients (50.1%) had lymph node metastases, 288 (50.5%) with ECS. The 8th TNM produced upstaging of 20.9% of pN1 patients to pN2a (n=33), and of 58.4% of the patients classified as pN2 to pN3b (n=220). The 7th TNM Classification (7thTNM), 5-year cause-specific survival for pN2 (35.5%) was similar to pN3 (21.6%). In the 8th TNM, 5-year cause-specific survival for pN2 (53.3%) sits in an more intermediate position between pN1 (70.5%) and pN3 (24.0%). Five-year cause-specific survival for pN2 patients with ECS (n=217) was 22.4%, and for patients without ECS (n=157) was 51.4%. There were statistically significant differences in survival between the two reclassified groups (P=0.0001). pN1 patients in the 7thTNM did not show survival differences when stratified by the presence of ECS: 5-y SV: 63.5% for ECS (n=33), 70.5% for non-ECS (n=125) (p=0.838). **Conclusions:** Inclusion of ECS in the pathological classification of the 8th TNM Classification edition improved the prognostic capacity, as compared with the previous version, basically produced by the migration of 58.4% of pN2 in the 7th TNM to the new pN3b category

Dose escalation of radiotherapy (RT) for locally advanced head and neck carcinomas treated with concomitant chemotherapy (CT) and RT: Results of the GORTEC 2004-01 randomized trial. *First Author: Jean Bourhis, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

Background: Concomitant CT-RT is a well established standard of care (SoC) in locally advanced (LA) squamous cell carcinomas of the head and neck (SCCHN). While there is a well established dose effect relationship for RT alone in these cancers, it is not known whether this also applies to concomitant CT-RT. **Methods:** Patients were randomized between 75 Gy/7 weeks (Arm A) versus 70 Gy/35F in 7 weeks (Arm B). A sequential boost of 10 times 2.5 Gy after 50Gy/25F was given to the initial gross tumor volume (GTV) in Arm A. IMRT was used for arm A and 3D conformal RT for arm B. In both arms, patients (pts) received during RT 3 cycles of cisplatin at 100 mg/m2. Inclusion criteria were pts fit for receiving high dose cisplatin, non metastatic, non operated stage III-IV SCC of oral cavity, oro/hypopharynx. A 1:1 randomization was done by minimization on centers, N & T stages & GTV uni/bilateral. To detect a hazard ratio (HR) of 0.56 in locoregional (LR) control, inclusion of 310 pts was required to observe 109 LR progressions and achieve 85% power at 2-sided significance level of 0.05. **Results:** Between 2005 and 2015, 188 pts were randomized: 82% males, median age 58 years, 85% oropharynx. The accrual rate was slower than expected, due to the fact that IMRT became a SoC and was only allowed in arm A. As a consequence the trial was discontinued after inclusion of 188 patients. The majority of pts had stage IVa (73% vs 72%). All initial characteristics were well balanced between arms. The median follow-up was 4.7 years, not different between arms. Acute and late xerostomia were markedly improved in arm A (IMRT arm). The 1-year grade 0-1 salivary toxicity (RTOG) was 81% and 34% ($p< 0.0001$) in arm A and B respectively. At 3 years these rates were 92% vs 53% (p=0.0003). The increase of the dose to the GTV with IMRT did not transfer in a higher LR control probability with an adjusted HR of 0.88 [95%CI 0.51-1.52] (p=0.63). PFS, overall survival were not significantly different between the 2 arms. **Conclusions:** The dose escalation of RT to the GTV did not improve LR control in patients treated with concomitant CT-RT. This trial adds some new evidence level 1 in favor of IMRT in LA SCCHN. Clinical trial information: NCT00158678.

6016 Poster Discussion Session; Displayed in Poster Session (Board #4), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Randomised phase-III-trial of concurrent chemoradiation (CRT) for locally advanced head and neck cancer (stage III-IVB): Comparing dose reduced radiotherapy (63,6 Gy) with paclitaxel/cisplatinum to standard radiotherapy (70,6 Gy) with fluorouracil/cisplatinum. *First Author: Rainer Fietkau, Universitatsklinikum Erlangen, Department of Radiation Oncology, Erlangen, Germany*

Background: Concurrent CRT with 70.6 Gy is the standard treatment for locally advanced head and neck cancer (LA-SCCHN). There exist no prospective data on safety and efficacy of a reduced radiation (RT) dose. **Methods:** Pts with stage III-IVB LA-SCCHN were randomized 1:1 to receive 70.6 Gy with concurrent cisplatinum (20mg/m²/d IV on days 1-5 and 29-33) and fluorouracil (600 mg/m²/d CIV on days 1-5 and 29-33) (standard arm A) versus 63,6 Gy with intensified chemotherapy using concurrent cisplatinum (20mg/m²/d IV on days 1-4 and 29-32) and paclitaxel (20mg/m²/d IV on days 2, 5, 8, 11 and 25, 30, 33, 36) (experimental arm B). After a planned interim analysis recruitment was stopped due to statistical reasons. **Results:** Between 06/2010 and 02/2015 a total of 221 pts were randomized with 105 pts receiving treatment in arm A and 112 in arm B (4 pts dropped out). Median follow-up was 38 months. Pts' characteristics: Oral cavity (15%), oropharynx (54%), hypopharynx (28%), larynx (14%); 17 pts had more than one primary site; tumor stage: III (14%), IV (86%); HPV-status (p16) was positive in 20%, negative in 38%, currently pending in 42%. A total of 96 PFS-related events occurred. 3-year PFS (ITT) was 58% in the standard arm A and 48% in experimental arm B (p = 0.454). 3-year OS (ITT) was 64% in arm A and 59% in arm B (p = 0.688). 3-year rates of distant metastases, loco-regional recurrences and death were 10% vs 12%, 17% vs 21% and 15% vs 19% for pts in arm A and B, respectively. As for the p16-positive subgroup, 3-year PFS/OS were 77%/76% in arm A (n = 21) and 69%/80% in arm B (n = 22), respectively. Grade 3+ hematologic adverse events during therapy (arm A/arm B): Anemia 11%/4% (p = 0.038); neutropenia 40%/16% ($p < 0.001$); thrombocytopenia 8%/3% (p = 0.130). **Conclusions:** These preliminary results indicate that pts receiving concurrent CRT for LA-SCCHN did not benefit from a lower total RT dose of 63.6Gy despite intensified chemotherapy. However, in the subgroup of p16-positive pts a reduced RT dose may be sufficiently effective. Clinical trial information: NCT01126216.

Randomized, double-blind, placebo-controlled, phase II trial of first-line platinum/docetaxel with or without erlotinib (E) in patients (pts) with recurrent and/or metastatic (R/M) head and neck squamous cell carcinomas (HNSCCs). *First Author: William Nassib William, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In a single-arm, phase 2 study, we previously demonstrated that in pts with R/M HNSCC, cisplatin, docetaxel and E improved progression-free survival (PFS) compared to historical data (Kim et al., ASCO 2006). Herein, we evaluated this regimen in a single center, randomized, phase 2 trial. **Methods:** Pts with R/M HNSCC, with a performance status (PS) 0-2, were randomized (1:1) to receive up to 6 cycles of first-line chemotherapy with cisplatin 75 mg/m2 (or carboplatin AUC 6) and docetaxel 75 mg/m2 i.v. on day 1 every 21 days, plus placebo (P) vs. E 150 mg p.o. daily, followed by maintenance P or E until disease progression. The primary endpoint was PFS. With 120 pts, the study had 80% power to detect an improvement in median PFS from 3.0 to 4.9 months with a two-sided type I error rate of 0.1. **Results:** From 05/2010 to 07/2015, 120 pts were randomized to the P (N = 60) or E (N = 60) groups. All pts but one initiated treatment and were eligible for evaluation of the primary endpoint – 92 males; median age 62 years; 52 oropharynx, 40 oral cavity, 19 larynx, 8 hypopharynx cancer pts; 86 current/former smokers; 43 with recurrence within 6 months of completion of local treatment; 27 with prior exposure to EGFR inhibitors. Median PFS was 4.4 vs. 6.1 months for the P and E groups, respectively (hazard ratio [HR] 0.63, 95% confidence interval [CI] 0.42-0.95 months, p = 0.026). Response rates were 44% vs. 56% for P vs. E (p = 0.21). Median overall survival (OS) for P- and E-treated pts was 13.7 vs. 17.0 months (HR = 0.67, 95% CI 0.43-1.04, p = 0.07). Benefits from E on PFS and OS were more pronounced in pts with oropharyngeal tumors ($p \leq 0.05$ for interaction). In the E group, first-cycle rash grade 2-4 (34% pts) was associated with longer OS (HR = 0.40, p = 0.02). E-treated pts experienced a higher incidence of grade 3-4 adverse events (33.9 vs. 53.3%), including diarrhea (3 vs.17%), dehydration (5 vs. 15%), nausea (5 vs. 14%), rash (0 vs. 12%). **Conclusions:** This study met its primary endpoint. Addition of E to first-line platinum/docetaxel improved PFS and OS. This regimen may warrant further evaluation in randomized, phase 3 trials. Clinical trial information: NCT01064479.

Results of a phase II randomized controlled clinical trial comparing efficacy of cabazitaxel versus docetaxel as second-line or above therapy in recurrent head and neck cancer. *First Author: Amit Joshi, Advanced Centre for Treatment, Research and Education in Cancer, Tata Memorial Center, Mumbai, India*

Background: Cabazitaxel has shown activity in squamous cancer cell lines and in taxane resistant cell lines. Hence we planned a randomized phase 2 study to evaluate the efficacy and safety of cabazitaxel against docetaxel in recurrent head and neck cancer, post first line treatment. **Methods:** This was a phase 2 open label, investigator initiated, randomized controlled trial of Docetaxel (75 mg/m2) versus Cabazitaxel (20 mg/m2), in adult patients with head and neck cancer, ECOG performance status 0-2, with measurable disease, who have been exposed to at least one line of chemotherapy (CTRI/2015/06/005848). 1:1 central randomization was performed and chemotherapy was administered till progressive disease or until patient had intolerable side effects. The sample size of 92 (46 per group) was determined based on an assumption for a difference in disease control rate of 25%, an alpha of 0.05 and 80% power. The data was censored for analysis on 3rd March 2017. Primary analysis of disease control at 6 weeks (CR/PR/SD) was assessed and compared using the chi-square test. Progression free survival (PFS) and overall survival (OS) curves were estimated using the Kaplan-Meier method. Cox proportional hazard model was used for comparison of PFS and OS between the 2 arms. **Results:** 92 patients were accrued in the study with 46 in each arm. The disease control rate at 6 weeks was better in the docetaxel arm which was statistically significant over the cabazitaxel arm (13.6% versus 52.3%, p = 0.017). The median PFS was 21 days (95% CI 5.28-36.72 days) in the cabazitaxel arm versus 61 days (95% CI 16.21 to 105.79 days) in the docetaxel arm (HR = 1.466, 95% CI 0.923-2.328, p = 0.105). The median OS was 172 days (95% CI 111.78 to 232.22 days) in the cabazitaxel arm versus 188 days (95% CI 134.4 to 241.6 days) in the docetaxel arm (HR-1.408, 95% CI 0.738-2.688, p = 0.299). **Conclusion:** In this phase 2 study, docetaxel had a superior disease control rate at 6 weeks and PFS compared to cabazitaxel. Clinical trial information: CTRI/2015/06/005848.

6019 Poster Discussion Session; Displayed in Poster Session (Board #7), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Nivolumab (Nivo) vs investigator's choice (IC) for platinum-refractory (PR) recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN; Checkmate 141): Outcomes in first-line (1L) R/m patients and updated safety and efficacy. *First Author: Maura L. Gillison, The Ohio State University, Columbus, OH*

Background: In CheckMate 141, a randomized, phase 3 trial, nivo demonstrated superior overall survival (OS) and better tolerability in patients (pts) with PR R/M SCCHN compared with IC. Pts with SCCHN progressing within 6 mos of platinum in the primary treatment setting have dismal prognosis. We report outcomes in pts who were PR in the primary or adjuvant setting, and updated results in the overall population. **Methods:** Pts (N = 361) with PR R/M SCCHN were randomized 2:1 to nivo 3 mg/kg every 2 weeks or weekly IC (methotrexate, docetaxel, or cetuximab). Primary endpoint was OS estimated by Kaplan-Meier method. Cox proportional hazards models were used to estimate hazard ratios (HRs) and confidence intervals (CIs). Additional endpoints include objective response rate (ORR) and safety. Outcomes were analyzed overall and post hoc in pts who were PR in the primary/adjuvant setting and received nivo/IC as 1L R/M therapy. **Results:** Characteristics of the 78 (21.6%) pts who received nivo (n = 52) or IC (n = 26) in the 1L R/M setting were similar to the overall population.Nivo significantly improved OS vs IC among 1L R/M pts (median [95% CI]: 7.7 mo [3.1, 13.8] vs 3.3 mo [2.1, 6.4]; HR [95% CI] = 0.56 [0.33, 0.95]); 12-mo OS rate: 39.2% vs 15.4%. ORR was 19.2% for nivo vs 11.5% for IC in this subgroup. At 11.4-mo minimum follow-up, updated efficacy and safety in the overall population were similar to the primary analysis. Median OS (95% CI) was 7.7 mo (5.7, 8.8) for nivo vs 5.1 mo (4.0, 6.2) for IC; HR (95% CI) = 0.71 (0.55, 0.90); $P = 0.0048$. For nivo vs IC, the 18-mo OS rate was 21.5% vs 8.3% and ORR was 13.3% vs 5.8%. Nivo doubled the median duration of response vs IC (9.7 vs 4.0 mo). Grade 3–4 treatment-related adverse event rates for nivo vs IC were 15.3% vs 36.0% overall and 27.5% vs 32.0% for 1L R/M pts; there were no new deaths due to study drug toxicity. **Conclusions:** Nivo significantly improved OS and increased ORR vs IC in a 1L R/M subgroup, supporting its use as 1L therapy for pts with PR R/M SCCHN. Nivo continued to show a significant survival benefit and better tolerability vs IC in pts with PR R/M SCCHN. Clinical trial information: NCT02105636.

6020 Poster Discussion Session; Displayed in Poster Session (Board #8), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Nivolumab (Nivo) vs investigator's choice (IC) in patients with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN): Efficacy and safety in CheckMate 141 by prior cetuximab use. *First Author: Robert L. Ferris, University of Pittsburgh Medical Center Cancer Center Pavilion, Pittsburgh, PA*

Background: In CheckMate 141, nivo resulted in significantly prolonged overall survival (OS), favorable safety, and stable quality of life vs IC in patients (pts) with platinum-refractory (PR) R/M SCCHN. Cetuximab, a formal trial stratification factor, permits exploratory subgroup assessment. Outcomes by prior cetuximab use are described. **Methods:** CheckMate 141 was a randomized, open-label, phase 3 trial (NCT02105636) in which pts (N = 361) with PR R/M SCCHN were randomized 2:1 and stratified by prior cetuximab use to nivo 3 mg/kg every 2 weeks or IC of methotrexate, docetaxel, or cetuximab. The primary endpoint was OS; additional endpoints were progression-free survival (PFS), objective response rate (ORR), and safety. A multivariate analysis will explore influence of additional factors. **Results:** Nivo improved OS vs IC regardless of prior cetuximab, and improvement was greater in pts without prior cetuximab (Table). Median OS was longer for nivo vs IC in pts with PD-L1 expression $\geq$ 1% regardless of prior cetuximab, and in pts with PD-L1 expression $<$ 1% without prior cetuximab. Among pts with PD-L1 expression $\geq$ 1%, ORR was higher with nivo vs IC with/without prior cetuximab. PFS was similar regardless of prior cetuximab. Grade 3–4 treatment-related adverse event rates for nivo vs IC were 11.7% vs 40.9% with prior cetuximab and 15.4% vs 26.7% without prior cetuximab. **Conclusions:** OS and ORR improved with nivo vs IC regardless of prior cetuximab use, and the magnitude of benefit was greater in pts without prior cetuximab exposure. These results support the use of nivo for R/M SCCHN regardless of prior cetuximab use. Clinical trial information: NCT02105636.

	Without Prior Cetuximab		With Prior Cetuximab	
	Nivo (n = 93)	IC (n = 47)	Nivo (n = 147)	IC (n = 74)
Median OS (95% CI), mo	8.1 (5.3, 12.7)	4.7 (3.0, 7.2)	6.9 (4.9, 8.8)	5.2 (4.1, 6.8)
HR (95% CI)	0.55 (0.35, 0.86)		0.81 (0.57, 1.15)	
ORR, % (n/N)	17.2 (16/93)	4.3 (2/47)	10.9 (16/147)	6.8 (5/74)

PREDICTOR (UNICANCER GEP11): Randomized phase II study of preoperative afatinib in untreated head and neck squamous cell carcinoma (HNSCC) patients. *First Author: Christophe Le Tourneau, Institut Curie - Centre de Lutte Contre le Cancer (CLCC) de Paris, Paris, France*

Background: Afatinib, a pan-HER irreversible tyrosine kinase inhibitor, demonstrated limited antitumor activity compared to methotrexate in unselected recurrent and/or metastatic HNSCC patients (LUX-HN1, Machiels et al, Lancet Oncol 2015). The UNICANCER (GEP 11) PREDICTOR study's objective was to identify predictive and pharmacodynamic biomarkers of biological activity and efficacy of afatinib (EUDRACT N° 2010-024046-29). **Methods:** This open-label, randomized, multicentric, controlled, phase II study included untreated patients with operable T2-4N0-2M0 HNSCC of the oral cavity, pharynx and larynx, with a PS $<$ 2, adequate organ function and LVEF $>$ 50%. Patients were randomized (2:1) to: oral afatinib (A) 40mg/day (d) for 14-28d or no treatment (NT). Patients had pre-treatment tumor biopsies, tumor imaging, and PET CT scan, with a 2nd tumor imaging before surgery and a PET scan at D15. Adverse events were classified by NCI CTCAE criteria. Based on the biological primary endpoint of tumor reduction the sample size was designed to identify biomarkers associated with a 20% difference between the study arms. **Results:** 61 patients were included (A: 41/NT: 20). 2 patients in the NT arm were not analyzed (consent withdrawal, no surgery). 7 patients in arm A received $<$ 14d of treatment, including 6 patients with unacceptable toxicity. Afatinib-related toxicities were: grade (G)1 37%, G2 41%, G3 7%, G4 5%, and G5 0%. G$\geq$3 toxicities were mainly gastrointestinal. Partial responses (RECIST1.1) were observed in 3 patients (7.3%) in arm A versus none in the NT arm (p = 0.018). Progressive disease was not observed in arm A versus 3 (16.6%) in the NT arm. Partial responses on PET CT scan by PERCIST were observed in 15/31 evaluable patients (48%) in arm A versus 1/15 (6.7%) in the NT arm (p = 0.005). **Conclusions:** Afatinib given to HNSCC patients in the preoperative setting is safe and is associated with improved response according to RECIST1.1 and PERCIST compared to no treatment. Clinical trial information: NCT01415674.

6022 Poster Discussion Session; Displayed in Poster Session (Board #10), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Results of randomized phase II trial of dabrafenib versus dabrafenib plus trametinib in BRAF-mutated papillary thyroid carcinoma. *First Author: Manisha H. Shah, Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: BRAF mutations are present in ~44% of papillary thyroid carcinoma (PTC) and its role in development of PTC is well established. We hypothesized that dabrafenib (BRAF inhibitor) would have efficacy in BRAF mutated PTC and that combining it with trametinib (MEK inhibitor) would result in greater clinical efficacy than dabrafenib alone, through vertical inhibition of the RAF/MAP/ERK pathway and mitigation of potential mechanisms of resistance. **Methods:** Patients (pts) with BRAF mutated radioiodine refractory PTC who had evidence of disease progression within 13 months prior were randomized to Arm A (dabrafenib 150 mg PO BID) or Arm B (dabrafenib 150 mg PO BID + trametinib 2 mg PO qd). Cross-over to Arm B was allowed at time of progression. Responses were assessed by modified RECISTv1.1 every 2 months. Primary endpoint was objective response rate (ORR) (complete-, partial- and minor-response). With assumed true ORR of 15% vs 35%; and 90% power to identify the correct regimen as most promising, 26 pts were to be accrued in each Arm. **Results:** In this randomized phase 2 trial, 53 pts (median age 63 years, 38 females) were enrolled; 25% of pts had 1-3 prior therapy with multi-kinase inhibitors. Median follow up was 13 months. Preliminary efficacy results are outlined in Table. The treatment-related adverse events were similar to previously reported phase III clinical trial of these drugs in melanoma. **Conclusions:** Single agent dabrafenib, as well as combination of dabrafenib/trametinib are well tolerated therapies that result in similar high objective response rates with durable responses in pts with progressive BRAF-mutated PTC. BRAF-pathway targeted therapies provide novel treatment options. Clinical trial information: NCT01723202.

	Arm A (n=26) Dabrafenib	Arm B (n=27) Dabrafenib + Trametinib	p-value
Assessable pts (n)	22	24	
Partial response	10	9	
Minor response (MR)*	1	4	
Objective Response	11/22 (50%)	13/24 (54%)	0.78
Stable ds	9	10	
Progressive ds	2	1	
Median Progression Free Survival (months) (95% CI)	11.4 (3.8 – NR)	15.1 (11.7 –NR)	0.27
Median Duration of response (months)(95% CI)	15.6 (4.2 – NR)	13.3 (9.7 – NR)	0.87

*MR was defined as 20-29% decrease in the sum of diameters of target lesions; NR=not reached

Efficacy of dabrafenib (D) and trametinib (T) in patients (pts) with *BRAF* V600E–mutated anaplastic thyroid cancer (ATC). *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ATC is a rare, aggressive malignancy with a dismal prognosis. Median overall survival (OS) is $<$ 6 mo. Combined BRAF and MEK inhibition is efficacious in *BRAF* V600–mutated melanoma and lung cancer. One-fourth of ATCs harbor activating *BRAF* V600E mutations; thus, D (BRAF inhibitor) + T (MEK inhibitor) was evaluated as a treatment for pts with *BRAF* V600E–mutated ATC. **Methods:** In this phase 2, open-label trial (NCT02034110), pts with *BRAF* V600E mutations in 9 rare tumor types, including ATC, received continuous D (150 mg BID) + T (2 mg QD) until unacceptable toxicity, disease progression, or death. Eligible pts had advanced or metastatic cancer with no standard-of-care treatment options. The primary endpoint was investigator-assessed overall response rate (ORR). Secondary endpoints included duration of response (DOR), progression-free survival (PFS), OS, and safety. We report data from the ATC cohort. **Results:** 16 pts with *BRAF* V600E–mutated ATC had evaluable data with a median follow-up time of 47 wk (range 4-120 wk). *BRAF* V600E mutations were centrally confirmed in 15/16 pts. Median age was 72 y; all 16 pts had undergone prior tumor radiation and/or surgery and 6/16 pts (38%) had received $\geq$1 prior line of systemic therapy. Investigator-assessed confirmed ORR was 69% (11/16; 95% CI, 41%-89%), with 7/11 responses ongoing at the time of data cut. The Bayesian estimate of ORR was 69% (95% credible interval, 47%-87%) with a 100% probability that this ORR exceeded the 15% historical RR. Median DOR, PFS, and OS were not estimable due to insufficient progression and death events. Kaplan-Meier estimates of DOR, PFS, and OS at 12 mo were 90%, 79%, and 80%, respectively. The safety population comprised 100 pts enrolled in 7/9 histologies. Among all pts, 92% had an AE. Common AEs of any grade for all histologies were fatigue (38%), pyrexia (37%), and nausea (35%). In the ATC cohort, the most common grade 3/4 events were hyponatremia (19%), pneumonia (13%), and anemia (13%). **Conclusions:** D+T combination therapy significantly improved outcomes in ATC with a favorable safety profile. This regimen represents a clinically meaningful therapeutic advance for pts with advanced/metastatic *BRAF* V600–mutated ATC. Clinical trial information: NCT02034110.

6024 Poster Discussion Session; Displayed in Poster Session (Board #12), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Notch pathway inhibition with LY3039478 in adenoid cystic carcinoma (ACC). *First Author: Caroline Even, Institut Gustave Roussy, Villejuif, France*

Background: ACCs have high levels of Notch-1 receptor expression and activation. LY3039478 (LY) is an orally bioavailable selective Notch inhibitor (Notch 1-4). Here we report on safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity of LY in patients (pts) with ACC. **Methods:** Ongoing, multi-part, phase I trial enrolled pts with advanced or metastatic ACC, measurable disease, ECOG ≤1, and baseline tumor tissue. Eligible pts received LY 50 mg three times per week (TIW), on a 28-day cycle until disease progression. Safety assessments were based on CTCAE V4.0. Tumor responses were assessed using RECIST 1.1. Primary objectives are to confirm the recommended phase II dose of LY and document antitumor activity. Secondary objectives are safety and toxicity, PK and progression-free survival (PFS). Exploratory objectives include assessment for PET metabolic responses. **Results:** 22 pts have been enrolled and received LY 50mg TIW (13 men, 9 women; median age 60, range 41-82). All pts had metastatic disease; median treatment duration was 3 cycles (range 1-10) with 6 pts continuing on treatment. One pt had an unconfirmed partial response. Disease control rate (DCR) was 16/22 (73%), of which 4 pts had stable disease ≥ 6 months. In the overall group (n = 22) median PFS (mPFS) was 5.3 months (95% CI: 2.4, NE). mPFS was 7.7 (95% CI: 4.0, NE) for pts in second line (n = 7), while mPFS was 2.4 (95% CI: 1.1, NE) for pts in third line or more (n = 9). In pts without prior systemic therapy (n = 6) mPFS could not be estimated since 4 of those patients were censored. In preliminary analysis, 14 pts were assessed by PET, with 2 (14%) achieving partial metabolic response. Most frequent related adverse events (all grades) occurring in ≥20% of pts included diarrhea (55%), fatigue (45%), vomiting (36%), decreased appetite (27%), dry mouth (27%), and dry skin (23%). Grade 3/4 related treatment-emergent adverse events observed in more than one pt were diarrhea (n = 3) and squamous cell carcinoma of skin (n = 2). PK was assessed in 17 pts, with peak concentrations occurring approximately 2 hours post-dose. Biomarker and histologic analyses of pre and post treatment biopsies will be presented. **Conclusions:** LY showed activity (73% DCR) in ACC with a manageable safety profile. Clinical trial information: NCT01695005.

6025 Poster Session (Board #13), Mon, 1:15 PM-4:45 PM

An open-label, multicohort, phase I/II study to evaluate nivolumab in patients with virus-associated tumors (CheckMate 358): Efficacy and safety in recurrent or metastatic (R/M) nasopharyngeal carcinoma (NPC). *First Author: Jean-Pierre Delord, Toulouse University Cancer Institute IUCT-Oncopole, Toulouse, France*

Background: Treatment options for patients (pts) with R/M NPC are limited to palliative chemotherapy. NPC is often associated with the Epstein–Barr virus (EBV), a potential antigen for immune recognition, and high expression levels of the immune checkpoint receptor programmed death-1 (PD-1) and its major ligand PD-L1. Nivolumab disrupts PD-1–mediated signaling, restoring T-cell antitumor function. **Methods:** In CheckMate 358 (NCT02488759), PD-L1–unselected adults with R/M NPC, ECOG PS of 0–1, and ≤2 prior systemic therapies in the R/M setting were eligible to receive nivolumab 240 mg every 2 weeks until progression or unacceptable toxicity, as part of an ongoing multicohort study of 5 virus-associated cancers. Human papillomavirus-associated NPC and keratinizing squamous cell carcinoma (WHO Type 1) were excluded. Primary endpoints were objective response rate (ORR) and safety; secondary endpoints were duration of response (DoR), progression-free survival (PFS), and overall survival (OS). **Results:** Of 24 treated pts with R/M NPC, median age was 51 years, 88% were male, 62% were white, 88% were European, and 88% had EBV+ tumors. At a median follow-up of 26 weeks (range: 4–40), ORR was 20.8% and appeared to be higher in pts with no prior R/M therapy (Table). The disease control rate (ORR + SD) was 45.8%. Responses were observed regardless of PD-L1 or EBV status. Median PFS was 2.4 mo (95% CI: 1.5, NR); median OS was NR. **Conclusions:** Nivolumab demonstrated clinical activity and a manageable safety profile in R/M NPC, supporting ongoing research with nivolumab in this disease. Updated efficacy and biomarker data will be presented. Clinical trial information: NCT02488759.

Cost-effectiveness of nivolumab for treatment of platinum-resistant recurrent or metastatic squamous cell carcinoma of the head and neck. *First Author: Kate Carroll, University of California, San Diego Moores Cancer Center, San Diego School of Medicine, La Jolla, CA*

Background: The Checkmate 141 randomized trial found that patients with platinum-refractory, recurrent or metastatic (R/M) squamous-cell carcinoma of the head and neck (SCCHN) treated with nivolumab had significantly longer overall survival than those treated with standard, single-agent therapy. However, nivolumab is more expensive than standard treatment. We conducted a cost-effectiveness analysis of nivolumab for the treatment of R/M SCCHN. **Methods:** We constructed a Markov model to simulate treatment with nivolumab or other single-agent therapy (docetaxel, cetuximab, or methotrexate) for patients with R/M SCCHN. Transition probabilities including disease progression, survival, and toxicity were derived from clinical trial data, while costs (in 2016 US dollars) and health utilities were estimated from the literature. Incremental cost-effectiveness ratios (ICERs), expressed as dollar per quality-adjusted life-year (QALY), were calculated with values less than $100,000/QALY considered cost-effective from a healthcare payer perspective. We conducted one-way and probabilistic sensitivity analyses to examine model uncertainty. **Results:** Our base-case model found that treatment with nivolumab increased overall cost by $59,000 and improved effectiveness by 0.2443 QALYs compared to single-agent therapy, leading to an ICER of $241,100/QALY. In sensitivity analyses, the model was most sensitive to the cost of nivolumab and assumptions about survival. Nivolumab would become cost-effective if the cost per cycle decreased from $13,432 to $5,716. If we assumed that all patients alive at the end of the Checkmate 141 trial were cured of their disease then nivolumab was still not considered cost-effective (ICER $160,000/QALY). Probabilistic sensitivity analysis also demonstrated relative stability of the cost-effectiveness model and found that treatment with nivolumab was cost-effective 0% of the time at a willingness-to-pay threshold of $100,000/QALY. **Conclusions:** While nivolumab significantly improves overall survival, at the current cost it would not be considered a cost-effective treatment option for patients with R/M SCCHN.

6027 Poster Session (Board #15), Mon, 1:15 PM-4:45 PM

Induction gemcitabine cisplatin followed by chemoradiation in locally advanced nasopharyngeal cancer. *First Author: Sadaf Usman, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan*

Background: The current standard of treatment in locally advanced nasopharyngeal cancer is concurrent chemoradiation, however recent addition of induction chemotherapy in the already established regimen has presented an attractive alternative approach. We report on survival with induction Gemcitabine and Cisplatin (GC) followed by chemoradiation (CRT) in the treatment of advanced nasopharyngeal carcinoma. **Methods:** Between 2005 and 2015, 300 patients (M 70%: F 30%) with histologically confirmed nasopharyngeal carcinoma. Histological subtypes WHO I 4% (13) and WHO III 96% (287). AJCC (7^{th} edition) stage was Stage III 28% (85) and Stage IV 72% (215) patients. IC included a 2 drug combination; intravenous gemcitabine 1000 mg/m^2 on day 1 and 8 and cisplatin 75 mg/m^2 on day 1 only. Radiotherapy was given as a phase treatment to a total dose of 70 Gy in 35 fractions. Concurrent three weekly cisplatin (75 mg/m^2) was administered to all patients. **Results:** Median follow up time was 30 months. The 5-year overall survival (OS), loco regional control (LRC) and relapse free survival (RFS) rates were 70% (95% CI 6.43 – 7.52), 69% (95% CI 6.52 – 7.64) and 52% (95% CI 5.25 – 6.34) respectively. One hundred and seven patients failed treatment; local or loco-regional 39% (42), regional 16% (17) and distant 45% (48). **Conclusions:** We conclude that induction gemcitabine and cisplatin followed by chemo-radiation is an effective regimen in management of nasopharyngeal carcinoma, meriting further investigation in randomized clinical trials.

6028 Poster Session (Board #16), Mon, 1:15 PM-4:45 PM

Nimotuzumab combined with cisplatin plus fluorouracil chemotherapy in patients with metastatic nasopharyngeal carcinoma after radical radiotherapy: A multicentre, open-label, phase II clinical trial. *First Author: Chong Zhao, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: Cisplatin plus fluorouracil (PF) is main therapy for metastatic nasopharyngeal carcinoma (NPC). However, the efficacy is not satisfactory, especially in patients with metastasis after radical radiotherapy. The purpose of this study was to investigate the efficacy and toxicity of Nimotuzumab combined with PF in patients with metastatic NPC after radical radiotherapy. **Methods:** Patients with untreated metastatic NPC after radical radiotherapy were recruited from 9 hospitals in China with Simon's two-stage design. All patients received Nimotuzumab (200mg/w) and cisplatin (100mg/m^2, day 1) plus fluorouracil (4g/m^2, day 1-4) every 3 weeks until progressive disease (PD) or unacceptable toxicity or a maximum of 6 cycles. If patients had still not progressed at this stage, Nimotuzumab (200mg/w) as monotherapy would be delivered until PD. This study was registered in ClinicalTrials.gov, Number NCT01616849. **Results:** Between Jun, 2012 and April, 2015, 35 patients were enrolled (Table). The objective response rate (ORR) and disease control rate (DCR) were 71.4% and 85.7%, and the median time of progression free survival (PFS) and overall survival (OS) were 6.97 and 11.01 months. The most common toxicities were leukopenia (94.1%), vomiting (97.1%) and nausea (97.1%); the grade 3/4 toxicities were leukopenia (62.9%) and mucositis (20.0%). There was only 1 patient have mild hypotension which related to Nimotuzumab. The ORR, DCR, median time of PFS and OS were 88.9%, 100.0%, 7.29 and 11.47 months in patients who received a total dose of Nimotuzumab $\geq$ 2400mg, respectively. **Conclusions:** Nimotuzumab combined with PF has achieved encouraging efficacy with an acceptable safety profile in metastatic NPC after radical radiotherapy. A phase III randomised study is needed. Clinical trial information: NCT01616849.

6029 Poster Session (Board #17), Mon, 1:15 PM-4:45 PM

Long-term survival in oligometastatic head and neck cancer patients. *First Author: Jonathan Eric Leeman, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Aggressive therapies for patients with oligometastatic disease are increasingly being administered with definitive intent in the context of clinical trials. However, outcomes in oligometastatic head and neck squamous cell carcinoma (HNSCC) patients have not been well characterized. **Methods:** We reviewed outcomes from 1147 patients who received intensity modulated radiotherapy (IMRT) as part of definitive management for stage I-IVB HNSCC from 2001-2013 at our institution. The primary sites included oropharynx (n=735), oral cavity (OCC, n=182), larynx (n=180) and hypopharynx (n=50). Among patients who developed distant metastasis (DM), the the number of clinically or radiographically apparent tumors was assessed. Survival estimates following DM were generated using the Kaplan-Meier method and compared using log-rank testing. Cox proportional hazards models were used for univariate (UVA) and multivariate analyses (MVA). **Results:** A total of 148 (13%) patients developed DM at a median time of 10.7 months (range 0.3-81.2) after IMRT. The median follow-up time following DM was 48 months. 5-year survival following DM was significantly longer in patients with a solitary metastatic lesion compared to multiple lesions (table 1, p=0.001). Of the 19 patients with solitary metastasis, the 14 who received definitive local therapy with either surgery or radiation survived longer than those who did not (5-year survival 55.7% vs 0%, p=0.001), though patients who did not receive local therapy were of poorer performance status. On UVA and MVA, longer survival after DM was associated with presence of a solitary metastatic tumor (MVA hazard ratio 0.31, 95% CI 0.16-0.59, p=0.001). **Conclusions:** An oligometastatic phenotype characterizes HNSCC patients with solitary metastasis, especially when amenable to definitive local therapy. These findings have important implications regarding clinical trial design for HNSCC in the recurrent and oligometastatic setting.

5-year survival following DM according to number of metastatic lesions.

# of metastatic lesions	N	5-year survival following DM (±Std. error)
1	19	39.1% (±12.6%)
2	31	7.9% (±5.3%)
3	20	5.7% (±5.5%)
4	11	0%
5+	67	0%

6030 Poster Session (Board #18), Mon, 1:15 PM-4:45 PM

Premilinary survival results and potential beneficiaries for locally advanced nasopharyngeal carcinoma treated with neoadjuvant chemotherapy followed by concurrent chemoradiotherapy. *First Author: Mei Feng, Sichuan Cancer Hospital, Sichuan, China*

Background: Neoadjuvant is a promising chemotherapy modality for recurrent nasopharyngeal carcinoma (NPC). However, there is still controversy for locally advanced NPC. We study the survival results of locally advanced NPC treated with neoadjuvant chemotherapy followed by concurrent chemoradiotherapy (NACT) retrospectively, and to explore the potential beneficiaries. **Methods:** 147 stage III-IVa+b NPC treated with IMRT were included and divided into two groups. NACT group (76) received 2-3 cycles of neoadjuvant chemotherapy with TP or TPF, and then 2-3 cycles of platinum-based chemoradiotherapy (CCRT). CCRT group (71) received 3 cycles of platinum-based chemoradiotherapy. TNM stage, age and whole blood count before treatment were all collected. The stratified analysis was used for distinguishing the potential beneficiaries. **Results:** median follow-up time was 30 months. For all patients, the 3-year LRRFS, DMFS and OS in NACT and CCRT were 94.5%, 96.8%; 85.8%, 82.8% and 81.6%, 83.4% respectively ($p>$ 0.05). For stage III patients, the 3-year LRRFS, DMFS and OS were 95.2%, 97.3%; 91.4%, 84.6% and 86.3%, 82.1% respectively (p= 0.38, p= 0.15, p= 0.58). Though there was no statistical significance, DMFS in NACT was better than it in CCRT. However, for stage IV, the survival rate had no significant difference. The incidence of grade 3-4 bone marrow suppression was higher in NACT (p= 0.007), and the other toxicities were similar. Univariate analysis showed the percentages of neutrophil and neutrophil-to-lymphocyte ratio (NLR) were significantly correlated with OS (p= 0.031, p= 0.049). N and clinical stage were the adverse prognostic factors for OS (p= 0.025, p= 0.007) and DMFS (p= 0.018, p= 0.001). Clinical stage was the prognostic factors for OS and DMFS in multivariate analyses (p= 0.019, p= 0.01). **Conclusions:** NACT had a comparable survival results and tolerable toxicity with CCRT for locally advanced NPC. Stage III might be the potential beneficiaries from NACT, especially for DMFS. Percentages of neutrophil and NLR might be the new adverse prognostic factor for OS. Clinical stage was still the prognostic factor for OS and DMFS.

6031 Poster Session (Board #19), Mon, 1:15 PM-4:45 PM

Impact of early trials in molecularly-characterized patients (pts) with head and neck cancer (HNC). *First Author: Neus Baste, Hospital Universitari Vall d'Hebron, Department of Oncology, Barcelona, Spain*

Background: Multiple genomic alterations were described in HNC, including squamous cell carcinomas (SCC), salivary gland (SG) and nasopharyngeal (NF) tumors. Tumor molecular profiling (TMP) may increase therapeutic alternatives in early trials for pts with refractory metastatic (met) HNC. We evaluate the impact of matched/unmatched therapy (mT/uT) in HNC with potentially targetable alterations. **Methods:** From 2010-16, 47 met HNC pts were treated in 57 early trials after TMP. Clinical benefit was measured by: time to progression (TTP); clinical benefit rate (CBR: complete response [CR], partial response [PR] and stable disease [SD] > 4months [m]); progression-free survival [PFS] ratio≥1.3 (PFS under molecular therapeutics/PFS upon last prior chemotherapy [pT]). **Results:** Median age was 51 years; median number of pT lines was 1 (0-5). In total, 26 SCC, 11 SG, 8 NF and 2 nasosinusal pts (mostly with lymph nodes and lung met) were treated with small kinases (SK) inhibitors (inh) (50%; main targets PI3K/HER/FGFR), immune-oncology (IO) drugs (40%, PD-1/PD-L1), angiogenesis inh (5%) or chaperone, cytidine analog, RNA polymerase (5%). 14/57 trials were mT including CDKinh (1 *CDKN2A* mutation [mut]), PI3Kinh (5 *PIK3CA* mut, 2 *PTEN* mut), PI3K/MEKinh (1 *NRAS* mut), HERinh (1 *ERBB3*mut), FGFRinh (2 *FGFR1*mRNA high, 1 FGF3/4/19 ligand amplified) and porcupine inh (1 *ZNFR3*mut). Distribution by tumor: IO (16 SCC/5 NF), SKmT (8SG/4SCC/2NF) and SKuT (9SCC/4SG). Responses: 1CR in SCC (IO), 5 PR in SCC (4 IO, 1 FGFRinh), 3 PR in NF (1 cytidin analog, 1 IO, 1 PI3K/MEKinh). Benefit: median TTP 9.33m (CI95% 7-20) with upward trend in NF and SG vs SCC (HR 0.6;p = 0.28), without differences according to target therapies (HR 0.8; p = 0.9); CBR of 58%, without differences by tumor type (p = 0.42) or therapy (SKmT, SKuT, IO; p = 0.5); 60% with PFS ratio≥1.3, significantly higher in SCC and SG (p = 0.016), particularly with IO drug and SKmT, respectively. **Conclusions:** Considering our preselected fit population as bias selection, individualized treatment selection with novel therapeutics based on TMP, especially in NF and SG irrespective of targets (SKmT, SKuT, IO), and in SCC with IO drugs, seems to confer substantial clinical benefit.

6032 Poster Session (Board #20), Mon, 1:15 PM-4:45 PM

A phase 1b/2 study of amcasertib, a first-in-class cancer stemness kinase inhibitor in advanced head and neck cancer. *First Author: Gregory Michael Cote, Massachusetts General Hospital, Boston, MA*

Background: Amcasertib (BBI-503) is an oral first-in-class cancer stemness kinase inhibitor. By targeting multiple serine-threonine stemness kinases, amcasertib inhibits Nanog and other cancer stemness pathways. A phase I clinical trial of amcasertib showed safety and signs of anti-cancer activity in patients (pts) with advanced solid tumors during dose-escalation and RP2D expansion, including pts with advanced head & neck cancer. **Methods:** Pts with advanced, pre-treated head & neck cancers were enrolled. Amcasertib was administered orally, once or twice daily, in continuous 28-day cycles at a starting dose of 10 mg to 300 mg total daily. Adverse events were categorized according to CTCAE v4.03 and tumor imaging was evaluated per RECIST 1.1 guidelines every 8 weeks. **Results:** A total of 21 pts were enrolled, 15 with HNSCC and 6 with salivary or parotid gland cancers. Prior treatments included radiation in 90% (19/21), surgery in 71% (15/21) and prior systemic therapy in 90% (19/21, average 3 prior lines, range 1 to 6). Amcasertib was well tolerated with 43% of pts treated at 300 mg daily (n = 9), 33% at 150 mg BID (n = 7), 19% at 200 mg daily (n = 4), and 5% at 10 mg daily (n = 1). Grade 3 AE included diarrhea (n = 4) and nausea (n = 1). Among all patients who received an evaluation per RECIST (n = 16), the objective responses rate (ORR, proportion with partial response [PR] or complete response [CR] per RECIST) was 13% and the disease control rate (DCR, proportion with stable disease [SD] at 8 weeks, PR or CR) was 50%. At 12 months, in the intent-to-treat population (n = 21) 38% of pts were alive. Median overall survival (mOS) of 7.2 months. **Conclusions:** Clinical safety and encouraging signs of anti-cancer activity were observed in pts with advanced head and neck cancers who have received treatment with amcasertib. Objective response, prolonged disease control, and extended survival have been observed in this pre-treated population with a poor prognosis. Further clinical evaluation of amcasertib in patients with head and neck cancers is warranted. Clinical trial information: NCT01781455.

6033 Poster Session (Board #21), Mon, 1:15 PM-4:45 PM

Treatment patterns in recurrent/metastatic head and neck squamous cell carcinoma in the US. *First Author: Eric S. Nadler, Texas Oncology, Dallas, TX*

Background: Given the most recent FDA approval of cetuximab in 2008 for treatment of recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC), the objective was to assess utilization of cetuximab and other treatments for R/M HNSCC in real world setting. **Methods:** Adult patients (pts) with R/M HNSCC who initiated systemic therapy between 9/1/2011-12/31/2014 were identified from iKnowMedelectronic health records database (McKesson Specialty Health) supplemented with chart abstraction. Pts were followed through 12/31/2015 to collect data on clinical characteristics, treatments and survival outcomes. **Results:** Among 325 pts with R/M HNSCC, median age was 62 yrs; 82% were male, and 67% had oropharyngeal cancer. The most common first line (1L) regimen consisted of platinum-based combinations (76%; Table 1); 63% received platinum+taxane +/-5FU and only 8% received platinum+cetuximab +/- 5FU. Median overall survival was 13.6 months (range 11.7-16.6). Following 1L therapy, 171 pts (53%) received a 2L regimen; 57 pts (18%) received platinum monotherapy and 8% received 2L platinum+taxane +/- 5FU, while only 12% received cetuximab mono- or platinum+ cetuximab + /- 5FU. Among pts receiving 1L platinum combination, 32% were re-treated with platinum based therapy of which platinum monotherapy (23%) and platinum+taxane +/- 5FU (7%) were most common. **Conclusions:** Despite FDA approval and NCCN guidelines recommending use of cetuximab for palliative treatment of R/M HNSCC, our study demonstrates underutilization in both 1L and 2L settings, underscoring the need to understand reasons for underutilization and the need for newer efficacious treatments.

1L Treatment, n (%)	N	No 2L Treatment	Platinum Mono	Cetuximab Mono	Platinum+ Taxane +/- 5FU	Taxane Mono	Platinum+ Cetuximab +/- 5FU

6034 Poster Session (Board #22), Mon, 1:15 PM-4:45 PM

A phase I clinical trial of AZD1775 in combination with neoadjuvant weekly cisplatin and docetaxel in borderline resectable head and neck squamous cell carcinoma (HNSCC). *First Author: Eduardo Mendez, Department of Otolaryngology: Head and Neck Surgery, University of Washington, Seattle, WA*

Background: The WEE1 tyrosine kinase regulates G2/M transition and maintains genomic stability. In TP53-deficient tumors (via mutation or HPV inactivation), inhibiting WEE1 with AZD1775 can lead to unrestrained mitosis and cell death. We conducted a Phase I clinical trial of AZD1775 in combination with chemotherapy to define the toxicity profile, establish the maximal tolerated dose (MTD) and assess preliminary efficacy in borderline resectable HNSCC. **Methods:** Stage III/IVB HNSCC deemed borderline resectable by a multidisciplinary team were enrolled in a phase 1, 3 + 3 design to evaluate escalating doses of AZD1775 starting at 125 mg PO BID x 2.5 days alone as lead-in and in combination with cisplatin (25mg/m2) and docetaxel (35 mg/m2) for three additional weeks. Tumors were sequenced with UWOncoPlex (262 cancer genes); HPV status assessed via p16 IHC; toxicities graded with CTCAE v. 4.04; responses measured via RECIST 1.1 and through pathologic assessment when available. Trial is open but primary endpoints were met. **Results:** Eleven patients were screened; 10 enrolled and were evaluable for toxicities. The most common Grade $\geq$ 2 toxicities were diarrhea (4), fatigue (4), neutropenia (3) and nausea (3). The drug-limiting toxicity was Grade 3 diarrhea (2). The MTD was established at 150mg PO BID x 2.5 days, alone and in combination with neoadjuvant cisplatin and docetaxel. Two patients were HPV+/TP53wt, 1 was HPV+/*TP53* mut; 6 were *TP53*mut/HPV-; 1 was TP53 wt/HPV-. Seven out 10 patients had a response. Two patients dropped out after the first week with AZD1775, one due to an allergic reaction to docetaxel and another due to non-compliance. Eight completed neoadjuvant therapy and 7 of those converted to surgery: 2 had pathologic CRs (both HPV+/TP53wt); 4 had PR (all TP53 mutants); 1 (TP53wt/HPV-) had a PR by RECIST, but SD by pathology and 1 had PD. **Conclusions:** AZD1775 is safe and tolerable in combination with neoadjuvant cisplatin and docetaxel. Results show this combination to have promising anti-tumor efficacy in borderline resectable HNSCC with TP53 deficiency, and merits further investigation with the established MTD as the recommended Phase II dose. Clinical trial information: NCT02508246.

6035 Poster Session (Board #23), Mon, 1:15 PM-4:45 PM

The impact of radiotherapy, in addition to chemotherapy, on overall survival in the initial management of patients with newly diagnosed metastatic head and neck squamous cell carcinoma. *First Author: Sujith Baliga, Montefiore Medical Center, Bronx, NY*

Background: The role of radiation therapy (RT) in the upfront management of patients with metastatic head and neck squamous cell carcinoma (HNSCC) is not clearly defined. In this study, we used the National Cancer Database (NCDB) to assess the association between RT use and overall survival (OS) for patients with metastatic HNSCC who received chemotherapy. **Methods:** We analyzed the NCDB to identify patients with newly diagnosed metastatic HNSCC from 2004-2013 who were treated with upfront chemotherapy. Associations between the use of RT and OS were evaluated using the Kaplan Meier method, univariate and multivariate cox regression, propensity score matching, and sequential landmark analysis. Survival outcomes were also compared for patients receiving a biologically effective dose (BED) $\geq$72 Gy_{10} and $<$ 72 Gy_{10}. **Results:** We identified 3,516 patients diagnosed with metastatic HNSCC who were treated with chemotherapy, of which 2,288 (65%) were also treated with RT. The median follow up was 11.9 months. The addition of RT to chemotherapy was associated with prolonged survival (median 13.6 *v* 11.3 months, logrank $p < 0.001$). On multivariate analysis, the use of RT remained associated with prolonged survival (HR = 0.71, 95% CI 0.61-0.82, $p < 0.001$). After propensity score matching, the addition of RT was associated with improved median survival (13.5 *v* 11.2 months) and 5-year (17% *v* 7%) OS compared to chemotherapy alone (log rank, $p < 0{\cdot}001$). Landmark analyses limited to patients who survived at least 3, 6, and 12 months after diagnosis continued to demonstrate improved OS with the addition of RT. Among patients treated with RT, the use of RT schedules with a BED exceeding 72 Gy_{10} was associated with prolonged survival (median 18.0 versus 11.7 months, logrank $p < 0.001$). **Conclusions:** For patients with metastatic HNSCC, the addition of RT to chemotherapy was associated with improved OS in this population based study. These results provide rationale for prospective randomized trials to validate these findings and to determine the optimal radiation therapy dose/fractionation and treatment schedule for these patients.

6036 Poster Session (Board #24), Mon, 1:15 PM-4:45 PM

A phase 1b/2 study of amcasertib, a first-in-class cancer stemness kinase inhibitor, in advanced adenoid cystic carcinoma. *First Author: Gregory Michael Cote, Massachusetts General Hospital, Boston, MA*

Background: Amcasertib (BBI-503) is an oral first-in-class cancer stemness kinase inhibitor. By targeting multiple serine-threonine stemness kinases, amcasertib inhibits Nanog and other cancer stemness pathways. A phase I clinical trial of amcasertib demonstrated safety and signs of anti-cancer activity in patients (pts) with advanced solid tumors. Cancer stemness pathways have been implicated in adenoid cystic carcinoma (ACC). An RP2D expansion cohort was opened for patients with ACC. **Methods:** Pts with metastatic, unresectable ACC for whom systemic therapy was indicated were enrolled. Amcasertib was administered orally, once or twice daily, in continuous 28-day cycles at a starting dose of 110 mg to 300 mg total daily. Adverse events were categorized according to CTCAE v4.03 and tumor imaging was evaluated per RECIST 1.1 guidelines. **Results:** 14 pts with ACC were enrolled. Prior treatments included surgery and radiation in all pts (100%), while 57% (n = 8) had received prior systemic therapy (average 2 prior lines, range 1 to 4). Treatment with amcasertib was well tolerated, with grade 3 diarrhea reported in 1 patient and no related grade 4 AEs. The disease control rate (DCR, proportion with stable disease at 8-weeks, partial response, or complete response per RECIST) was 86% (n = 12) with prolonged disease control (≥ 6 months) achieved in 57% (n = 8) patients. At 12 months, 79% of pts were alive. Median overall survival (mOS) was 28.3 months. **Conclusions:** Clinical safety and encouraging signs of anti-cancer activity were observed in pts with advanced ACC who received treatment with amcasertib. Long term follow-up demonstrates prolonged duration of disease control and that a majority of pts in this cohort have survived beyond 2 years. Further clinical evaluation of amcasertib in pts with ACC is warranted. Clinical trial information: NCT01781455.

6037 Poster Session (Board #25), Mon, 1:15 PM-4:45 PM

A phase II multicenter trial of the multitargeted kinase inhibitor sulfatinib in advanced medullary thyroid cancer (MTC) and radioiodine (RAI)-refractory differentiated thyroid cancer (DTC). *First Author: Jiaying Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Sulfatinib is an oral tyrosine kinase inhibitor targeting Vascular Endothelial Growth Factor Receptor (VEGFR), Fibroblast Growth Factor Receptor 1 (FGFR 1), and Colony Stimulating Factor 1 Receptor (CSF1R). In a proof of concept (PoC) phase II study, sulfatinib showed promising efficacy in patients (pts) with neuroendocrine tumors (NETs). **Methods:** This is an open label, two cohorts phase II study using Simon's two-stage design. In stage I, 15 pts will be enrolled in each cohort (advanced MTC or iodine-refractory DTC), and 10 more pts will be enrolled in a cohort in stage II if at least 2 PR observed in that cohort in stage I. Pts are required to have progressive disease in the past 12 months, but could not have received > 1 prior anti-angiogenesis therapy. Pts are treated with oral sulfatinib 300 mg once daily until disease progression, death, or intolerable toxicity. Primary endpoint is Objective Response Rate (ORR) by investigator per RECIST 1.1. **Results:** As of Dec 31 2016,the studyenrolled 18 pts (MTC: 6, DTC: 12), amongst whom 17 pts were efficacy evaluable. There were a total of 4 confirmed PRs, 1 in the MTC cohort and 3 in the DTC cohort, respectively. The others best response was stable disease (SD). 11 pts (61.1%) had dose interruption due to adverse events (AEs) and 5 pts (27.8%) had dose reduction. Two pts discontinued therapy (1 patient due to disease progression, another due to subject's decision). The most commonly reported AEs were proteinuria 72.2% (Grade 3-4: 22.2%), hypertriglyceridemia 50.0% (Grade 3-4: 0%), hypertension 44.4% (Grade 3-4: 16.7%), blood bilirubin increased 44.4% (Grade 3-4: 5.6%), and diarrhea 33.3% (Grade 3-4: 0%). No Grade 5 AE was reported by the time of data cut-off. **Conclusions:** Sulfatinib appears to be well tolerated in the pts with advanced MTC and RAI refractory DTC. Safety profile seems to be consistent to previous report, with mostly manageable AEs. Efficacy is encouraging in both indications. Further investigation is warranted. Clinical trial information: NCT02614495.

6038 Poster Session (Board #26), Mon, 1:15 PM-4:45 PM

Phase I study of the anti-HGF monoclonal antibody (mAb), ficlatuzumab, and cetuximab in cetuximab-resistant, recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Julie E. Bauman, University of Arizona Cancer Center, Tucson, AZ*

Background: Cetuximab, an anti-EGFR mAb, is approved for R/M HNSCC but only a minority benefits. Activation of cMet, the receptor for hepatocyte growth factor (HGF), overcomes EGFR inhibition in preclinical models and high serum HGF is associated with resistance in patients (pts). We conducted a phase I trial evaluating the combination of cetuximab and ficlatuzumab, an IgG1 anti-HGF mAb, in pts with cetuximab-resistant, R/M HNSCC. **Methods:** In this Narayana k-in-a-row phase I design, cetuximab 500 mg/m^2 was administered every 2 weeks. Ficlatuzumab dose tiers were 10 mg/kg (tier 1) or 20 mg/kg IV every 2 weeks (tier 2), with inter-patient escalation or de-escalation based on cumulative dose-limiting toxicities (DLT). The recommended phase II dose (RP2D) was set at tier 2 if no DLTs were observed after 8 enrolled pts; expansion continued to n = 12. Key eligibility criteria: R/M HNSCC; recurrence within 6 months of cetuximab-radiation or progression during/within 6 months of palliative cetuximab; ECOG PS 0-1. Candidate biomarkers included serum Veristrat, a proteomic classifier in lung cancer where "good" predicts benefit from anti-EGFR therapy and "poor" indicates resistance and poor prognosis. **Results:** From Sept 2015–June 2016, 12 pts were enrolled and treated. Primary site: 1 oral cavity; 3 oropharynx (1 p16+); 2 hypopharynx; 5 larynx; 1 external auditory canal. Platinum-refractory: 11/12. Veristrat: 8 poor; 4 good. Three pts were treated at tier 1 and 9 at tier 2. No DLTs were observed. Grade 3 adverse events included: edema (1), hypoalbuminemia (1), infection (2), thromboembolic event (2). Median PFS and OS at RP2D were 6.0 mos (90% CI = 2.0 mos–not reached) and 8.2 mos (90% CI = 2.7 mos–not reached), respectively. Response rate was 17% (90% CI = 0–28%): 2/12 partial response (PR); 1/3 at 10 mg/kg; 1/9 at 20mg/kg. Clinical benefit rate (PR + stable disease) was 67%. Veristrat was not associated with PFS. **Conclusions:** The RP2D is cetuximab 500 mg/m^2 and ficlatuzumab 20 mg/kg every 2 weeks. This well-tolerated combination demonstrated promising activity in pts with poor prognosis, cetuximab-resistant R/M HNSCC. Phase II testing is justified. Clinical trial information: NCT02277197.

6039 Poster Session (Board #27), Mon, 1:15 PM-4:45 PM

A pilot study of the pan-class I PI3K inhibitor buparlisib in combination with cetuximab in patients with recurrent/metastatic head and neck cancer. *First Author: Ryan J. Brisson, Oakland University William Beaumont School of Medicine, Rochester, MI*

Background: R/M HNC carries a poor prognosis with a median survival of 10-12 months. PI3K pathway aberrations are present in 30% of HNC. This pilot dose-escalation study assesses the safety and tolerability of the PI3K inhibitor buparlisib when given concurrently with cetuximab in R/M HNC, as well as assess efficacy in an expansion cohort. **Methods:** Patients (pts) with R/M HNC who were not amenable to curative intent therapy were enrolled. Pts were given oral buparlisib starting day -7 and daily thereafter. The dose of buparlisib was escalated in a 3+3 design (Level 1: 80mg daily, Level 2: 100 mg daily) followed by a dose expansion cohort. The maximum dose of buparlisib was 100 mg daily. Cetuximab (500mg/m^2) was given intravenously every 14 days starting day 0. Pts continued on treatment until progression of disease. Prior cetuximab failure was allowed. **Results:** Of the 12 pts enrolled, 10 had at least 2 previous treatment regimens (11 with prior cetuximab). 5 pts were HPV+, 4 were HPV-, and 3 had unknown HPV status. 3 pts were treated at the 80 mg dose level while 9 were treated at the 100 mg dose level (3 + 6 patient expansion). Treatment was well tolerated with 2 pts experiencing grade 3 adverse events (AEs) (no grade 4 AEs). The most common AEs were fatigue (83.3%), maculopapular rash (50.0%), and anorexia (50.0%). 3 pts experienced grade 1 anxiety. There were no SAEs. Of the 10 pts who were evaluable for response one patient achieved a PR (10%), and 4 achieved stable disease (40%) per RECIST 1.1. Median overall survival was 280 days (HPV+: 370 days, HPV-:191 days). The study was closed early due to poor enrollment on the expansion cohort as patients opted for concurrently open immunotherapy trials. **Conclusions:** Based on this pilot study, buparlisib plus cetuximab proved to be well-tolerated and showed limited evidence of activity in a heavily pre-treated patient population. Further research is warranted to determine activity of buparlisib in a larger cohort of R/M HNC. Clinical trial information: NCT01816984.

6040 Poster Session (Board #28), Mon, 1:15 PM-4:45 PM

A retrospective cohort study of PD-L1 expression in recurrent and/or metastatic squamous cell carcinoma of the head and neck (SUPREME-HN). *First Author: Sara I. Pai, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Patients with recurrent and/or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC) have a poor prognosis. Targeting the PD-1/PD-L1 axis has resulted in clinically meaningful antitumor activity and improved overall survival (OS) in R/M HNSCC patients. Tumoral PD-L1 expression correlates with response to blocking PD-1/PD-L1 antibodies. We investigated the prognostic value of PD-L1 expression in R/M HNSCC patients. **Methods:** Archival tumor samples from R/M HNSCC patients diagnosed between March 2011 and June 2015 at 12 institutions in 6 countries were stained for PD-L1 and clinic-demographic data were abstracted from medical records. Tumoral PD-L1 protein expression was assessed with the validated Ventana SP263 assay and scored as high ($\geq$25% of tumor cells [TC]) or low/negative ($<$ 25% of TC). Extracted data included demographic and tumor characteristics, treatment patterns, and clinical outcomes. Descriptive analyses were conducted and survival estimated by the Kaplan-Meier method. OS was defined from the diagnosis index date of R/M disease to time of death. **Results:** As ofSeptember 26, 2016 (interim analysis), data were available for 143 patients of whom 138 were eligible for analysis. Median age was 62.0 years (range, 28.0−88.0), 76.8% were male, and 84.0% were white. PD-L1 protein expression was high in 43 patients (31.2%), low/negative in 91 (65.9%), and unknown in 4 (2.9%). Median OS (8.2 vs. 8.8 months; P = 0.94) and progression-free survival (PFS) from the start of first-line (6.0 vs. 5.6 months; P = 0.29) or second-line therapy (7.1 vs. 1.8 months; P = 0.11) did not significantly differ between PD-L1 high and low/negative patients, respectively. There were no significant differences in OS based on PD-L1 status within subgroups defined by age, race, tobacco or alcohol use, primary tumor site, performance status, metastatic disease at diagnosis, or treatment with platinum-based chemotherapy. **Conclusions:** Interim analyses indicate that PD-L1 status is not associated with OS or PFS in R/M HNSCC patients.

6041 Poster Session (Board #29), Mon, 1:15 PM-4:45 PM

The negative predictive value (NPV) of FDG-PET/CT in the Head and Neck Squamous Cell Carcinoma (HNSCC) N0 patient, the first report of the ACRIN 6685 trial. *First Author: Brendan C. Stack, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: This study evaluated the negative predictive value for node negativity in HNSCC. **Methods:** Patients were enrolled from 8/10 until 12/16 from 38 centers in the US and 1 center in China. This was a prospective, non-randomized trial. The study was designed to recruit 292 patients; however, 287 were enrolled by study closure. Inclusion criteria were newly diagnosed cT2-T4 SCC patients from the head and neck with one side cN0 who were willing to undergo an elective neck dissection. CN0 was determined by a negative neck CT or MR scan. Exclusions included non-SCC, non-surgical candidates, skin, nasopharynx or sinus primaries. PET/CT imaging reading performed centrally and pathology were analyzed at the neck level (left or right). To estimate confidence intervals, we used a nonparametric bootstrap to account for the correlation of data between sides of neck of the same patient. Correlative data and other image analyses will be reported separately. **Results:** PET/CT scans and pathology were available for 211 (table) N0 sides of neck for review at last interim analysis. NPV estimate with 95% CI for bilateral necks: 0.896 (0.831, 0.950) and specific to the N0 sides: 0.922 (0.862, 0.973). **Conclusions:** FDG PET/CT has high NPV for node negativity in HNSCC. This may obviate the need for elective neck dissection in N0 HNSCC patients. This trial was open about three times longer than planned, and a major obstacle to accrual was the generalized assumption among the oncology community that PET/CT had a high NPV. Therefore, patients sent to study centers for further diagnosis and treatment often had their PET/CT scans performed on non-ACRIN certified equipment. This required investigators to forgo offering the trial or the PET/CT was repeated. Our results may suggest application for pre-operative PET/CT nodal imaging of other primaries/lymphatic basins staged cN0. Funding from the National Cancer Institute through the grants U01 CA079778, U01 CA080098, CA180820, CA180794. Clinical trial information: NCT00983697.

		FDG PET-CT Negative	FDG PET-CT Positive

Pathology	Positive	9	42

6042 Poster Session (Board #30), Mon, 1:15 PM-4:45 PM

Aspirin use and survival in head and neck squamous cell cancer (HNC) patients. *First Author: Hind Rafei, Department of Medicine, the George Washington University School of Medicine and Health Sciences, Washington, DC*

Background: The phosphatidylinositol-3-kinase (PI3K) signaling pathway is the most common genetic alteration in HNC, particularly in oropharynx cancers (OPC). Up-regulation of the PI3K pathway enhances the production of prostaglandins inhibiting apoptosis in cancer cells. We hypothesized that aspirin (ASA) improves survival in HNC patients (pts) by counteracting the effects of prostaglandins. **Methods:** This is an IRB-approved retrospective cohort study of 584 veterans with HNC treated at the Washington DC Veterans Affairs Medical Center between 1995 and 2015. Charts were reviewed for clinical-pathologic and treatment data; recurrence/distant metastases; cause of death; and for the number, date and dose of ASA prescriptions. Pts who filled more than one prescription, excluding refills, after diagnosis of HNC were considered ASA users. All others were considered non-ASA users. The Kaplan-Meier method and log-rank test were used to compare disease-free survival (DFS) and disease-specific survival (DSS) between users and non-users. **Results:** 332 pts met inclusion criteria. Primary subsites included oropharynx (n = 146), larynx (n = 105), oral cavity (n = 62), and hypopharynx (n = 19). 86 pts were ASA users after diagnosis (25.9%) and more likely to be older (p = 0.002), African American (p = 0.03), never-alcohol users (p = 0.044), and have early stage cancer (I/II; p $<$ 0.0005) compared to non-ASA users. Among all HNC pts, ASA users demonstrated significantly better 5-year (y) DSS (82%) compared to non users (43%; p = 0.009). 5-y DFS was also significantly higher among users (72%) vs non users (39%; p $<$ 0.001). Among the OPC pts, 5-y DSS was higher for ASA users (74%) vs non users (41%; p = 0.024). 5-y DFS was also better for users (72%) vs non users (39%; p = 0.004). For stages III and IV, 5-y DFS was significantly higher among ASA users (64%) vs non users (44%; p = 0.035). 5-y DSS was higher as well in users (69%) vs non users (44%) but p = 0.098. On multivariate analysis, aspirin use remained an independent prognostic factor associated with improved DSS and DFS when accounting for age, race, gender, subsite, stage, tobacco and alcohol use. **Conclusions:** Aspirin use following diagnosis and curative treatment of HNC is associated with improved DSS and DFS.

6043 Poster Session (Board #31), Mon, 1:15 PM-4:45 PM

Predicting response to radical (chemo)radiotherapy (R-CRT) with circulating HPV DNA and tumor DNA (ctDNA) analysis in locally-advanced head and neck squamous cell carcinoma (LAHNC). *First Author: Shreerang Bhide, The Royal Marsden Hospital, Sutton, United Kingdom*

Background: Following R-CRT for human papilloma virus positive (HPV+) and negative (HPV-) LAHNC, patients frequently undergo unnecessary neck dissection (ND) and/or repeated biopsies for abnormal PET-CT findings even in the presence of a complete pathological response (pCR), which causes significant morbidity. We assessed the role of circulating tumor DNA analysis in identifying patients with true residual disease. **Methods:** We prospectively recruited development (DC, n=55) and test (TC, n=33) cohorts of LAHNC patients having R-CRT. For HPV+ tumors we developed a novel amplicon based next generation sequencing assay (HPV-detect) to detect circulating HPV DNA and for HPV- tumors we used personalised droplet digital PCR assays of somatic mutations. Circulating tumor DNA levels at 12 weeks post-R-CRT were correlated to residual disease assessed by PET-CT and surgery. **Results:** In the DC (27 HPV+), baseline HPV-detect demonstrated 100% sensitivity and 93% specificity, confirmed in the TC (20 HPV+). 37 HPV+ patients (DC&TC) had complete samples-set. 36 had a negative HPV-detect at end of treatment, including 6 patients who underwent ND (3) and repeat primary site biopsies (3) for positive PET-CT but had pCR on surgical/biopsy specimen. 1 patient had positive HPV-detect and positive biopsy, indicating 100% agreement for HPV-detect and residual cancer. In a 10 HPV- patients with complete sample-set, there was 90% agreement between ctDNA and residual disease in HPV- tumors (3 ctDNA positive and tumor present, 1 ctDNA negative but tumor present, and 6 negative ctDNA negative tumor) with 80% sensitivity for residual disease and 100% specificity. Combined agreement between ctDNA testing (HPV+ and -) & residual disease was 98% (Table). **Conclusions:** Circulating HPV DNA quantified using HPV-detect and ctDNA identifies patients with residual disease post-R-CRT in LAHNC. Further studies are required to validate these findings.

		HPV detect/ctDNA		
Residual disease		Present	Absent	Total
	Present	4	1	5 (Sensitivity 80%)
	Absent	0	40	40(Specificity 100%)
	Total	4 (Positive predictive value 100%)	41 (Negative predictive value 97%)	45 (Accuracy 98%)

6044 Poster Session (Board #32), Mon, 1:15 PM-4:45 PM

Two-year clinical outcomes of de-intensified chemoradiotherapy for low-risk HPV-associated oropharyngeal squamous cell carcinoma. *First Author: Bhishamjit S. Chera, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: We here-in report 2 year cancer control outcomes from a prospective phase II clinical trial evaluating de-intensified chemoradiotherapy (CRT) for patients with favorable risk, HPV-associated oropharyngeal squamous cell carcinoma (OPSCC). **Methods:** The major inclusion criteria were: T0-T3, N0-N2c, M0, HPV or p16 positive, and minimal smoking history. Treatment was limited to 60 Gy intensity modulated radiotherapy with concurrent weekly intravenous cisplatin (30 mg/m^2). Patients neither received induction chemotherapy nor definitive surgery. The primary study endpoint was pathologic complete response rate (pCR) based on required biopsy of the primary site and dissection of pretreatment positive lymph node regions, regardless of radiographic response. Secondary endpoint measures included 2 year local control (LC), regional control (RC), cause specific survival (CSS), distant metastasis free survival (DMFS), and overall survival (OS), and patient reported symptoms (PRO-CTCAE) and quality of life (EORTC QLQ-C30 & H&N35). **Results:** Forty-four patients enrolled and the median f/u was 36 months (range 5-53 months, 93% with $>/=1$ year, 88% $>/=2$ years). We have previously reported the pCR to be ~ 86%. Two year LC, RC, CSS, DMFS, and OS are the following: 100%, 100%, 100%, 100%, and 95%. All 6 patients who had pathological partial responses are alive with no evidence of disease with a median f/u of 34 months (range 9-48 months). Two patients have died (stroke and glioblastoma). Mean pre and 2-year post EORTC QOL scores were: Global 80/82 (lower worse), Swallowing 11/10 (higher worse), Dry Mouth 16/54, and Sticky Saliva 6/33. 39% of patients required a feeding tube (none permanent) for a median of 15 weeks (5 - 22 weeks). Mean pre and 2 year post PRO-CTCAE (1 to 4 scale, higher worse) scores were: Swallowing 0.4/0.8 and Dry mouth 0.4/1.8. There were no $>/=$ Grade 3 late adverse events. **Conclusions:** The 2-year clinical outcomes with decreased intensity of therapy with 60 Gy of IMRT and weekly low-dose cisplatin are excellent in favorable risk OPSCC with evidence of better preservation of quality of life as compared to standard therapies. Clinical trial information: NCT01530997.

6045 Poster Session (Board #33), Mon, 1:15 PM-4:45 PM

Population assessment of head and neck cancer outcomes by race and HPV status in chance. *First Author: Siddharth Sheth, University of North Carolina, Chapel Hill, NC*

Background: Growing literature suggests that racial disparities exist in patients with head and neck squamous cell carcinoma (HNSCC). Currently, there are many hospital-based cohorts assessing racial disparities, however only a limited number of population-based cohorts exist. This study aims to explore the association between clinical characteristics and patient demographics with overall survival by race and HPV status. **Methods:** Patients were identified from the Carolina Head and Neck Cancer Study (CHANCE), a population based case-control study with enrollment from 2001-2006 in North Carolina. Vital status was determined by linkage with the National Death Index. Survival was considered at 5 years after diagnosis or study enrollment. We used Kaplan-Meyer analyses and Cox proportional hazards regression modeling to estimate adjusted hazard ratios (HR) and 95% confidence intervals (CI). **Results:** A total of 1361 HNSCC patients with no baseline metastasis and adequate survival time were identified. Of these, 1010 patients were white while 351 patients were black. Black patients were statistically more likely to be younger at age of diagnosis, have a history of tobacco or alcohol use, be uninsured, and not have completed high school (p-value < 0.001). In an unadjusted cox regression analysis, blacks had 1.50 times (95% CI 1.01-1.57) decreased overall survival than whites. Adjusting for gender, stage of disease, age, treatment, and smoking status, this relationship remained (HR 1.30, CI 1.1-1.6). In a subset analysis of male patients by disease site, there was decreased overall survival in black patients in oral cavity cases ($p < 0.01$). This relationship trended towards significant in pharynx cancer ($p = 0.054$) and was not found in laryngeal cancer. In pharyngeal cases only, there was decreased overall survival in black patients with HPV+ disease ($p = 0.03$) but not in HPV- cases ($p = 0.33$). **Conclusions:** This is the first population-based study that confirms racial disparities in HPV+ HNSCC. We also found worse overall survival prognosis for black patients with oral cavity cancer and a similar trend in pharynx cancer. Further studies are needed to evaluate if this difference is driven by either biological or socioeconomic factors.

6046 Poster Session (Board #34), Mon, 1:15 PM-4:45 PM

HPV status and survival in non-oropharyngeal squamous cell carcinoma of the head and neck. *First Author: Vanessa Wookey, University of Nebraska Medical Center, Omaha, NE*

Background: HPV positive squamous cell carcinoma of the oropharynx and tonsil has been associated with increased survival. However, the prognostic value of HPV status for other primary sites is unclear. We assessed the effect of HPV status on survival in patients with non-oropharyngeal head and neck squamous cell carcinoma at all stages. **Methods:** Data was obtained from the National Cancer Database (NCDB) to determine the effect of HPV status on overall survival (OS) in adults with non-oropharyngeal head and neck squamous cell carcinoma (gum, lip, floor of mouth, tongue (excluding base), hypopharynx and nasopharynx) using SAS software. Pearson's Chi square test was used for comparisons by HPV status. The Kaplan-Meier method was used to estimate OS and differences were compared using a log-rank test. A multivariate Cox proportional hazards regression model analysis was performed to determine effects of individual variables on outcomes. **Results:** Patients with all stages of squamous cell carcinoma of the gum, lip, floor of mouth, tongue (excluding base), hypopharynx and nasopharynx diagnosed from 2010 to 2013 with complete HPV data were included (n = 13,908). In univariate analysis, HPV positivity, female gender, Asian race, primary site (lip, tongue, nasopharynx and hypopharynx), private insurance and any treatment (except for chemotherapy alone) were associated with increased OS, whereas increased age, Black race, higher Charlson-Deyo comorbidity score, hypopharynx primary, and higher AJCC stage were associated with worse OS. After adjustment for covariates, HPV positivity was associated with improved OS (HR 0.83, 95% CI 0.74-0.93; $p < 0.001$). Female gender, gum, lip, nasopharynx primaries, and private insurance on multivariate analysis predicted for improved OS, while age > 70, higher Charlson-Deyo score and higher AJCC stage were associated with worse OS. **Conclusions:** HPV positivity and female gender are good prognostic factors in squamous cell carcinoma of the head and neck, independent of primary site. Trials evaluating de-escalation of treatment should be considered for HPV positive tumors from non-oropharyngeal sites in the head and neck region.

6047 Poster Session (Board #35), Mon, 1:15 PM-4:45 PM

Cellular immune biomarkers to prognosticate for survival to adoptive T-cell therapy in advanced nasopharyngeal cancer. *First Author: Han Chong Toh, Department of Medical Oncology, National Cancer Centre, Singapore, Singapore*

Background: We have published a Phase II clinical trial in 35 advanced incurable stage 4c NPC patients employing upfront first line chemo-immunotherapy of four cycles of gemcitabine and carboplatin, followed by six cycles of adoptive transfer autologous EBV-specific cytotoxic T lymphocytes (CTL). The 2- and 3-year overall survival rates were 62.9 and 37.1% respectively, which represent the best reported survival outcome for first-line treatment of advanced NPC when compared to historical clinical trials. **Methods:** From this Phase II trial, we completed serial multiple deep immune phenotyping analyses including flow cytometry, nanostring, and multiplex ELISA assays. We then investigated how these factors influence and determine successful therapy using 2-year survival rates. **Results:** Longitudinal modular transcriptome analysis of patient PBMCs revealed significant increases in T cell, NK, and B cell modules post chemotherapy within the 2-year survivor group. Administration of CTLs restored expression of lymphocyte transcripts in the non-survivor group at 2-weeks post infusion. However, as immunotherapy proceeded, 2-year survivors displayed significant increases in multiple lymphocyte module associated transcripts. These immune correlates were associated with increased IFN-γ and decreased myeloid chemokine concentrations in peripheral sera during immunotherapy in 2-year survivors. Longitudinal immunophenotyping of patient PBMCs at serial timepoints showed that 2-year survivors displayed significant decreased amounts of monocytic myeloid-derived suppressor cells (mMDSCs), compared to non-survivors after chemotherapy, which subsequently determined successful CTL immunotherapy survival benefit. **Conclusions:** This is the first report in human cancer patients that successful adoptive T cell immunotherapy correlates with lower mMDSCs following chemotherapeutic preconditioning. We have also identified potential prognostic immune biomarkers that effectively predicts efficacy of CTL immunotherapy, following upfront combination chemotherapy, and thus survival. Lymphodepletion with chemotherapy appears to be vital for adoptive T cell therapy efficacy.

6048 Poster Session (Board #36), Mon, 1:15 PM-4:45 PM

The impact of HPV infection on survival of patients with non-oropharyngeal head and neck cancer. *First Author: Samer Alsidawi, Mayo Clinic, Rochester, MN*

Background: The role of Human Papilloma Virus (HPV) infection in non-oropharyngeal squamous cell carcinoma (non-OPSCC) of the head and neck is unknown. Current available studies have yielded conflicting results due to limited number of patients. We present a large analysis from the National Cancer Database (NCDB) evaluating HPV-positive non-OPSCC. **Methods:** Using the NCDB registry, we included adults diagnosed with non-OPSCC from 2004-2012 with available HPV status. A cohort of patients with OPSCC was analyzed for HPV prevalence comparison. Survival analysis was performed using Kaplan-Meier method and stratified using HPV-status. The prognostic effect of variables was studied using Cox proportional hazards models. The JMP software was used for statistical analysis. **Results:** A total of 8726 non-OPSCC patients were identified and primary sites included the oral cavity (50%), larynx (41%) and hypopharynx (9%). 11% of non-OPSCC patients had evidence of infection with high-risk HPV strains compared to 61% of OPSCC patients. HPV-positive non-OPSCC patients presented at slightly younger age, had more advanced stage and higher tumor grade compared to HPV-negative patients ($P < 0.01$). HPV-positive non-OPSCC patients had better survival than HPV-negative patients (HR 0.82, 95% CI 0.72-0.93, $P < 0.01$) and this was most pronounced in patients with locally advanced disease (5-year survival 50% versus 40%, HR 0.69, 95% CI 0.6-0.8, $P < 0.01$). A univariate and multivariate analysis were performed adjusting for age, sex, race, stage, primary site, Charlson/Deyo comorbidity score, financial income, tumor grade, surgery, radiation and chemotherapy administration. Smoking history was unavailable. HPV positivity was an independent predictor of better survival in non-OPSCC in multivariate analysis (HR 0.69, 95% CI 0.59-0.8, $P < 0.01$). **Conclusions:** HPV infection is seen in a subset of patients with non-OPSCC head and neck cancer and these present with more advanced tumors. The survival of patients with HPV-positive non-OPSCC is significantly better than HPV-negative tumors. Routine HPV testing and enrollment in treatment de-intensification clinical trials similar to OPSCC might be appropriate for this patient population.

6049 Poster Session (Board #37), Mon, 1:15 PM-4:45 PM

Correlation of constitutive PD-1 resistance in HNC with GM-CSF expression and presence of myeloid derived suppressor cells (MDSCs). *First Author: Tanguy Y. Seiwert, University of Chicago, Chicago, IL*

Background: PD-1 checkpoint blockade is active in head and neck squamous cell carcinomas (HNC) with a response rate of ~18% and significant impact on survival. However, only a subset of patients benefits (Seiwert, Lancet Oncol). Biomarkers such as PD-L1 IHC and the Interferon-Gamma gene expression profile (INF-G GEP) identify inflamed tumors with a higher chance of response (~35-40%). However, it remains unclear why the majority of INF-G inflamed tumors still do not respond, or how to overcome constitutive resistance. **Methods:** 50 anti-PD-1 treated recurrent/metastatic HNC patients were included. Tumor RNA was analyzed using a 638-gene immune panel on the Nanostring nCounter. HPV status was assessed by HPV E6/E7 mRNA. T-cell inflamed phenotype was calculated using the 6-gene INF-G GEP (geometric mean) using both a low (6) and a high cutpoint. Differential gene expression was determined between inflamed-benefitting (IB) patients (defined as OS $\geq$ 250days), and inflamed-non-benefitting (INB) patients. Candidate biomarkers were evaluated in the entire cohort. **Results:** CD8 correlated highly with INF-G GEP ($R = 0.80$), suggesting T cell-driven inflammation. Comparing inflamed benefitting with inflamed non-benefitting tumors, the most differentially expressed gene was CSF-2, encoding GM-CSF, with 4-fold higher expression in inflamed non-benefitting (INB) tumors (with both cutpoints). In the overall anti-PD-1 treated cohort of 50 patients, CSF-2/GM-CSF correlated strongly with poor overall survival ($P = 0.02$), outperforming both HPV status, or PD-L1 expression in cox PH multivariate analysis. GM-CSF expression has been linked to myeloid derived suppressor cells (MDSC); MDSC marker CD34, as well as JAK2/IL10 were significantly elevated in inflamed non-benefitting (INB) tumors. There was no difference in M2 macrophage marker CD163 between the two groups. **Conclusions:** Constitutive resistance to PD-1 checkpoint blockade in inflamed HNC associates with expression of GM-CSF and Myeloid Derived Suppressor Cell (MDSC) markers. Strategies to deplete MDSCs, such as chemotherapy, should be considered in combination or sequentially with anti-PD-1.

6050 Poster Session (Board #38), Mon, 1:15 PM-4:45 PM

Characterization of potential predictive biomarkers of response to nivolumab in CheckMate 141 in patients with squamous cell carcinoma of the head and neck (SCCHN). *First Author: Fernando Concha-Benavente, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Nivolumab, an anti-programmed death-1 (PD-1) monoclonal antibody, demonstrated longer median overall survival (7.5 vs 5.1 months) and improved response (13.3% vs 5.8%) versus investigator choice chemotherapy (ICC) in patients with recurrent SCCHN after platinum failure in CheckMate 141 (NCT02105636), a randomized, open-label Phase 3 trial. We screened peripheral blood lymphocytes (PBL) to identify biomarkers which may predict response to nivolumab. **Methods:** Paired baseline (day 1) and on treatment (day 43) PBL samples ($n = 36$; 24 nivolumab; 12 ICC) were analyzed using multicolor flow cytometry and a non-competing anti-PD-1 antibody. Results were correlated with clinical outcome: responders (complete/partial response) and non-responders (stable or progressive disease). **Results:** Levels of CD8+ T cells at baseline and on treatment were higher in nivolumab responders compared to non-responders (23% vs 13%; $P < 0.05$). Interestingly, PD-1+ CD8+ and PD-1+ CTLA-4+ CD8+ effector T cells (likely exhausted T cells) decreased about 2-fold following nivolumab in both responders and non-responders ($P < 0.05$), whereas, the decrease in CTLA-4+ CD8+ effector T cells following nivolumab was significant in responders only (8% vs 5%; $P < 0.05$). Levels of PD-1+ TIM-3+ CD8+ effector cells decreased following nivolumab in non-responders only (11% vs 7%; $P < 0.05$), a similar non-significant reduction was observed in responders. Levels of PD-1+ Tregs were lower in responders than non-responders at baseline (19% vs 33%; $P < 0.01$), and following nivolumab (12% vs 20%; $P < 0.001$). As in T-effector cell populations, PD-1+ Tregs decreased about 1.6-fold after nivolumab in both responders and non-responders ($P < 0.01$). Interestingly, baseline Ki67+ Treg levels were lower in non-responders (28% vs 17%; $P < 0.05$). **Conclusions:** Response to nivolumab may be associated with higher levels of CD8+ T cells and CTLA-4+ CD8+ effector T cells, and lower PD-1+ CD8+ effector T cells and PD-1+ Tregs at baseline. Targeting both PD-1 and CTLA-4 axes is warranted in SCCHN to overcome suppressive signals in CD8+ effector T cells and in Treg cells expressing both checkpoint receptors. Clinical trial information: NCT02105636.

6051 Poster Session (Board #39), Mon, 1:15 PM-4:45 PM

Association of mannitol (MAN) with cisplatin (CIS)-induced nephrotoxicity (NTX) and cumulative CIS dose (CCD). *First Author: Sri Ramalingam, Medical College of Wisconsin, Milwaukee, WI*

Background: CIS is widely used in cancer therapy with CCD linked to survival outcome. CCD, however, is constrained by side effects—particularly NTX (incidence 20-30%). MAN is widely used to prevent CIS NTX despite low level of evidence. Herein, we took advantage of a national shortage of MAN to examine renoprotective effects of MAN in CIS treated patients. **Methods:** Between 2006-2012, 704 consecutive pts undergoing CIS therapy, with or without MAN, were analyzed. Pt characteristics, oncologic diagnosis, treatment, and renal function data were collected. The primary objective was to compare clinically significant NTX, as defined by $>$ 25% reduction in glomerular filtration rate (GFR) from baseline, between the treatment groups. Cox proportional hazards regression was used to model the hazard of NTX as a function of CIS dose. **Results:** Of 704 pts, 442 were treated with MAN and 262 without. The median age was 58.9 years. Age ($p = 0.83$), gender ($p = 0.77$), and race ($p = 0.056$) were similar between groups whereas baseline GFR (MAN 91.2 $\pm$ 22; CIS 86.3 $\pm$ 24; $p = 0.005$) and diagnoses ($p < 0.001$) differed. The distribution of diagnoses was: head and neck (25.9%), genitourinary (26.0%), lung (14.3%), gastrointestinal (10.4%), lymphoma (4.5%), and other (18.9%). The mean CIS dose (mg) per cycle in MAN versus CIS only group was 126.1 $\pm$ 58 and 109.3 $\pm$ 58 respectively ($p < 0.001$). The CCD (mg) was higher in the MAN compared to the CIS only group (469.8 $\pm$ 295 versus 299.0 $\pm$ 241; $p < 0.001$). After adjusting for baseline GFR, age, gender, race, and diagnoses, the MAN group experienced lower risk of $>$ 25% decrease in GFR at any given CCD (HR: 0.68, CI: 0.51-0.91, $p = 0.01$). Females (HR: 1.72, CI: 1.28-2.32; $p = 0.0003$), older pts (HR: 1.24, CI: 1.10-1.40; $p = 0.0003$), and Hispanic pts (HR: 2.39, 1.04-5.50; $p = 0.04$) were more likely to sustain $>$ 25% reduction in GFR. **Conclusions:** MAN enhances CCD by protecting against CIS-induced NTX. Pts with MAN experienced a lower risk of clinically significant acute kidney injury (AKI) and received a higher average CIS dose per cycle and CCD. Women, older pts, and Hispanic pts had a higher risk of AKI. Future investigation is warranted to examine whether MAN-associated CCD effects translate into survival advantages.

6052 Poster Session (Board #40), Mon, 1:15 PM-4:45 PM

Molecular signatures of class II HLA and p-16 status as an immune-based classification of OPSCC relying on known predictors of sensitivity to PD-1 blockade. *First Author: Nabil F. Saba, Winship Cancer Institute, Atlanta, GA*

Background: PD-1 inhibitors are known to have significant clinical activity in head and neck squamous cell cancer (SCCHN); there is, however, no selection criterion for SCCHN patients who may benefit from PD-1 inhibition. Utilizing RNA-seq analysis we explored a set of human genes encoding leukocyte antigens (HLAs) as part of a 37-gene panel predictive of response in melanoma patients to PD-1 inhibitors (Chen et al, Cancer Discov. 2016 Aug;6(8):827-37). We investigated whether this panel could define an immune-based classification of oropharyngeal squamous cell carcinoma (OPSCC). **Methods:** We have applied a minimal mutation and copy number content (151 genes) using an Agilent Clearseq DNA and an extensive Illumina Truseq RNA panel providing key information on gene fusions, differential gene expression, coding mutation and metagenomics on 47 SCCHN FFPE samples including 27 OPSCC. We performed an unsupervised hierarchical clustering of the samples. Two clusters with high and low expression were noted. Fisher's exact test was performed to determine if the samples in each clusters were associated with p16 as a surrogate marker for HPV status. The same procedure was repeated on Level 3 transcriptome data from the TCGA via GDC data portal. **Results:** A set of fourteen immune related HLA antigen genes were identified within the 37-gene panel predictive to response to PD-1 inhibitors in p16+ versus - OPSCC ($p = 0.015$).We applied the same set of immune related HLA genes on the 103 patient samples from TCGA with known p16 status. When applied on all samples, there was no correlation between the HLA gene expression and p16 status ($p = 0.1366$); however, when restricted to OPSCC patients there was a high correlation with p16 status ($p = 0.0047$). **Conclusions:** We have identified a set of immune related HLA type II genes that are over-expressed in p16 positive OPSCC. This opens the door for further evaluation of these genes to better understand the immune related factors affecting the biology of HPV-associated OPSCC and its response to PD-1 inhibitors. (This research was supported by a grant NCI R21 CA182661-01A1to NFS and GZC).

6053 Poster Session (Board #41), Mon, 1:15 PM-4:45 PM

IDO1 as a mechanism of adaptive immune resistance to anti-PD1 monotherapy in HNSCC. *First Author: Lori J Wirth, Massachusetts General Hospital, Boston, MA*

Background: Patients with recurrent/metastatic human papillomavirus-associated head and neck squamous cell carcinoma (HPV-HNSCC) demonstrate improved response rates to anti-PD-1 blockade, which may be attributed to the inherent inflammation associated with the local expression of foreign, highly immunogenic viral antigens. However, these response rates are at best 25%, suggesting there may be immune resistance networks that are limiting clinical responses to anti-PD-1 therapy. To address this question, we investigated other potential immune checkpoint pathways that may be upregulated in PD-L1 expressing HPV-HNSCCs. **Methods:** Using a custom microarray of 59 immune-related genes, we compared the gene expression profile of laser-captured micro-dissected PD-L1 (+) and (-) immune fronts in HPV-HNSCCs. Gene expression was validated using quantitative PCR (qPCR) and protein expression geographically localized using quantitative multiplex biomarker imaging in a separate cohort of HPV-HNSCCs. Furthermore, we assayed pre- and post-treatment biopsies from anti-PD-1 treated patients and correlated gene expression with clinical responses. **Results:** Of the immune-related genes, IDO1 was increased 65-fold in 10 PD-L1(+) as compared to 5 PD-L1(-) HPV-HNSCCs ($p = 0.004$). qPCR confirmed upregulated expression of IDO1 and quantitative immunofluorescence demonstrated that PD-L1 and IDO1 geographically co-localized within the tumor microenvironment in a validation cohort of 25 HPV-HNSCC patients. In anti-PD1 treated patients, IDO1 expression increased up to two-fold and correlated with disease progression in HNSCC patients. **Conclusions:** IDO1 is an immune checkpoint molecule that modulates T cell activity through the depletion of L-tryptophan. We propose that IDO1 is an adaptive immune resistance pathway to anti-PD-1 monotherapy. The results provide rationale for combinatorial therapies targeting the IDO1 and PD-1:PD-L1 networks in HNSCC patients.

6054 Poster Session (Board #42), Mon, 1:15 PM-4:45 PM

Association of DRB1 and DRBQ haplotype 04:01~03:01 with HPV positive head and neck squamous cell carcinoma. *First Author: Arun Khattri, The University of Chicago, Chicago, IL*

Background: The incidence of human papilloma virus (HPV) associated oropharyngeal head and neck cancer (HNC) is increasing rapidly in the US, Europe, and Asia. HPV16 is etiologic in 90-95% of HPV+ HNC. Sexual transmission and inability to clear infection leading to viral genome integration or chronic presence of episomal HPV16 DNA are precursors to HPV+ HNC carcinogenesis. However it remains unclear why a majority of HPV16 exposed individuals are able to clear the initial infection and avoid the risk of cancer. We hypothesized that difference in the ability eradicate infection may be mediated by certain HLA haplotypes. **Methods:** HPV(+) HNC patients from the TCGA cohort were HLA-typed based on available exome sequencing data. HLA typing was performed using the ATHLATES algorithm. We compared the distribution of alleles and haplotypes of classical HLA genes (A, C, B, DRB1 and DQB1) among HPV(+) HNC patients with those found in HPV(-) patients. Furthermore we evaluated enrichment of candidate alleles compared to publically available data in Caucasian non-cancer individuals. **Results:** Out of 528 HNC samples in the TCGA cohort, 450 were of Caucasian ancestry. The DRB1~DQB1 haplotype 04:01~03:01 was significantly increased in HPV(+) HNSCC patients compared to normal, non-cancer individuals (p-value = 0.0045, OR = 2.52, 95% CI = 1.2–5.03). This was not the case for HPV(-) HNC patients. The number of African American samples in TCGA was comparably small (N = 48, with N = 5 being HPV+) however the frequency of DRB1~DQB1 haplotype 04:01~03:01 in the general African American population is significantly lower. **Conclusions:** DRB1~DQB1 haplotype 04:01~03:01 associates with an elevated risk for HPV+ HNC. Similar findings were reported 17 years ago for cervical cancer (Br J Cancer, 82(7), 1348–1352), and further validate our findings across tumor types. Mechanistic studies to understand potential DRB1~DQB1 haplotype 04:01~03:01 HPV specific immune dysfunction, as well as evaluation in different risk and racial populations are indicated.

6055 Poster Session (Board #43), Mon, 1:15 PM-4:45 PM

Cell-free DNA for treatment monitoring and outcome predictor in head and neck cancer. *First Author: Julia Beck, Chronix Biomedical, Göttingen, Germany*

Background: Copy number instability (CNI) signatures of cancers can be readily detected by Next Generation Sequencing of plasma cell-free DNA (cfDNA). HPV detected in oropharyngeal carcinomas is currently the only prognostic biomarker available. We report here CNI scores for disease monitoring of Head and Neck Cancers (HNC) with potential predictive value for personalized therapeutic options. **Methods:** A total of 132 plasma samples were collected from 54 HNC patients under informed consent and IRB approval. cfDNA was extracted from plasma, ~20M paired-end NGS mappable reads (reference: HG19) per sample were generated and CNI scores were calculated by read counting statistics. After unblinding CNI scores were evaluated as diagnostic parameter for association with disease characteristics and progression. Survival analysis was conducted after dichotomization of baseline CNI scores at a value of 31 corresponding to the 97.5thpercentile of a normal reference group (RG, n = 141). **Results:** CNI scores above the 97.5th RG percentile were detected in 40 out of 54 (74%) treatment naïve baseline samples. 29 patients with tumors $\leq$ T3 (62%, n = 42) and 11 out of 12 (92%) with T4 tumors had CNI scores $>$ 31, with significantly higher CNI scores ($p = 0.04$) seen for T4 tumors. Higher CNI scores were also found in patients with tumor lymph node invasion (n = 37; median: 381, Q25-Q75: 57-1573) compared to negative lymph nodes (pN0, n = 17; 27, 19-64, p= 0.0004). A steep decline of CNI scores was detected after surgical resection, with increasing CNI scores in later disease progression. The pre-operative CNI scores were a stronger predictor of time to recurrence ($p = 7*10^{-5}$) than the pN status ($p = 0.05$) (Cox regression). High baseline CNIs ($>$ 31) strongly correlated with time to recurrence (Kaplan-Meier log-rank $p = 0.018$) with a median of 20 months and median overall survival of 30 months in the high CNI group, neither reached in the low CNI-score group (60 m follow-up). **Conclusions:** Chromosomal instability within HNC was quantified from plasma cfDNA as CNI score. The CNI score may serve as better predictor for the time to recurrence interval than pN status. The data suggests that cfDNA analysis as CNI score may serve as real-time marker of treatment efficacy and outcome.

6056 Poster Session (Board #44), Mon, 1:15 PM-4:45 PM

Poor-prognosis nasopharyngeal carcinoma as defined by a molecularly distinct subgroup and prediction by a miRNA expression signature. *First Author: Lan Zhao, City University of Hong Kong, Hong Kong, Hong Kong*

Background: Nasopharyngeal carcinoma (NPC) is a highly invasive and metastatic cancer, with diverse molecular characteristics and clinical outcomes. Our aim in this study is to dissect the molecular heterogeneity of NPC, followed by construction of a prognostic model for prediction of distant metastasis. **Methods:** For molecular subtyping of NPC using miRNA expression data, we selected 86 stage II (AJCC 7th Edition) NPC patients from GSE32960 as training cohort. The remaining 226 NPC patients from GSE32960 and 246 NPC patients from GSE70970 were used as two validation cohorts. Consensus clustering was employed for unsupervised classification of the training cohort. Classifier was built using support vector machine (SVM), and was validated in the two validation cohorts. Univariate and multivariate Cox regression analyses were employed for feature selection and constructing a prognostic model for predicting high-risk distant metastasis, respectively. **Results:** We identified three NPC subtypes (NPC1, 2, and 3) that are molecularly distinct and clinically relevant. NPC1 (~45%) is enriched for cell cycle related pathways, and patients classified to NPC1 have an intermediate survival; NPC3 (~19%) is enriched for immune related pathways, and has good clinical outcomes. More importantly, NPC2 (~36%) is associated with poor prognosis, and is characterized by upregulation of epithelial-mesenchymal transition (EMT). Out of the total 25 differentially expressed miRNAs in NPC2, miR-142, miR-26a, miR-141 and let-7i have significant prognostic power ($p < 0.05$), as determined by univariate Cox regression analysis. For identification of high-risk distant metastasis, we built a multivariate Cox regression model using the selected 4 miRNAs. Our model can robustly stratify NPC patients into high- and low- risk groups both in GSE32960 (HR 3.1, 95% CI 1.8-5.4, p = 1.2e-05) and GSE70970 (HR 2.2, 95% CI 1.1-4.5, p = 0.022) cohorts. **Conclusions:** We proposed for the first time that NPC can be stratified into three subtypes. Using a panel of 4 miRNAs, we established a prognostic model that can robustly stratify NPC patients into high- and low- risk groups of distant metastasis.

6057 Poster Session (Board #45), Mon, 1:15 PM-4:45 PM

FGFR3 correlation with mutant p53 and its prognostic value in oropharyngeal squamous cell carcinoma (OPSCC). *First Author: Zhuo Georgia Chen, Winship Cancer Institute, Atlanta, GA*

Background: Fibroblast growth factor receptor 3 (FGFR3) is expressed in squamous cell carcinoma of the head and neck (SCCHN) including oropharyngeal squamous cell carcinoma (OPSCC) and is a potential therapeutic target. Information on its prognostic value and its correlation with other relevant cancer related proteins is limited. **Methods:** We performed immunohistochemistry (IHC) analyses of p16, mutant p53 (mp53), and FGFR3 on 221 retrospectively collected OPSCC tissue samples. mp53, and FGFR3 were semi-quantified as weighted index [WI = % positive x intensity (0. 1+, 2+, and 3+)]. Correlations of FGFR3 WI with p16 status, and mp53 WI were analyzed. Association of FGFR3 with disease-free survival (DFS) or overall survival (OS) was assessed. **Results:** A total of 144/221 (65%) were p16 +, 93/172 (54%) had mp53, and 140/221 (63%) expressed FGFR3. FGFR3 was highly correlated with mp53 ($p < 0.001$), which was true in both p16 + and – OPSCC ($p < 0.0001$ and $p = 0.0006$, respectively).mp53 level was significantly lower in p16 positive *versus* p16 negative group ($p < 0.0001$). Univariate analysis revealed an association of p16 negative and high mp53 with worse OS ($p < 0.001$ and $p < 0.001$, respectively) and DFS ($p < 0.001$ and $p = 0.004$, respectively). FGFR3 was associated with worse OS and DFS ($p = 0.014$ and $p = 0.047$, respectively). On multivariable analysis FGFR3 was associated with worse DFS ($p = 0.005$), but not OS. Kaplan-Meier plot using medians of both FGFR3 and mp53 as the cut-off values showed that higher FGFR3 and mp53 correlated to worst DFS (p = 0.025) and OS (p = 0.009). **Conclusions:** Our results suggest that FGFR3 is associated with mp53 and p16 – OPSCC and correlates with worse clinical outcome. The biologic relation of FGFR3 and mp53 in OPSCC deserves further investigation. (This research was supported by a grant NCI R21 CA182661-01A1to NFS and GZC).

6058 Poster Session (Board #46), Mon, 1:15 PM-4:45 PM

Intact APM and PD-1:PD-L1 pathway upregulation in HIV-infected head and neck cancer patients. *First Author: Sara I. Pai, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: HIV-infected individuals have a higher incidence of oral infection with human papillomavirus (HPV) and possibly a higher incidence of head and neck cancer (HNC). Whether this observation reflects defects in the ability of this Òimmune-compromisedÓ patient population to mount sufficient tumor specific immune responses and/or reflects activation of immune escape mechanisms is not known. To address this question, we investigated the expression of HLA class I antigen processing machinery (APM) components and PD-1:PD-L1 pathway activation in HIV(+) HNC patients. **Methods:** 62 HIV(+) HNC patients diagnosed between 1991-2011 from five tertiary care referral centers in the United States and matched HIV (-) HNC controls were identified. HLA class I APM component, PD-1, and PD-Ll expression were analyzed by immunohistochemical staining. Clinical data was abstracted from the medical records. **Results:** 44 of 62 (71%) HIV(+) HNC cases were matched based on gender, age (< 10 years), and anatomic sub-site to HIV(-) HNC patients. There was no significant difference between the cases and controls in HLA-A, HLA-B/C, LMP2, and TAP1, as well as PD-1 and PD-L1 expression. Overall, 62% of all subjects had high PD-1 expression and 82% of the subjects expressed PD-L1. HLA-A, HLA-B/C, and LMP2 expression was significantly correlated with moderate to high PD-1 expression in the HIV(+) HNC cases (p = 0.004, p = 0.026, and p = 0.006, respectively) but not in the HIV(-) controls. Similarly, HLA-A expression was also significantly associated with PD-L1 expression only in the HIV(+) HNC cases (p = 0.029). **Conclusions:** No defects were detected in the expression of the HLA class I APM components tested. PD-1:PD-L1 pathway was found to be upregulated in both HIV(+) and HIV(-) HNC patients. Our data suggest that recently approved anti-PD-1 immunotherapy should not exclude HIV(+) patients.

6059 Poster Session (Board #47), Mon, 1:15 PM-4:45 PM

Comprehensive targeted next-generation sequencing to reveal limited clonal evolution after concurrent chemoradiation in patients with squamous cell carcinoma of the head and neck. *First Author: Inge Tinhofer, Department of Radiooncology and Radiotherapy, Charité Unversity Hospital and German Cancer Research Center Heidelberg (DKFZ)/German Cancer Consortium (DKTK), Berlin, Germany*

Background: Recent next-generation sequencing (NGS) studies revealed a wide mutational spectrum in SCCHN. However, little is known about spatial intratumoral heterogeneity and temporal clonal evolution. Precise understanding of the genomic architecture of primary and recurrent/metastatic (R/M) tumors will be crucial for the development of personalized treatment and molecular biomarkers. **Methods:** In this pilot study, paired tumor samples (primary, R/M lesions) from 10 patients with locally advanced SCCHN who progressed after concurrent chemoradiation (CTRX) were included. Mutational profiling was performed by NGS targeting the exonic regions of 327 genes. Only somatic mutant variants with a difference of $\geq$0.15 in allele frequency (AF) between primary and R/M tumors were considered for further analysis. **Results:** Median time to progression was 6.2 months (range: 2.5-30.2). Overall, the difference in mutational patterns of primary and R/M tissue was very small. On average, one mutant variant (range: 0-2) was selectively detected in only one of the paired samples or differed in AF for $\geq$0.15. Nonetheless, clonal selection of mutant variants previously linked to disease progression was observed in 8 of 10 cases. In line with their gain of function, an increase in AF of *TP53* missense mutations (R175H, R248Q) in the recurrent tumor - suggestive of the selection of treatment-resistant mutant *TP53* subclones - was observed in two patients. Further variants with increased mutant AF in recurrent tumors were found in *ADCY2*, *CDKN2A*, *FGFR3*, *MET*, *NOTCH1, PIK3CA* and *TGFBR2*. **Conclusions:** We here provide first evidence that treatment-induced clonal selection after CRTX frequently occurs in SCCHN but is limited to only few gene alterations associated with an aggressive phenotype. This result is surprising given CRTX being a DNA-damaging regimen with inherent risk of de-novo mutagenesis and abundant time for clonal tumor evolution. Further investigations of spatial intratumoral heterogeneity and clonal evolution in larger patient cohorts are required for improving our understanding of treatment resistance and disease progression in SCCHN.

6060 Poster Session (Board #48), Mon, 1:15 PM-4:45 PM

CDKN2A copy number loss in HPV- and HPV+ head and neck cancer to indicate poor prognosis: An integrated genomic and clinical TCGA analysis. *First Author: William S. Chen, Yale School of Medicine, New Haven, CT*

Background: HPV infection is associated with high p16 expression and relatively good prognosis in head and neck cancers. Analysis of CDKN2A, the gene that encodes the p16 tumor suppressor protein, may further elucidate the association between HPV status and prognosis in head and neck squamous cell carcinomas (HNSCCs). We aimed to identify whether CDKN2A copy number loss was associated with poor survival in HNSCCs stratified by HPV status. **Methods:** We analyzed The Cancer Genome Atlas (TCGA) head and neck cancer data, integrating genomic measurements with clinical metadata. Patients 85 years old or younger with a primary tumor in the oral cavity, oropharynx, hypopharynx, or larynx were included. Defining CDKN2A copy number loss as a relative log2 copy number ratio < -0.6, CDKN2A mRNA and p16 protein expression levels were compared to confirm significant differences in gene transcription and translation between the copy number loss and non-copy number loss patient groups. Overall survival (OS) and disease-free survival (DFS) were evaluated to characterize prognostic differences between genomic groups. **Results:** 397 patients negative for HPV (HPV−) and 91 patients positive for HPV (HPV+) HNSCC were identified. 139 HPV− patients and 9 HPV+ patients demonstrated CDKN2A copy number loss. The CDKN2A copy number loss group expressed significantly lower levels of CDKN2A mRNA and p16 protein than did the non-copy number loss group in both HPV+ and HPV− disease. Median OS for HPV− patients with and without CDKN2A copy number loss was 21.8 months and 46.0 months ($P = 0.02$). Median DFS was 12.0 and 19.4 months respectively ($P < 0.05$). Median OS for HPV+ patients with and without CDKN2A copy number loss was 12.7 months and 57.4 months ($P = 0.004$) and median DFS was 7.0 and 36.6 months respectively ($P = 0.02$). **Conclusions:** CDKN2A copy number loss was associated with low CDKN2A mRNA and p16 protein expression, with poor prognosis in terms of disease-free and overall survival.

6061 Poster Session (Board #49), Mon, 1:15 PM-4:45 PM

PTEN and cetuximab resistance in head and neck squamous cell carcinoma (HNSCC). *First Author: Alexandre Andre B. A. Da Costa, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Platinum-based chemotherapy in association to cetuximab is the standart first-line treatment for metastatic HNSCC. There is no established biomarker for cetuximab efficacy in HNSCC. We have previously shown that PTEN loss of expression is a bad prognostic factor for patients treated with platinum-based chemotherapy and cetuximab. The aim of the present study was evaluate the prognostic impact of PTEN loss of expression in patients treated with or without cetuximab and to evaluate its predictive value to cetuximab benefit. **Methods:** One hundred and nineteen patients with metastatic or locally recurrent HNSCC were included. Clinical data on treatment and outcomes was retroespectively colected from medical charts. Tissue micro-array was constructed to evaluate PTEN protein expression through immunohistochemistry. Citoplasmatic staining was evaluated using H-score. Tumors with H-score < 10 were considered to present PTEN loss of expression. **Results:** From the 119 patients 72 were treated with chemotherapy plus cetuximab while 47 were treated with chemotherapy alone. Median overall survival (mOS) was 9.2 months and median progression free survival (PFS) was 4.6 months. Patients treated with cetuximab compared to those who were not treated with cetuximab had a mOS of 11.4 vs 7.0 months ($p = 0.770$) and a median PFS of 6.2 vs 3.0 months ($p = 0.249$). Patients with PTEN loss of expression had a worse OS and PFS with mOS of 5.8 vs 10.5 months ($p = 0.002$) months and mPFS of 3.2 vs 5.2 ($p = 0.015$). On multivariate analysis including PTEN loss of expression and ECOG performance status both remained independently associated to survival with HR 2.25 (CI95% 1.28-3.97, $p = 0.005$) for PTEN loss of expression and a HR 1.63 (CI95% 1.07-2.50, $p = 0.023$) for ECOG. Negative prognostic impact of PTEN loss of expression was seen only in the cetuximab treated patients (mOS 7.3 vs 13.0 months; $p = 0.002$) but not in the chemotherapy only group (mOS 3.2 vs 7.5 months; $p = 0.051$). Interaction test for treatment group and PTEN loss of expression showed a $p = 0.418$. **Conclusions:** The present study confirms PTEN as a prognostic factor for metastatic HNSCC and suggests PTEN expression should be studied in larger cohorts to evaluate its predictive value to cetuximab response.

6063 Poster Session (Board #51), Mon, 1:15 PM-4:45 PM

A phase II randomized, multicentric clinical trail comparing recombinant human endostatin plus intensity-modulated radiotherapy versus concurrent chemoradiotherapy in locally advanced low-risk nasopharyngeal carcinoma. *First Author: Min Kang, Department of Radiation Oncology, The First Affiliated Hospital of Guangxi Medical University, Nanning, China*

Background: A prospective, randomized, and multicentric phase II study was performed to evaluate the short-term efficacy and safety of Endostar plus intensity-modulated radiotherapy (IMRT) versus concurrent chemoradiotherapy(CCRT) in locally advanced low-risk nasopharyngeal carcinoma (NPC). **Methods:** From September 2014 to August 2016, 120 patients with low-risk NPC at stages III-IVa from 9 centers were randomly divided into experimental group (Endostar plus radiotherapy (ERT); n = 60) and control group (CCRT; n = 60). ERT patients were given Endostar (7.5 mg/m^2/day) by continuous intravenous infusion (CIV) from 5 days before radiotherapy for consecutive 10 days for 2 cycles with an interval of 14 days. Then, ERT patients received 2 cycles of 10 days of maintenance treatment with Endostar after radiotherapy. The CCRT patients were given cisplatin (100 mg/m^2) on days 1, 22, and 43 for 3 cycles. Immediate and 3-month efficacy and adverse effects were evaluated between the two groups. ClinicalTrials registration number was NCT02237924. **Results:** All patients were eligible for toxicity and response analysis. Regarding immediate efficacy, the complete response(CR) rates were 45.0% for ERT arm and 33.3% for CCRT arm in nasopharynx ($P = 0.190$), and 43.3% for ERT arm and 36.7% for CCRT arm in regional nodes ($P = 0.456$). Three months after RT, the CR rates were 71.2% for ERT arm and 60.0% for CCRT arm in nasopharynx ($P = 0.151$), and 74.6% for ERT arm and 63.3% for CCRT arm in regional nodes ($P = 0.172$). The rate and severity of leukopenia, hemoglobin reduction and thrombocytopenia in ERT arm were significantly lower than CCRT arm ($P < 0.01$). The occurrence rates of Xerostomia, oral mucositis, nausea / vomiting, constipation and weight loss in ERT arm were significantly lower than those in CCRT arm ($P < 0.01$). **Conclusions:** The present study demonstrates that ERT has similar short-term efficacy on locally advanced low-risk NPC compared with CCRT, but the acute adverse effects of ERT are fewer, and the compliance and tolerability of patients are better. Clinical trial information: NCT02237924.

6064 Poster Session (Board #52), Mon, 1:15 PM-4:45 PM

Multimodality risk adapted therapy with induction carboplatin/paclitaxel/lapatinib for SCCHN amenable to transoral surgery. *First Author: Jared Weiss, University of North Carolina Hospitals, Chapel Hill, NC*

Background: Induction chemotherapy in SCCHN has mostly been studied prior to XRT where proof of improved survival is lacking. Regimens using weekly platinum, taxane and targeted therapy have resulted in high RR. Attempts are frequently made to intensify or de-intensify, but few have adapted therapy by response. **Methods:** Patients with transorally resectable, treatment naïve SCCHN and node positivity or $T > 3$ were treated weekly 6 times with Carboplatin AUC 2, paclitaxel 135mg/m2 and daily lapatinib 1000mg followed by transoral resection. Subjects with pN0/1 received no radiation; those with close margins, ECE, pN2a-b, PNI/LVSI were treated with weekly cisplatin 30mg/m2 and XRT with involved-field XRT allowed while those with pN2c/3 were treated with cisplatin 100mg/m2 Q3W and standard XRT. Primary endpoint was clinical RR (cRR) following induction chemotherapy. **Results:** Primary sites: oropharynx (OP) (30), supraglottic larynx (5), oral cavity (4) and hypophyarnx (1). Of OP patients, 17 were HPV low risk. Grade 3/4 toxicity during induction: decreased WBC (7), fatigue (3), diarrhea (2), febrile neutropenia (2), neuropathy (2), rash (2) and 1 each of ALT and AST increased, hyperglycemia, hypotension, nausea, PPDE. 39/40 proceeded to surgical resection (1 patient refused for non-study reasons). 29/39 subjects who were projected to require XRT were able to avoid it. 8/10 subjects with study-defined indication for adjuvant XRT received it. cRR 37/40, pRR 14/40. Clinical and pathologic responses correlated poorly (see table). With median FU of 1.7 years, there has been no recurrence or death. Mean VRQOL was 91.7 before induction, 92.3 before surgery and 92.3 1 year post surgery. Mean MDADI was 82.8 before induction, 85.9 before surgery and 84.5 1 year post surgery. **Conclusions:** The regimen led to excellent feasibility of surgical resection, high cRR and a real pCR. cR predicted poorly for pR. Most patients were able to avoid XRT. Speech and swallowing function were preserved. NCT01612351. Clinical trial information: NCT01612351.

6065 Poster Session (Board #53), Mon, 1:15 PM-4:45 PM

LIHNCS: Lugol's Iodine in Head and Neck Cancer Surgery—A multi-centre, randomised, controlled trial assessing the effectiveness of Lugol's Iodine to assist excision of moderate dysplasia, severe dysplasia and carcinoma in-situ at mucosal resection margin of oral and oropharyngeal squamous cell carcinoma. *First Author: James Anthony McCaul, Regional Maxillofacial Unit, Queen Elizabeth University Hospital, Glasgow, United Kingdom*

Background: Oral cavity and oropharynx cancer are increasing worldwide but survival has not significantly improved over the last thirty years. Presence of dysplasia or carcinoma in-situ at surgical margins following resection of squamous carcinoma (SCC) of the head and neck is associated with increased local recurrence and reduced survival. While carcinoma can usually be distinguished from normal mucosa, dysplasia is less readily distinguished at operation. We describe outcomes of LIHNCS, a RCT assessing effectiveness of Lugol's iodine staining for visualization and excision of margin dysplasia at primary surgery. **Methods:** Patients planned for curative surgical resection of oral cavity/ oropharynx SCC were recruited. Participants were randomised 1:1 into either a standard surgical treatment arm or surgical treatment including Lugol's iodine staining according to defined SOP. Randomisation was stratified by centre and surgeon using computer-generated random permuted blocks. Data monitors, pathologists and external reviewers were blinded to treatment allocations. Chief investigator, surgeons and other health care professionals were blinded to results. Primary endpoint is presence of carcinoma or dysplasia at mucosal margins. **Results:** Sixty-five surgeons in 24 centres recruited and LIHNCS was powered for 300 cases. Following successful recruitment, extension was granted for progression to 409, including 300 T1 and T2 cases. Patient acceptance was 89%. Median follow up is 36.5 months and 118 patients have died to date. Significantly fewer patients in the Lugols arm required further mucosal resection after primary surgery ($p = 0.005$). In as treated analysis dysplasia is reduced at resection margins for T1 and T2 tumours ($p = 0.04$). **Conclusions:** Lugol's iodine visualisation of dysplasia at curative surgical resection of oral and oropharynx SCC is associated with reduced requitement for further mucosal resection and appears to result in reduced dysplasia at mucosal resection margins. Clinical trial information: ISRCTN03712770.

6066 Poster Session (Board #54), Mon, 1:15 PM-4:45 PM

Optima: A phase II dose and volume de-escalation trial for high- and low-risk HPV+ oropharynx cancers. *First Author: James Melotek, University of Chicago, Chicago, IL*

Background: In this prospective phase II de-escalation study, we used induction chemotherapy to identify favorable HPV+ oropharyngeal cancer (OPC) pts, including those with high-risk tumors, and applied significantly lower radiation or chemoradiation doses than previously reported. **Methods:** Pts with HPV+ OPC were classified as low-risk ($\leq$T3, $\leq$N2B, $\leq$10 PYH) or high-risk (T4 or $\geq$N2C or $>$ 10 PYH). Pts received 3 cycles of carboplatin (AUC 6, D1) and nab-paclitaxel (100 mg/m2, D1/8/15). 1) Low-risk pts with $\geq$50% response received low-dose radiotherapy alone to 50Gy (RT50). 2) Low-risk pts with 30-50% response OR high-risk pts with $\geq$50% response received low-dose chemoradiotherapy to 45Gy (CRT45). 3) All other (= poor response) pts received regular-dose CRT (CRT75). All pts also received de-escalated RT volumes limited to the first echelon of uninvolved nodes. CRT consisted of paclitaxel, 5-FU, hydroxyurea, and 1.5Gy twice daily RT every other week. Primary site biopsy and neck dissection were performed only after de-escalated treatment (RT50, CRT45) for pathologic confirmation. The primary endpoint was 2-year PFS. Secondary endpoints included pathologic complete response (pCR) rate and toxicity. **Results:** 62 pts were enrolled. 28 pts (45.2%) were low-risk and 34 pts (54.8%) were high-risk. 71.4% of low-risk pts received RT50 and 21.4% received CRT45. 70.6% of high-risk pts received CRT45. The pCR rate was 94.4% after RT50 and 92.3% after CRT45. Median follow-up is 1 year. The 2-year PFS and OS were both 100% for low-risk pts, and 91.6% and 97.0% for high-risk pts. Significant decrease in the rates of grade $\geq$3 mucositis (15.8% RT50, 46.4% CRT45, 60.0% CRT75, $p = .033$) and grade $\geq$3 dermatitis (0% RT50, 21.4% CRT45, 30.0% CRT75, $p = .056$) were observed. PEG-tube dependency was improved at 3 months (0% RT50, 14.8% CRT45, 70.0% CRT75, $p < .001$) and 6 months (0% RT50, 3.7% CRT45, 20.0% CRT75, $p = .066$) post-treatment. **Conclusions:** Favorable response to induction chemotherapy appears to be a powerful biomarker for dose and volume de-escalation with 50Gy RT or 45Gy CRT. Outstanding survival and high pCR rates suggest that completion neck dissection may not be necessary. Toxicity and functional outcomes are significantly improved. Clinical trial information: NCT02258659.

6067 Poster Session (Board #55), Mon, 1:15 PM-4:45 PM

Resource utilization in patients with head and neck cancer: Analysis of CCTG HN6 (NCT00820248). *First Author: Ketan Ghate, Queen's University/ Cancer Centre of SE Ontario, Kingston, ON, Canada*

Background: As new treatments for head and neck cancer arise, further information is required regarding resource utilization. The Canadian Cancer Trials Group HN.6 study included collected resource utilization data prospectively on patients with locally advanced squamous cell carcinoma of the head and neck treated with cisplatin or panitumumab plus radiotherapy (RT). **Methods:** The HN.6 phase III trial enrolled 320 patients across Canada between 2008-2011. The economic analysis was conducted from the societal perspective. Resource utilization was collected prospectively for 3 categories: outpatient, hospitalization and institutionalization (end of life care) at baseline, 8 weeks, every 3 months(mo) for 2 years and every 4 mo until 3 years. Lost productivity questionnaires were collected in the last week of RT. Descriptive statistics were used to summarize the outcomes. Categorical variables were reported by percentage and continuous variables were reported by mean and standard deviation. **Results:** Of 320 pts randomized, resource utilization and lost productivity data were available for 317 (99%) and 285 (89%) pts, respectively. Eighty nine pts required 130 emergency room visits (mean 1.46$\pm$0.85). There were 696 (mean 3.74$\pm$3.22) office visits among 186 pts and 367 (mean 3.95$\pm$6.43) outpatient visits among 93 pts. Surgeons, radiation oncologists and emergency room physicians were the top three providers of outpatient care with 234 (mean 2.05$\pm$1.54), 137 (mean 1.67$\pm$1.19) and 118 (mean 1.4$\pm$0.78) visits for 114, 82 and 84 pts, respectively. CT scans (286), lab tests (418), x-rays (182) and other tests (400) were conducted in 136, 180, 120 and 194 pts, respectively. Three pts were institutionalized for end of life care (mean 28 days$\pm$26.06), and 214 pts were hospitalized (mean 14.5 days$\pm$28.8). One hundred and thirteen (41%) pts reported a change in work status at the end of RT. **Conclusions:** Radical treatment for locally advanced SCCHN is resource intensive. Tracking resources utilized prospectively in clinical trial settings and reporting this information consists of an efficient way to inform health resource allocation decisions. Clinical trial information: NCT00820248.

6069 Poster Session (Board #57), Mon, 1:15 PM-4:45 PM

Standard of care vs reduced-dose chemoradiation after induction chemotherapy in HPV+ oropharyngeal carcinoma patients. *First Author: Hope Rainey, Mount Sinai School of Medicine, New York, NY*

Background: Locally advanced Human Papillomavirus (HPV) + oropharyngeal carcinoma (OPC) has a significantly better response, locoregional control and survival compared to non HPVOPC. Standard-dose chemoradiotherapy (sdCRT) results in significant side effects, leading to acute and life-threatening late morbidity. We studied whether reduced dose chemoradiation (rdCRT) after induction chemotherapy (IC) resulted in equivalent progression-free survival (PFS) compared to sdCRT + IC with decreased late morbidity. **Methods:** Patients with locally advanced OPC and $<$ 20 pack years (py) smoking history were tested for p16 and then HPV by type-specific PCR. After 3 cycles of docetaxel, cisplatin and fluorouracil (TPF) IC all HPV+/p16+ subjects underwent clinical and radiographic evaluation. Clinical responders were randomized to either sdCRT (70Gy) or rdCRT (56Gy) with weekly carboplatin (AUC 1.5) at a 1:2 ratio. The primary endpoint was 2 year PFS; the secondary endpoint was 2 year overall survival (OS). Toxicity, late morbidity and swallowing were monitored. **Results:** 23 patients were enrolled and 20 randomized, 8 to sdCRT and 12 to rdCRT; 2 were HPV- and 1 refused further therapy after IC and were not randomized. Median age was 56.5 yrs (range 36-78); 30% were African-American, 10% were Hispanic, 5% were female; 16 were HPV 16+ and 4 were other high risk (HR) variants; 60% never smoked, 25% were $<$ 10 py, and 15% were 10-20 py; 70% had high risk features: T4, N2c, or N3. Clinical response to TPF was 100%; 70% had a clinical complete response. As of February 1, patients have been followed for a median of 37.5 months (range 21.7 – 49.5). 2 year PFS/OS for sdCRT and rdCRT are 87.5% vs 83.3% (log-rank test $p = 0.85$), respectively. All 3 failures were local or regional and 2 of 3 occurred in non HPV16 HR variants. **Conclusions:** HPV+ OPC patients who received rdCRT after TPF IC had similar PFS/OS compared to those receiving sdCRT. These results uphold the potential clinical benefit of radiation dose reduction as a treatment option with comparable survival to the standard radiation dose. A Phase III trial comparing IC plus rdCRT to sdCRT alone or with IC is warranted in this population. Non-HPV16 HR variants may have a worse outcome. Clinical trial information: NCT01706939.

6070 Poster Session (Board #58), Mon, 1:15 PM-4:45 PM

Impact of p16 expression on induction taxotere-cisplatin-5 FU (TPF) followed by cetuximab-radiotherapy in N2b-N3 head and neck squamous cell carcinoma (HNSCC): Results of GORTEC 2007-02 phase III randomized trial. *First Author: Yungan Tao, Gustave Roussy Cancer Campus, Villejuif, France*

Background: TPF is a reference induction chemotherapy regimen in non-operated locally advanced (LA) HNSCC. GORTEC 2007-02 phase III randomized trial was restricted to HNSCC patients with large nodal spread (N2b-N3). Results showed no benefit of 3 cycles of induction TPF followed by cetuximab-radiotherapy (RT), as compared to concurrent chemoradiotherapy (CRT) (Geoffrois *et al ASCO 2016*). **Methods:** Patients were randomized to receive concurrent CRT (arm A) or induction TPF followed by cetuximab-RT (arm B). RT was 70 Gy/35F/7 weeks. Concurrent chemotherapy was 3 cycles of carboplatin-5FU as previously described (Calais JNCI 1999). About 2/3 of patients had oropharyngeal cancers (OPC) and HPV status was determined in these patients using p16 expression as a surrogate (immunohistochemistry). Smoking status was also collected. Primary endpoint was progression free survival (PFS). **Results:** Between May 2009 and Aug 2013, 360 eligible patients were randomized including 231 (64%) OPC. Overall, p16 expression could be assessed in 172 / 231 OPC patients (74%) with 84 in arm A and 88 in arm B. 26 patients were found p16+ in arm A (31%) and 19 in arm B (22%). Only 8 out 45 (18%) p16+ patients were non-smokers showing that the large majority of OPC patients randomized were p16- (127/172) and smokers (117/129). A significant improvement in PFS was found in p16+ compared to p16- OPC ($p < 0.0001$). The absence of benefit in PFS associated with TPF + cetux-RT compared with CRT was suggested both in p16+ (HR: 0.78, 95% CI: 0.28 – 2.20) and in p16- OPC (HR: 1.28, 95% CI: 0.84 – 1.93), and the interaction between p16 and treatment modality was not significant ($p = 0.35$). A significant benefit was observed in favor of arm B regarding distant metastasis, but this effect was not different between the p16+ and p16- OPC, while there was no benefit of TPF + cetux-RT compared with CRT for loco-regional control, regardless of p16 status. **Conclusions:** The OPC p16 subpopulations were small. No benefit of induction TPF chemotherapy followed by cetuximab-RT compared with CRT in OPC patients regardless of p16 status. Clinical trial information: NCT01233843.

6071 Poster Session (Board #59), Mon, 1:15 PM-4:45 PM

A multicenter phase II trial of docetaxel, cisplatin and cetuximab (TPE) followed by cetuximab concurrent with radiotherapy in patients with local advanced squamous cell carcinoma of the head and neck (ECRIPS study). *First Author: Sadamoto Zenda, National Cancer Center East, Chiba, China*

Background: Induction chemotherapy is a treatment option for locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). However, Docetaxel, Cisplatin, and 5-FU (TPF) followed by Cisplatin with radiotherapy is currently not recommended due to toxicity concerns. The aim of this phase II study was to assess the feasibility of Docetaxel, Cisplatin, and Cetuximab (TPE) followed by Cetuximab with concurrent radiotherapy for LA-SCCHN. **Methods:** Patients were eligible if they had histologically proven SCC of oropharynx, hypopharynx or larynx, a PS of 0-1, adequate organ function, and no distant metastasis. Induction chemotherapy consisted of Cisplatin 75mg/m^2 and Docetaxel 75mg/m^2 on day1 and the induction regimen was repeated every 3 weeks up to a total of 3 courses. Cetuximab was administered at an initial dose of 400mg/m^2 followed by 250mg/m^2 weekly until the end of radiotherapy. Radiotherapy (70Gy/35fr/7w) was started after last administration of Docetaxel. Primary endpoint was the rate of treatment completion. The planned sample size was 55 with one-sided alpha of 0.025 and the power of more than 90% based on the expected and threshold treatment completion rates of 65% and 40%. **Results:** Between August 2013 and October 2015, 54 patients with a median age of 58 years were eligible and had the study treatment. There were 50 males, hypopharynx/oropharynx/larynx cancer of 28/19/7 cases, and 48 Stage IV disease. Response rate at induction chemotherapy was 72% while that after radiotherapy was 76% . Of 54 patients, 50 (93%) received > 2 courses of induction chemotherapy, and 41 (76%) had the full dose of radiotherapy. The rate of treatment completion was thus 76% (95%CI, 62–87%). The frequency of grade 3-4 neutropenia, febrile neutropenia, and allergy/infusion reaction was 93%, 39%, and 11%, respectively. One treatment-related death was observed. **Conclusions:** Induction TPE followed by Cetuximab with concurrent radiotherapy was feasible with a promising efficacy. A phase III study to evaluate this treatment strategy is warranted. Clinical trial information: UMIN000009928.

6072 Poster Session (Board #60), Mon, 1:15 PM-4:45 PM

Prognostic factors associated with benefit to post-operative chemotherapy: A National Cancer Data Base analysis. *First Author: Jessica Lyn Geiger, Cleveland Clinic, Cleveland, OH*

Background: Addition of chemotherapy to adjuvant radiation (RT) confers an OS benefit and is recommended in HNSCC patients with nodal extracapsular extension (ECE) and positive surgical margins based on pooled data. The purpose of this study is to retrospectively evaluate a larger patient data set in an attempt to confirm this observation and to assess current patterns of practice. **Methods:** The National Cancer Data Base (NCDB) was queried to identify patients with HNSCC who were treated with primary definitive surgery followed by adjuvant RT between 2004 and 2012. For patients treated with surgery and post-operative RT with or without chemotherapy, the effect of the systemic therapy on OS was explored using multivariable Cox proportional hazards modeling and stratified by patient and disease factors. **Results:** 6,351 patients were identified meeting study criteria; 3157 patients (49.7%) received adjuvant RT alone, and 3194 patients (50.3%) received adjuvant chemo-radiotherapy (CRT). An increase in chemotherapy usage was observed over time (6% of patients in 2004; 16% in 2012). No difference was seen in OS by use of CRT (median OS 8.3 years in patients without CRT vs. 9.4 years in patients with CRT, $p = 0.0893$). On multivariate analysis OS was improved in younger patients, patients with less co-morbidity, oropharynx, lower T and lower N. OS was also improved in patients given chemotherapy if either ECE or positive surgical margins were present (HR 1.166, $p = 0.0438$) but not in those with negative surgical margins and no ECE (HR 1.037, $p = 0.5888$). Nonetheless, chemotherapy was given to 38% of post-operative patients without these risk factors and not given to 35% of patients with risk factors. **Conclusions:** This NCDB analysis confirms an OS benefit with addition of chemotherapy to post-operative RT in HNSCC patients with ECE or positive surgical margins but not in patients without these risk factors, consistent with current guidelines. National practice patterns, however, do not mirror these recommendations. These results are subject to limitations of retrospective analysis of a large database and further studies are needed to better elucidate high risk factors benefiting from intensifying adjuvant therapy.

6073 Poster Session (Board #61), Mon, 1:15 PM-4:45 PM

Immunogenicity results using human papillomavirus (HPV) specific DNA vaccine, INO-3112 (HPV16/HPV18 plasmids + IL-12) in HPV+ head and neck squamous cell carcinoma (HNSCCa). *First Author: Charu Aggarwal, Abramson Cancer Center, Philadelphia, PA*

Background: Oropharyngeal HNSCCa is frequently associated with HPV. We hypothesize that immunotherapy with INO-3112 will generate immune responses in patients (pts) with HPV+ HNSCCa. **Methods:** This Phase I/IIa trial included pts with p16+ locally advanced HNSCCa, ECOG PS 0-1. INO-3112 was delivered IM along with electroporation with the CELLECTRA device, Q3 weeks x 4 doses. Cohort 1 (C1) pts received INO-3112 pre and post-surgery; Cohort 2 (C2) pts received INO-3112 post cisplatin-based definitive chemoradiation. 1° and 2° endpoints were safety and immune responses. Pre- and post INO-3112 tissue samples (C1) were assessed for tumor infiltrating lymphocytes (TILs). Peripheral immune responses were assessed by ELISA for HPV16/18 specific antibody levels, and by IFNɣ ELISpot for antigen specific response, at each dose visit and q3 months (mos). **Results:** As of 08/2016, 22 pts were treated, completing accrual. C1: $n = 6$, C2: $n = 16$; 20 male, median age 57.5 years (32-76); base of tongue = 10, tonsil = 12; never smoker = 10. All pts are alive, median follow up is 15.9 mos (1-26). INO-3112 was well-tolerated with no related Grade 3-5 AEs. In 5 C1 pts post immunotherapy, increase in CD8+ infiltration into tumor was noted in 2 pts (1.6-3.6 fold) and decrease in FoxP3+ was noted in the other 3 (1.8-2.1 fold). This resulted in positive shift in CD8+/FoxP3+ ratio in neoplastic tissue in 4/5 pts. Peak mean/median antibody responses to HPV16 E7 and HPV18 E7 antigens for 19 evaluable pts were 1:1235/1:150 and 1:2853/1:450, respectively. As compared to baseline, 18 evaluable pts showed elevated HPV16/HPV18 specific T cell activity (by IFNɣ ELISpot), with peak mean/median responses of 179.99/68.33 SFU per 10^6 PBMC (HPV16) and 107.18/53.3 SFU per 10^6 PBMC (HPV18). Persistent cellular responses > 100 SFU/10^6PBMC were noted out to 12 mos. 3 pts have progressed; 1 pt received Nivolumab for progressive disease, and remains in CR. **Conclusions:** These data show that INO-3112 generates HPV-specific peripheral humoral and cellular immune responses that may persist out to 12 months and influences the composition of CD8+ and FoxP3+ immune infiltration into tumor tissue in HPV+ HNSCCa. Clinical trial information: NCT02163057.

6074 Poster Session (Board #62), Mon, 1:15 PM-4:45 PM

Assessment of established patient reported outcomes (PROs) instruments measuring toxicities and quality of life (QOL) for patients (pts) with head and neck cancer (HNC) treated on ECOG 1308 and 2399 studies. *First Author: Anthony Cmelak, Vanderbilt University Ingram Cancer Center, Nashville, TN*

Background: HPV HNC pts are younger and have a higher cure rate than smoking-related pts, and therefore carry treatment toxicities longer. Dose deintensification and conformal RT may result in decreased toxicity. We report the impact of these techniques on patient outcomes in E2399 and E1308 as measured through PROs. **Methods:** Longitudinal data on acute and late toxicities were recorded prospectively at baseline, post-treatment, and at 6, 12, 24 and 30 months in HPV+ pts on E1308 and HIV+/- pts on E2399 using the following measures: *E1308*: FACT-HN, KATZ Index of Independence (ADL), Brief Fatigue Index (BFI), Instrumental Activities of Daily Living (IADL), and the Vanderbilt Head and Neck Symptom Survey Version 2 (VHNSS V2); on *E2399*: FACT-HN. We correlated acute and late toxicities with de-escalation of RT dose (69.3Gy to 54Gy) on E1308, and with IMRT (E1308) vs. conformal RT (E2399). **Results:** 38 pts on E1308 completed 12 mo VHNSS V2; 32 received low dose IMRT and 6 standard dose, and 56 E2399 pts completed 12 mo FACT-HN. Items from the VHNSS V2 showed that difficulty eating solids (40% vs. 89%, $p = 0.011$) and improved nutrition (10% vs 44%, $p = 0.025$) were statistically improved at 12 months by lowering IMRT dose from 69.3Gy to 54Gy. The FACT-HN showed an improvement in eating solids at 12 mo when comparing low dose IMRT vs. 3DRT (65% vs. 33% had no or minimal solid food problems, $p = 0.057$). No other statistically significant reductions in toxicity were noted on any of the other PRO instruments. **Conclusions:** Both FACT-HN and VHNSS V2 demonstrated an improvement in eating solids by reducing IMRT dose. FACT-HN demonstrated that IMRT is associated with an improvement in eating solids when compared to 3DRT. Analyses are exploratory and need to be validated using randomized data.Future studies should stress accurate and complete PRO data. The KATZ, BFI, and IADL were not sensitive to detecting differences in toxicities from IMRT dose reduction on E1308. The VHNSS V2 and FACT-HN instruments corroborated specific toxicities both by RT technique as well as IMRT dose, and will therefore be utilized in future ECOG-ACRIN HNC studies. Clinical trial information: NCT01084083.

6075 Poster Session (Board #63), Mon, 1:15 PM-4:45 PM

Cost-effectiveness of prophylactic antibiotics to prevent pneumonia in patients treated with chemoradiotherapy (CRT) for locally advanced head and neck carcinoma (LAHNC). *First Author: Janneke Ham, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Recently, we reported about a prospective randomized study (PANTAP-study) investigating the effect of prophylactic antibiotics in LAHNC pts treated with CRT. We did not show a reduction in pneumonias, but did find a significant decrease in the number of hospitalizations. Detailed quality of life (QoL) results have been reported elsewhere. Now we present the results of the cost-effectiveness analysis. **Methods:** A multicenter study was performed in LAHNC pts treated with CRT, i.e.cisplatin weekly or 3-weekly combined with radiotherapy for 42 or 49 days. The standard treatment group (STG) received no prophylactic antibiotics; the intervention group (IG) received prophylactic antibiotics, i.e. amoxicillin/clavulanic acid, from day 29 until 14 days after completion of CRT. QoL questionnaires, including EQ-5D, QLQ-C30, EORTC Head&Neck35 and PSSHN, were taken before start of CRT, before start of antibiotics, at the end of CRT and at the end of follow up. Costs of hospitalization, prophylactic antibiotics, pain medication and anti-emetics were taken into account for the cost-effectiveness analysis. **Results:** A total of 94 pts were randomized; 48 pts to the STG and 47 pts to the IG. Between the STG and IG we found a difference per patient in costs of hospitalization of €2076 and €682 ($p = 0.03$), respectively, but not in the costs for pain medication per patient €78 and €46, respectively, ($p = 0.382$). The total costs of hospitalization in combination with prophylactic antibiotics, pain medication and anti-emetics were €2462 and €1037 ($p = 0.046$) in the STG and IG respectively, leading to a difference in total costs per patient of €1425 in favor of the IG. There were no significant differences in QoL between the groups. **Conclusions:** Prophylactic antibiotics during CRT for LAHNC did not reduce the rate of pneumonias, but reduced the number of hospitalizations in the IG, which led to a significant reduction in costs. Given the lack of adverse clinical effects, the same QoL, the cost savings and the impact of costs of hospitalization on health care globally, we recommend the use of prophylactic antibiotics in LAHNC pts receiving CRT. Clinical trial information: NCT01598402.

6076 Poster Session (Board #64), Mon, 1:15 PM-4:45 PM

A personalized approach using hypoxia resolution to guide curative-intent radiation dose-reduction to 30 Gy: A novel de-escalation paradigm for HPV-associated oropharynx cancers (OPC). *First Author: Nadeem Riaz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We conducted a pilot study using functional imaging to guide reduction in radiation (RT) to 30Gy with concurrent chemotherapy in patients with HPV+ OPC. **Methods:** 19 patients were enrolled prospectively from 7/2015-10/2016. Primary tumors were excised and analyzed for DNA repair foci *ex-vivo*. A pre-RT dynamic ^{18}F-FMISO (fluoromisonidazole) PET was then used to assess tumor hypoxia (defined as > 1.2 tumor to muscle SUV ratio) in cervical lymph nodes. Patients without hypoxia on baseline or repeat scan done 5-10 days after initiation of chemoRT received 30Gy (57% reduction) over 3 weeks to the tumor bed and neck with 2 cycles of concurrent chemotherapy (high-dose cisplatin or carboplatin/5-FU). Patients with persistent hypoxia received the standard dose of 70Gy over 7 weeks with chemo. Neck dissection (ND) was done 4-months post chemoRT. Weekly DWI MRI, ctDNA, whole exome & RNA sequencing were performed. **Results:** 19 patients (11 tonsil, 5 BoT, 3 unknown primaries) were enrolled. Staging: 11 T1, 5 T2, 3 Tx; 5 N1, 3 N2a, 11 N2b; all M0. On pre-RT ^{18}F-FMISO scans, 13 were positive and 6 were negative for hypoxia. Of the 12 intra-treatment ^{18}F-FMISO scans (1 not done due to intermittent illness, this patient received 70Gy), 3 were positive and these patients received 70Gy chemoRT. 15 patients were de-escalated to 30Gy. To date, analysis showed complete pathologic response in 8 of 9 patients (all 15 expected to have ND by April 2017. The one positive case received only 1 cycle of cisplatin. To date, 18 of 19 patients (95%-6 pending ND) remain disease free. Correlative analysis with sequencing, DNA repair foci, ctDNA, and results from pathologic and intra-treatment imaging response will be presented. **Conclusions:** This is the first report of apersonalized approach to a major decrease in RT dosing for definitive treatment of HPV+ oropharyngeal carcinoma guided by patient-specific imaging-based treatment response. De-escalation to 30Gy informed by intra-treatment imaging for hypoxia appears feasible, safe and efficacious. A multi-center trial to validate these pilot results is planned. Clinical trial information: NCT00606294.

6077 Poster Session (Board #65), Mon, 1:15 PM-4:45 PM

Disparities in supportive therapy for head and neck cancer and impact on missed radiation days and weight loss. *First Author: Stephen Ramey, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: National guidelines emphasize the importance of speech and swallowing (SS) and nutrition services (NS) for head and neck cancer patients (pts). This study evaluates influences of demographic and treatment factors on receipt of SS and NS at a safety-net hospital (SH) and an adjacent private hospital (PH). It also examines associations between lack of these services and negative outcomes. **Methods:** This retrospective analysis included non-metastatic laryngeal or oropharyngeal cancer pts treated with radiotherapy (RT) at a PH or SH. Univariate (UVA) and multivariable (MVA) analyses utilized linear regression, logistic regression, and zero-inflated Poisson regression. Covariates included race, ethnicity, preferred language, insurance status, immigration status, gender, age, treating hospital, comorbidity score, primary treatment modalities, time to treatment initiation (TTI), and stage. Potential negative outcomes of not receiving SS and/or NS were analyzed only among pts treated with chemoradiation (CRT). **Results:** Of 239 pts (PH = 138 pts; SH = 56 pts), 28.6% of SH pts received SS pre-RT vs 54.1% at the PH ($p < 0.001$). Receipt of pre-RT NS did not differ significantly between SH (14.3%) and PH (19.7%) but was low at both. On MVA, SH care (OR 0.29; $p = 0.029$) and longer TTI (OR 0.99; $p = 0.033$) were associated with decreased pre-RT SS. In contrast, surgery before RT (OR 10.1; $p = 0.002$) and surgery before CRT (OR 10.7; $p = 0.001$) vs RT alone were associated with increased pre-RT SS. No covariates were significantly associated with receipt of NS on MVA. For pts receiving CRT, pre-RT SS was associated with less weight loss during RT (mean difference = 2%; $p = 0.036$). Receiving both pre-RT SS and NS was associated with fewer missed RT days (RR 0.49; $p = 0.004$). Receipt of SS and/or NS were not associated with gastric tube placement, emergency room visits, or non-chemotherapy admission days during or within 90 days of CRT. **Conclusions:** SS was received less often at a SH vs a PH. NS were delivered at a low level at both centers. Lack of supportive services was associated with increased missed RT days and increased weight loss during CRT. Quality metrics to establish supportive care benchmarks may help reduce disparities.

6078 Poster Session (Board #66), Mon, 1:15 PM-4:45 PM

Phase II study: Induction chemotherapy & transoral surgery as definitive tx for locally advanced oropharyngeal squamous cell carcinoma (OPSCC)—A novel approach. *First Author: Robert S. Siegel, George Washington University School of Medicine, Washington, DC*

Background: The standard of care for OPSCC includes chemoradiation (CRT) or surgery with adjuvant radiation (RT). However, RT is associated with significant life long morbidity. We assessed the efficacy of a two-drug induction regimen, followed by transoral robotic assisted surgery (TORS) & neck dissection for locally advanced OPSCC. **Methods:** This is an IRB approved single-arm phase II study for untreated stage III or IVA OPSCC patients (pts) with an ECOG < 2 and GFR > 50 cc. Induction chemotherapy consisted of cisplatin 75 mg/m2 and taxotere 75 mg/m2 every 21 days for 3 cycles. Tumor shrinkage was examined after each cycle. If the primary tumor was $> 80\%$ smaller, pts underwent TORS and neck dissection(s). At post-op visits, flexible laryngoscopy, blood work, and imaging with PET/CT and/or MRI were done. Short and long term toxicity, progression-free survival (PFS) and overall survival (OS), and quality of life (QOL) were evaluated. **Results:** Nineteenpts were treated and 14 are available for analysis. Thirteen were male, 12 were Caucasian, 2 were African-American, and 13 were HPV+. Median age at diagnosis was 57. Tumors involved the tonsil (11 pts) and base of tongue (3 pts). Three pts were stage III, and 11 were stage IVA. Tumor size was reduced on average by 58%, 84% and 92% after the 1st, 2^{nd} and 3^{rd} induction cycles respectively. Pathologic complete remission of primary disease occurred in 11 pts and in 7 pts with cervical lymph node disease. Four pts were given dose-reduced chemo and one pt was changed to carboplatin per protocol because of renal dysfunction. In addition, adverse events included three patients with grade I fatigue, neuropathy or nausea. Pre vs post tx QOL scores were not significantly different. At a mean follow-up (f/u) of 13 months (range 2.5 to 19.7), 13 pts are alive and well. Three pts recurred, and were treated with salvage CRT. One pt died of metastatic disease. **Conclusions:** Cisplatin + Taxotere is an effective induction tx for OPSCC, Induction tx followed by transoral & neck resections without RT is a promising tx model for OPSCC. It appears effective while avoiding adverse effects of RT. Longer f/u is required to assess its true efficacy. Clinical trial information: NCT02760667.

6079 Poster Session (Board #67), Mon, 1:15 PM-4:45 PM

Treatment outcomes of 257 patients with locally advanced nasopharyngeal carcinoma treated with nimotuzumab plus intensity-modulated radiotherapy with or without chemotherapy: A single institution experience. *First Author: Wang Fang Zheng, Zhejiang Cancer Hospital, Hangzhou, China*

Background: To report the long-term outcome and toxicitie of locally advanced nasopharyngeal carcinoma (NPC) treated with nimotuzumab plus intensity- modulated radiotherapy (IMRT) with or without chemotherapy. **Methods:** From October 2009 to March 2014, 257 newly histology-proven, non-metastatic NPC patients were retrospectively enrolled. They are aged 10-76 years. The distribution of disease was stage III in 150 (58.4%), stage IV A in 88 (34.2%), and stage IV B in 19 (7.4%). All the patients received the treatment of nimotuzumab plus IMRT, and 239 cases were used for cisplatin-based chemotherapy. Acute and late radiation-related toxicities were graded according to the Acute and Late Radiation Morbidity Scoring Criteria of Radiation Therapy Oncology Group. The accumulated survival was calculated according to the Kaplan-Meier method. Log-rank test was used to compare the survival difference. Multivariate analysis was performed using Cox's proportional hazard model. **Results:** All patients had completed the combined treatment. With a median follow-up of 48 months (range, 13–94 months), the estimated 3-year and 5-year overall survival rates were 92.6% and 86.2%, respectively. Univariate analysis showed that age, T stage, clinical stage and neoadjvant chemotherapy were related with OS. Multivariate analysis indicated that age and clinical stage were independent prognosticators. The median cycle for nimotuzumab addition was 12 weeks. The incidence of grade 3–4 acute mucositis and leukocytopenia were 10.9% and 9.3%, respectively, with no cases of skin rash and infusion reaction. Xerostomia was the most common late complication, and the degree of dry mouth in most survivors was mild-to-moderate at the last follow-up time. **Conclusions:** Nimotuzumab plus IMRT with or without chemotherapy showed promising outcomes in terms of loco-regional control and survival, without increasing the incidence of radiation-related toxicities for patients.

6080 Poster Session (Board #68), Mon, 1:15 PM-4:45 PM

A phase 1 trial of NBTXR3 nanoparticles activated by intensity-modulated radiation therapy (IMRT) in the treatment of advanced-stage head and neck squamous cell carcinoma (HNSCC). *First Author: Christophe Le Tourneau, Institut Curie, Paris, France*

Background: Functionalized hafnium oxide nanoparticles (NBTXR3) have been developed as selective radioenhancers, which may represent a breakthrough approach for the local treatment of solid tumors. The high electron density of the nanoparticles, when exposed to radiotherapy (RT), allow the absorption/deposition of a high radiation dose within the tumor cells, to physically kill the cells and possibly improve outcome. A phase I trial was implemented for the treatment of locally advanced HNSCC in patients (pts) older than 65 years who cannot receive cisplatin. **Methods:** Pts received a single intratumor (IT) injection of NBTXR3, volume dose levels escalated at 5%, 10%, 15% and 22% of baseline tumor volume, followed by RT (IMRT, 70Gy/ 35 fractions / 7 weeks). Primary endpoints included feasibility of the IT implantation and safety. Secondary endpoints included IT residency of NBTXR3 using CT scan and RECIST 1.1 response. **Results:** Enrollment was completed for volume 5%, 10%, and 15% (11 pts) and 1 patient at volume dose level 22%. Feasibility of the IT injection was confirmed. The treatment was easily administered, was safe with no SAE, or early DLT, which allowed the pts for completion of the planned RT schedule. Adverse events related to the injection procedure included grade 1-2 injection pain (1 pt), and tumor hemorrhage (1 pt). Results demonstrated that a single injection of NBTXR3 provides adequate bioavailability of NBTXR3 IT over seven weeks of RT. No leakage of NBTXR3 to the adjoining healthy tissues was observed. Preliminary results of antitumor activity according to RECIST 1.1 are presented below: 11 evaluable pts, 10 showed complete or partial response (RECIST 1.1) including, 1/5 complete response at dose levels $\leq 10\%$ and 3/6 complete responses at dose levels $> 10\%$ Follow up results with duration of response and tolerance will be disclosed. **Conclusions:** Injection of NBTXR3 was safe and well tolerated. All pts received the planned RT. Clinical trial information: NCT01946867.

6081 Poster Session (Board #69), Mon, 1:15 PM-4:45 PM

Phase Ib study of cetuximab + BYL719 + IMRT in stage III-IVB head and neck squamous cell carcinoma (HNSCC). *First Author: Lara Dunn, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Activation of the PI3K/mTOR signaling pathway is common in HNSCC. PI3K inhibitors have been shown to enhance radiosensitivity. BYL719 is an α-specific PI3K inhibitor that is synergistic and efficacious when combined with cetuximab, an FDA-approved radiosensitizing agent in HNSCC. This study evaluates the addition of BYL719 to cetuximab and radiation in the treatment of locally advanced HNSCC. **Methods:** This is a single-institution, phase I study. Patients with Stage III-IVB HNSCC received cetuximab 400 mg/m^2 IV loading dose prior to intensity modulated radiation therapy (IMRT), followed by 250 mg/m^2 weekly infusions during IMRT. BYL719 was given orally during IMRT in 3 dose levels (DLs): 1) 200 mg, 2) 250 mg, and 3) 300 mg per day in a standard 3 + 3 dose escalation design. **Results:** 11 patients are evaluable; median age-60 years (36-73); Stage III-1, IVA-9, IVB-1; oropharynx primary-9, unknown primary-2; HPV-positive -10. 8 patients completed treatment. 3 patients were treated on DL 1 and 2 without a dose limiting toxicity (DLT). Both patients on DL 3 experienced a DLT of grade 3 mucositis. Related adverse events (AEs) of any grade experienced by all 8 patients include: mucositis, weight loss, and hyperglycemia. Related grade 3 and 4 AEs in at least 2 patients include: mucositis (4), dysphagia (4), and decreased lymphocyte count (2). An additional 3 patients have been enrolled onto DL 2 and are undergoing treatment. All other patients had a complete response (CR) on post-treatment PET (from 6/2015 - 9/2016) and remain free of disease. Of 6 patients with mutational analysis, 1 had an activating *PIK3CA* mutation associated with a rapid response on serial intra-treatment MRIs. **Conclusions:** BYL719 administered at DLs 200 mg or 250 mg oral daily with cetuximab and IMRT resulted in expected AEs of radiation-based treatment with cetuximab and tolerable class-related AEs of PI3K inhibitors. BYL719 300 mg oral daily exceeds the maximum tolerated dose; the phase II recommended dose is pending completion of expansion of DL 2. All patients who completed treatment had a CR. Further evaluation of the addition of BYL719 to the platinum-sparing regimen of cetuximab + IMRT in the treatment of locally advanced HNSCC is warranted. Clinical trial information: NCT02282371.

6082 Poster Session (Board #70), Mon, 1:15 PM-4:45 PM

Institutional treatment volume and outcomes in salivary gland cancer. *First Author: Conor Ernst Steuer, Winship Cancer Institute, Atlanta, GA*

Background: Salivary gland cancer (SGC) is a rare malignancy and has been understudied in the literature. Given the rarity of SGC, we sought to compare outcomes of SGC within high volume (HV) and low volume (LV) centers, utilizing the National Cancer Database (NCDB). **Methods:** The NCDB was queried from 2004 to 2014 for SGC using ICD-O-3 codes for the 4 most common histologies: (mucoepidermoid carcinoma (ME), adenoid cystic carcinoma (AdCC), acinic cell carcinoma(ACC), and adenocarcinoma NOS (A)) for consistency. The number of cases treated at each facility was calculated, and the threshold for distinguishing high volume vs. low volume was determined using the 80th percentile of the number of cases treated per facility. Patient characteristics were compared using chi-squared tests and ANOVA. Overall survival was estimated using the Kaplan-Meier method, and was compared using log-rank tests. Statistical analyses were performed using SAS 9.4. **Results:** There were 31,189 SG patients overall; 16,373 were either ME, AdCC, ACC, or A and were included in the analysis. There were 6534 patients treated in LV (41%) and 9839 in HV (59%). HV centers were more likely to be academic and integrated network cancer programs ($p < .001$). The median age for LV vs. HV was 61y vs. 58y ($p < .001$), 49% vs. 47% male ($p = .007$), and 84% vs. 80% White ($p < .001$), respectively. Patients presented with slightly more advanced disease at HV, with 24.4% having stage 3-4 disease, vs 23% in LV ($p = .004$). The majority of patients underwent surgical resection (57% LV vs. 64% HV). HV had more negative margins (59% vs 55%, $p < .001$), more neck dissections (72% vs. 64%, $p < .001$), and longer hospital stays (mean 2.21d vs 1.55d, $p < .001$). More patients in LV received radiation than HV (55% vs. 52%, $p < .001$), but there was no difference in chemotherapy use ($p = 0.650$). Patients had better survival (m1 disease excluded) in HV as compared to LV (5-year OS HV 77.4% vs LV 75.5%, HR 0.89, $p = 0.002$). **Conclusions:** Our results indicate that survival of SGC is affected by institutional treatment volume and the significant differences in treatment at LV vs. HV institutions urges for the need of better standardization of care.

6083 Poster Session (Board #71), Mon, 1:15 PM-4:45 PM

RNAseq analysis of the sorafenib phase III DECISION trial in differentiated thyroid cancer (DTC): Correlation with clinical outcome. *First Author: Jaume Capdevila, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: In DECISION, sorafenib significantly impacted progression-free survival (PFS) and response rate (RR) in radioactive-iodine refractory DTC. The aim of this biomarker study was to identify RNA expression profiles related with PFS, overall survival (OS) and RR and to describe the expression profiles of DTC histologies. **Methods:** Of the 417 patients in the trial, 247 had sufficient formalin fixed paraffin embedded archival tumor material for RNAseq. We generated on average 77 million paired-end reads for each sample on HiSeq2000 (Illumina). RNAseq reads were mapped against the human reference genome (GRCh38) with STAR (v2.5.1b) using ENCODE parameters. 125 samples had sufficient quality to be included in the analysis. **Results:** The analysis subset included 68 sorafenib and 57 placebo patients (PFS 10.3 vs 7.4 months, HR: 0.62 CI 95% 0.38-0.99, $p = 0.046$). Unsupervised clustering using the 100 most variable genes identified 3 groups: BRAF-like (included most of the BRAF-mutated tumors), RAS-like (included most of the RAS mutated tumors) and non-BRAF-non-RAS-like group (included most wild-type tumors). These groups, based on the mutational profile, can be correlated with tumor type: the papillary BRAF-mutant, the follicular wild-type, and a third group with papillary, follicular and poorly differentiated with predominant RAS mutations. A Student t-test comparing papillary and follicular histologies revealed a signature of 283 genes with significantly different expression that, within the papillary tumors, identifies a subset with an expression profile more similar to follicular. No RNA signatures correlating with benefit from sorafenib were identified. **Conclusions:** While papillary and follicular thyroid cancers have significantly different RNA expression profiles, a subset of papillary has been identified with an expression profile more similar to follicular. In addition, a unified RAS-like expression profile spans subsets of papillary, follicular, and poorly differentiated thyroid cancers, suggesting that tumor biology can be similar across histologies. Clinical trial information: NCT00984282.

6084 Poster Session (Board #72), Mon, 1:15 PM-4:45 PM

Interim baseline characteristics from RIFTOS MKI, a global non-interventional study assessing the use of multikinase inhibitors (MKIs) in the treatment of patients with asymptomatic radioactive iodine-refractory differentiated thyroid cancer (RAI-R DTC). *First Author: Marcia S. Brose, Abramson Cancer Center, Philadelphia, PA*

Background: RIFTOS MKI was designed to compare the time to symptomatic progression from study entry in patients with RAI-R DTC for whom there was a decision to treat or not to treat with an MKI in the real-life setting. Here, we report interim baseline characteristics for the first 274 patients enrolled in the study. **Methods:** RIFTOS MKI is a non-interventional study enrolling patients with asymptomatic RAI-R DTC. The decision to initiate MKIs at study entry was at the discretion of the treating physician. Final analysis will be performed once 700 patients have been enrolled and the last enrolled patient has been followed for 24 months. **Results:** Of 274 patients, the median duration of observation was 169.5 days. Patients have been enrolled from USA (n = 74), Japan (n = 55), Europe (n = 80), and rest of the world (n = 65); 54% were female and the median age was 68 years. Most patients had an ECOG performance status of 0 or 1 (97%) and distant metastases (81%). The most frequent histology was papillary (73%). The median time from initial diagnosis of DTC to study entry was 7 years. RAI refractoriness was mainly due to lack of RAI uptake (60%), primarily in Japan (80%). Japan also had the shortest median time from RAI classification to initial visit (2 months) vs other regions, and the average dose per RAI treatment and median cumulative activity of RAI were lower in Japanese patients (3.4 and 3.7 GBq, respectively) (Table). **Conclusions:** The RIFTOS MKI study is the largest non-interventional study in RAI-R DTC. The regional differences in treatment history observed in the RIFTOS MKI study reflect differences in accessibility and treatment practice. The study is ongoing. Clinical trial information: NCT02303444.

6085 Poster Session (Board #73), Mon, 1:15 PM-4:45 PM

Combination of dabrafenib (DAB). *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: BRAFV600E mutations (BRAFm) are the most common mutations in thyroid cancer. BRAF inhibitors are active in BRAFm melanoma, but there is less activity noted in BRAFm thyroid cancer. Preclinically, BRAF inhibitors inhibit BRAFm thyroid cancers only transiently due to activation of HER2/HER3, driven by a neuregulin-dependent autocrine loop. The addition of LAP, a HER2/HER3 kinase inhibitor, sensitizes the cell to growth suppression by BRAF inhibitors (Cancer Discov 5(3):520, 2013). A phase I study evaluating the combination of DAB, a BRAF inhibitor, and LAP was initiated to evaluate the safety and pharmacodynamic changes the combination. **Methods:** Eligibility included thyroid cancers with the presence of a BRAFV600E mutation. Any prior treatment was allowed. All patients received DAB 150 mg bid starting 2 weeks prior to LAP. Doses of daily lapatinib were escalated in a standard 3+3 design at (1) 750 mg; (2) 1250 mg; (3) 1500 mg. Toxicities, including Dose Limiting Toxicities (DLT), were noted only after both drugs were started. Patients (pts) removed before the start of LAP were not included in the analysis. Biopsies were done at baseline, after the start of DAB, and after the start of both DAB and LAP. Responses were defined using RECIST 1.1. **Results:** 15 evaluable pts were enrolled on the phase I portion of the study. Gender – 10/15 (67%) male; median age – 63 years; histology – differentiated thyroid cancer (DTC) 13 (87%), anaplastic thyroid cancer (ATC) 2 (13%); brain metastases – 4/15 (27%); prior tyrosine kinase inhibitor – 9/15 (54%). There was one DLT - Grade 5 event unlikely related to drugs in a pt with ATC. Grade 4 toxicities – 0. Grade 3 toxicities –lymphocytes (1). The partial response rate is 60%. The response rate in the DTC group is 69% (0% in ATC). One other pt came off treatment due to withdrawal of consent. Median progression-free survival is 15 months (range, 2-34+ months). Median follow up is 15 months. Translational studies are pending. **Conclusions:** The combination of DAB 150 mg bid and LAP 1500 mg daily was safe and well-tolerated. Furthermore, significant activity was noted, especially at the top dose level. Further investigation with this regimen is warranted. Clinical trial information: NCT01947023.

Dose level	#	DLT	Response rate	# with ATC
1-LAP 750mg	6	1	50%	1
2-LAP 1250mg	3	0	33%	1
3-LAP 1500mg	6	0	83%	0

Targeted therapy for advanced salivary cancer with HER2 or hedgehog alterations: Interim data from MyPathway. *First Author: Razelle Kurzrock, Moores Cancer Center, University of California San Diego School of Medicine, San Diego, CA*

Background: Salivary gland cancers comprise <1% of cancers. Advanced cases have a 40% 5-year survival rate. Due to their rarity, no standard treatment guidelines exist. However, salivary duct carcinomas have morphological and gene expression profiles similar to breast cancers, and 20–40% of this subset have HER2 alterations. MyPathway (NCT02091141) is an ongoing, phase 2, multi-basket study evaluating the efficacy of targeted treatments in nonindicated tumor types with alterations in the HER2, BRAF, Hedgehog (Hh), or EGFR pathways. We present interim data for patients with salivary cancer. **Methods:** Patients had advanced salivary cancer with HER2 (amplification, overexpression, and/or mutation) or Hh (SMO or PTCH-1) alterations, locally assessed by gene sequencing, FISH, or IHC, as applicable. Patients received standard doses of pertuzumab + trastuzumab or vismodegib, respectively, until disease progression or unacceptable toxicity. The primary endpoint is investigator-assessed objective response rate (ORR) by RECIST v1.1. **Results:** As of Nov 30, 2016, 8 patients had been treated for salivary cancer, all carcinomas (7 had HER2 alterations; 1 had an Hh alteration). One HER2 patient without a post-baseline tumor assessment by data cut-off was not evaluable for efficacy. Characteristics and outcomes are shown (Table). Of 6 patients with a complete response (CR) or partial response (PR), 5 patients were still receiving study treatment by the data cut-off, with a median time on treatment of 4.6 months (range 1.4–12.5). There were no new safety signals. **Conclusions:** Six of 7 patients (86%) with advanced salivary carcinoma achieved CR or PR by targeting HER2 (n=5) or Hh (n=1) alterations. These promising results merit study of these treatments in additional patients. Accrual to MyPathway is ongoing. Clinical trial information: NCT02091141.

	HER2 (n=7)[a]	Hh (n=1)[b]
Median age, years	59 (range 47–80)	65
Male, n	6 (86%)	1
Prior lines of treatment, median	1 (range 0–3)	0
Objective response[c], n	5 (1 CR, 4 PR) ORR: 83% (95% CI 36–100)[d]	1 (PR)

[a]Six patients had HER2 amplification/overexpression (1 patient with PR also had HER2 mutations [D769H/L755F]). The unevaluable patient had a HER2 mutation (S310F); [b]PTCH-1 (Q400*); [c]CR + PR; [d]In 6 evaluable patients.

6087 Poster Session (Board #75), Mon, 1:15 PM-4:45 PM

***NTRK1-3* point mutations in poor prognosis thyroid cancers.** *First Author: Nicole M. Iniguez-Ariza, Mayo Clinic, Rochester, MN*

Background: *NTRK1-3* fusions, identified in pediatric radiation-associated thyroid cancers, are low frequency oncogenic drivers that can trigger constitutive activation of TrK1-3 tyrosine kinase domains with responsively heightened downstream signaling through RAS-MAPK, PI3K-AKT, and/or PLCγ-PKC. *NTRK* point mutations are rare and of largely uninvestigated oncogenic potential, but some appear oncogenic. **Methods:** Advanced thyroid cancer (TC) patients (pts) requiring systemic therapy at Mayo Clinic sites underwent tumor genetic interrogation using Foundation One analyses with the goal of informing salvage therapeutic strategies. In this IRB-approved study, data from pts with TCs bearing *NTRK* point mutations were retrospectively analyzed, as this occurrence was unexpected but potentially of prognostic and/or therapeutic relevance. **Results:** Five of 55 pts (9%) with advanced TCs subject to Foundation One tumor interrogation had *NTRK1-3* point mutations (allele frequency, AF, 15-49%); none had fusions. All 5 tumors had microsatellite stability; 4/5 had low tumor mutation burden (2-5 mutations/megabase). *NTRK* mutations in 3 anaplastic TC (ATC) pts (15% prevalence) were: *NTRK3* I749M (AF 15%; overall survival, OS, 15 mos), *NTRK1* R744H (AF not available; OS 9.5 mos), and *NTRK1* R583H (AF 20.1%; OS > 4.9 mos); *NTRK2* S167Y (AF 49%; OS > 51 mos) or *NTRK1* R6W (AF 42%; OS > 60 mos) were found in one papillary (PTC) and one Hürthle cell (HCC) TC pt respectively (summary table below). **Conclusions:** *NTRK* point mutations, but not fusions, were unexpectedly identified in 9% of assessed advanced TCs - but remarkably in 15% of ATCs. Mutated NTRKs, along with oncogenic p53 and TERT, may contribute to TC progression, especially in ATC, consequent to downstream activation of MAPK and PI3K-AKT pathways. We posit that *NTRK* point mutations may have therapeutic implications for treatment of refractory disease.

6088 Poster Session (Board #76), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling of parathyroid carcinoma. *First Author: Hyunseok Kang, The Sidney Kimmel Comprehensive Cancer Center and Bloomberg-Kimmel Institute for Cancer Immunotherapy at Johns Hopkins, Baltimore, MD*

Background: Parathyroid carcinoma (PC) is a rare endocrine malignancy, which can cause life-threatening hypercalcemia. Initial surgery is often noncurative, and adjunctive radiotherapy and previous chemotherapies have not been shown to be effective. Previous studies identified recurring mutations in *CDC73* and *PRUNE2*in a limited number of patients. We queried whether comprehensive genomic profiling (CGP) would have potential to discover novel targets of therapy. **Methods:** DNA was extracted from 40 microns of FFPE sections from 13 consecutive cases of relapsed/metastatic PC. CGP was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 672x for up to 315 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer. Genomic alterations (GA) included base substitutions (SUB), INDELs, copy number alterations (CNA) and fusions/rearrangements. Clinically relevant GA (CRGA) were defined as GA linked to drugs on the market or under evaluation in mechanism driven clinical trials. **Results:** Total of 13 specimens were identified from 7 male and 6 female patients. The mean age of the patients in this study was 54 years (range 38 to 76 years). All (100%) cases were Stage IV at the time of CGP. Tumor mutation burden was generally low - median mutation load per mega base was 1.8. There were 58 total GA (4.5 GA/sample) and 10 CRGA (0.8 CRGA/sample). The most frequent GA were non-CRGA mutations in *TP53* (31%) and *CDC73* (31%). *MEN1* mutations were identified in 23% of cases. Frequent alterations in genes controlling cell cycle progression at G1 including *CDKN1B*, *CDKN2A*, *CDKN2B* and *CDKN2C* were identified (30%). The most frequent CRGA involved *PTEN* (23%), NF1 (23%) and *KDR* (15%). No alterations in *BRAF* or *RET*were identified. A patient with KDR mutation treated with cabozantinib experienced > 50% drop in PTH level and radiographic partial response in 3 months. **Conclusions:** CGP identified previously unreported TP53 mutations in PCs and potentially actionable genomic alterations including *PTEN*, *NF1* and *KDR*. Clinical benefit and response observed in a patient treated with VEGFR targeted therapy suggest that patients with this rare tumor may be candidates for targeted therapies.

6089 Poster Session (Board #77), Mon, 1:15 PM-4:45 PM

Association of activating NOTCH1 mutations in adenoid cystic carcinoma with shorter progression-free survival to systemic therapy. *First Author: Renata Ferrarotto, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We previously reported that activating *NOTCH1* mutations occurs in approximately 20% of ACCs and drive a phenotype with solid histology, liver and bone metastases, poor prognosis, and potential responsiveness to Notch1 inhibitors; however the impact of *NOTCH1*mutations on responsiveness to systemic therapy in ACC is unknown. The aim of this study was to evaluate the ORR and median PFS (mPFS) to systemic therapy in patients with metastatic ACC according to their Notch1 status. **Methods:** We identified 20 ACC patients with measurable disease that underwent treatment at MDACC and had tumor molecular profile. A radiologist blinded to the patient's *NOTCH1*status performed review of all images. Measurement of target lesions was captured by a quantitative imaging analysis tool for ORR assessment by RECIST 1.1. PFS was estimated by Kaplan-Meier method. Comparisons of PFS between groups were performed using log-rank test. P≤0.05 was considered statistically significant. **Results:** Out of 20 patients, 4 (20%) were *NOTCH1* mutant. Notch1 pathway activation status by immunohistochemistry (NICD) was available for 15 patients, 10 were positive. The median number of therapy lines was 2 (range 1-6). Best ORR among 49 treatment plans across all lines of systemic therapy including chemotherapy (15), anti-EGFR (10), anti-VEGFR (11), and others (13) was PR in 2 (4%), SD in 29 (59%), and PD in 18 (37%). During first line treatment, patients with *NOTCH1* mutations had significantly shorter mPFS compared to *NOTCH1* wild-type (2.97 vs. 6.92 months, P = 0.02). The PFS rate at 3 months was 25% for *NOTCH1*-mutants vs. 81% for wild-type. A trend towards shorter PFS was seen in NICD positive vs. negative (3.58 vs. 6.74 months, P = 0.2). **Conclusions:** *NOTCH1* mutations in ACC are associated with shorter PFS during first-line treatment. Validation of these findings is warranted in larger patient cohorts.

TPS6090 **Poster Session (Board #78a), Mon, 1:15 PM-4:45 PM**

KEYNOTE-412: Pembrolizumab (pembro) in combination with chemoradiation versus chemoradiation alone in locally advanced head and neck squamous cell carcinoma (LA-HNSCC). *First Author: Jean-Pascal H. Machiels, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: Approximately half of patients (pts) with HNSCC are diagnosed with locally advanced disease and treated with surgery or concomitant chemoradiotherapy (CRT) with cisplatin. Unfortunately, disease recurs in 40% to 60% of patients. The PD-l inhibitor pembro is approved for recurrent/metastatic HNSCC. CRT has immunomodulatory effects; preclinical data suggest that efficacy can be improved by adding pembro. The phase 3 KEYNOTE-412 trial (NCT03040999) will explore if CRT + pembro can improve outcomes of pts with LA-HNSCC. **Methods:** Adult pts with newly diagnosed, pathologically proven, treatment-naive LA-HNSCC will be enrolled. Study population will include p16-negative HNSCC (any T3-T4 or any N2a-N3 [AJCC 7th edition]) and p16-positive oropharyngeal cancer (any T4 or any N3). Other eligibility criteria: measurable disease per RECIST v1.1 by blinded independent central review (BICR), provision of tumor sample for biomarker analyses, ECOG PS 0 or 1, and eligible for definitive CRT but not considered for primary surgery. Pts will be randomly assigned 1:1 to receive either pembro 200 mg every 3 weeks (Q3W) plus CRT, which includes radiotherapy (RT; accelerated [70 Gy, six 2 Gy fractions/wk] or standard [70 Gy, five 2 Gy fractions/week] fractionation) plus cisplatin 100 mg/m^2 Q3W for 3 cycles only, or placebo Q3W plus CRT. Pts will be stratified by RT regimen, tumor site/p16 status, and disease stage. Treatment will continue until centrally confirmed disease progression, unacceptable AEs, decision to withdraw by pt or investigator, or completion of 17 doses of pembro/placebo. Disease status will be evaluated by CT or MRI 12 weeks after end of CRT, every 4 months during the next 2 years, and then every 6 months during years 3-5. Pts will be evaluated for neck dissection at 12 weeks after CRT. AEs will be monitored and graded using CTCAE v4.0 throughout the trial and for 30 days (90 days for serious AEs) after end of treatment. Primary efficacy end point is event-free survival per RECIST v1.1 by BICR. Key secondary end points: overall survival, quality of life, and safety and tolerability of pembro. Approximately 780 pts will be enrolled. Clinical trial information: NCT03040999.

TPS6091 **Poster Session (Board #78b), Mon, 1:15 PM-4:45 PM**

Phase III randomised controlled trial (RCT) comparing alternative regimens for escalating treatment of intermediate and high-risk oropharyngeal cancer (CompARE). *First Author: Hisham Mohamed Mehanna, University of Birmingham, Birmingham, United Kingdom*

Background: Patients with intermediate and high-risk oropharyngeal cancer (OPC) have poorer response to standard treatment and poorer overall survival compared to low-risk OPC. The CompARE trial is designed to test alternative approaches to intensification of treatment for these patients to improve survival. **Methods:** CompARE is a pragmatic phase III open-label multicenter RCT with an adaptive multi-arm multi-stage design. Eligible OPC patients include those with; HPV negative, T1-T4, N1-N3 or T3-4, N0 or HPV positive current smokers (or $\geq$ 10 pack years previous smoking history) with T1-T4, N2b-N3. The primary outcome measure is overall survival. Secondary outcome measures include quality of life, toxicity, swallowing outcomes, feeding tube incidence, surgical complications and cost-effectiveness. The trial is powered to detect a hazard ratio of 0.69 (an improvement of 10% in OS at 3-years) requiring 128 control events. It is estimated that the study will take 6.5 years to recruit sufficient patients to experience the number of events needed. Planned interim futility analyses using event-free survival (EFS) will be performed when 70 and 114 control EFS events have occurred. Current treatment arms are; (1) control: standard treatment of 3-weekly cisplatin 100mg/m^2 or weekly 40mg/m^2 with Intensity Modulated Radiotherapy (IMRT) using 70Gy in 35F +/- neck dissection determined by clinical and radiological assessment 3-months post treatment. (3) IMRT 64Gy in 25F + cisplatin 100mg/m^2 day 1 of week 1 and week 5 or weekly 40mg/m^2+/- neck dissection as per standard treatment. (4) Resection of primary + selective neck dissection followed by standard treatment. (5) One cycle of induction durvalumab 1500mg followed by standard treatment then durvalumab 1500mg every four weeks for a total of 6 months. Recruitment to arm (2) involving induction chemotherapy from the original protocol is suspended. Since July 2015, 42 patients have been randomised with 16 sites open to recruitment. The Data Monitoring Committee last reviewed progress and conduct of the trial in September 2016 and recommended continuation. ISRCTN Number: 41478539, CRUK CRUK/13/026 Clinical trial information: 41478539.

TPS6092 **Poster Session (Board #79a), Mon, 1:15 PM-4:45 PM**

An open-label, single-arm, multi-institutional phase II trial of avelumab for recurrent, metastatic nasopharyngeal carcinoma. *First Author: Assuntina Gesualda Sacco, University of California San Diego Moores Cancer Center, La Jolla, CA*

Background: The majority of patients with nasopharyngeal carcinoma (NPC) present with locally advanced disease, with a predilection for early systemic dissemination. For patients who develop recurrent and/or metastatic (R/M) NPC, survival is poor. Following first-line platinum-based regimens, there is no well-defined paradigm for subsequent therapies. Inhibition of PD-L1 with Avelumab is an attractive strategy because Epstein-Barr virus (EBV), the primary causative agent in NPC pathogenesis, universally upregulates PD-L1 expression; proposed mechanisms of upregulation include immune resistance via innate (EBV-induced latent membrane protein-1) and adaptive (Interferon-gamma) mechanisms; increased PD-L1 expression is an independent poor prognostic factor for disease-free survival. **Methods:** Patients with histologically/cytologically confirmed, EBV-related NPC not amenable to curative intent therapy who received $\geq$1 prior line of systemic therapy for R/M disease are eligible. Patients must be at least 18 years old, ECOG 0-2, willing to undergo tumor biopsy, have adequate organ and marrow function, and no prior therapy with PD-1/PD-L1 inhibitors. 39 patients will be enrolled across 6 sites. Patients will receive Avelumab 10 mg/kg IV on days 1 and 15 of each 28-day cycle. Treatment will continue until disease progression, unacceptable toxicity, investigator/patient decision. A newly obtained tumor specimen is required at enrollment; optional biopsy at time of progression. EBV plasma DNA titers will be evaluated at baseline, during treatment and at progression, using an EBV BamHI-W DNA PCR. Blood samples at baseline and 12 weeks after treatment initiation will be obtained for correlatives. Primary endpoint is overall response rate (ORR; complete and partial responses) at 6 months per RECIST. A two-stage design will reject H_0 (ORR 15%) if the observed ORR is $\geq$30%, α 0.1, β 0.8, required sample size n = 39. Secondary endpoints include duration of response, progression-free and overall survival. Correlative analyses will evaluate PD-L1 expression, T and B-cell subsets, frequency and clonality. The study has accrued 2 of planned 39 patients. NCT02875613. Clinical trial information: NCT02875613.

TPS6093 **Poster Session (Board #79b), Mon, 1:15 PM-4:45 PM**

JAVELIN head and neck 100: A phase 3 trial of avelumab in combination with chemoradiotherapy (CRT) vs CRT for 1st-line treatment of locally advanced squamous cell carcinoma of the head and neck (LA SCCHN). *First Author: Nancy Y. Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cisplatin + radiotherapy is a standard-of-care treatment for patients (pts) with LA SCCHN. Combining avelumab (fully human IgG1 anti–PD-L1 antibody) and CRT may synergistically activate multiple immune-mediated mechanisms to effect a robust and durable antitumor response and improve long-term disease control. **Methods:** JAVELIN Head and Neck 100 (NCT02952586) is a global, multicenter, randomized, double-blind, phase 3 trial of avelumab + cisplatin-based CRT vs placebo + CRT as 1st-line treatment for pts with LA SCCHN. The primary objective is to demonstrate superiority of avelumab + CRT in prolonging progression-free survival (PFS) vs CRT alone. Eligible pts have LA SCCHN of the oral cavity, oropharynx, larynx, or hypopharynx; HPV− or non-oropharyngeal HPV+ disease of stage III, IVa, or IVb; or HPV+ oropharyngeal disease T4, N2c, or N3. Pts must be candidates for cisplatin-based CRT. Other eligibility criteria include ECOG PS $\leq$1 and no prior systemic treatment for advanced disease. Approximately 640 pts will be randomized 1:1 to receive avelumab 10 mg/kg (1-hour IV) + CRT (intensity-modulated RT [70 Gy/35 fractions] + cisplatin 100 mg/m^2 [x3]) or placebo + CRT. There will be 3 treatment phases: lead-in (single dose of avelumab or placebo), CRT (concurrent avelumab or placebo + CRT for 7 weeks), and maintenance (avelumab or placebo Q2W for 12 months). The rationale for this design is to induce an immune response during lead-in and CRT phases, followed by maintenance treatment to prolong and support immune memory development. The primary endpoint is PFS per modified RECIST v1.1. Secondary efficacy endpoints include overall survival, objective response, locoregional failure, distant metastatic failure, and duration of response. Other endpoints include safety, pharmacokinetics, immunogenicity, pt-reported outcomes, and biomarker assessments. Treatment will continue for 12 months following initiation of the maintenance phase or until progressive disease, unacceptable toxicity, or any other protocol-defined criterion for withdrawal occurs. Enrollment in this phase 3 trial began in November 2016. Clinical trial information: NCT02952586.

TPS6094 **Poster Session (Board #80a), Mon, 1:15 PM-4:45 PM**

Anti-PD-L1 durvalumab combined with cetuximab and radiotherapy in locally advanced squamous cell carcinoma of the head and neck: A phase II study. *First Author: Pierluigi Bonomo, University of Florence, Florence, Italy*

Background: Head and neck squamous cell carcinoma (HNSCC) is characterized by prominent immune escape mechanisms. Potentially, the blockade of immune check points such as the PD-1/PD-L1 axis may stimulate the host T-cell activation against tumor cells and favor the FcγRIIIa-mediated, Cetuximab (CTX) induced antibody dependent cellular cytoxicity (ADCC). Durvalumab (DUR) is a humanized monoclonal IgG1, anti-PD-L1 antibody with promising activity in recurrent/metastatic HNSCC (NCT01693562). The aim of our study is to test the hypothesis that a restored ability of the host immune system via blockade of the PD1/PD-L1 axis through DUR may enhance the antitumor activity of both CTX and radiotherapy (RT) in locally advanced HNSCC, a setting with unmet needs for effective treatment options. **Methods:** In this open-label, multi-center, single-arm, phase II study, enrolled patients will receive RT (69.9 Gy/2.12 Gy fx in 33 fractions over 7 weeks) with concurrent CTX (400 mg/m^2 1 week before RT start followed by 250 mg/m^2 q1w) and DUR (1500 mg q4w starting from RT-CTX week 1) followed by adjuvant DUR (to a maximum of 6 months after completion of RT-CTX). Primary endpoint of the study is 2-year progression-free survival (PFS). Assuming a 2-year PFS of 66% based on historical data from RTOG study 0129, the experimental regimen is hypothesized to yield a 12% absolute increase at 2 years, corresponding to a hazard ratio of 0.6 ($\alpha = 0.1$, power is 0.80 when the 2-year PFS is 78%). The required sample size with this design is 69 patients. A safety run-in is planned after the enrollment of first 12, 24 and 36 patients. Patients affected by high-risk ($>$ N2a or $>$ T3, any N) larynx, hypopharynx and HPV negative oropharynx or HPV-positive oropharynx ($>$ N2b, $>$ 10 pack/years) will be eligible. To avoid potential RT-induced chronic loco-regional immunosuppression, protocol-indications will be undertaken to restrict target volumes to sites of gross disease and subclinical high risk lymph node basins excluding areas deemed at very low risk of disease spread. For this purpose, dose-painting intensity modulated radiotherapy (IMRT) is mandatory for this study. Clinical trial information: 2016-004668-20.

TPS6095 **Poster Session (Board #80b), Mon, 1:15 PM-4:45 PM**

A randomized, double-blind phase II study of pembrolizumab versus placebo in patients with head and neck cancers at high risk for recurrence or low-volume residual disease: The PATHWay Study. *First Author: Joshua Bauml, University of Pennsylvania, Philadelphia, PA*

Background: Head and neck squamous cell carcinoma (HNSCC) is a major medical problem worldwide. While some patients may be cured with a combination of surgery, radiation, and systemic therapies, a significant percentage of patients will have recurrent and incurable disease. Despite our epidemiologic understanding of which patients are likely to recur, there are no consolidative therapies that have been shown to improve outcomes in this high-risk population. Pembrolizumab is a PD-1 inhibitor that has shown significant single agent activity in recurrent/metastatic HNSCC after treatment with other systemic therapies. While drug development of pembrolizumab is ongoing in Phase III studies in the 2nd and 1stline recurrent/metastatic disease settings, the ultimately the biggest potential impact based on patient volume and survival will potentially be in the curative intent setting. This randomized study is intended to explore the incorporation of pembrolizumab into the treatment of patients with locally advanced HNSCC at high risk for recurrence. **Methods:** Eligible patients must have HNSCC, completed therapy with definitive intent, and have an estimated risk of recurrence ≥40-50% (including tumors with extensive lymphadenopathy, extracervical lymphadenopathy, indeterminate residual local or distant mass after treatment, non-responders to induction chemotherapy, incomplete definitive therapy, receipt of salvage therapies, or oligometastatic disease treated definitively). Patients will be randomized to 1 year of either pembrolizumab 200 mg or placebo, administered intravenously day 1 of each 3-week cycle. The primary hypothesis of the study is that the addition of pembrolizumab will improve the 2-year progression-free survival (PFS) rate, compared to placebo. A sample size of 90 (45 patients per treatment arm, assuming 10% loss of follow up in N = 100 patient trial) will achieve 92.7% power at alpha = 0.10 (one-sided) to detect a difference between 50% and 72.5% PFS at 2 years. Approximately 51 events are required to detect such a difference. Patient screening and enrollment are expected to begin spring 2017.

TPS6096 **Poster Session (Board #81a), Mon, 1:15 PM-4:45 PM**

Phase ɯ (window) preoperative study of olaparib with cisplatin or with durvalumab or alone or no treatment in patients with histologically proven head and neck squamous cell carcinoma who are candidates for surgery (OPHELIA). *First Author: Amanda Psyrri, University General Hospital Attikon, National and Kapodistrian University of Athens, Athens, Greece*

Background: Novel agents are often investigated in unselected end-stage cancer patients and their efficacy is evaluated by the classical RECIST criteria making unlikely to fully exploit the antitumor potential of these targeted agents. Olaparib (O) is a potent inhibitor of PARP especially active in tumors that have homologous recombination DNA repair pathway deficiencies. Durvalumab (D) is a selective, high-affinity human IgG1 monoclonal antibody that blocks PD-L1 binding to PD-1 and CD80, overcoming PD-L1-mediated inhibition of T-cell activation. There is substantial evidence that tumor cells use PARP to repair platinum-induced DNA damage and thus escape apoptosis. In addition, O may complement the antitumor activity of D by increasing DNA damage through repair inhibition. **Methods:** OPHELIA is an open-label randomized multicenter phase II (window) trial in patients (pts) with head and neck squamous cell carcinoma (HNSCC). Treatment-naive HNSCC pts selected for primary curative study are randomized 3:3:3:1 in 4 neoadjuvant treatment groups: D 1500 mg on day 1 followed by O 600mg daily for 21-28 days (12 pts), cisplatin 60 mg/m^2 on day 1 followed by O 75mg daily for 5 days (12 pts), monotherapy with O 600mg daily for 21-28 days (12 pts) and no treatment (5 pts). Preoperative therapy is discontinued 24 to 36 hours before surgery. Tumor biopsies, CT scans, PET and blood specimens are obtained at diagnosis and at surgery. Primary endpoint is the change in the tumor Ki-67 before and after treatment. Secondary endpoints are objective response rate according to RECIST 1.1 criteria, pathologic complete response rate and metabolic response rate assessed by FDG-PET/CT scan. Exploratory endpoints will include tumor and blood biomarkers. Translational correlates will be tested in tumor tissue, plasma and germline DNA and will include mutations in genes associated with DNA repair assessed by next generation sequencing and circulating tumor cells (CTCs) evaluated for DNA repair biomarkers and PD-L1. Trial is open to enrollment. Clinical trial information: NCT02882308.

TPS6097 **Poster Session (Board #81b), Mon, 1:15 PM-4:45 PM**

A randomized phase II study of chemoradiation (CRT) +/- nivolumab (Nivo) with sequential safety evaluations of Nivo +/- lirilumab (Liri) or ipilumumab (Ipi) concomitant with (C) RT in intermediate (IR) and high-risk (HR) head and neck squamous cell carcinoma (HNSCC) (RTOG 3504, NCT02764593). *First Author: Maura L. Gillison, Ohio State University, Columbus, OH*

Background: Nivolumab (Nivo), a monoclonal antibody to the programmed death-1 (PD-1) immune checkpoint receptor, improved overall survival (OS) for patients (pts) with platinum-refractory, recurrent/metastatic HNSCC compared with standard therapy. A placebo controlled phase IIR trial was designed to investigate the hypothesis that Nivo added to platinum-based CRT will improve progression free survival (PFS) for pts with newly diagnosed IR/HR HNSCC. **Methods:** Eligibility includes IR HNSCC (p16+, oropharynx T1-2N2b-N3/T3-4N0-3, $>$ 10 pack-years (pys) or T4N0-N3, T1-3N3 ≤ 10 pys) and HR HNSCC (oral cavity, larynx, hypopharynx, or p16(-) oropharynx, stage T1-2N2a-N3 or T3-4N0-3). After safety evaluation in 8 evaluable pts, 176 pts will be randomized (1:1) to cisplatin (40 mg/m^2/week X 7) with radiation (IMRT, 70 Gy in 7 weeks) +/- Nivo/placebo (240 mgs q14 days X 5, then 480 mgs q28 X3). Primary endpoint is PFS. Secondary endpoints include OS, acute and chronic toxicity, quality of life and biomarkers (tumor PD-L1 expression; E6/7 seroreactivity and frequency of functional circulating and intraumoral T cells). Parallel with Phase IIR are sequential safety evaluations (see Table) in platinum eligible and ineligible ($>$ 70 years; ≥3 grade neuropathy; ≥2 hearing loss; or CrCl $<$ 60 ml/min) cohorts (N = 10-20) of Nivo +/- Liri (anti-KIR) or Ipi (anti-CTLA4) concomitant with RT alone, cisplatin-RT or cetuximab-RT platforms followed by 3 months of adjuvant immunotherapy. The primary endpoint is safety and feasibility. With 8 evaluable pts, the probability of treatment assessed as toxic is $>$ 78% when the true toxicity rate is $>$ 45% and treatment assessed tolerable is $>$ 80% if the true toxicity rate is $<$ 20%. Clinical trial information: NCT02764593.

Cohort	Cisplatin Eligible	Immunotherapy	Chemotherapy	RT IMRT 70 Gy/7 weeks
1	Yes (Y)	Nivo	Weekly cis	Y
2	Y	Nivo	High dose cis	Y
3	Y	Nivo	Cetuximab	Y
4	Y	Nivo + Liri	High dose cis	Y
5	Y	Nivo + Ipi	High dose cis	Y
A	No (N)	Nivo	–	Y
B	N	Nivo	Cetuximab	Y
C	N	Nivo + Liri	–	Y
D	N	Nivo + Ipi	–	Y

TPS6098 **Poster Session (Board #82a), Mon, 1:15 PM-4:45 PM**

Phase II trial of ribociclib and everolimus in p16 low anaplastic thyroid cancer (ATC). *First Author: Bernard Tawfik, University of Texas Southwestern Medical Center, Dallas, TX*

Background: ATC is a rare thyroid cancer with a highly aggressive clinical course. Median OS is 3-4 months and 90% of patients die within 1 year of the diagnosis. There are no effective treatment options in metastatic disease. Targeted therapies to ALK and BRAF are occasionally associated with dramatic responses. Retinoblastoma (Rb) inhibits cell cycle progression and is inactivated by CDK 4/6, which is the target for ribociclib. Nearly all differentiated thyroid cancers are Rb negative, conversely nearly 100% of ATC expresses intact Rb which may be crucial for rapid cell cycle progression. Ribociclib is a CDK 4/6 inhibitors that slows cell cycle progression and DNA replication in tumors with functional Rb. The p16 protein similarly inhibits CDK4/6; if p16 levels are high Rb is phosphorylated and thus inactive. p16 is low in ATC, and from our comprehensive genomic analysis 30% of ATC lacks the p16 gene *CDKN2a*. Most ATC demonstrates PI3K/Akt/mTOR abnormalities, this pathway represents an attractive target in ATC. The mTOR inhibitor everolimus has shown promising efficacy in ATC cell lines, especially in those with TSC2 mutation whose wild type negatively regulates mTOR. **Methods:** The combination of everolimus and ribociclib targets mutations/abnormalities that are frequently seen in ATC, and is tolerable based on Phase I/II trial results in the latest arm of the biomarker/oncogene driven ATC Master Protocol . This open-label trial treats metastatic Rb+ ATC patients with p16-/*CDKN2a*-. Treatment is ribociclib 400 mg + everolimus 5 mg QD. The primary endpoint is the overall response rate; secondary endpoints are PFS, OS, safety and toxicity. Exploratory objectives include if tissue biomarkers or mutations noted on Next Generation Sequencing correlate for enhanced/impaired response to combination therapy. Simon's two-stage design will be used with the null hypothesis that the true response rate is 5%, this will be tested against a one-sided alternative. In the first stage, 9 patients will be accrued. If no response in these 9 patients, the study will be stopped. Otherwise, 21 additional patients will be accrued for a total of 30. Clinical trial information: NCT02289144.

TPS6099 **Poster Session (Board #82b), Mon, 1:15 PM-4:45 PM**

A phase II study of pembrolizumab and docetaxel for aggressive RAI refractory thyroid carcinomas or salivary gland cancers: The iPRIME study. *First Author: Tanguy Y. Seiwert, University of Chicago, Chicago, IL*

Background: Both aggressive, radioactive iodine refractory thyroid cancers as well as high-grade salivary gland cancers respond poorly to chemotherapy, and there is no widely used standard of care. Targeted thearpies as well as cytotoxic chemotherapy (e.g. doxorubicin, or taxanes) are commonly used, but are only modestly effective. Both salivary gland and thyroid cancers have been shown to have tumor infiltrating lymphocytes, tumor inflammation, and PD-L1 expression (*Ayers, AACR 2015*). Early data with anti-PD-1 immunotherapy using pembrolizumab (Keynote 28) show activity in ≤10a% of patients in a biomarker selected population (Keynote 28 thyroid and salivary gland cohorts). However, most patients are not PD-L1 positive and were not eligible. Recently synergy of anti-PD-1 checkpoint blockade with cytotoxic chemotherapy was reported in several studies (e.g. Langer et al, Keynote 21G). Mechanistically chemotherapy may increase tumor inflammation, and eradicate immusupressive myeloid derived suppressor cells (MDSCs). Data suggest a significant increase in the response rate e. g. in KN21G from 29% to 55%. Furthermore the depths of responses and durability improve, including patients with PD-L1 negative tumors. **Methods:** We hypothesize that the combination of PD-1 checkpoint blockade and cytotoxic chemotherapy will show synergistic activity in aggressive thyroid cancers and salivary gland cancers. Eligible patients will have radioactive iodine refractory, aggressive thyroid cancer (cohort A, N = 25 pts), or progressive salivary gland cancers (cohort B, N = 25 pts). There will be no PD-L1 or other biomarker selection. Patients must have progressed on prior therapy. Patients will receive docetaxel at a dose of 75mg/m2 Q21 days as well as pembrolizumab 200mg flat-dose Q21 days intravenously. The primary outcome of this study is response rate. The addition of pembrolizumab to chemotherapy will increase the response rate from 20% (H0) to 40% (H1). A simon two-stage design will be used for each cohort (cohorts A and B) with an estimate 81% power in each arm. Patient screening and enrollment are expected to begin mid 2017. Clinical trial information: pending.

6500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Primary outcomes analysis of a multicenter randomized controlled trial of an interactive decision tool for patients with breast cancer. *First Author: Sarah T. Hawley, University of Michigan Medical School, Ann Arbor, MI*

Background: High quality treatment decisions require that patients are well informed about treatment and that their values are considered. Yet studies show that patient knowledge about breast cancer treatment trade-offs is low and appraisal of decision-making is not optimal. **Methods:** We conducted a randomized controlled trial (RCT) of a tailored, comprehensive (locoregional and systemic treatment) and interactive decision tool (iCanDecide), compared with static online information. 537 newly diagnosed, early stage breast cancer patients were enrolled at the first visit in 22 surgical practices. Participants were surveyed 5 weeks (N = 496; RR 92%) post enrollment after locoregional treatment decision-making. The primary outcome was a high quality decision, including two components: high knowledge about treatment options and a values concordant treatment decision. The main secondary outcome was preparation for decision making. We evaluated the distribution of participants in each arm, and conducted logistic regression modeling to assess the association between the intervention and the outcomes controlling for patient characteristics and strength of treatment preference at enrollment. **Results:** Significantly more intervention than control patients had high knowledge (60% vs. 42%, $p < 0.001$), although the majority of both groups reported values concordant treatment (~84%). Intervention patients also reported feeling prepared for decision making significantly more often than controls (45% vs. 32%, $P < 0.01$). Patients randomized to the interactive intervention had higher knowledge (OR: 2.2; 95% CI 1.2-4.0) and preparation for decision making (OR: 1.5; 95% CI 1.1-1.4), even after adjusting for age, education, race, stage and clinical site. **Conclusions:** In this large RCT, a tailored, interactive treatment decision tool for breast cancer improved knowledge and prepared patients for complicated decision making, more than access to static online information. Future work to further integrate such tools into the clinical workflow is needed. Clinical trial information: NCT01840163.

6501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Cognitive technology addressing optimal cancer clinical trial matching and protocol feasibility in a community cancer practice. *First Author: J. Thaddeus Beck, Highlands Oncology Group, Rogers, AR*

Background: IBM Watson for Clinical Trial Matching (CTM) is a cognitive computing solution that uses natural language processing (NLP) to help increase the efficiency and accuracy of the clinical trial matching process. This solution helps providers locate suitable protocols for their patients by reading the trial criteria and matching it to the structured and unstructured patient characteristics when integrated with the Electronic Medical Record (EMR). It is also designed to determine which sites have the most viable patient population and identify inclusion and exclusion criteria that limit enrollment. **Methods:** This project was a collaboration among Highlands Oncology Group (HOG), Novartis and IBM Watson Health to explore the use of CTM in a community oncology practice. HOG is in Northeast Arkansas and has 15 physicians and 310 staff members working across 3 sites. During the 16-week pilot period, data from 2,620 visits by lung and breast cancer patients were processed by the CTM system. Using NLP capabilities, CTM read the clinical trial protocols provided by Novartis, and evaluated the patient data against the protocols' inclusion and exclusion criteria. Watson excluded ineligible patients, determined those that needed further screening, and assisted in that process. Feedback on the user experience was also obtained. **Results:** In an initial pre-screening test, the HOG clinical trial coordinator (CTC) took 1 hour and 50 minutes to process 90 patients against 3 breast cancer protocols. Conversely, when the CTM screening solution was used, it took 24 minutes. This represents a significant reduction in time of 86 minutes or 78%. Watson excluded 94% of the patients automatically, providing criteria level evidence regarding the reason for exclusion, thus reducing the screening workload dramatically. **Conclusions:** IBM Watson CTM can help expedite the screening of patient charts for clinical trial eligibility and therefore may also help determine the feasibility of protocols to optimize site selection and enable higher and more efficient trial accruals.

6502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Global impact of a clinical informatics system: Scalable delivery of on-time access to evidence-based multidisciplinary expert treatment decisions for all cancers. *First Author: Rajendra A. Badwe, Department of Surgical Oncology, Breast Disease Management Group, Tata Memorial Centre (TMC), Mumbai, India*

Background: There is a scarcity of expert oncologists in the world. Patients in nonurban areas have poor access to evidence-based treatment decisions and worse outcomes. In India, there are ~1600 experts for 1.8 Million patients. Created in May 2014, "TMC NCG Navya Online" is an expert opinion service based on an informatics system. We prospectively study its real-world impact. **Methods:** Navya exhaustively searches and outputs evidence and experience based treatment options for an individual patient. Its accuracy was validated in trials at TMC (one of the world's largest tertiary care centers) and UCLA-OVMC. Navya's patient data summary and treatment options are rapidly reviewed and vetted (1-2 minutes) on mobile by experts from TMC and NCG, (consortium of 104 cancer centers in India). Expert decisions are converted into a simple language report for patients. System generated evidence based information on diagnostics, regimens, side effects etc are also provided. To prospectively assess impact, from July to December 2016, all patients were asked via phone follow-up: 1. If report was shared with treating provider, 2. Final treatments delivered. **Results:** 9361patients from 22 developing countries registered with TMC NCG Navya Online. 3402 expert decisions were provided and converted into 2614 simple language reports. 5229 patients received system generated evidence based information. Median time to deliver a report was 24 hours. The prospective sample was 582 decisions with a 75% (n = 436) follow-up rate. 74% of reports were shared with treating providers. 73% of TMC NCG Navya's decisions, (n = 306), were the final treatments delivered. Common reasons for non-implementation included decline in ECOG status and not testing biomarkers (ER/PR etc). **Conclusions:** Expert oncologists use Navya to provide rapid online opinions to patients across 22 developing countries. Patients shared the expert opinions with their providers and received evidence-based treatments. Expanding the reach and impact of such a service to nonurban USA and the world, can maximize outcomes for patients without ready access to expertise.

6503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Impact of the timing of hepatitis B virus (HBV) identification and anti-HBV therapy initiation on the risk of adverse liver outcomes in patients receiving cancer therapy. *First Author: Jessica Hwang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with cancer and hepatitis B virus (HBV) infection receiving cancer therapy are at risk for HBV reactivation. We aimed to determine the impact of early vs. late HBV identification and early vs. late/no anti-HBV therapy on adverse liver outcomes of patients with cancer with chronic (HBsAg+/anti-HBc+) or past (HBsAg-/anti-HBc+) HBV infection. **Methods:** We retrospectively studied adult patients with solid or hematologic malignancies who received chemotherapy during 2004-2011. Adverse liver-related events included hepatitis flares, liver failure, and death. Time-to-event analysis was used to determine incidence, and multivariable hazard models to determine predictors of outcomes. *Early* was defined as at the initiation of cancer therapy and *late* as after therapy initiation. **Results:** There were 18,688 study patients (80.4% had solid tumors). Among patients with hematologic malignancies, 89.6% had HBV testing of which 90.4% was early. Among patients with solid tumors, 10.8% had HBV testing of which 46.4% was early. Prevalence of chronic HBV was 1.1% (52/4905) and past HBV was 7.1% (350/4905). Among patients with chronic HBV with hematologic or solid malignancy, those identified late had 2.95 times (1.45-6.01) higher risk of liver failure than those identified early. Among chronic HBV patients, 59% (23/39) with early testing had early initiation of anti-HBV therapy, while all of those tested late had late/no initiation of anti-HBV therapy. Predictors of liver failure were male sex, chronic HBV, and late HBV identification for patients with solid tumors, and allogeneic SCT for patients with hematologic malignancies. **Conclusions:** Early HBV identification correlated with early anti-HBV therapy initiation and reduced risk of liver failure after chemotherapy in chronic HBV patients with solid tumors or hematologic malignancies as well as patients with past HBV and solid tumors.

6504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Post-discharge transitions of care for hospitalized patients with advanced cancer. *First Author: Daniel E Lage, Harvard Medical School, Boston, MA*

Background: Patients with advanced cancer experience frequent hospitalizations and burdensome transitions of care post-discharge. We examined predictors of discharge location for patients with advanced cancer. **Methods:** We prospectively enrolled patients with advanced cancer with unplanned hospitalizations from 9/14 to 3/16. Upon admission, we used the Edmonton Symptom Assessment Scale and Patient Health Questionnaire-4 to assess physical and psychological symptoms, respectively. We used logistic regression models to identify predictors of discharge to location other than home, including post-acute care (PAC) [skilled nursing facility or long term acute care hospital] or hospice [any setting]. We used Cox regression models adjusted for clinical variables to assess the relationship between discharge location and survival. **Results:** Out of 932 patients, 726 (77.9%) were discharged home, 118 (12.7%) to PAC and 88 (9.4%) to hospice. Compared with patients discharged home, those discharged to PAC or hospice had higher symptom burden, including dyspnea, constipation, low appetite, drowsiness, fatigue, depression, and anxiety (all $p < 0.05$). Patients discharged to PAC or hospice vs. home were more likely to be older (OR 1.03, $p < 0.0001$), live alone (OR 1.95, 95% CI: 1.25-3.02, $p < 0.003$), have impaired mobility (OR 5.08, 95% CI: 3.46-7.45, $p < 0.0001$), longer length of stay (OR 1.15, 95% CI: 1.11-1.20, $p < 0.0001$), higher ESAS physical symptoms (OR 1.02, 95% CI: 1.003-1.032, $p < 0.017$), and higher PHQ-2 depression symptoms (OR 1.13, 95% CI: 1.01-1.25, $p < 0.027$). Patients discharged to hospice vs. PAC were more likely to receive palliative care consultation (OR 4.44, 95% CI: 2.12 to 9.29, $p < 0.0001$) and have shorter length of stay (OR 0.84, 95% CI: 0.77 to 0.91, $p < 0.0001$). Compared with patients discharged home, those discharged to PAC had lower survival (HR 1.53, 95% CI 1.22-1.93, $p < 0.0001$). **Conclusions:** Patients with advanced cancer discharged to PAC or hospice have substantial physical and psychological symptom burden and poor physical function. Patients discharged to PAC also have inferior survival compared with those discharged home. They may benefit from targeted interventions to improve their quality of life and care.

6505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

The role of chronic disease in the costs of potentially preventable emergency department use during treatment: A regional study. *First Author: Laura Elizabeth Panattoni, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The Centers for Medicare and Medicaid Services (CMS) released a quality metric for potentially preventable chemotherapy-associated emergency department (ED) use, effective in 2020. This metric excludes diagnoses with emerging evidence for outpatient management, such as proactive symptom management (PSM) and those for ambulatory care sensitive chronic conditions. Little is known about the intersection between potentially preventable ED visits due to cancer vs. other chronic disease. This study characterized the number and costs of ED visits during treatment. **Methods:** Western Washington cancer registry records from 2011- 2015 were linked with claims from two commercial insurers. Patients with newly diagnosed solid tumors undergoing initial treatment with chemotherapy or radiation were eligible. ED use was tracked one year post treatment initiation. ED diagnosis codes for fields 1-10 from the CMS metric and the PSM literature were labeled "Potentially Preventable" (Pp). Codes from the Agency for Healthcare Research and Quality's Prevention Quality Indicators (PQI) for Chronic Conditions were labeled "Potentially Preventable-Chronic Disease" (PpChronic). Costs were adjusted to $2016. **Results:** Of the 7,053 eligible patients, 2,543 (36.1%) visited the ED (median # visits [IQR]: 1 [1-2]). The most commonly listed codes included Pain (1,054 visits) and Dyspnea (279 visits) for Pp, Hypertension-PQI (652 visits) and COPD-PQI (206 visits) for PpChronic, and Diabetes (247 visits) and Hyperlipidemia (181 visits) for the other codes. Spending on ED visits including both potentially preventable cancer and chronic disease diagnoses totalled $706,552 (20% of ED costs). **Conclusions:** One fifth of ED costs potentially resulted from simultaneous poor cancer symptom and chronic disease management. Future research should explore the role of chronic illness in categorizing which ED visits are potentially preventable during cancer treatment.

Diagnoses Codes	*Visits*	*Total Cost*
Pp + PpChronic + others	542 (19.1%)	20%
Pp + *no* PpChronic + others	1,260 (44.4%)	53%
***no* Pp + PpChronic + others**	259 (9.1%)	6%
***no* Pp + *no* PpChronic + others**	778 (27.4%)	21%
Total	**2,839**	**$3,529,523**

6506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Analysis of reimbursement (R) for next generation sequencing (NGS) on patients' tumors in the context of a personalized medicine program. *First Author: Thomas D. Brown, Swedish Cancer Institute, Seattle, WA*

Background: R policies for NGS testing vary widely among private and public insurers. While drug costs are the greatest challenge in personalized or precision medicine, cost and R are substantial barriers to genomic profiling with NGS. We examined variation in coverage and R for a cohort of cancer patients (pts) treated at a tertiary oncology center. **Methods:** An Institutional Review Board approved prospective registration protocol was activated with the objective of establishing a centralized longitudinal clinical, molecular phenotypic, and research data repository for pts diagnosed with cancer. Based on provider assessment of medical necessity, mutations in 68 cancer associated genes were analyzed. Evaluation of R for NGS was performed from Sept, 2014 through Jan, 2017, with use of CPT code 81455. R was analyzed based on: payer type; pt age; localized vs. metastatic disease; and actionability of data. **Results:** 588 pts with evaluable analytic cases, and NGS testing, with R results shown in the table below. For groups with >= 10 pts: R frequency was highest in managed care programs, either private or Medicare, and least frequent in non-HMO Medicare ($p<.001$). In pts receiving R, payments by private HMOs were highest ($p<.02$). NGS results with labelled drug indications were associated with less frequent R (26% vs. 35%; $p<.05$), and lower payments (mean of $358 vs. $567; $p<.02$) compared to other NGS results. Younger age was associated with more frequent R (38% in pts <60 years, 24% in pts >= 60 years; $p<.005$). Neither cancer diagnosis nor stage were significantly associated with R. **Conclusions:** One third of pts received some R for NGS testing. R was more frequent and higher in managed care programs, both private and Medicare. R was more likely for younger age pts, while actionable NGS results were associated with lower R. These data demonstrate the need for rational, transparent, and consistent R policies, along with a value-based R model for NGS across all payer groups.

	Private		Medicare					
	Non-HMO	HMO	Non-HMO	HMO	Medicaid	Self-Pay	Tricare	VA

# pts with R	85 (33%)	36(50%)	7 (5%)	35 (73%)	30 (59%)	0 (0%)	0 (0%)	1 (100%)
R if paid (mean)	$1,448	$2,134	$1,211	$1,590	$1,341	$0	$0	$4,000

6507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Implementation of precision oncology in the Veterans Health Administration (VHA). *First Author: Michael J. Kelley, Department of Veterans Affairs, Durham, NC*

Background: VHA is the US's largest integrated healthcare system providing care to over 6 million Veterans (~40% in rural areas). Precision Oncology offers the promise of effective, low-toxicity targeted therapies tailored to individual tumor genomics but is unequally available to patients in the US. As part of the Cancer Moonshot, VHA is implementing a system-wide Precision Oncology Program (POP) including patients in rural areas, where specialty oncology care has historically had limited availability. **Methods:** Patients tested with multigene NGS tumor sequencing through 1 of 2 contracted vendors were identified from POP records and cancer characteristics were extracted from POP and medical records. Drug use data was obtained from the VA Corporate Data Warehouse. NGS testing results and annotations were extracted from POP records. **Results:** A total of 978 tumor samples were sent for NGS testing since program inception in 2015. The most common diagnoses are lung (464: adeno 314, squamous 107), GI (87), LN (75), liver (56), H&N (52), and prostate (43). The rate of sample test requests increased rapidly after national implementation in July 2016 (mean 23 samples/month prior to implementation to mean 126 samples/month 3 months later) as did the number of participating facilities (mean 8/month to 27/month). Sequencing success rate increased from 68% to 71% over the same interval while mean turn around time remained similar at 19.7 and 19.1 d, respectively. NGS results are available for a cohort of 344 patients including: lung 200 (adeno 138, squamous 51), skin 28, LN 20, liver 19, GI 16. 979 variants were found including TP53 278, KRAS 106, STK11, APC 38, PIK3CA 38, and CDKN2A 37. 228 patients had actionable results (on-label drug 24, off-label drug 165, clinical trial 213). To date, 8 patients received a recommended drug outside a clinical trial between 11 and 288 d after testing (median 82 d); 4 additional patients had received an NGS-recommended drug prior to testing. **Conclusions:** Implementation of tumor NGS testing as part of Precision Oncology Program in a US distributed healthcare system is feasible. Further program implementation and provision of appropriate targeted drugs both on and off study will be necessary to impact patient outcomes.

6508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Utilization of consultative molecular tumor board in community setting. *First Author: Carol J. Farhangfar, Levine Cancer Institute, Charlotte, NC*

Background: Physicians in the community have a broad range of experience using genomics data to inform treatment decisions. They typically have a heavier patient load than found in academic centers and treat a variety of tumor types. Genomic data has been reportedly used less than anticipated, even when results were actionable. Monthly didactic molecular tumor boards have been implemented in a number of cancer centers to try to fill gaps in knowledge. **Methods:** A weekly virtual consultative molecular tumor board (MTB) was implemented (Mar 2016) at an academic hybrid, multi-site community-based cancer institute to provide rapid molecularly-driven treatment guidance to physicians, augment genomics education, provide supporting documents for off-label use and clinical trials. A baseline survey was performed prior to first MTB. MTB assessments were summarized and provided to treating physician. Data was abstracted from the electronic medical records and clinical trials management system. Descriptive statistics were utilized to summarize utilization of MTB and treatment recommendations. **Results:** Genomics testing with a large panel (~600 genes) was requested for 809 patients (Jun 2015-Feb 2017). The MTB received 81 requests for review from 32 physicians from 14 locations. Most commonly reviewed disease sites were lung, ovary, pancreatic, colon, breast and head and neck cancers; 37% of reviews requested were for rare tumors. Median time to review request was 15 days from receipt of results. MTB recommendations were followed in 70% of cases, 16% continued current/other therapy, 11% declined rapidly (hospice/died), and 3% of patients decided against recommendations. Forty-four (44) percent were screened for recommended clinical trials; 26% went on study. **Conclusions:** Implementation of a weekly virtual consultative MTB facilitates molecularly-driven treatment decisions in community setting, especially in rare tumor types and enhances clinical trial accruals.

6509 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM

Do the American Society of Clinical Oncology (ASCO) Value Framework and the European Society of Medical Oncology (ESMO) Magnitude of Clinical Benefit Scale measure the same construct of clinical benefit? *First Author: Sierra Cheng, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*

Background: Whether the American Society of Clinical Oncology (ASCO) Value Framework and the European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) measure similar constructs of clinical benefit is unclear. It is also unclear how they relate to quality-adjusted life-years (QALYs) and funding recommendations in the UK and Canada. **Methods:** Randomized clinical trials (RCTs) of oncology drug approvals by the Food and Drug Administration, European Medicines Agency and Health Canada between January 2006 and August 2015 were identified and scored using the ASCO version 1 (v1) framework (August 10, 2015), ASCO version 2 (v2) framework (May 31, 2016) and ESMO-MCBS (May 30, 2015) by at least two independent reviewers. Spearman correlation coefficients were calculated to assess construct (between frameworks) and criterion validity (against incremental QALYs from the National Institute of Clinical Excellence (NICE) and the pan-Canadian Oncology Drug Review (pCODR)). Associations between scores and NICE/pCODR recommendations were examined by logistic regression models. Inter-rater reliability was assessed using intra-class correlation coefficients. **Results:** From 109 included RCTs, 108 ASCOv1, 111 ASCOv2 and 83 ESMO scores were determined. Correlation coefficients for ASCOv1 vs. ESMO, ASCOv2 vs. ESMO, and ASCOv1 vs. ASCOv2 were 0.36 (95% CI 0.15-0.54), 0.17 (95% CI -0.06-0.37) and 0.50 (95% CI 0.35-0.63), respectively. Compared with NICE QALYs, correlation coefficients were 0.45 (ASCOv1), 0.53 (ASCOv2) and 0.46 (ESMO); with pCODR QALYs, coefficients were 0.19 (ASCOv1), 0.20 (ASCOv2) and 0.36 (ESMO). None of the frameworks were significantly associated with NICE/pCODR recommendations. Inter-rater reliability was good for all frameworks. **Conclusions:** The weak-to-moderate correlations between the ASCO frameworks and ESMO-MCBS, with QALYs, and with NICE/pCODR funding recommendations suggest different constructs of clinical benefit measured. Construct convergent validity with the ESMO-MCBS in fact did not increase with the updated ASCO framework.

6510 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM

Pharmaceutical industry payments and oncologist drug selection. *First Author: Aaron Philip Mitchell, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Financial relationships between physicians and the pharmaceutical industry are common, and have the potential to influence clinical practice in potentially inappropriate ways. Oncology may be an ideal setting to study the influence of industry payments on physician drug choice given the high levels of competition for market share and high prices commanded by orally administered oncologic drugs. **Methods:** We linked the Open Payments database of industry-physician financial transactions with the Medicare Part D Prescriber file by physician name and practice location. We used McFadden's conditional logit model to determine whether receipt of industry payments was associated with higher odds of using a drug manufactured by the same company. We applied this model to clinical scenarios in which oncologists may choose between multiple, on-patent drugs: metastatic renal cell cancer (mRCC) (sunitinib, sorafenib, and pazopanib) and chronic myeloid leukemia (CML) (imatinib, dasatinib, and nilotinib). The primary, binary independent variable was receipt of payments from a manufacturer of one of these drugs in 2013; the primary dependent variable was choosing that manufacturer's drug in 2014. We divided industry payments into two categories, research payments and non-research "general" payments (including meals, travel, lodging, and speaking/consulting fees), and analyzed each payment type separately. **Results:** Physicians who received general payments from a manufacturer had increased odds of prescribing that manufacturer's drug for both mRCC (OR: 1.78, 95%CI 1.23-2.57, mean payments $566) and CML (OR: 1.29, 95%CI 1.13-1.48, mean payments $166). Research payments were associated with an increased odds of manufacturer drug use for mRCC (OR: 2.13, 95%CI 1.13-4.00, mean payments $33,391) but not CML (OR: 1.10, 95%CI 0.83-1.45, mean payments $185,763). **Conclusions:** Receipt of general payments from pharmaceutical companies is associated with increased prescribing of those companies' drugs. An association between research payments and prescribing was less consistent. This study suggests that conflicts of interest with the pharmaceutical industry may influence oncologists in high-stakes treatment decisions for patients with cancer.

6511 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM

Oncologists' perceptions of affordability in the NCCN evidence block value frameworks. *First Author: William Bruce Wong, Roche/Genentech, San Francisco, CA*

Background: The increasing prevalence of cancer coupled with approvals of new drugs and technologies used in therapy have brought increased scrutiny to the cost and value of treatments in oncology. To address the rising concern about oncology drug costs, NCCN has developed the Evidence Blocks (EB) framework to help assess the value of oncology regimens. The objective of this study was to assess and understand oncologist's perceptions of affordability in the context of the NCCN EB framework. **Methods:** Data were collected from an electronic cross-sectional survey of 200 US-based oncologists recruited from an online panel. Using the NCCN EB framework, oncologists were asked to rate a variety of hypothetical cancer therapies and assign costs (in US dollars) to the five levels of affordability. Additional questions assessing perceived patient out-of-pocket costs and comfort level in assessing affordability were also included in the survey. **Results:** Oncologists' ratings for an existing cancer immunotherapy were generally similar across the EBs (ratings of 4), however oncologists rated affordability higher (3: Moderately Expensive) vs. the actual NCCN panel affordability rating (1: Very Expensive). The affordability rating was similar across a variety of hypothetical cancer therapies and tumor types (rating of 3). Oncologists estimated the costs for this rating of 3 to range from $4600-$6000 per month, which was inconsistent with actual drug costs. Oncologists estimated the mean monthly out-of-pocket costs for patients with insurance to range from $1260 for a new oral medication to $1700 for a new infused medication. Only 26% of oncologists were comfortable or very comfortable with rating costs associated with affordability levels. **Conclusions:** Surveyed oncologists rated cancer therapies as more affordable than NCCN panel ratings. Costs associated with affordability were not consistent with actual treatment costs; however, most oncologists were not comfortable with rating affordability.

6512 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM

How costs get discussed (or not) in routine oncology practice. *First Author: Rahma M. Warsame, Mayo Clinic, Rochester, MN*

Background: Cancer patients are nearly 3x more likely to declare bankruptcy than people without cancer. However, little is known about the dynamics of the healthcare provider/patient (pt) conversations around cost issues, the range of topics explored, and the factors that may influence them. We reviewed audio recordings of a cross-section of medical oncology conversations to determine frequency, patterns and attitudes of pts and providers on cost. **Methods:** We audio recorded conversations between 5/3/2012 & 11/20/2013 for adult patients with any solid tumor malignancy seen in an outpatient medical oncology clinic at one of three sites in the Upper Midwest and Southern California. Basic demographic variables were abstracted from chart review. Recordings were de-identified, reviewed and flagged for any mention of cost. We used descriptive statistics and inductive qualitative content coding methods to further characterize conversation themes. **Results:** Among 525 recordings, 151 (28%) contained any mention of cost. Median age (range) of pts was 58 years (22-93), and 75% Caucasian, 18% Hispanic, 5% Asian, and 1% Black. Average length of cost discussions was $<$ 2 minutes, and pts usually initiated the discussion (106/151). Among the 151 conversations, social service referrals were mentioned only 6 times (4%). Through qualitative analysis we identified several key topics: *insurance coverage*, *disability*, *drug copays*, and *transportation*. The recording dynamics most frequently displayed *acknowledging but not taking action* on the part of clinicians. Only 25% of clinicians behave confidently in how to address a patients cost concerns. **Conclusions:** In a diverse cross-section of oncology visits, cost comes up only 1/4 to 1/3 of the time and focuses on insurance coverage, disability and out of pocket drug costs. However clinicians often leave these issues unaddressed. Discussing financial burdens and identifying way to improve existing conversations will be important to mitigate additional financial distress.

Institution	Avg. Conversation (min)	Avg. Cost conversation (min)	Provider initiated N (%)	Patient initiated N (%)	Both initiated N (%)
Mayo Clinic	28.6	1.8	28 (33)	54 (64)	3 (3)
USC Norris	15.2	1.2	1 (5)	18 (90)	1 (5)
LA County	14.9	1.5	10 (22)	34 (76)	1 (2)

The impact of positive SWOG treatment trials on population survival. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Recently, tremendous prominence has been given to the investigation of the impact of different research processes as part of the Cancer Moonshot. More than half a century ago, the National Cancer Institute (NCI) established a network of publicly-funded cancer cooperative research groups to systematically advance the science of clinical trial research and the evaluation of new treatments for efficacy and safety. Our objective was to examine the extent to which positive NCI-sponsored cancer treatment trials have benefited cancer patients in the U.S. population. **Methods:** We used study data from SWOG, an NCI-sponsored Network cooperative research group. We identified all treatment trials over SWOG's 60-year history (1956-2016) for which the new experimental therapy provided a statistically significant improvement in overall survival. We assumed the new, proven treatments from these trials established new standards for care in the treatment community. Twenty-three treatment trials were identified from a variety of difference cancer types. We estimated population life-years gained from the trials through 2015 by mapping the impact of the new treatments onto the U.S. cancer population, using an area-under-the-survival-curve approach that combined trial-specific hazard function and hazard ratio results with SEER and life-table data. Calculations were age-adjusted. Dollar return on investment was estimated as the ratio of total investment by the National Cancer Institute in the SWOG treatment trial program divided by the estimate of life-years gained. **Results:** In total, 12,361 patients were enrolled to the 23 positive trials from 1965-2012. We estimated that 3.34 million years of life were gained through 2015. Estimates were greater than 2 million life years gained under 95% of model simulations. The dollar return on investment was $125 per life year gained. **Conclusions:** SWOG treatment trials have had a substantial impact on population survival for cancer patients over 60 years. The National Cancer Institute's investment in its cancer cooperative group research program has provided exceptional value and benefit to the American public.

Comparison of reporting phase I trial results in ClinicalTrials.gov and matched publications. *First Author: Daniel Shepshelovich, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The 2007 Food and Drug Administration (FDA) Amendments Act mandated reporting of results of clinical trials in ClinicalTrials.gov, a large public registry, within 12 months of completion. We compared results reported for phase I trials in ClinicalTrials.gov and matched primary publications. **Methods:** The ClinicalTrials.Gov database was searched for completed adult phase I cancer trials with reported results. Only trials with dose escalation of systemically administered medications were included. PubMed was searched for matching primary publications, defined as identical intervention, number of arms and enrolled subjects, published prior to November 1, 2016. Results reported in the primary publication were compared with the ClinicalTrials.gov database using a 28-point score (2 = complete agreement; 1 = partial agreement; 0 = no mention) for 14-items related to study design (4 items), outcome measures (4 items) and safety profile (6 items). The ClinicalTrials.gov database was used as the reference for results reporting. Linear regression was used to identify factors associated with incomplete reporting. **Results:** After a review of 583 trials in ClinicalTrials.gov, 163 matching primary publications were identified, comprising 95 (58%) phase I and 68 (42%) phase I/II trials. Publications reported outcomes that did not appear in ClinicalTrials.gov in 25% of trials. Outcomes were omitted or downgraded in publications in 39% of trials. The overall median reporting score was 23/28 (interquartile range 21-25). Items that were incompletely reported in publications were: inclusion criteria (29%), primary outcome definition (26%), secondary outcome definitions (53%), adverse events (71%), serious adverse events (80%) and dates of study start and database lock (91%). Phase I ($p < 0.001$) and multicenter trials ($p = 0.002$) were associated with higher reporting scores than phase I/II and single center trials. **Conclusions:** Reported results in primary publications for early phase cancer trials are frequently inconsistent or incomplete compared with ClinicalTrials.gov entries. ClinicaTrials.gov may provide a more comprehensive overview of safety data from new cancer drug trials.

Trends in the geographic distribution of cancer clinical trials in the US: 2008-2015. *First Author: Caroline Savage Bennette, University of Washington, Seattle, WA*

Background: Access to and patient enrollment in cancer clinical trials is likely strongly impacted by where trial enrollment sites are located. Our objective was to evaluate temporal trends in the geographic location of cancer clinical trials launched in the US. **Methods:** We obtained the recruiting location(s) of all public- and privately-funded phase II/ III cancer clinical trials launched in the US between 2008 and 2015 from the ClinicalTrials.gov database. We linked the recruiting location(s) of each trial to the relevant hospital service area (HSA), which are defined by ZIP codes as local health care markets for hospital care (n = 3436). We estimated the number of cancer clinical trial sites in each HSA each year between 2008 and 2015. We also calculated a statistical measure of inequality, the Gini coefficient. The Gini coefficient would be 0 if all hospital service areas launched the same number of cancer clinical trials, and would be 1 if all cancer clinical trials were launched in only a single hospital service area. **Results:** 62% of HSAs (n = 2133) did not launch a single cancer clinical trial between 2008 and 2015. There was a small and non-statistically significant decline in the overall number of cancer clinical trial sites in the United States between 2008 and 2015 (-1.6% per year [95% CI: -4.0, 0.9]). During this same period of time, however, inequality in the geographic distribution of cancer clinical trial sites considerably deepened. For example, in 2008-09, no trials were launched in 68% of HSAs while 19% of trial sites were in only 1% of HSAs. Trials launched in 2014-15 were even more concentrated: no new trials were launched in 74% of HSAs while 25% of trial sites were in the top 1% of HSAs. The Gini coefficient increased significantly from 0.683 (95% CI: 0.666, 0.700) for trials launched in 2008-09 to 0.726 (95% CI: 0.706, 0.746) for those launched in 2014-15. **Conclusions:** Our findings indicate increased inequality in the geographic distribution of cancer clinical trials launched in the United States since 2008. The underlying causes and consequences of such increasing concentration warrant further analysis given the importance in ensuring equitable geographic access to cancer clinical trials in the US.

Quantifying gender ascertainment bias in hereditary cancer testing. *First Author: Anthony Chen, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

Background: Historically, hereditary cancer genetic testing has been much more prevalent among women, in part due to gender-specific cancer risks associated with Hereditary Breast and Ovarian Cancer Syndrome (HBOC). Despite expanded genetic testing that includes hereditary cancer syndromes that affect both men and women, the gender gap still persists. Here we report on gender ascertainment bias in hereditary cancer testing by evaluating the proportion of test cancellations in men and women who were not affected with cancer at the time of testing. **Methods:** A commercial testing cohort was queried to identify individuals for whom genetic testing with a multi-gene pan-cancer panel was ordered between September 2013 and December 2016. Individuals who were ascertained for testing based on a clinical suspicion of HBOC or Lynch syndrome (LS) and did not have cancer at the time of testing were included. Test cancellations (i.e. a test order that did not yield any reported result) due to lack of insurance coverage were assessed, as this is directly related to clinical testing criteria. **Results:** Genetic testing was ordered for 259,919 individuals who did not have cancer at the time of testing, which included 6007 men (2.3%) and 253,912 women (97.7%). Overall, 21.2% of tests ordered for men were cancelled due to lack of insurance coverage, which is significantly higher than the cancellation rate among women (14.4%, $p < 0.001$). This trend was observed among individuals tested for suspicion of HBOC (18.7% for men vs. 13.2% for women; $p < 0.001$), but not for those tested for LS (26.6% for men vs. 25.1% for women; $p = 0.137$). Among those whose tests were not cancelled, the positive mutation rate was twice as high for men compared to women (9.6% vs 4.6%, respectively; $p < 0.001$). **Conclusions:** In this analysis, the proportion of genetic tests ordered was substantially biased towards women. Cancellation rates for men were significantly higher compared to women, while the mutation positive rate was twice as high. Although men and women who are unaffected with cancer have an equal probability of having a family cancer history that meets HBOC testing criteria, the data presented here suggests that there is a higher clinical standard for men to receive genetic testing.

Factors influencing prostate cancer treatment decisions for African American (AA) and Caucasian (CA) men. *First Author: Brittaney-Belle Elizabeth Gordon, University of North Carolina School of Medicine, Chapel Hill, NC*

Background: Prostate cancer causes a disproportionate burden to AA men, and AA men are less likely than CA men to receive aggressive treatment. This is the first study to examine factors influencing treatment decision-making of AA vs. CA men in a population-based cohort. **Methods:** 1171 men were enrolled soon after diagnosis and before treatment through Rapid Case Ascertainment of the North Carolina state cancer registry. Researchers asked patients regarding their priorities in treatment decision-making and information sources. Differences in AA and CA men were compared using the chi-square test. **Results:** The most important factor for both AA and CA men was curing cancer, and preserving QOL was second most important. However, AA men were more concerned about additional factors including impact on daily activities (74% very important AA vs 58% CA for intermediate/high risk disease), recovery time (81% vs 50%), cost (66% vs 32%) and treatment time (76% vs 39%) ($p < .001$ for each item). The most important source of information impacting treatment decisions for CA men were physician recommendations (61%), personal research (32%) and family/friend opinion (7%); for AA men, the corresponding numbers were 50%, 32% and 19%. **Conclusions:** AA and CA men with prostate cancer are both concerned about curing cancer, but AA men are more likely to consider multiple other social and personal factors as important in their decision-making process. Improved understanding of these differences may provide opportunities to address racial disparities in prostate cancer.

Factors influencing treatment decisions in AA vs CA men with low and intermediate/high risk cancer.

Racial composition in trials supporting the U.S. approval of anti-cancer new molecular entities (NMEs): 2011- 2016. *First Author: Lola A. Fashoyin-Aje, U.S. Food and Drug Administration, Silver Spring, MD*

Background: In New Drug- and Biologics License Applications, clinical trials provide the primary safety and efficacy data upon which approval decisions are made. Low numbers of patients from racial groups that experience higher incidence and/or mortality from some cancers compared to the overall US population, may limit the generalizability of trial results. The Census estimates that the US population is 77.1%White, 13.3% Black/ African American (AA), 5.6% Asian, 1.2% American Indian/ Alaska Native (AIAN), and 0.2% Native Hawaiian/ Other Pacific Islander (NHPI). FDA conducted an analysis to compare the racial composition in trials supporting the approval of NMEs for the treatment of solid tumor malignancies. **Methods:** We reviewed the marketing applications of the 33 NMEs approved between 2011- 2016 to identify trials that provided the primary evidence of safety and efficacy. **Results:** A total of 29941 patients were enrolled. The table below illustrates enrollment by race (excluding Non-Hispanic, Hispanic, Other, Mixed Race & Missing) and approval year. **Conclusions:** The proportion of White patients enrolled in the US (88%) is higher than the proportion of Whites in the US population. However, the enrollment of AA and NHPI/AIAN patients is low and below the proportional representation of AA and NHPI/AIAN in the US. While enrollment targets may differ across cancer type and by race, the racial composition of patients enrolled in the trials that support the approval of cancer therapeutics should be reflective of the likely US patient population for whom these agents will be prescribed. The majority of Asian patients enrolled were from RoW while the majority of AA and NHPI/AIAN patients were enrolled from the US. Increasing the representation of racial minority patients in oncology trials will require targeted recruitment and enrollment of these patients in US sites.

	2011		2012		2013		2014		2015		2016		Total

Comparison of comorbidity measures to predict postoperative lung cancer survival in the National Cancer Database (AFT-03). *First Author: Melisa L. Wong, Divisions of Hematology/Oncology and Geriatrics, University of California, San Francisco, San Francisco, CA*

Background: Comprehensive assessment of comorbidity in cancer registries is critical for comparative effectiveness research. The National Cancer Database (NCDB) measures comorbidity with a diagnosis code-based Charlson Comorbidity Index (CCI) abstracted from discharge abstracts or billing face sheets. However, the prognostic performance of this code-based CCI has not been compared with a medical chart-based CCI or individual comorbid conditions in a nationally representative sample of patients with lung cancer. **Methods:** Through a special study of the NCDB, cancer registrars performed chart abstraction for 18 perioperative comorbid conditions for 9,640 randomly selected patients with stage I-III non-small cell lung cancer resected in 2006-07 at 1,150 Commission on Cancer-accredited facilities. We compared the prognostic performance of the NCDB code-based categorical CCI (0, 1, 2+), special study chart-based continuous CCI, and individual comorbid conditions in 3 separate Cox proportional hazards models for 5-year postoperative overall survival. All models adjusted for demographic and clinical characteristics. **Results:** Median age was 67 (IQR 60-74). The most common comorbidities were COPD (40%) and CAD (21%). Five-year postoperative overall survival was 55.5%. Agreement between the code- and chart-based CCIs was 51.9% with the code-based CCI underestimating comorbidity for 36.2% patients. The model including individual comorbid conditions had the best prognostic performance (R^2 0.196, C index 0.654). COPD, CAD, CHF, dementia, diabetes, moderate/severe renal and liver disease, peripheral vascular disease, psychiatric disorder, and substance abuse were independently associated with decreased survival. The chart-based CCI model (R^2 0.189, C index 0.650) predicted postoperative survival better than the code-based CCI model (R^2 0.181, C index 0.645). **Conclusions:** The NCDB code-based CCI underestimates comorbidity in patients with surgically resected lung cancer. The chart-based CCI and data on individual comorbid conditions improved prognostic performance and would be valuable additions to the NCDB to strengthen comparative effectiveness research.

6520 Poster Discussion Session; Displayed in Poster Session (Board #342), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Asymptomatic distant recurrence detection and survival in early stage breast cancer: A nationally representative study. *First Author: Jessica R. Schumacher, Department of Surgery, University of Wisconsin, Madison, WI*

Background: Breast cancer follow-up guidelines recommend imaging for distant metastases only in the presence of signs/symptoms. However, data supporting this recommendation predates the current era of improved imaging and targeted therapies based on molecular subtype. The objective was to assess the relationship between mode of distant recurrence detection and survival. **Methods:** A stage-stratified random sample of Stage II-III breast cancer patients diagnosed in 2006-7 was selected from NCDB records from 1,217 CoC-accredited facilities (10/hospital n = 10,853). Women were categorized by subtype: 1) ER or PR+/HER2-; 2) ER and PR-/Her2- (triple negative); 3) HER2+. Medical records abstracted for 5-years post-surgery supplemented NCDB data and assessed distant recurrence and mode of detection (prompted by signs/symptoms or surveillance imaging), imaging (chest CT, abdomen/pelvis CT/MRI, head CT/MRI, bone scan, PET/CT), death date. The relationship between mode of recurrence detection and days from initial cancer diagnosis to death was assessed using propensity-weighted multivariable Cox proportional hazards regression stratified by subtype. Propensity weights, based on receipt of surveillance systemic imaging, accounted for sociodemographic and tumor/treatment factors. **Results:** 5-year distant recurrence was 22.3% for triple negative, 14.8% HER2+, and 11.2% for ER or PR+/ HER2- patients. Asymptomatic imaging detected recurrence in 22.9% and signs/symptoms in 77.1%. Patients with asymptomatic as compared to sign/symptom detected recurrences had reduced risk of death in 5 years if triple negative (HR = 0.68, 95% CI = 0.50-0.93) or HER2+ (HR = 0.40, 95% CI = 0.24-0.65) with no significant association for ER or PR+/HER2- (HR = 1.2, 95% CI = 0.88-1.51). This translated to a between-group difference in weighted median survival of 5 months for triple negative and 13 months for HER2+ patients. **Conclusions:** This is the first nationally representative study to show a survival advantage with asymptomatic detection of distant metastases for patients, with the benefit limited to triple negative and HER2+ disease. Further research to confirm observational findings is warranted.

Changes in stage at diagnosis of screenable cancers after the Affordable Care Act. *First Author: Xuesong Han, American Cancer Society, Atlanta, GA*

Background: Extensive evidence links inadequate insurance with later stage at cancer diagnosis, particularly for cancers that can be detected by screening. The Affordable Care Act (ACA) implemented in 2014 has substantially increased insurance coverage for Americans 18-64 years old. This study aims to examine any changes in stage at diagnosis after the ACA for the following cancers for which screening is recommended for individuals at risk: female breast cancer, colorectal cancer, cervical cancer, prostate cancer, and lung cancer. **Methods:** We used National Cancer Data Base, a nationally hospital-based cancer registry capturing 70% new cancer cases in the US each year, to identify nonelderly cancer patients with screening-appropriate age who were diagnosed during 2013-2014. The percentage of stage I disease was calculated for each cancer type before (2013 Q1-Q3) and after (2014 Q2-Q4) the ACA. 2013 Q4-2014 Q1 was excluded as a washout/phase-in period. Prevalence ratios (PR) and 95% confidence intervals (CI) were calculated using log-binomial models controlling for age, race/ethnicity and sex if applicable. **Results:** 121,855 female breast cancer patients aged 40-64 years, 39,568 colorectal cancer patients aged 50-64 years, 11,265 cervical cancer patients aged 21-64 years, 59,626 prostate cancer patients aged 50-64 years, and 41,504 lung cancer patients aged 55-64 years were identified. After the implementation of the ACA, the percentage of stage I disease increased statistically significantly for female breast cancer (47.8% vs. 48.9%; PR = 1.02 [95%CI 1.01-1.03]), colorectal cancer (22.8% vs. 23.7%; PR = 1.04 [95%CI 1-1.08]), and lung cancer (16.6% vs. 17.7%; PR = 1.06 [95% CI 1.02-1.11]). A shift to stage I disease was also observed for cervical cancer (47.2% vs. 48.7%; PR = 1.02 [95% CI 0.98-1.06]) although not statistically significant. In contrast, the percentage of stage I decreased for prostate cancer (18.5% vs. 17.2%; PR = 0.93 [95%CI 0.9-0.96]) in 2014. **Conclusions:** The implementation of the ACA is associated with a shift to early stage at diagnosis for all screenable cancers except prostate cancer, which may reflect the recent US Preventive Services Task Force recommendations against routine prostate cancer screening.

Closure of Medicare Part D coverage gap by the Affordable Care Act (ACA) and use of oral anti-myeloma agents. *First Author: Adam J. Olszewski, Alpert Medical School of Brown University, Providence, RI*

Background: Medicare Part D pays for oral anti-myeloma immunomodulatory drugs (IMiDs, lenalidomide and thalidomide), but has a coverage gap resulting in an out-of-pocket (OOP) expense of > $ 3000 for the 1st prescription (Rx). Patients (pts) eligible for Low Income Subsidies (LIS) are exempt from cost sharing, and LIS is associated with IMiD receipt (*Olszewski, ASH 2016*). In 2011, the ACA partly closed the coverage gap with a 50% manufacturer discount on the price of brand-name drugs within the gap. We examined effects of this policy on IMiD use. **Methods:** From the Surveillance, Epidemiology, and End Results (SEER)-Medicare database, we selected Part D enrollees who started anti-myeloma chemotherapy in 2008-2012. We identified IMiD use in periods pre-ACA (2008-10) and post-ACA (2011-12), among pts with or without LIS. After confirming parallel trends in IMiD use before the ACA, we examined the effect of ACA discount on IMiD use in a difference-in-differences (DiD) model, using LIS recipients as controls whose OOP costs were not influenced by the ACA. **Results:** Among 3,313 Part D enrollees (of whom 31% received LIS), 41% received IMiDs as part of their anti-myeloma regimen. Compared with the pre-ACA period, in the post-ACA period the median gross IMiD cost of the 1st Rx increased for all pts (Table). OOP costs for the 1st Rx, and for the 1st year of IMiD therapy, decreased for LIS non-recipients. Proportion of pts entering catastrophic coverage with their 1st IMiD Rx decreased from 71% to 49%. However, there was no statistically significant effect of the ACA discount on the proportion of pts treated with IMiDs (DiD estimator, 3% [95% CI, -4 to 10]; *P*=.40), or on the time from diagnosis to 1st Rx (median 1.5 mo. in all groups). **Conclusions:** The ACA-mandated partial closure of coverage gap lowered the OOP costs for Part D enrollees treated with IMiDs. As the median OOP cost remains > $2400 for the 1st Rx, and > $4900 for the 1st year of therapy, the policy may be insufficient to overcome the financial barrier for beneficiaries who do not receive the LIS.

	No LIS		LIS	
	Pre-ACA	Post-ACA	Pre-ACA	Post-ACA
% Receiving IMiD	40%	41%	41%	39%
Median IMiD cost				
1st Rx - Gross	$ 6936	$ 7765	$ 6854	$ 7846
1st Rx - OOP	$ 3869	$ 2433	$ 3	$ 3
1st year - OOP	$ 6002	$ 4925	$ 6	$ 7

A multicenter analysis of patient reported risk factors for not working during cancer therapy. *First Author: Victoria Susana Blinder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Treatment for most types of cancer results in work disruptions. The aim of this study is to identify risk factors for not working during cancer therapy using a patient-reported outcome tool. **Methods:** Patients of all cancer types, who were undergoing treatment with curative or palliative intent, were enrolled in a survey-based study at Memorial Sloan Kettering Cancer Center and the North Carolina Cancer Hospital from 1/2014 to 7/2015. All patients working full- or part- time at the time of cancer diagnosis were included in this analysis. Patient reported outcomes were collected using a survey tool at any time during active cancer treatment. The primary outcome of this analysis was self-reported work status at the time of survey completion. **Results:** Of 119 patients who were working before their cancer diagnosis, 68% were working at the time of survey completion. The mean age was 52.9 (range 20-80). Younger age was associated with working: 82% of patients age < 40 were working during treatment vs. 31% of patients age > 65 (p=0.01). The number of days patients reported being completely unable to work in the past month was significantly associated with work status; only 26% of patients who missed > 10 days continued to work compared to 69% who missed ≤ 10 days (p<0.01). Patients who report having a flexible work schedule were 23% more likely to continue to work during treatment (69% vs. 46%, p=0.01). In a multivariable model controlling for having an employer contingent health plan, and household income > 200% of the federal poverty level (fpl), only age, having a flexible work schedule, and inability to work > 10 days were independently associated with work status during treatment (Table). **Conclusions:** Having a flexible work schedule allowed for more work interruptions without job loss. Patients who are likely to miss more than 10 days of work and who have inflexible work schedules are at high risk of unemployment and should be targeted for employment retention initiatives.

Variables associated with working	Odds Ratio	95% CI
Age (continuous)	**0.94**	**0.90 – 0.99***
Flexible work schedule	**3.11**	**1.12 – 8.67***
Inability to work > 10 days	0.15	0.05 – 0.50*
Employer contingent insurance	2.57	0.83 – 7.90
Income > 200% FPL	0.66	0.14 – 3.16

*p-value <0.03

Relationship between out-of-pocket spending and drug value for oral oncolytics reimbursed by commercial insurers: 2007-2014. *First Author: Lisa Rotenstein, Harvard Medical School, Boston, MA*

Background: With total and out-of-pocket (OOP) spending for oral oncolytics rising, there is increased interest in choosing oncology treatments based on their clinical value relative to cost. We sought to determine if OOP spending varied for higher versus lower-value oral oncology drugs reimbursed by commercial insurers. **Methods:** This was a retrospective analysis of commercial insurer prescription drug claims filed between 2007-2014 for 13 oral oncolytics approved before 2009. We calculated mean monthly OOP payments for each patient. We then categorized oral oncolytics by their overall and progression-free survival benefits for each FDA-approved indication, using evidence from published studies. We assessed the relationship of survival benefit with mean monthly OOP payment, adjusting for demographic and plan characteristics. **Results:** Our population included 44,109 patients ages 18-65 (mean age = 52.5 years, SD = 9.4 years) with a cancer diagnosis who filled 731,261 prescriptions. The most commonly represented oncolytics were imatinib (37.4% of fills) and lenalidomide (17.7% of fills). Approximately 57.6% of fills were for drug-indication pairs with an overall survival benefit of 5+ months. In adjusted analyses, there was no significant difference in mean monthly OOP payment between drugs without evidence of benefit and those with 0-5 months progression-free survival benefit or 5+ months of overall survival benefit ($p > 0.05$). Meanwhile, drugs with 5-10 months progression-free survival benefit or 0-5 months overall survival benefit had higher OOP payments than those without benefit ($p < 0.01$). **Conclusions:** OOP payments for oral oncolytics were not clearly related to indication-specific value. This suggests that despite increased attention to value- and indication-based drug pricing, cost-sharing for oral oncolytics does not currently reflect these goals.

6525 Poster Session (Board #347), Mon, 1:15 PM-4:45 PM

Disrupting end-of-life cancer care delivery: Results from the engagment of patients with advanced cancer trial. *First Author: Manali I. Patel, Stanford Hospital, Menlo Park, CA*

Background: Sustainable approaches to improve quality and safety of care of patients with advanced cancer while concurrently reducing costs is a growing national need. As part of the Veterans Administration Engagement of Patients with Advanced Cancer (EPAC) trial, we trained a lay health worker (LHW) to engage patients with stage 3 and 4 cancer in early advance care planning (ACP). The goal of this follow-up study was to examine the effect of the LHW intervention on patient-reported care experiences, healthcare utilization, and costs in the last 30 days of life for patients who died within 15 months of enrollment. **Methods:** We evaluated patient-reported experiences with decision-making, healthcare utilization, and total healthcare costs 30 days prior to death. A T-test was used to compare patient experiences with decision-making. To compare ED use and hospitalizations, we utilized an exact Poisson regression. A generalized linear model with gamma link-log function was used to compare total costs. The latter methods adjusted for length of follow-up. **Results:** In the 30 days prior to death, 60 patients died in each arm within 15 months of enrollment (difference not statistically significant). Patients in the intervention had significantly improved rates of ACP documentation (98% versus 18% $p < 0.001$), improved experiences with decision-making as measured by an index ranging from 0-5 with higher values representing more favorable experience (4.73 (SD 0.61) vs 4.15 (SD 1.02)) $p < 0.001$), higher utilization of hospice (77% vs 52%, $p < 0.005$), lower rates of any emergency department use (5% versus 45% $p < 0.001$) and any hospitalization (5% versus 43% $p < 0.001$), and significantly lower total costs of care ($1,048 versus $23,482 $p < 0.001$) compared to the patients randomized to the usual care arm. **Conclusions:** Integrating a LHW into oncology care to engage patients in early advance care planning resulted in significantly improved patient experience, decreased utilization and decreased total costs in the last month of life. LHWs may represent a sustainable resource to facilitate optimal patient-centered cancer care at the end-of-life. Clinical trial information: NCT02966509.

6526 Poster Session (Board #348), Mon, 1:15 PM-4:45 PM

Cancer drug assessment: What is driving high clinical added value in France? *First Author: Judith Fernandez, French National Authority for Health, La Plaine Saint-Denis, France*

Background: Concerns about the increase of cancer drug prices emphasized the need to base pricing decisions on clinical added value (CAV). In France, the CAV assessment is done by the National Authority for Health (HAS) on a 5-point scale based on clinical data. The magnitude of the CAV is partly used by the economic committee for healthcare products to determine drugs prices: a major to moderate CAV leads to the highest prices. Recognizing the importance of presenting clear statements, we analyzed which criteria are taking into account for CAV appraisal. **Methods:** A retrospective and descriptive study analysis of all new hematology/oncology cancer indications assessed by HAS between 2010 and 2015 has been conducted. For each appraisal, information regarding the level of evidence and clinical effect has been collected. **Results:** 78 new cancer indications (58 drugs) have been assessed: 20 had a major to moderate CAV (25%), 32 a minor CAV (41%) and 26 no CAV (33%). The percentage of major to moderate CAV was higher when a comparative pivotal trial was conducted (25%, 16/62 vs. 20%, 4/16). Among the 62 comparative trials, 58 had a superiority design (94%) supporting a major to moderate CAV in 27% (16/58) of the cases. Overall survival (OS) was measured in 91% of the pivotal trials (n = 71) and in 24% (n = 19) as a primary outcome. A higher proportion of major to moderate CAV were observed in trials using OS as a primary endpoint (31%, 6/19) than progression free survival (PFS) (23%, 9/39) or response rate (25%, 5/20). When a major to moderate CAV was obtained, a median absolute gain of 4 and 8 months for OS and PFS respectively were observed. All non-inferiority or non-conclusive designs led to no or minor CAV whatever the quantity of clinical effect. **Conclusions:** CAV is assessed in a two-step process where clinical effect is taken into account when level of evidence is appropriate. Consequently, there is not a unique profile of outcomes supporting a major to moderate CAV but a combination of several key elements such as study design, primary endpoint, and statistical significance. HAS appraisals remain multi-factorial, and medical need add a nuance to HAS expectations in terms of level of evidence.

6527 Poster Session (Board #349), Mon, 1:15 PM-4:45 PM

Changes in insurance coverage associated with health care reform for cancer survivors aged 19-64 years. *First Author: Amy J. Davidoff, Yale School of Public Health, New Haven, CT*

Background: Beginning in 2014, Medicaid eligibility was expanded in over half of states, enrollment was simplified, and insurance marketplaces were created in all states with premium subsidies for selected individuals, as a result of implementation of the Affordable Care Act (ACA). We examine changes in insurance coverage for cancer survivors overall, and for targeted subgroups affected by specific ACA elements. **Methods:** We pooled data for cancer survivors aged 19-64 years from the 2012-2015 National Health Interview Survey. Using information on family structure, income, and employment, and linked state-specific Medicaid eligibility policies, we assigned survivors to 3 targeted groups: 1) Medicaid eligible pre-ACA; 2) Medicaid expansion eligible; 3) eligible for premium tax credits for Marketplace plans; and 3 groups not targeted for benefit: a) eligibility gap (income < 100% federal poverty level (FPL) in states not expanding Medicaid); b) with alternative "affordable" coverage; and c) high income (> 400% FPL). Linear probability regressions examined pre(2012-13)/post (2014-15) coverage changes by eligibility category, adjusting for demographic characteristics. **Results:** Among 4,115 (wtd N = 6.90M) cancer survivors, insurance pre-ACA was 69% private, 15.2% public, and 12.2% uninsured. Post-ACA, overall public coverage increased by 3.2 percentage points (pct pt) ($p = .036$), whereas the percent uninsured decreased by 4.5 pct pt ($p < .001$). Relative to the high income category, the adjusted percent uninsured decreased by 8.4 pct pt (95% CI:1.2-15.5) among pre-ACA Medicaid eligible, by 16.7 pct pt (95% CI:8.9-24.4) among the newly Medicaid eligible, and by 11.3 pct pt (95% CI:1.0-23.4; $p = .069$) among premium subsidy eligible. No coverage gains were observed for the other 2 categories. Approximately 531,000 cancer survivors remained uninsured after ACA implementation, with over half eligible for either Medicaid (12%) or subsidized Marketplace plans (44%). **Conclusions:** In the first 2 years post-ACA, cancer survivors experienced substantial increases in insurance coverage, with changes limited to targeted subgroups. Over half of remaining uninsured were eligible for coverage.

6528 Poster Session (Board #350), Mon, 1:15 PM-4:45 PM

Validation of natural language processing (NLP) for automated ascertainment of EGFR and ALK tests in SEER cases of non-small cell lung cancer (NSCLC). *First Author: Bernardo H. L. Goulart, Seattle Cancer Care Alliance, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The Surveillance, Epidemiology, and End Results (SEER) registries lack information on the Epidermal Growth Factor Receptor (EGFR) mutation and Anaplastic Lymphoma Kinase (ALK) gene rearrangement test results. With the goal of enabling population-based outcomes research in molecularly selected NSCLC subgroups, we conducted a validation study of NLP for ascertainment of EGFR and ALK testing from electronic pathology reports (e-paths) of patients included in the Seattle-Puget Sound (SPS) and Kentucky Cancer (KCR) SEER registries. **Methods:** We obtained 4,278 and 1,041 e-paths pertaining to 1,634 and 565 patients with stage IV non-squamous NSCLC diagnosed from 1/1/2011 to 12/31/2013 and included in the SPS and KCR registries, respectively. Two oncologists independently reviewed all reports to generate a gold-standard dataset. We used 855 of the SPS reports to train hybrid rule-based and machine learning algorithms for detection of test status (reported vs. not reported), and test result if reported (positive vs negative) for EGFR mutational analysis and ALK testing by FISH, IHC, or gene sequencing. In the remaining 3,423 SPS reports, we conducted a 5-fold cross-validation analysis to estimate the internal NLP sensitivity, specificity, positive predictive value, and negative predictive value for test status and results, respectively. We used a hierarchical rules system to assess the NLP accuracy at the patient level. For external validation, we repeated all analyses in the KCR dataset. **Results:** In the SPS internal validation report sample, the validity metrics ranged from 97% to 99% for EGFR and ALK test status, and from 95% to 100% for EGFR and ALK test results, respectively. In the KCR external validation report sample, the metrics ranged from 74% to 96% for EGFR and ALK test status, and 2% to 100% for test results, respectively. At the patient level, the NLP accuracy for EGFR and ALK was 95% and 96% (SPS cohort), and 70% and 72% (KCR cohort) respectively. **Conclusions:** NLP is a valid method for determining EGFR and ALK test status and results for patients included in SEER registries with access to e-path, but the algorithms likely need to be registry-specific.

6529 Poster Session (Board #351), Mon, 1:15 PM-4:45 PM

Financial conflicts of interest at three prominent oncology clinical pathway vendors. *First Author: Robert Michael Daly, Thoracic Oncology Service, Division of Solid Tumor Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The American Society of Clinical Oncology (ASCO) reports that in 2015 62% of oncology practices are adhering to a clinical pathway and 31% are adhering to more than one pathway. ASCO and the American Medical Association have raised concerns about the conflicts of interest of those that design these pathways. **Methods:** Using the public Centers for Medicare and Medicaid Services Open Payments database, we abstracted the 2015 financial conflicts of interest for the 2016 voting members of the Value Pathways (a combined effort of US Oncology and NCCN), the medical oncology committee chairs for Via Oncology, and the medical advisory board for eviti. We focused on national pathway vendors and on non-research general payments, such as gifts, consulting, and speaker fees. **Results:** Nearly all involved in pathway development received non-research general payments in 2015, including 92% of US oncology, 84% of NCCN, 84% of Via Oncology, and 69% eviti. The average general payments ranged from $3.5K for US Oncology Value Pathways voting members to $15.3K for NCCN Value Pathways voting members. Eight percent of US Oncology voting members, 19% of the eviti medical advisory board, 28% of Via Oncology chairs, and 42% of NCCN voting members received $10,000 or more in general payments in 2015. **Conclusions:** Given the prominent role clinical pathways have on oncologists' prescribing behavior and the often subjective nature of determining on-pathway treatment, pathway vendors should take care to make accessible their conflict of interest policies and elucidate how they manage relationships of concern.Steps would include potentially limiting the number of committee members receiving payments and limiting the amount of general payments to each physician.

6530 Poster Session (Board #352), Mon, 1:15 PM-4:45 PM

What does the general population think about chemotherapy shortages? *First Author: Zachary Ak Frosch, Brigham and Women's Hospital, Boston, MA*

Background: Chemotherapy shortages have been increasingly recognized, and most oncologists report their patients have been at least intermittently affected. Despite their potential impact, little is known about the perspectives of the general population regarding shortages. **Methods:** In October 2016, we conducted a survey using the GfK KnowledgePanel, an online probability-based sample representative of adults in the United States. We assessed awareness of shortages, and provided vignettes in which a substitute chemotherapy drug had either a major or minor difference in side effects or effectiveness. We asked respondents whether they would want to be informed of a substitution, and, if the original drug were available elsewhere, would transfer care to receive it. We also asked if cancer centers were to publish drugs in shortage at their center, if such data would affect decisions about where to seek care. Analyses applied post-stratification sampling weights to draw national inferences. **Results:** Of 737 potential participants, 420 (57%) responded; 16% had heard of chemotherapy shortages. Respondents with a personal history of cancer were more likely to have heard of shortages (31% vs 14%, $p = 0.03$), as were those with greater education ($p = 0.01$) and those who reported more sources of health information ($p = 0.01$). Most desired to be informed about a chemotherapy substitution in the setting of both major (87%) and minor (83%) differences in side effects, as well as both major (87%) and minor (82%) differences in effectiveness. In contrast, only 61% reported they would transfer care if a substitute drug had major differences in side effects, and even fewer (40%) for minor differences. Similarly, 72% and 46% reported they would transfer care if a substitute had major or minor differences in effectiveness respectively. Finally, 57% reported that publically-reported shortage data would be a "big factor" in deciding where to be treated. **Conclusions:** Our data suggest that the general population is largely unaware of chemotherapy shortages. Moreover, in the setting of even minor changes in effectiveness or side effects, respondents wanted to be made aware of substitutions. With major differences, many would seek care elsewhere.

6531 Poster Session (Board #353), Mon, 1:15 PM-4:45 PM

Mammography use in breast cancer survivors: An administrative claims study. *First Author: Kathryn Jean Ruddy, Mayo Clinic, Rochester, MN*

Background: Annual mammography is recommended to screen residual breast tissue for new cancers and recurrent disease after treatment for early stage breast cancer. This study aimed to assess mammography rates over time in breast cancer survivors. **Methods:** We used administrative claims data from a large U.S. commercial insurance database, OptumLabs, to retrospectively identify privately- and Medicare Advantage-insured women with operable breast cancer who had residual breast tissue after definitive breast surgery between 2006 and 2015. We required coverage for at least 13 months following surgery. For each subsequent 13-month time period, we only included women without a loss of coverage, bilateral mastectomy, metastatic breast cancer diagnosis, or non-breast cancer diagnosis. We calculated the proportion of patients who had a mammogram during each 13-month period following breast surgery. We used multivariable logistic regression to test for factors associated with mammography in the first 13 months. **Results:** The cohort included 26,011 women followed for a median of 2.9 years (IQR 1.9-4.6) after surgery; 63.1% were less than 65 years of age, and 74.4% were white. In their first year of follow-up, 86% underwent mammography, but by year 7, this decreased to 73%. Fewer than 1% underwent MRI instead of mammography. In multivariable analysis, mammograms were less likely during the first year after surgery among women aged < 50 years (odds ratio [OR], 0.7; 95% confidence interval [CI], 0.6 to 0.8), African Americans (OR, 0.7; 95% CI, 0.7 to 0.8), patients who underwent mastectomy (OR, 0.7; 95% CI, 0.6 to 0.7), and patients residing in the Western part of the country (OR, 0.9; 95% CI, 0.7 to 0.9). Those with 1-2 comorbidities were more likely (OR, 1.1; 95% CI 1.1-1.2) than those with none to have a mammogram during that period. Mammography use did not differ significantly by year of diagnosis (2006-2015). **Conclusions:** Even in an insured cohort, a substantial proportion of breast cancer survivors do not undergo annual surveillance mammography. Mammography use falls as the time from the early stage breast cancer diagnosis increases. Understanding factors associated with lack of mammographic screening may help improve survivorship care.

6532 Poster Session (Board #354), Mon, 1:15 PM-4:45 PM

Impact of insurance status on treatment for stage 0-IV breast cancer. *First Author: Rachel Adams Greenup, Department of Surgery, Duke University Medical Center, Durham, NC*

Background: Health insurance can influence utilization of cancer care. We sought to determine whether insurance status impacts treatment patterns and survival in women with stage 0-IV breast cancer. **Methods:** Women ages 18-69 years old, diagnosed with unilateral stage 0-IV breast cancer between 2004 and 2014 were selected from the National Cancer Data Base. Insurance status was categorized as Private, Medicare (65+ yo), Medicare (18-64 yo), Medicaid, or Uninsured. After adjustment for known covariates, generalized and binary logistic regression were used to estimate the association of insurance type with receipt of treatment. A multivariate Cox proportional hazards model was used to estimate the association of insurance status with overall survival. **Results:** A total of 610,450 women met inclusion criteria. Median age was 56 (48-63). Insurance status included: 72.1% Privately insured, 13.9% Medicare 65+, 4.8% Medicare 18-64, 7.1% Medicaid, and 2.1% Uninsured. Women with private insurance were more likely to present with stage 1 breast cancer, and less likely to present with stage 4 disease when compared to Medicaid or Uninsured patients (stage 1: 63.4%, 49.4%, 48.2%, $p < 0.01$; stage IV: 0.8%, 1.8%, 2.1%, $p < 0.01$). Risk of death was higher in uninsured or Medicaid patients when compared to those with private insurance (HR 1.52, 95% CI 1.41-1.64; HR 1.6, 95% CI 1.52-1.68). Receipt of chemotherapy and radiation did not differ between Medicaid, Uninsured, or Privately insured patients, but women without private insurance were more likely to receive neoadjuvant chemotherapy (OR 1.14, 95% CI 1.09-1.19; OR 1.16, 95% CI 1.07-1.25, respectively, $p < 0.01$). Uninsured women were more likely to undergo mastectomy without reconstruction (OR 1.57, 95% CI 1.49-1.65), and less likely to undergo unilateral or bilateral mastectomy with reconstruction than lumpectomy and radiation (OR 0.57, 95% CI 0.53-0.61; OR 0.35, 95% CI 0.32-0.39). **Conclusions:** Stage at diagnosis and risk of death were higher in Medicaid and uninsured breast cancer patients when compared to those with private insurance. Insurance status did not predict differences in receipt of surgery, chemotherapy, or radiation but did affect oncologic outcomes.

6533 Poster Session (Board #355), Mon, 1:15 PM-4:45 PM

Assessment of actionability of cancer genomic testing panels based on a structured clinical trial knowledge base. *First Author: Mia Alyce Levy, Vanderbilt University, Nashville, TN*

Background: Today's oncologist is responsible for choosing appropriate cancer genomics tests to inform patient treatment from multiple available platforms, weighing cost, availability, sensitivity and specificity, and clinical actionability. Knowledge-driven clinical decision support tools can assist clinicians in choosing the panel that is most informative in a given clinical space. **Methods:** Using a queryable knowledgebase of >1800 active clinical trials containing structured eligibility criteria curations for diagnosis and genomic alterations, we compared two CLIA-regulated genomic panels for clinical actionability over the landscape of solid, breast, and lung cancer clinical trials. **Results:** The larger panel (73 genes) was more actionable than the smaller panel (62 genes) in the breast cancer (10x more trials returned) and solid tumor (2.7x more trials returned) clinical trial space, while the smaller panel returned 1.2x more trials in the lung cancer space (see table). **Conclusions:** This analysis demonstrates that patient diagnosis has a significant effect on the potential clinical actionability of a given genomic panel. Further, this analysis demonstrates the clinical utility of knowledge-driven clinical decision support tools for test selection, especially given the often-limited tumor sample available, cost of genomic panel testing, and continuously shifting trial landscape.

Number of trials with eligibility criteria containing genes tested on two-CLIA regulated panels.

	Breast Cancer Trials	Lung Cancer Trials	Solid Cancer Trials
Panel 1 (73 genes)	22	15	71
Panel 2 (62 genes)	2	18	19

6534 Poster Session (Board #356), Mon, 1:15 PM-4:45 PM

Disparities in access to breast cancer treatment: An observational study based on insurance status. *First Author: Karthik Kailasam, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Background: Breast cancer is the second leading cause of cancer death in Caucasians and African-Americans, and the most common cause of cancer death in Hispanic women. **Methods:** A retrospective analysis was done with data obtained from 1473 hospitals by National cancer database (NCDB) for the years 2004-2014. Patients with breast cancer were analyzed for differences in treatment offered based on their insurance status. Patients in the insurance group were enrolled under either Private, Medicare, Medicaid or other government insurance. Treatments offered were surgery, chemotherapy, radiation therapy or a combination of the above. Patients with unspecified insurance status and those who were on active surveillance were excluded from the analysis. **Results:** A total of 2,245,259 patients with breast cancer from all age groups were identified from the registry. 47,294 patients did not have insurance; among which 3275 (7.4%) were not offered any treatment. Among 2,093,809 patients with insurance, 58,726 (2.8%) patients were not offered any treatment. Hence, patients without insurance were twice (OR 2.65; CI 2.55-2.75 $p < 0.0001$) more likely to not receive any first course treatment. Sub-group analysis for different stages of breast cancer showed; carcinoma in-situ (OR 2.44; CI 2.20-2.71 $p < 0.0001$), stage1 (OR 2.68; CI 2.43-2.96 $p < 0.0001$), stage2 (OR 2.86; CI 2.61-3.12 $p < 0.0001$), and stage 3 (OR 2.56; CI 2.25-2.92 $p < 0.0001$) have similar odds for not being offered any treatment. However, the odds of receiving treatment were better for stage 4 breast cancer (OR 1.44; CI 1.32-1.55 $p < 0.0001$). Uninsured Caucasians (OR 2.70; CI 2.56-2.85 $p < 0.0001$) were less likely to receive any treatment compared to uninsured African-Americans (OR 2.16; CI 2.00-2.33 $p < 0.0001$) and uninsured Hispanics (OR 1.66; CI 1.52-1.82 $p < 0.0001$) **Conclusions:** With the recent suggested changes in health care policy, we can expect the number of uninsured patients to rise and therefore more patients might not have access to breast cancer treatment.

6535 Poster Session (Board #357), Mon, 1:15 PM-4:45 PM

Does access to cancer drugs relate to survival benefit? A European study in countries with different economic status. *First Author: Nils Erik Wilking, Skane University Hospital, Stockholm, Sweden*

Background: As new cancer drugs come at a high cost, it is of interest to examine if drugs with high impact on survival has a relative higher uptake compared to drugs with limited impact on survival in countries with limited resources (low Gross National Product; GDP/capita) versus countries with better resources (medium or high GDP/capita). **Methods:** Based on published clinical trial data, including ESMO- and ASCO value scales, we selected three drugs with high impact on survival and their main indications; imatinib/Chronic Myeloid Leukemia (CML), rituximab (some use outside oncology)/lymphoma and trastuzumab/breast cancer compared to everolimus/ renal cancer, sorafenib/renal cancer and bevacizumab/colorectal cancer as drugs with limited impact on survival. Countries in Europe were divided into three economic groups: upper-tier GDP/ capita 36,000 – 73,400 €; (Austria, Belgium, Denmark, Finland, Ireland, The Netherlands, Norway, Sweden, Switzerland); mid-tier GDP 22,800 – 35,400 €; (France, Germany, Italy, Spain, UK) low-tier GDP 5,800 – 18,100 € (Bulgaria, Croatia, Czech Republic, Greece, Hungary, Poland, Portugal, Romania, Slovakia, Slovenia). Sales data from IMS Health and epidemiological data from IARC Cancer Mondial, (WHO) were used. Access to drugs was measured as use in g/case (defined as cancer mortality in 2012) and includes total usage from introduction until end of 2014. Access in the upper-tier country group was set as 100% usage. **Results:** As seen in the table, access in mid-tier countries was 64-76% and low-tier countries 34-55% respectively for drugs with higher survival impact and access in mid-tier countries was 73-105% and low-tier countries 34-59% respectively, for drugs with lower survival impact. More detailed data on access in individual countries within each GDP/capita group will also be presented. **Conclusions:** Proven survival benefit did not affect spending on costly cancer drugs in countries with lower GDP.

Drug	High-tier GDP access g/case	Mid-tier GDP % of high-tier	Low-tier GDP % of high-tier
Imatinib	2093.9	76	55
Rituximab	386.6	64	52
Trastuzumab	57.1	67	34
Everolimus	6,4	73	36
Sorafenib	699.1	105	59
Bevacizumab	27.6	83	34

6536 Poster Session (Board #358), Mon, 1:15 PM-4:45 PM

Enrollment of high-risk patients with diffuse large B-cell lymphoma in clinical trials. *First Author: Kah Poh Loh, University of Rochester Medical Center, Rochester, NY*

Background: Contemporary precision medicine trials in DLBCL often require real-time central pathology review for enrollment. Central review may lead to treatment delays and prevent high risk patients (pts) with aggressive presentations from enrolling onto clinical trials. We explored reasons pts with DLBCL were not enrolled on trials and the implication of non-enrollment on trial design and interpretation. **Methods:** We retrospectively analyzed all pts with histologic diagnosis of DLBCL or HGBL from 4/14 to 6/16 at the University of Rochester. Therapeutic trials open during this time included 3 sponsored and 2 NCTN studies. The Kaplan-Meier method was used to estimate the distribution of progression-free survival (PFS; time from start of treatment until progression/death or until the last date the patient was known to be progression free) and overall survival (OS). **Results:** 140 pts were identified; 22% enrolled on a trial. Reasons for non-enrollment included: 1) Protocol ineligibility (n=58); (2) Physician choice (n=24) and; 3) Patient choice (n=20). Reasons were unclear in 8 pts. Of the 24 pts who were not enrolled due to physician choice, 21 required urgent treatment secondary to symptoms or rapid progression. Compared to pts treated on trial, pts with rapid progression had higher risk clinical features (table). There was a trend towards a lower 1-year PFS rate in pts who required urgent treatment compared to those on trial (72.1% vs. 56.1%; p=0.08). There was no statistical difference in OS. **Conclusions:** At our institution, for patients with DLBCL meeting trial eligibility criteria, 42% required urgent chemotherapy and failed to enroll. Exclusion of these high risk patients in precision medicine trials has important implications in the interpretation and generalizability of clinical trials in DLBCL. In this curable malignancy, excluding high risk patients from trials limits the event rate, and associated power to demonstrate impact of novel therapies.

Comparison between Canadian and British oncology drug review recommendations and their impact on patient access. *First Author: Matthew K. Smith, University of Calgary Cumming School of Medicine, Calgary, AB, Canada*

Background: Access and funding for oncology medications in Canada and the United Kingdom are influenced by recommendations released by the pan-Canadian Oncology Drug Review (pCODR) and the National Institute for Health and Care Excellence (NICE), respectively. This study investigated variations between these organizations' recommendations and the clinical implications these differences had on access to medications. **Methods:** The pCODR Drug Review and NICE Technology Appraisal Guidance databases were reviewed to identify all oncological drug recommendations made by both agencies between 2008 and 2016. Recommendations were matched and then evaluated according to an algorithm to identify clinically relevant differences that restricted access in one jurisdiction relative to the other. Length of time from drug submission to final recommendation by NICE and pCODR were compared using Wilcoxon rank sum tests, as was the length of time between regional funding approval. **Results:** Between 2008 and 2016, 31 medication indications were evaluated by both pCODR and NICE. For 12 indications, funding was only supported by one agency. Eight indications were approved by both agencies, but with clinically relevant differences in wording, with each agency making a more restrictive recommendation four times. Average time from submission to recommendation was faster for pCODR than NICE (213.8 days vs. 407.9 days; $p < 0.001$) but the average time to funding decision (see table) was similar (410.1 days in Canada vs. 407.9 days in the United Kingdom; $p = 0.71$). **Conclusions:** Although clinically relevant differences in recommendations do exist between NICE and pCODR, neither agency was consistently more restrictive. pCODR recommendations were made more quickly than NICE, but this did not translate into faster funding approval in Canada. Jurisdictional barriers exist for cancer patients which could be mitigated through harmonization and acceleration of drug review processes.

Length of time from the submission of a medication indication to a funding decision.

Agency	Mean Length (days)
NICE (n=31)	407.9
pCODR to Provincial Funding Decision	
AB(n=22)	417.6
BC (n=17)	410.1
SK (n=21)	401.8
MN (n=20)	448.0
ON (n=20)	373.5

6538 Poster Session (Board #360), Mon, 1:15 PM-4:45 PM

A machine learning approach to predicting short-term mortality risk for patients starting chemotherapy. *First Author: Ravi Bharat Parikh, Brigham and Women's Hospital, Boston, MA*

Background: Patients who die soon after starting chemotherapy incur symptoms and financial costs without survival benefit. Prognostic uncertainty may contribute to increasing chemotherapy use near the end of life, but few prognostic aids exist to guide physicians and patients in the decision to initiate chemotherapy. **Methods:** We obtained all electronic health record (EHR) data from 2004-14 from a large national cancer center, linked to Social Security data to determine date of death. Using EHR data before treatment initiation, we created a machine learning (ML) model to predict 180-day mortality from the start of chemotherapy. We derived the model using data from 2004-11 and report predictive performance on data from 2012-14. **Results:** 26,946 patients initiated 51,774 discrete chemotherapy regimens over the study period; 49% received multiple lines of chemotherapy. The most common cancers were breast (23.6%), colorectal (17.6%), and lung (16.6%). 18.4% of patients died within 180 days after chemotherapy initiation. Model predictions were used to rank patients in the validation cohort by predicted risk. Patients in the highest decile of predicted risk had a 180-day mortality of 74.8%, vs. 0.2% in the lowest decile (area under the receiver-operating characteristic curve [AUC] 0.87). Predictions were accurate for patients with metastatic disease (AUC 0.85) and for individual primary cancers and chemotherapy regimens—including experimental regimens not present in the derivation sample. Model predictions were valid for 30- and 90-day mortality (AUC 0.94 and 0.89, respectively). ML predictions outperformed regimen-based mortality estimates from randomized trials (RT) (AUC 0.77 [ML] vs. 0.56 [RT]), and National Cancer Institute Surveillance, Epidemiology, and End Results Program (SEER) estimates (AUC 0.81 [ML] vs. 0.40 [SEER]). **Conclusions:** Using EHR data from a single cancer center, we derived a machine learning algorithm that accurately predicted short-term mortality after chemotherapy initiation. Further research is necessary to determine applications of this algorithm in clinical settings and whether this tool can improve shared decision making leading up to chemotherapy initiation.

6539 Poster Session (Board #361), Mon, 1:15 PM-4:45 PM

Accelerating clinical trial enrollment with comprehensive genomic profiling (CGP) and just-in-time clinical trial sites: An index case of a paradigm shift. *First Author: Gaurav Singal, Foudation Medicine, Inc., Cambridge, MA*

Background: In many instances, trials may offer the best or only therapeutic option for patients with rare findings. However, conducting clinical trials of novel therapeutics targeting rare molecular variants is challenging. Patient populations are small, distributed, and predominantly in community settings where trial access remains limited by awareness and site availability. These challenges increase costs of drug development and approval, delaying widespread patient access. **Methods:** Foundation Medicine deployed a trial education and access program, "Precision Enrollment," with Ignyta (a trial sponsor) and Pharmatech (a site management organization, or SMO, enabling "Just-In-Time" clinical trials) (Wiener, JCO 2007). Infrastructure and algorithms developed at Foundation Medicine ("SmartTrials Engine") matched sequenced patients (avg n = 800/wk) with activating NTRK, ROS1, or ALK fusions to the phase II study of Entrectinib (NCT02568267). Oncologists at Foundation Medicine, through peer-to-peer outreach, facilitated trial access by providing trial and nearest site information to treating providers of matched patients. **Results:** 107 treatment-eligible patients with NTRK, ROS1, or ALK fusions were matched by the SmartTrials Engine; 36 (33%) expressed interest in trial participation. One such patient with NSCLC and a CD74-ROS1 fusion was unable to participate at an open trial site due to inability to travel. The patient's site was part of the "Just-In-Time" network, with IRB and contract pre-approval, and was activated in only 3 days. Total time from patient identification to initiation of therapy was 7 days. **Conclusions:** We demonstrate a novel methodology for patient matching to trials targeting rare genomic findings, including in community settings. If extended, such innovative partnerships combined with computational matching infrastructure, could improve drug development and therapeutic access.

6541 Poster Session (Board #363), Mon, 1:15 PM-4:45 PM

Thirty-day readmissions in metastatic cancer patients: Room for improvement? *First Author: Rachel Solomon, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: To date, cancer has been excused from most readmission reduction efforts. Yet reported readmission rates for cancer patients discharged from medical services are as high as 27%. Some readmissions for patients with metastatic disease may be avoidable. We assessed the prevalence of potentially preventable readmissions and associated factors in adult patients with metastatic cancer. **Methods:** We measured 30 day readmissions for dehydration, cancer-related pain, and failure to thrive in patients with primary diagnosis metastatic cancer on index admission to a New York State hospital between December 1, 2012 and December 31, 2014. We used competing risk models to assess the effects of demographics, comorbidities, hospital type, payor, and discharge disposition. **Results:** During the study period, 11,275 patients had 19,307 index hospitalizations with primary diagnosis, metastatic cancer. The 30 day readmission rate was 24.5% of which 8.9% (424) were potentially preventable. Black (HR 1.26, 1.17-1.35) and Hispanic patients (HR 1.19, 1.09-1.31) had higher rates of readmission than whites. Being older (HR per 10 years of age 0.94, 0.90-0.97), female (HR 0.95, 0.91-0.99), having private insurance (HR 0.87, 0.87-0.81) and discharge to hospice (HR 0.62, 0.42-0.91) decreased risk of readmission. Discharge home with services (HR 1.21, 1.14-1.27) or to a skilled nursing facility (SNF) (HR 1.11, 1.01-1.23) conferred higher risk than going home unaided. Index hospitalization at public hospitals increased risk (HR 1.1, 1.02-1.18); teaching hospitals were protective (HR 0.84, 0.774-0.92). Patients with potentially preventable readmissions were younger (HR per 10 years of age 0.85, 0.78-0.93). Compared to those who went home unaided, patients discharged with services were more likely (HR 1.31, 1.05-1.64) and those discharged to SNF were less likely to have avoidable returns (HR 0.55, 0.37-0.81). Payor, gender, race, comorbidities, and index hospital type did not contribute. **Conclusions:** While the overall rate of potentially preventable admissions among metastatic cancer patients is low, higher readmission rates among those discharged home with help suggests that services supplied are not sufficient to address their health needs.

6542 Poster Session (Board #364), Mon, 1:15 PM-4:45 PM

National coverage analyses for NCI clinical trials: A pilot project to reduce participation barriers. *First Author: Andrea Denicoff, National Cancer Institute, Rockville, MD*

Background: Since the implementation of the ACA, many insurers have followed Medicare's lead in covering routine care costs associated with clinical trials (CTs). However, questions remain on how to distinguish routine care from non-billable research costs, and this has important financial implications for both sites and patients. As a result, many sites individually conduct coverage analyses (CAs) prior to opening CTs to determine billable routine costs. This is a significant duplication of effort for NCI network CTs that are open at hundreds of sites. A 2015 ASCO-NCI initiative identified the centralized creation of CAs for national CTs as a potential solution to reduce site burden, increase CT transparency and billing compliance, and ultimately reduce barriers to CT participation. We provide initial findings from the resulting NCI pilot program. **Methods:** NCI set up a Coverage Analysis Working Group (CAWG) made up of representatives from NCI's Cancer Trials Support Unit (CTSU), network groups, NCI, and billing compliance consultants. CAWG created a CA template and development process for NCI network trials. CAWG will survey site users in April 2017 to evaluate the first year of the pilot project. **Results:** CAs for 7 CTs were first posted to the CTSU website on 4/20/16. As of January 2017, CAs have been posted for 22 CTs: 17 NCTN and 5 NCORP. This represents 14.6% of the 150 large, later-phase network trials available on the CTSU. These CAs had been posted for a mean of 219 days (median 238) as of 1/31/17. In this time, CAs were downloaded an average of 319 times (median 301), for a total of 7,007 downloads. An additional 26 CAs have been posted for MATCH (n = 20) and LUNG-MAP (n = 6) sub-studies and downloaded 7,035 times. Survey results evaluating this CA pilot will be presented in June 2017. **Conclusions:** Providing centralized CAs to NCI's national network trials is feasible and well received with sites reporting that this pilot is reducing the time and effort of opening CTs and improving CT funding transparency. Collaboration is needed with CMS and third party payers to enhance clarity around CT coverage policy and billing compliance, along with continued feedback to make further improvements to reduce trial barriers.

6543 Poster Session (Board #365), Mon, 1:15 PM-4:45 PM

Communication about immunotherapy: Barriers and information to discuss. *First Author: Kristen Gillespy, Winship Cancer Institute, Atlanta, GA*

Background: Since immunotherapy is a promising new therapeutic approach to cancer treatment, improving physician/patient communication about this approach is important. No communication guidelines exist. To begin to fill this gap, we identified provider and patient preferences for information, and identified barriers to communication about immunotherapy. **Methods:** We qualitatively interviewed 15 oncology professionals who offer immunotherapy treatment about the information they deemed important to communicate to patients and the communication barriers. After a discussion about immunotherapy options with a provider, we interviewed 18 oncology patients about the information that was most useful to them and their impressions of immunotherapy. We captured impressions on two 1-5 scales with 5 being 'very positive impression' and 'very likely to be cured' and by picking words from a list of positive and negative terms like 'effective' and 'risky.' All open-ended questions were qualitatively coded. We reached saturation of themes with 18 patients. **Results:** Patients identified 4 useful topics to discuss: treatment options, benefits, treatment logistics, and side effects. Providers identified 3 topics important topics to convey: side effects, realistic view of benefit and treatment logistics. The most frequently provider-identified barrier to communication was patients' baseline misconceptions about immunotherapy's effectiveness. Supporting this, patients' impressions were very positive (average of 4 on impressions scale and 3.9 on potential to be cured scale.) The most frequently chosen word patients chose to describe immunotherapy treatment was 'hopeful' (10/18 55%). **Conclusions:** There is largely agreement on the important topics to discuss about immunotherapy, though half of the patients thought a discussion of treatment options would be useful and only one physicians mentioned options. Of note, communication is hampered by patients' preconceptions about immunotherapy's effectiveness. Communication guidelines should identify techniques to effectively overcome this barrier.

6544 Poster Session (Board #366), Mon, 1:15 PM-4:45 PM

A patient navigation program to enhance access to care for undeserved patients with a suspicion or diagnosis of cancer in Mexico City. *First Author: Alexandra Bukowski, Global Cancer Institute, Boston, MA*

Background: High cancer mortality rates in developing nations are partially driven by advanced stages at diagnosis and limited access to care. In Mexico, the interval from problem identification to start of treatment can be up to 7 months, mostly due to healthcare system delays. We implemented a patient navigation (PN) program aimed at reducing time to referral to cancer centers for patients (pts) with a suspicion or a diagnosis of cancer seen at a public general hospital in Mexico City. **Methods:** Pts age $>$ 18 seen at *Hospital General Ajusco Medio* in Mexico City who required referral to a cancer center were enrolled. Baseline demographic, economic and psychosocial data were collected. A Patient Navigator assisted pts with scheduling; paperwork; obtaining results in a timely manner; transportation; and with other cultural barriers. The goal of the PN program was for at least 70% of enrolled patients to obtain a specialized appointment at a cancer center within the first 3 months from enrollment. **Results:** 53 pts (median age 54, range 19-80; 51% female) were included between 01/16 and 12/16. 19% (n = 10) had breast/GYN, 19% (n = 10) GU, 19% (n = 10) endocrine, 19% GI (n = 10) and 14% (n = 13) other tumors. All the pts were uninsured, 59% (n = 30) had less than middle school education, 80% (n = 41) were unemployed and 96% (n = 49) had a monthly household income of $<$ $360 USD. 54% (n = 28) reported deprivation in at least one basic living need (education, running water, toilet, electricity or flooring). The most commonly identified barriers to healthcare access were financial (73%, N = 37), lack of transportation (47%, N = 24), fear (37%, N = 19) and poor communication with healthcare workers (35%, N = 18). Mean time to referral was 11 days (range 0–46, SD 11.2) and mean time to cancer specialist appointment 26 days (range 1–94, SD 21.18). 92% of pts successfully obtained appointments at a cancer center in $<$ 3 months. **Conclusions:** Compared with previously reported data, this PN program shortened time to referral to a cancer center for pts with a suspicion or diagnosis of cancer in Mexico City. PN represents a potential solution to overcome barriers to healthcare access for underserved pts with cancer in developing countries.

6545 Poster Session (Board #367), Mon, 1:15 PM-4:45 PM

Exploring the time delay between regulatory approval and health techonology assessments (HTAs) of oncology therapies in France, Germany, England, Scotland, Canada, and Australia. *First Author: Ashley Jaksa, Context Matters, New York, NY*

Background: Drugs in the USA become available from the moment of FDA approval. Access to oncology therapies outside of the USA may be delayed by regulatory and additional payer HTA processes. This study aimed to examine the time from regulatory approval to an HTA reimbursement decision in countries with mandatory HTA. **Methods:** Oncology HTAs (N=569) for medicines approved by the EMA, Health Canada, and the Therapeutic Goods Administration (Australia) were matched on indication with HTAs from France, Germany, Canada, England, Scotland, and Australia. Resubmissions were excluded. The date of the first reimbursement decision was subtracted from the date of the regulatory approval to determine the time taken to complete HTA and to issue reimbursement decision. Trends by country were examined. **Results:** Time between regulatory approval and HTA reimbursement required a mean of 321 days (Median=214 days; Std.Dev. 330 days). Access in England took the longest, on average, (547 days) to issue a decision compared to the other countries. This time was two to three times longer than any other country. Australia had the shortest time to issue a reimbursement decision, which was approximately 6 months. **Conclusions:** Approximately one additional year is required after regulatory approval for oncology medicines to complete HTA and receive a reimbursement decision, potentially delaying patient access to oncology medicines outside the USA. The large variability in time to a reimbursement decision by country is likely due to varying processes. Additional research is needed to clarify the impact of these delays on access to care and patient outcomes.

Country	HTA agency	HTAs (n)	Time to HTA conclusion (# days)	Min (# days)	Max (# days)
Australia	PBAC	66	182	-296	1422
Canada	pCODR	21	220	23	795
Scotland	SMC	141	313	10	1247
France	HAS	135	269	21	1814
Germany	G-BA	87	237	99	727
England	NICE	119	547	0	2772
Overall	All	569	321	-296	2772

6546 Poster Session (Board #368), Mon, 1:15 PM-4:45 PM

Telehospice: Implementation lessons from rural hospice care with mobile tablets. *First Author: Gary C. Doolittle, University of Kansas Medical Center, Westwood, KS*

Background: In underserved rural communities, hospice personnel often travel great distances to reach patients, resulting in challenges to maintain access, quality, cost-effectiveness and safety. To address these disparities, the University of Kansas Medical Center piloted the country's first TeleHospice (TH) service in 1998. Barriers such as technology limitations, costs and attitudes towards technology limited adoption (Cook et al., 2001). An updated academic-community project utilizes secure mobile videoconferencing to support TH services in Kansas' frontier communities. **Methods:** Leveraging lessons learned from the early work, a secure cloud-based videoconferencing solution was chosen for ease of use. To maximize limited resources, the selection of hospice partners was guided by Gustafson et al.'s (2003) Organizational Change Manager, which also informed implementation gaps. The academic team partnered with Hospice Services, Inc., a leader in rural hospice care, providing services to 16 Kansas counties. **Results:** From February 2016 through January 2017, 116 TH encounters occurred, encompassing 707 attendees over 7,462 minutes. The most common TH uses to date have been: administrative (e.g., connecting hospice staff across 16 counties); professional-to-professional (e.g., connecting hospice nurses at homes to additional TH professionals); and family support (e.g., connecting adult children with loved ones). Initial use of videoconferencing for administrative purposes developed a comfort level in using it for clinical and family support purposes. For staff meetings alone, the hospice has saved approximately $2,500/month in travel, with TH staff noting increased morale driven by increased team communication. **Conclusions:** Compared with early work, technology advances and a community-centered approach have increased TH adoption. With decreasing budgets as well as rural hospice closures, innovative, cost-effective and community-driven approaches such as TH are needed to decrease disparities. As dissemination occurs in national hospice organizations, continued research is needed to understand best fit within frontier hospices, to inform future urban applications and to address reimbursement.

6547 Poster Session (Board #369), Mon, 1:15 PM-4:45 PM

Implementation of a telechemotherapy center in the Peruvian jungle to improve patients' quality of life. *First Author: Tatiana Vidaurre, Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru*

Background: Instituto Nacional de Enfermedades Neoplásicas (INEN) is located in Lima (capital of Peru). There are no oncologists in regions like Peruvian jungle. Approximately 6% of medical attentions at INEN are people from this cities; so they must spend money and time to receive their treatment far from their cities. The purpose was to implement a module of outpatient chemotherapy in a non-specialized hospital, located in Peruvian jungle, for chemotherapy administration monitored by oncologists from INEN through the use of information and communication technologies (ICT). **Methods:** Two working teams were organized by formal agreement between INEN and local authorities to properly implement the infrastructure and to train local staff from December 2014 to November 2015. Questionnaire EORTC QLQ-C30 (v3) was used to assess QoL at the beginning and 3 months later. **Results:** A chemotherapy room with 18 armchairs, an area with a laminar flow hood to mix drugs at pharmacy, and videoconferencing equipment were implemented in Lamas, San Martin (1100 Km from Lima). Two general practitioners, 3 nurses and a pharmacist from Lamas, were trained during 3 months at INEN. Since November 2015, 31 patients were admitted. They received 181 cycles of chemotherapy in 248 rounds of administration, monitored by teleconference. Additionally 227 videoconference meetings to evaluate patients and to coordinate with local team were performed. Global health status improved from 76.67% to 83.33%. We observed benefit in functional scales, likewise symptoms related to disease did not vary, nevertheless financial difficulties decreased from 33.3% to 6.67%. In terms of money and time, this meant an average saving of $150.00 and 4 hours of travel time. **Conclusions:** Using ICT, we successfully implemented a tele-chemotherapy module in the heart of Peruvian jungle without harming patients quality of life. They will not need to travel to Lima for receiving their treatment.

6548 Poster Session (Board #370), Mon, 1:15 PM-4:45 PM

Themes and costs underlying avoidable terminal oncology ICU hospitalizations. *First Author: Robert Michael Daly, Thoracic Oncology Service, Division of Solid Tumor Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ICU admissions in the last 30 days of life are an indicator of poor care. Our prior research found nearly half of terminal oncology ICU hospitalizations are potentially avoidable. **Methods:** Data were derived from 72 patients consecutively cared for in an academic medical center's oncology practice who died in an ICU between July 1, 2012 and June 30, 2013. Oncologists, intensivists, and hospitalists used a standardized assessment tool to review each patient's electronic health record from 3 months prior to hospitalization until death; they made a clinical determination of avoidability. Two investigators, blinded to the specialty, used a grounded theory approach to extract clinical themes associated with the reviewer's determination of avoidability. Total, direct, and indirect costs were abstracted for each avoidable hospitalization. **Results:** Thirty-four (47%) of the examined hospitalizations were deemed avoidable. The primary themes associated with avoidability, and the percentage by specialty, were as follows: 1) failure to initiate appropriate advance care planning in the outpatient setting (68% oncologists, 55% intensivists, 65% hospitalists), 2) failure to integrate understanding of limited prognosis (23% oncologists, 24% intensivists, 26% hospitalists), and 3) failure of clinical management (6% oncologists, 21% intensivists, 6% hospitalists). A failure to educate and integrate surrogates into timely medical decision-making was a prominent secondary theme for oncologists (22%), intensivists (18%), and hospitalists (29%). The total cost per patient averaged $44,532 with direct and indirect costs averaging $25,215 and $19,317, respectively. High cost areas were ICU level care (35%) and pharmaceuticals (16%). **Conclusions:** The themes identified suggest potential preventative interventions, including higher rates of outpatient advance care planning, oncology inpatient communication to promote patient's prognostic understanding, prevention of failures in clinical management, and better education and integration of surrogates. Given 8% of oncology patients expire in the ICU and 47% were identified as avoidable, the potential national annual cost of these avoidable hospitalizations is $997MM.

6549 Poster Session (Board #371), Mon, 1:15 PM-4:45 PM

Forecasting financial impact of alternative payment models to cancer drug manufacturers. *First Author: Jennifer M. Hinkel, McGivney Global Advisors, Wayne, PA*

Background: Payers are moving from fee-for-service (FFS) reimbursement models towards value-based Alternative Payment Models (APMs). In Medicare, this trend has emerged via MACRA legislation and the Oncology Care Model (OCM). Reimbursement changes carry financial implications for payers, providers, and drug manufacturers. **Methods:** Financial impact of APMs was modeled as a function of Volume Factors and Price Factors in sales of a cancer drug product. Volume Factors included utilization patterns and market share. Price Factors included launch price, price increases, and both mandated and negotiated discounts. The model described three APM categories: Buy & Bill Plus (similar to OCM), Episode-Based Payment, and Third-Party Buy & Bill. The model included assumed timelines of APM implementation and the share of commercial insurer and Medicare markets implementing. Assumptions were generated in a multi-stakeholder workshop applying a modified Delphi method and Nominal Group Technique to arrive at consensus. The model included input ability for existing product forecast data including expected patient numbers, market share, payer mix, channel mix, price, 340B discount parameters, and additional concessions. Combinations of inputs and assumptions were run through the model as scenarios to generate results. **Results:** Across all scenarios, Episode-Based Payment resulted in revenues averaging 34% below baseline forecast at the ten-year mark. Third-Party Buy and Bill resulted in revenues averaging 100% of baseline at the ten-year mark. Buy and Bill Plus resulted in revenues averaging 66% below baseline at the ten-year mark. Market share as a function of clinical differentiation appeared to be a significant factor influencing revenue impact, with highly differentiated products outperforming others in all APMs. **Conclusions:** While much attention is paid to the impact of reimbursement reform on oncology provider economics, with subsequent impacts to patient access, less attention has been focused on impact to drug manufacturers. APM implementation could significantly impact manufacturer revenues, which in turn may impact both access to such therapies and research investment towards new anti-cancer therapies.

6550 Poster Session (Board #372), Mon, 1:15 PM-4:45 PM

Are physicians social networks linked to breast cancer screening recommendations for older adults? *First Author: Craig Evan Pollack, Johns Hopkins University, Washington, DC*

Background: Physicians' prior experiences caring for patients with breast cancer along with experiences in their social networks including family members and friends may be a key and understudied driver of recommendations for cancer screening. **Methods:** The Breast Cancer Social Networks study (CanSNET) is a national, mailed survey of 2,000 primary care providers (PCPs) randomly selected from the American Medical Association Masterfile. PCPs were asked to provide detailed characteristics on up to 2 women they know who have been diagnosed with breast cancer and "whose cancer, broadly speaking, had the greatest impact" on them, including friends, family members and patients. Each woman was categorized as being diagnosed (a) through screening with a good prognosis, (b) not through screening with a good prognosis, (c) through screening with a poor prognosis or (d) not through screening with a poor prognosis. We used a logistic regression model to assess the association between the network member and recommendations for routine screening mammograms to average-risk women ages 75+, adjusting for provider and practice characteristics. **Results:** Overall 871 physicians responded to the survey yielding an adjusted response rate of 52.3% (out of 1665 eligible). We found that 67% of physicians recommended screening for women 75+. The sample reported on 762 patients, 378 family members and 476 other network members who had been diagnosed with breast cancer. Ten percent of patients and 25.1% of family members reported on died of their disease. In adjusted models, we found that physicians who reported on family members who did not receive a mammogram and had a poor prognosis were significantly more likely to recommend screening compared to those who did not (Odds Ratio 1.22, 95% Confidence Interval 1.03, 1.43). **Conclusions:** Physicians' experiences with their social networks was linked to their breast cancer screening recommendations, underscoring the potential for information that is learned from social networks to differ from clinical guidelines and highlighting the need to address a broad array of influences in trying to reduce potential overscreening in cancer.

6551 Poster Session (Board #373), Mon, 1:15 PM-4:45 PM

The association between employment changes and healthcare use in the year after cancer diagnosis. *First Author: John F. Dickerson, Kaiser Permanente Center for Health Research, Portland, OR*

Background: Employed adults diagnosed with cancer face difficult decisions about continuing/returning to work and intensity of work following diagnosis. We examined the association between employment changes and healthcare use among cancer survivors. **Methods:** Data on adults enrolled at two health plans (Kaiser Permanente (KP) Colorado and KP Washington), diagnosed with breast, colorectal, lung, melanoma, and prostate cancers between 2003-2008, who responded to a 2013 survey with items on employment patterns following diagnosis were used. Survey data were linked to electronic health record (EHR) data on healthcare use, demographics, and cancer characteristics. Employment status and changes following diagnosis were measured. Multivariable logistic and negative binomial regression models were used to assess associations between employment changes and healthcare use in the year after diagnosis, adjusting for demographic and cancer characteristics. **Results:** Among 465 cancer survivors with complete survey and EHR data, 225 (48.4%) reported being employed since diagnosis. Among employed survivors, 126 (56.0%) reported making an employment change. Those who made a change were more likely to be female, diagnosed with AJCC stage 3 or 4 cancer, have received chemotherapy or hormone therapy, and had a caregiver (all $p < 0.01$). The most common employment changes were taking extended paid time off (53.2%), unpaid time off (39.7%), and switching to a flexible schedule (29.4%). Employment changes were made at initial diagnosis (18.3%), during treatment (70.6%), and ≤12 months post-treatment (26.2%); 28.6% made more than one change. Survivors who made an employment change had significantly more oncology visits (IRR = 1.85 [95% CI: 1.14-3.00]) and higher odds of hospitalization (OR = 5.18 [95% CI: 2.50-10.8]), but not primary care visits (IRR = 1.19 [95% CI: 0.94-1.50]) in the year after diagnosis, compared to those who did not make a change. **Conclusions:** Employment changes among cancer survivors are common and may be associated with treatment intensity and other healthcare use in the year after diagnosis. Prospective studies are needed to assess the impact of employment and healthcare use patterns on health outcomes.

6552 Poster Session (Board #374), Mon, 1:15 PM-4:45 PM

Temporal trends in the intensity and duration of oncologic care among colorectal cancer (CRC) patients (pts). *First Author: Leo Chen, University of British Columbia (UBC), Surrey, BC, Canada*

Background: Substantial advances in therapy of CRC pts occurred between 2000 and 2012 contributing to a significant increase in overall survival. The objective of this study is to quantify the change in treatment (tx) intensity as measured by clinic and tx visits at a network of medical and radiation oncology clinics. **Methods:** Electronic scheduling records of stage I-IV CRC patients referred between 2000-2012 to the six oncology centers comprising the British Columbia Cancer Agency were reviewed and stratified by tx phases: I and II (adjuvant first 6 months, continued), III and IV (palliative first 6 months, continued), and V (last 6 months of life). Clinic Visit Intensity (CVI), Chemo Tx Intensity (CTI), number of chemo agents and number of cycles (CC), Radiotherapy (Rx) courses (RC) and fractions (RF) were measured, and trends by referral year were modelled using zero inflated negative binomial regression. Mean duration of visit for chemo tx (CHD) and clinic visits (CVD) were modelled using linear regression. Sex, age at diagnosis, stage, income, and community size were included in models if terms were significant. **Results:** 15,157 pts were included across 10 cohorts. CTI and CC increased significantly in tx phases II-V with later year of referral, while phase I results were stable or decreased, likely due to the substitution of oral for intravenous regimens. Rx increased only in advanced phases. Mean duration of scheduled time showed significant increases. **Conclusions:** CRC pts referred in 2012 vs 2000 receive significantly greater intensity and duration of care in tx phases II-V. Results have significant implications for resource allocation and the patient experience.

Relative metric if referred in 2012 vs. 2000.

Site		Colon					Rectal				
Phase		I	II	III	IV	V	I	II	III	IV	V

Self-reported financial stress among patients evaluated at a community cancer program. *First Author: Christopher S. Lathan, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer related financial stress has been linked to a multitude of factors including socio-economic status, but its impact on the quality of life (QOL) for underserved populations is less well characterized. We evaluated patient reported financial stress, QOL, and quality of health (QOH) at an outreach cancer program located in a federally qualified health center. **Methods:** Study participants were interviewed at initial clinic visit for financial stress, QOH and QOL between January 2012 and December 2016. Demographic information, insurance coverage, clinical parameters, and comorbidities were abstracted from participants' medical records. Responses to the financial stress index question "how difficult is it for you or your family to meet monthly payment of your/your family bills?" and overall QOL and QOH of the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-C30 were analyzed. Proportional odds logistic regression models were constructed for 5-point quality of life measures and three levels of financial toxicity. **Results:** Of the 288 participants analyzed, 52% and 12% reported somewhat and extreme financial stress. In an adjusted analysis, patients who reported financial stress were more likely to be younger in age (OR = 4.03, $p < 0.001$) unemployed (OR = 3.24, $p = 0.002$), have less than bachelor's degree (OR = 0.035, $p = 0.018$), insured by Medicaid (OR = 3.22, $p < 0.011$), and were more likely to rate their QOL (OR = 3.76, $p = 0.031$) as poor, compared to those without financial stress. Race, gender, presence of cancer diagnosis and comorbidities were not associated with financial distress. Independent predictors of poor QOL were disability (OR = 3.12, $p = 0.005$), depression (OR = 2.12, $p = 0.007$) and extreme financial difficulty (OR = 2.57, $p = 0.011$). There was a nearly perfect positive correlation between overall QOL and QOH ($r = 0.984$, $p < 0.001$). **Conclusions:** There is a high prevalence of financial burden among underserved minority patients seeking cancer related care, and this is closely associated with poor quality of life. Interventions targeting cancer disparities need to assess financial stress in order to address this issue.

6554 Poster Session (Board #376), Mon, 1:15 PM-4:45 PM

Factors associated with 21-gene assay receipt among women with lymph node positive breast cancer. *First Author: Megan Roberts, National Cancer Institute, Bethesda, MD*

Background: The 21-gene Breast Recurrence Score (RS) assay predicts breast cancer (BC) recurrence and adjuvant chemotherapy benefit in select patients with lymph node-positive (LN+), hormone receptor-positive (HR+), HER2 negative BC. This study examines factors associated with assay uptake among women with LN+ BC in SEER databases. **Methods:** In this population-based study, incident BC cases in SEER registries (2010-2013) were linked to RS results from assays performed by Genomic Health. Our study sample included women with non-metastatic, LN+ ($\geq$1 positive LN), HER2-, HR+, BC. We use logistic regression to identify demographic, SES, and tumor characteristics associated with having the 21-gene assay ordered. **Results:** A total of 4428 (14.0%) of 31520 women with LN+, HR+, HER2-, BC had the assay ordered. Uni- and multi-variate analyses identified key factors that were significantly associated with the proportion of women tested. In the multivariable analysis, age (aOR: 2.23, $p<0.001$, 65-74 v <45 years) and BC diagnosis year (aOR:1.75, $P<0.001$ 2013 vs 2010) were positively associated with assay receipt; whereas number of positive LN (aOR: 0.14, $p<0.001$, 4+ positive LN vs 1 positive LN), tumor grade and size, low SES, being black, and being widowed were negatively associated with assay uptake ($p<0.001$). Having Medicaid was associated with lower odds of test receipt ($p=0.01$). Finally, we identified geographic variation in assay ordering. See univariate results (Table). **Conclusions:** Important demographic and SES variables were associated with test receipt in LN+ disease, and differed from those previously reported in node negative disease. Moving forward, increased awareness of these disparities, particularly among low SES, Medicaid, Black and widowed patients, along with targeted interventions may help to improve quality of care and equity in test receipt.

Most Commonly Tested Groups		Least Commonly Tested Groups	
Age <45	18.6	Age 65-74	8.4
1 Positive LN	25.0	4+ Positive LN	3.5
2013 Diagnosis	17.0	2010 Diagnosis	11.1
Tumor Grade I	23.1	Tumor Grade III/IV	8.1
Tumor ≤1 cm	23.6	Tumor Size >5 cm	4.8
White	14.7	Black	11.3
SES 5th Quintile	17.2	SES 1st Q	10.8

6555 Poster Session (Board #377), Mon, 1:15 PM-4:45 PM

Financial assistance for fertility preservation at cancer diagnosis: An analysis of the LIVESTRONG Fertility program. *First Author: Lenore Omesi, New York-Presbyterian, Columbia University Medical Center, New York, NY*

Background: Fertility preservation (FP) is a critical component of comprehensive adolescent and young adult (AYA) cancer care that is discussed and/or offered to only a fraction of eligible patients. Barriers include lack of insurance coverage making FP prohibitively expensive for many patients. The Sharing Hope program, now known as LIVESTRONG Fertility, was created by Fertile Hope in 2004 and acquired by LIVESTRONG in 2009. LIVESTRONG Fertility provides financial assistance to AYA cancer patients through discounted FP rates and access to free medications through a pharmaceutical company. Our aims were to review demographic characteristics of patients served, identify geographic utilization patterns, and quantify the program's financial impact. **Methods:** De-identified records maintained by Fertile Hope/LIVESTRONG from 2004 to 2011 were retrospectively reviewed. Patient population, treating institutions and cost savings/patient were summarized using descriptive statistics. **Results:** 1171 men and 1319 women were approved for financial assistance between 2004 and 2011. Median age was 24 years (range 12-67) for men and 30 years (range 13-49) for women. The most common diagnoses included testicular cancer (34%) and Hodgkin Lymphoma (HL) (18%) among males and breast cancer (48%), HL (13%) and genitourinary cancers (13%) among females. Applications were received from individuals residing in 49 of the United States, as well as Washington DC and Puerto Rico. The applicants received care from a total of 1,245 cancer centers. For men, $438,711 was saved, averaging $375/patient. For women, $3,904,303 was saved in practitioner cost and $4,665,775 in medication costs averaging $6,497/patient. **Conclusions:** Financial assistance for FP at the time of a cancer diagnosis for AYAs is a persistent and growing need. Female cancer patients face significantly greater costs to preserve fertility. Further studies are needed to determine the true financial burden to patients and the degree to which lack of financial resources and insurance coverage prevent FP in this population.

Utilization rates by year.

	2004	2005	2006	2007	2008	2009	2010	2011

female	4	25	67	124	180	238	284	397

6556 Poster Session (Board #378), Mon, 1:15 PM-4:45 PM

Global Cancer Institute multidisciplinary tumor boards as a tool to improve patterns of clinical practice for breast and gynecologic cancer in resource-limited settings. *First Author: Jessica St. Louis, Global Cancer Institute, Boston, MA*

Background: Multidisciplinary tumor boards (MTBs) are commonly practiced in high-income countries (HICs) to ensure adherence to guidelines through a team approach to patient care. The Global Cancer Institute (GCI) established online MTBs in 2012 to facilitate live telemedicine discussions of breast and gynecologic case scenarios between specialists in low- and middle-income countries (LMICs) and expert specialists in HICs. GCI MTBs aim to improve clinical knowledge and patterns of practice for specialists in LMICs through an interactive online forum. **Methods:** In each monthly MTB, three patient case scenarios are presented by specialists in LMICs for live discussion with an expert panel of specialists based in HICs. Guideline or clinical trial-based discussions are held for each case scenario. Best practices for clinical care in limited resource settings are also discussed. Links to clinical practice guidelines, clinical trials, and resources are provided to all MTB attendees. For educational purposes, each MTB is live streamed and uploaded to a private YouTube channel for viewing by community oncologists and trainees worldwide. **Results:** The GCI MTBs program has recruited over 500 LMIC participants from 48 hospitals in 24 countries across Latin America, Eastern Europe, Africa, and Asia. 17 expert breast cancer specialists and 13 expert gynecologic cancer specialists provide multidisciplinary guidance. To date, 130 breast cancer case scenarios and 80 gynecologic cancer case scenarios have been presented. For breast MTBs, 73% of case scenarios were invasive ductal carcinomas. Common subtypes presented were ER/PR+ (63%), HER2+ (30%), and triple negative disease (28%). 56 cases involved advanced disease management (43%). For gynecologic MTBs, common gynecologic cancer case scenarios were cervical (74%) and ovarian (15%). 37 cases involved advanced disease management (46%). **Conclusions:** GCI MTBs are a useful educational tool for specialists in LMICs to improve patterns of clinical practice and engage in multidisciplinary discussions. GCI continues to expand its MTBs to cancer facilities in LMICs.

6557 Poster Session (Board #379), Mon, 1:15 PM-4:45 PM

Increase in time to initiating cancer therapy and association with worsened survival in curative settings: A U.S. analysis of common solid tumors. *First Author: Alok A. Khorana, Cleveland Clinic, Cleveland, OH*

Background: Increase in time to treatment initiation (TTI) for new cancer diagnoses causes patient distress and may adversely affect outcomes. We investigated trends in TTI for common solid tumors treated with curative intent, determinants of delayed TTI and impact on overall survival. **Methods:** We utilized population-based, prospective data from the National Cancer Database for newly diagnosed US patients with early-stage breast, prostate, lung, colorectal, renal and pancreas cancers from 2004-13. TTI was defined as days between diagnosis of cancer and first treatment (surgery, systemic or radiation therapy). Negative binomial regression and Cox proportional hazard models were used for analysis. **Results:** The study population of 3,672,561 patients included breast (N = 1,368,024), prostate (N = 944,246), colorectal (N = 662,094), non-small cell lung (NSCLC) (N = 363,863), renal(N = 262,915) and pancreas (N = 71,419) cancers. Median TTI increased from 21 days in 2004 to 29 days in 2013 ($P < 0.0001$). Aside from year, determinants of delays included care at academic centers and change in treating facility. Increased TTI was associated with worsened overall survival (OS) for stages I and II breast, lung, renal, and pancreas cancers, and stage II colorectal cancers, with hazard ratios per week of delay ranging from1.005 (1.002-1.008) to 1.030 (1.025-1.035), adjusting for comorbidities and other variables. Prolonged TTI ($>$ 6 wks) was associated with substantially worsened OS e.g., 5-yr OS for stage I NSCLC was 56% ($\pm$0.2) for TTI $\leq$ 6wks v 43% ($\pm$0.2) for TTI $>$ 6 wks and for stage I pancreas was 38% ($\pm$0.6) v 29% ($\pm$1) respectively ($P < 0.0001$ for both). **Conclusions:** TTI has lengthened significantly over recent years, associated with multiple factors. Increase in TTI is associated with substantial increase in mortality ranging from 0.5-3.2% per week of delay in curative settings such as early-stage breast, lung and pancreas cancers. Simplifying access and navigation of complex health systems is essential to diminish this apparently iatrogenic impact on outcomes.

6558 Poster Session (Board #380), Mon, 1:15 PM-4:45 PM

Minority patient reported attitudes regarding tissue donation and participation in cancer research. *First Author: Davendra Sohal, Cleveland Clinic, Cleveland, OH*

Background: Minority populations are underrepresented in biospecimen banks created for cancer research, which has implications for future therapeutic approaches. Patients' reluctance to donate biospecimens is perceived to be a potential barrier but is poorly studied. We present interim analyses of a survey to assess attitudes in a patient cohort comprised of racial/ethnic minorities. **Methods:** Patients filled out a validated 23-item survey [*J Cancer Educ, 2014. 29: p. 580-7*] for this prospective cohort study approved by the Cleveland Clinic IRB. Surveys were provided in the outpatient oncology clinic of a Cleveland Clinic community hospital. Eligibility requirements included tissue diagnosis of any solid tumor malignancy in non-curative setting; age $\geq$ 18 years, ECOG PS 0-2, self-reported race/ethnicity as any other than non-Hispanic White, undergoing cancer therapy in the next 30 days. Data are presented for the first 90 patients surveyed in 2015-2016. **Results:** Median age was 69 years (range, 35-92). Only 24 (27%, 1 missing) had been asked to donate samples in the past; of those, 20 (83%) had donated. The majority (n = 60, 67%) were willing to donate samples. A higher proportion (75%) responded as being likely to donate samples if they learned more about the research and reasons for sample donation. A smaller proportion was likely to donate samples if they received money (30%) or health services (40%) in return. Many (55-73%) disagreed with negative statements such as, "I will be treated as a guinea pig," and only (3-4%) disagreed with trust statements such as, "I trust sample banks/medical researchers/procedures." However, 42% endorsed being "concerned that something like the Tuskegee study could happen again." **Conclusions:** The majority of racial and ethnic minority patients in this study were willing to donate biospecimens for research, with an even greater likelihood of participation if appropriate rationales were provided. While systemic mistrust persists, the vast majority trusted medical researchers and procedures. Our findings suggest that underrepresentation of minorities in cancer biospecimen repositories, not likely attributable to patient reluctance, must be addressed to achieve health equity.

6559 Poster Session (Board #381), Mon, 1:15 PM-4:45 PM

Racial disparities in treatment and outcomes of colorectal cancer in young adults. *First Author: Olatunji Boladale Alese, Winship Cancer Institute, Atlanta, GA*

Background: The incidence of colorectal cancer (CRC) in young adults is increasing. Minority populations with CRC are known to have worse outcome. The objective of this study is to evaluate the impact of race on the outcome of young adults with CRC. **Methods:** Data were obtained from all US hospitals that contributed to the National Cancer Database (NCDB) between 2004 and 2013. Univariate and multivariate testing was done to identify factors associated with patient outcome. Kaplan-Meier analysis and Cox proportional hazards models were used for association between patient characteristics and survival. **Results:** A total of 83,449 patients between 18 and 50 years of age were identified. The mean age was 43.6 years (SD$\pm$6), with a male preponderance (53.9%). About 72% were non-Hispanic Whites (NHW) while African Americans (AA) made up 15.1%. Distribution across stages I-IV was 15.6%, 22.4%, 33.9% and 27% consecutively, similar among the races. 41.8% of NHW and 28.4% of AA had rectal cancers ($p<0.001$). Despite equally receiving standard of care (SOC) as per NCCN guidelines, AA had significantly lower 5year survival rates (58.8%) compared to Hispanics (64.8%) and NHW (66.9%; HR 1.42; 1.38-1.46; $p<0.001$). Patients with colon cancer had worse outcome compared to rectal cancer (HR 1.21; 1.18-1.24; $P<0.001$). In terms of survival, NHW (HR 0.85; 0.81-0.88; $p<0.001$) and Hispanics (HR 0.75; 0.70-0.79; $p<0.001$) were more likely to benefit from chemotherapy compared to AA. As expected, SOC utilization was associated with improved survival across all racial groups, especially in AA with HR of 0.64 (0.60 – 0.69; $p<0.001$). **Conclusions:** Despite comparable rates of standard of care utilization, AA young adults with CRC had worse outcomes compared to other races. Colon cancer was significantly more common in AA than rectal cancers, which may have contributed to their worse outcomes.

Survival by race among patients who received standard of care (77.8% of all patients).

Race Group	No. of Subject	12 Mo Survival (95% CI)	60 Mo Survival (95% CI)
AI/API/Other	3234	93.1% (92.2%, 93.9%)	67.6% (65.7%, 69.5%)
AA	9749	91.1% (90.5%, 91.7%)	58.8% (57.7%, 59.9%)
Hispanic	5233	93.3% (92.6%, 94.0%)	64.8% (63.2%, 66.3%)
NHW	46668	93.7% (93.4%, 93.9%)	66.9% (66.4%, 67.4%)

6560 Poster Session (Board #382), Mon, 1:15 PM-4:45 PM

An intervention study to reduce black-white treatment disparities in early stage non-small cell lung cancer. *First Author: Paul R. Walker, East Carolina University Brody School of Medicine, Greenville, NC*

Background: Racial disparities in the treatment of non-small lung cancer (NSCLC) continue to exist leading to poorer outcomes in African-Americans (AA) compared to Caucasians (C). Our previous multi-institutional prospective cohort study of 386 patients identified a surgical rate in early stage NSCLC of 66% C but only 55% AA ($p = 0.05$; OR 0.75; 95% CI 0.57-0.99). *(Cykert et al JAMA 2010)* A 3 year retrospective chart review of all patients with early stage NSCLC at the 3 academic institutions involved in this current intervention study identified 714 patients with early stage NSCLC. Baseline surgical rates 69% for C and 66% for AA. Combined stereotactic body radiation therapy (SBRT) with surgery C 80% and AA 76%. Controlling for comorbidities, COPD, age and other demographic data, the OR for surgery AA compared to C 0.64 (95% CI 0.43-0.96) and for combined surgery or SBRT AA compared to C 0.61 (95% CI 0.43-0.96). **Methods:** Patients with a stage I or II NSCLC were identified and randomized to each institution's standard of care approach or to an 'intervention' component utilizing a trained navigator to enhance patient communication and treatment understanding. **Results:** 244 patients were prospectively recruited into this intervention study. Mean age 65.7 years; 54% women; 89 (34%) AA. The intervention group showed an overall surgical rate of 74% (74.8% C, 71.4% AA; $p = 0.6$). Combined treatment of either surgery or SBRT increased an ablative treatment to 91.9% for C and 94.1% AA patients ($p = 0.5$). Logistic regression was performed comparing the intervention group to the baseline group. Results showed that overall treatment improved for both C and AA, the surgical and overall treatment disparity between C and AA was no longer present, while age, COPD, and clinical stage remained significant predictors of treatment. **Conclusions:** A multifaceted intervention designed to enhance patient communication and treatment understanding removed the surgical and overall early lung cancer treatment disparity between AA and C. Clinical trial information: NCT01687738.

6561 Poster Session (Board #383), Mon, 1:15 PM-4:45 PM

The Affordable Care Act Dependent Coverage Expansion (ACA-DCE): Disparities in impact in young adult oncology patients. *First Author: Elysia Marie Alvarez, Stanford University Medical Center, Palo Alto, CA*

Background: Private health insurance is associated with improved outcomes in cancer patients. We know little, however, about the impact of the ACA-DCE, which extended private insurance to young adults (up to age 26) beginning in 2010, on the insurance status of young adults with cancer. This study sought to determine the effect of the ACA-DCE on having private insurance coverage among hospitalized young adult oncology patients. **Methods:** We performed a retrospective, population-based analysis of hospitalized young adult oncology patients (22-30 years-old) in California during 2006-2014 (n = 11,062) using the Office of Statewide Health Planning and Development database. Multivariable regression analyses examined the social and clinical predictors of having private insurance. Results are presented as adjusted odds ratios (OR) and 95% confidence intervals (CIs). A difference-in-difference analysis examined the influence of the ACA-DCE on insurance coverage by race/ethnicity and zip code federal poverty level. **Results:** Multivariable regression demonstrated patients of black and Hispanic race/ethnicity were less likely to have private insurance both before and after the ACA-DCE, compared to non-Hispanic white patients. Younger age (22-25 years) was associated with having private insurance after the ACA-DCE implementation (OR 1.18, CI 1.05-1.33; reference, 27-30 years). In the difference-in-difference analysis, private insurance increased among non-Hispanic whites aged 22-25 living in medium- (2006-2009: 64.6% versus (vs) 2011-2014: 69.1%; p = 0.003) and high-income zip codes (80.4% vs 82%; p = 0.043) and among Asian patients aged 22-25 living in high-income zip codes (73.2 vs 85.7%; p = 0.022). Private insurance decreased for all Hispanic patients aged 22-25 between the two time periods. **Conclusions:** The ACA-DCE provision was an important first step in increasing coverage, but it was not universal and generated disparity in coverage as gains occurred for non-Hispanic white and Asian patients living in higher income zip codes. This policy change was shown to increase coverage for a traditionally underinsured population and attention should now focus on those remaining uninsured.

6562 Poster Session (Board #384), Mon, 1:15 PM-4:45 PM

Disparities in prognosis communication among parents of children with cancer: The impact of race and ethnicity. *First Author: Maya Ilowite, Dana-Farber Cancer Institute, Boston, MA*

Background: Most parents of children with cancer say they want detailed prognostic information about their child's cancer. However, prior work has been conducted in populations of limited diversity. We sought to evaluate the impact of parental race/ethnicity on prognosis communication experiences amongst parents of children with cancer. **Methods:** We surveyed 357 parents of children with cancer, and the children's physicians at Dana-Farber Cancer Institute/Boston Children's Hospital and Children's Hospital of Philadelphia. Our outcome measures were parental preferences for prognostic information, physician beliefs about parental preferences, prognosis communication processes and communication outcomes. Except where noted, associations were assessed by logistic regression with generalized estimating equations to correct for physician clustering. **Results:** 87% of parents wanted as much detail as possible about their child's prognosis, with no significant differences by race/ethnicity (P = .50). Physician beliefs about parental preferences for prognosis communication varied based on parent race/ethnicity. 60% of physicians for White parents reported they believed parents wanted as much detail as possible about their child's prognosis, versus 36%, 38%, and 64% of physicians, respectively, for Black, Hispanic, and Asian/Other parents (P = .04). Parent race/ethnicity was not associated with actual prognostic disclosure as reported by parents (P = .79) or by physicians (P = .61). Accurate understanding of prognosis was higher amongst White (51%) versus non-White parents (range 22%-29%), although this difference was not statistically significant (P = .13, unadjusted). **Conclusions:** The majority of parents, regardless of racial and ethnic background, want detailed prognostic information about their child's cancer. However, physicians rarely recognize the information needs of Black and Hispanic parents. Despite this discrepancy, prognosis communication outcomes were largely equivalent. Our findings suggest that in order to meet parents' information needs, physicians should ask about the information preferences of parents of children with cancer prior to prognosis discussions.

Disparities in next generation sequencing in a population-based community cohort of patients with advanced non-small cell lung cancer. *First Author: Carolyn Jean Presley, Yale Cancer Center, New Haven, CT*

Background: The use of next generation sequencing (NGS) in patients with advanced non-small cell lung cancer (NSCLC) is increasing. This study explored disparities in the use of NGS testing. **Methods:** This retrospective observational study utilized Flatiron Health's longitudinal, demographically and geographically diverse database containing electronic health record data from 191 oncology practices across the U.S. We identified patients diagnosed with advanced (stages IIIB/IV or recurrent) non-squamous NSCLC who received first line treatment and either NGS testing or standard biomarker testing (e.g., EGFR, ALK) alone. NGS included any multi-gene panel testing $>$ 30 genes. Logistic regression modeled the association between patient characteristics and receipt of NGS testing, accounting for clustering of patients by oncology practice. **Results:** Among 5,688 adults with advanced NSCLC, 4,813 (84.6%) patients received standard biomarker testing alone and 875 (15.4%) patients received NGS testing. The median age of the sample was 67y (IQR: 41-85), the majority was white (63.6%) vs. black (7.5%) vs. unknown (13.4%), and had a history of smoking (79.9%). Among the youngest patients ($<$ 45y), 31.5% received NGS compared to 11.3% among the oldest (76-85y; P $<$ .001). Approximately 16% of white patients received testing, compared to 11.4% of black patients (P $<$ .001). Patients with Medicaid received testing less often than commercially insured patients (11.7% vs 17.0%; P = .10). Patients had significantly lower odds of receiving NGS testing if they were older ($\geq$75 vs. $<$ 45 years of age; adjusted OR: 0.21, 95% CI: 0.13-0.34), black vs. white race (aOR: 0.63, 95% CI: 0.44-0.90) or were Medicaid vs. commercially insured (aOR: 0.54, 95% CI: 0.30-0.97). **Conclusions:** Significant age, race, and insurance-related disparities exist in the receipt of NGS testing among patients with advanced lung cancer in real world clinical practice.

6564 Poster Session (Board #386), Mon, 1:15 PM-4:45 PM

Asian representation in clinical trials of new drugs for the treatment of cancer. *First Author: Lola A. Fashoyin-Aje, U.S. Food and Drug Administration, Silver Spring, MD*

Background: In the US, statistics for Asians are often aggregated with other racial groups. This poses challenges in estimating the cancer burden and in defining cancer clinical trial enrollment targets in this demographic subgroup. 'Asian' refers to persons with origins in the Far East, Southeast Asia, or the Indian sub-continent. Asians comprise 6% of the US population and the largest Asian subgroups in the US are of Chinese (22%), Filipino (19%), Asian Indian (19%), Vietnamese (10%), Korean (9%), and Japanese (7%) descent. The representation of Asian patients in global clinical trials may not be reflective of the Asian subgroups in the US. FDA conducted an analysis to describe patients categorized as 'Asian' in clinical trials supporting the approval of new drugs. **Methods:** We reviewed the marketing applications of 33 new molecular entities approved for the treatment of solid tumor malignancies between 2011- 2016 to identify trials that provided the primary evidence of safety and efficacy. **Results:** A total of 29,941 patients were enrolled; 17 % were Asian. Most Asian patients were enrolled in Korea (20%), Taiwan (20%), mainland China (20%), Japan (16%), and US (5%). Few patients were enrolled in India (3%); the Philippines (1%); Vietnam (0). In the US, Asian patients comprised 3% of the total number of patients enrolled. **Conclusions:** Asian patients represented a heterogeneous mix. A large proportion was enrolled in Taiwan (20%) and Korea (20%), whereas the largest proportion of US Asians have origins in mainland China (22%), the Philippines (19%), India (19%), and Vietnam (10%). Nevertheless, although Asians share a common ancestry, it is not clear whether data from global clinical trials are generalizable to Asian patients in the US. Therefore, strategies to improve the enrollment of US Asian patients in clinical trials are needed. Among patients enrolled in the US, 3% were Asians, a proportion that is below US Asian population estimates (6%). While most site-specific cancer incidence and death rates are lower in US Asians compared to Whites, the rates of some cancers (e. g., stomach and liver) are higher in this group. Therefore, studies are needed to determine adequate enrollment targets in this demographic subgroup.

6565 Poster Session (Board #387), Mon, 1:15 PM-4:45 PM

Difference in cardiovascular disease incidence by sociodemographic factors in adolescent and young adult (AYA) cancer survivors. *First Author: Theresa Keegan, Center for Oncology Hematology Outcomes Research and Training (COHORT), UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: AYA cancer survivors are at increased risk of developing cardiovascular disease (CVD) compared to AYAs without a history of cancer. In AYA cancer survivors, few population-based studies have focused on CVD risk and none have considered whether the occurrence of CVD differs by sociodemographic factors. **Methods:** Analyses focused on 64,918 patients aged 15-39 y at diagnosis for one of 14 first primary cancers during 1996-2010 and surviving > 2 years after diagnosis, with follow-up through 2013. Data were obtained from the California Cancer Registry and State hospital discharge data. CVD included coronary artery disease, heart failure, and stroke. We estimated the cumulative incidence of developing CVD, accounting for death as a competing risk, stratified by race/ethnicity, neighborhood socioeconomic status (SES) at diagnosis, health insurance status at diagnosis/initial treatment and cancer type. We examined the impact of CVD on mortality using multivariable Cox proportional hazards regression with CVD as a time-dependent covariate. **Results:** Overall, 2374 (3.7%) patients developed CVD, and 7690 (11.9%) died over the follow-up period. Survivors of acute myeloid leukemia (12.6%), acute lymphoid leukemia (11.1%), central nervous system cancer (9.0%) and non-Hodgkin lymphoma (6.0%) had the highest incidence of CVD at 10-years. Incidence was significantly higher among Blacks (6.7%) at 10-years than non-Hispanic Whites (3.0%), Hispanics (3.7%) and Asian/Pacific Islanders (3.7%) ($p < 0.001$). AYA survivors with public or no insurance (vs private) had a higher 10-year incidence of CVD (5.8% vs 2.9%; $p < 0.001$), as did survivors residing in low (vs high) SES neighborhoods (4.1% vs 2.7%; $p < 0.001$). These sociodemographic differences in CVD incidence were apparent across most cancer sites. The risk of death was increased by five-fold or higher among AYAs who developed CVD. **Conclusions:** AYA cancer survivors who were uninsured or publicly insured, of Black race/ethnicity, or who resided in lower SES neighborhoods are at increased risk for developing CVD and experiencing higher mortality. The proactive management of CVD risk factors in these subgroups may improve patient outcomes.

6566 Poster Session (Board #388), Mon, 1:15 PM-4:45 PM

Audit study of cancer research mentorship opportunities by NCI-funded PIs: Analysis of a pathway barrier for diversity. *First Author: Jeffrey D. Robinson, Portland State University, Portland, OR*

Background: The pipeline of diverse cancer researchers is critical. Audit studies suggest that racial discrimination disadvantages black (vs. white) people with respect to educational/professional advancement (Milkman, 2012). We hypothesized that prospective Black (B) male doctoral students would experience greater disparity in responses when seeking access to NCI-funded PIs compared to prospective Caucasian (W) males. Primary aim: To explore response and acceptance rates for B (vs. W) men seeking cancer-research mentorship. We also explore similar differences when considering evaluators' race and sex. **Methods:** Between 9-9:30 am (local time) during a Monday in Oct 2015, identical emails were sent to 1028 randomly selected PIs affiliated with 65 NCI-designated cancer centers. PIs were randomly assigned to receive emails from either 'Brad Anderson' (W; n = 513) or 'Lamar Washington' (B; n = 515). Primary outcomes: (1) any response within one week (yes/no); and (2) type of response if received (agree to meet/not agree to meet). Logistic regression was used to examine unadjusted and adjusted effects of condition (W/B) on the primary outcomes. In adjusted models, PI sex and time zone were included as covariates (PIs identified as African American = 1.2%). **Results:** Approximately 50.0% and 48.3% of the sample responded to 'Brad' and 'Lamar,' respectively. Condition was not a significant predictor of 'any response' in either unadjusted (p = .62, odds ratio 95% CI = 0.83-1.35) or adjusted (p = .62, odds ratio 95% CI = 0.83-1.36) models. In the adjusted model, neither PI sex nor time zone were significant predictors of 'any response.' For those who responded, 43.7% and 40.9% 'agreed' to meet with Brad and Lamar, respectively. Condition was not a significant predictor of 'response type' in either unadjusted (p = .53, odds ratio 95% CI = 0.78-1.61) or adjusted (p = .51, odds ratio 95% CI = 0.78-1.64) models. In the adjusted model, only PI sex was a significant predictor of 'response type' (p = .03, odds ratio 95% CI = 1.04-2.29), with males (45.8%) being more likely to 'agree to meet' than female PIs (35.6%). **Conclusions:** We did not find strong evidence of bias by NCI-funded PIs against B (vs. W) prospective Ph.D. students.

6567 Poster Session (Board #389), Mon, 1:15 PM-4:45 PM

Associations between cancer patients' advance care and financial planning and surviving spouses' financial well-being. *First Author: Alexi A. Wright, Dana-Farber Cancer Institute, Boston, MA*

Background: The "financial toxicity" associated with cancer treatment, including high out-of-pocket expenses and lost earnings, may have lasting financial effects for surviving spouses. Although advance care planning (ACP) is used as a cancer quality metric, the value of financial planning is unknown. **Methods:** We examined associations between cancer patients' written ACP and financial planning (will) and surviving spouses' financial well-being using prospective, nationally representative data from the 2004-2014 waves of the Health and Retirement Study. We assessed change in household, non-housing (financial) wealth, including debt, among 962 surviving spouses of cancer decedents. Because wealth varies widely in the US, we fit multivariable quantile regression models at the 25^{th}, 50^{th}, and 75^{th} percentiles to examine associations between cancer decedents' ACP, financial planning, and wealth, adjusting for sociodemographic characteristics. **Results:** Among cancer decedents, 33% completed both ACP and a will, 27% only a will, 10% only ACP, and 30% neither. The median wealth of surviving spouses was \$22,309 (25^{th} percentile = \$0, 75^{th} percentile = \$134,238). Among spouses of cancer decedents in the 25^{th} percentile of wealth before death, completion of ACP and a will was associated with \$5,348 (95% CI = \$1,172-\$9,523) more financial wealth after death compared with no planning. Use of ACP and a will was also associated with \$46,851 (95% CI = \$2,810-\$90,891) more financial wealth at the 75^{th} percentile. There were no differences in the wealth of surviving spouses after death between patients who completed only a will, only ACP, or no planning (Ps > .09). **Conclusions:** Completion of ACP and financial planning was associated with greater wealth among both affluent and non-affluent surviving spouses compared with no planning. Efforts to sensitively incorporate financial planning into cancer patients' care have the potential to improve surviving family members' financial well-being.

6568 Poster Session (Board #390), Mon, 1:15 PM-4:45 PM

Miami NICE trial: Nutritional support for patients incurring chemotherapy side effects. *First Author: Damien Mikael Hansra, Oncology and Radiation Associates/Mercy Research Institute, Miami, FL*

Background: Few studies have been performed addressing nutritional interventions & mitigation strategies to address side effects such as weight gain, anorexia, dysgeusia, in patients (pts) undergoing chemotherapy. We aim to study the effect of nutritional counseling on body mass index (BMI) and other side effects in pts undergoing systemic chemotherapy. **Methods:** Prospective randomized study of 50 pts into two groups (A & B). Group A was randomized to standard of care: oncologist visits once per month x 3 months, routine physician counseling & dietary recommendations. Group B: standard of care + nutritionist intervention which included 3 visits x 30 mins each. Nutritionists performed an initial assessment of pts at the first session (template provided in poster) then tailored dietary counseling monthly x3 months which includes dietary strategies to mitigate side effects, pt & caregiver education, recipes, & handouts (provided in poster). Inclusions: medically insured male & female adults with active malignancies (hematologic &boncologic) on chemotherapy (neoajuvant, adjuvant, palliative). Exclusions: pts with head & neck, stomach, esophagus, pancreatic tumors & pts with pre-existing cachexia. Data collected: pt gender, age, race, ethnicity, cancer subtype, TNM staging, chemotherapy regimen. Primary objective: compare change in BMI at visit 1, 2, &3. Secondary endpoints: anorexia, nausea, vomiting, depression, etc. reported in poster. Mean change in BMI, secondary endpoints compared using students T-test with ANOVA using SAS software version 8.0 & minitab version 17. **Results:** Group A initial BMI = 28.85 vs group B initial BMI = 27.34 (p = 0.05). Change in BMI group A vs B at visit 1 (0.4 vs 0.09, p = 0.002), visit 2 (4.6 vs -0.52, p = 0.001), visit 3 (6.5 vs 0.46, p = 0.003). Demographics & secondary endpoints reported in poster. **Conclusions:** We found dietary counseling in addition to standard of care was associated with significant mitigation of weight gain in patients on systemic chemotherapy. Dietary counseling is a relatively simple, inexpensive, individualized, & reproducible method to mitigate chemotherapy related weight gain.

6569 Poster Session (Board #391), Mon, 1:15 PM-4:45 PM

Prospective assessment of psychosocial outcomes of contralateral prophylactic mastectomy. *First Author: Abenaa M. Brewster, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Increasing numbers of women are choosing contralateral prophylactic mastectomy (CPM) despite the lack of knowledge about its effect on long-term psychosocial adjustment. The objective of the study was to examine patient-centered psychosocial outcomes of women with breast cancer who have CPM versus those who do not in order to enhance shared surgical decision making. **Methods:** We enrolled 308 women with newly diagnosed, non-hereditary breast cancer prior to surgery (CPM or no CPM) at MD Anderson Cancer Center and Kelsey-Seybold Clinic between 2012 and 2015. Women completed validated questionnaires assessing psychosocial factors including quality of life (QOL), body image concerns, cancer distress, trust in physician and decision satisfaction pre-surgery and at 1, 6 and 12-months post-surgery. Repeated measures models were fitted to assess the association between psychosocial outcomes measured at each time point and CPM status adjusting for time effect. **Results:** Among 252 women (mean age 56) who completed pre and post-surgery questionnaires, 60% were non-Hispanic white, 16% non-Hispanic black, 16% Hispanic, 8% mixed race and 17% had CPM. Women who had CPM had higher scores for cancer distress and body image concerns and lower scores for QOL than women who did not have CPM at pre-surgery ($p = 0.04$, $p < 0.01$, $p = 0.20$, respectively), and at 1 month ($p = 0.42$, $p < 0.001$, $p < 0.01$, respectively), 6 months ($p = 0.03$, $p < 0.001$, $p = 0.05$, respectively) and 12 months ($p = 0.01$, $p < 0.001$, $p = 0.01$, respectively) post-surgery. After adjusting for time effect, women who had CPM had higher post-surgery scores for cancer distress ($p = 0.03$), body image concerns ($p < 0.0001$), QOL ($p < 0.01$) and lower trust in physician ($p = 0.03$) than women who did not have CPM. There was no statistically significant difference by CPM status for cancer knowledge or decision satisfaction. **Conclusions:** This is the first study to demonstrate that psychosocial factors such as cancer distress, QOL and body image concerns are not improved by having CPM. The results highlight the importance of evaluating psychosocial factors pre- and post- surgery and the need to incorporate psychosocial assessment and counseling in the CPM decision making process.

6570 Poster Session (Board #392), Mon, 1:15 PM-4:45 PM

PROMs and PREMs in Dutch integrated head and neck cancer care. *First Author: Rosella Hermens, Scientific Institute for Quality of Healthcare, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

Background: Providing patient-centred care is an essential component of high quality integrated care. A method to get insight in patients perspectives about the quality of health care they received, is measuring Patient Reported Outcome Measures (PROMs) and Patient Reported Experience Measures (PREMs). We aimed to determine the outcomes of, and differences between PROs and PREs over time and between treatment groups for patients with head and neck cancer (HNC). **Methods:** Patientswere recruited from nine hospitals participating in the DHNA. Validated questionnaires were distributed at baseline, 3, 6 and 12 months follow-up. Included PROMs were EuroQol 5 Dimension 3 Level (EQ-5D-3L), EORTC QLQ-C30 and -H&N35. Included PREMs, Consumer Quality index for Oncologic care (CQO) and Radiotherapeutic care (CQR), have similar domains with different questions. With descriptive analysis, ANOVA and mixed model analysis, differences over time and between treatment groups were analyzed. **Results:** Questionnaires were filled in by 426 patients. Pain decreased significantly at 6 and 12 months follow-up (14 and 21 points on a scale of 0-100) and dry mouth increased significantly at 3, 6 and 12 months follow-up compared to baseline (35, 27 and 20 points). Sticky Salvia, problems with social eating and sense problems increased at 3 and 6 months follow-up, but were similar to the baseline score at 12 months follow-up. Pain and sticky saliva differed between radiotherapy and chemoradiotherapy or surgery and radiotherapy respectively ($p \leq 0.05$). Regarding the CQO domain scores, all treatment groups differed significantly from each other ($p \leq 0.05$), especially for the domain Personal input. There was no difference regarding the CQR domain scores. Recognizing the emotional side of HNC and guidance after the treatment scored low in patients. **Conclusions:** This study gives clues to improve healthcare according the experiences of the patient and we can predict more carefully the outcomes of the patients with different treatment types. PROMs according to the ICHOM criteria and PREMs are promising for measuring and improving quality and personalization of HNC care. However, recognizing the emotional side of HNC and intensifying guidance after the treatment period needs improvement.

6571 Poster Session (Board #393), Mon, 1:15 PM-4:45 PM

Assessing performance status and clinical outcomes with wearable activity monitors. *First Author: Gillian K. Gresham, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Performance status (PS) is assessed to inform treatment decisions and predict outcomes in cancer. PS is often evaluated using ECOG or KPS scales, limited by their subjective and static nature. Wearable activity monitors provide oncologists with the opportunity to obtain continuous objective data on patients' daily activity including steps, stairs climbed, and sleep. We evaluated the association between wearable activity monitor data, PS, and clinical outcomes. **Methods:** Patients with advanced cancer were enrolled in a prospective, observational study conducted at Cedars-Sinai Medical Center. Patients wore a Fitbit Charge HR for 3 consecutive clinic visits. ECOG/KPS were rated by treating physicians and serious adverse events (AE, clinically relevant grade 3+ by CTCAE v4), hospitalizations, and 6-month survival were collected. Correlations between PS and activity metrics were calculated. Multivariable regression models were fit to predict AEs and hospitalizations with activity data. The association between activity metrics and time to death was evaluated using survival analysis. **Results:** 35 patients (median age 62 years, 53% male) were evaluated. Most had gastrointestinal cancers (82%). Patients had ECOG PS of 0 (20%), 1 (40%), 2 (23%), and 3(17%). There were 10 (29%) pts with serious AEs, 14 (40%) hospitalizations, and 11 (31%) deaths. Average daily steps were significantly correlated with ECOG PS and KPS (r=0.73 and 0.70, respectively). Relationships between activity metrics, AEs, hospitalizations, and overall survival (OS) are displayed in the table below. **Conclusions:** We found a significant association between wearable activity monitor data and the risk of AEs, hospitalization and death. There is a strong correlation between step counts and KPS/ECOG PS. The potential of wearable activity data to predict outcomes and supplement PS assessment should be explored in future studies. Clinical trial information: NCT02659358.

	Adverse Events Odds ratios (p-value)	Hospitalizations Odds ratios (p-value)	Overall Survival Hazard Ratios (p-value)
Steps (per 1000 step increase)	0.36 (0.03)	0.23 (0.02)	0.48 (0.01)
Stairs (per 10 stair increase)	0.59 (0.11)	0.44 (0.06)	0.27 (0.04)
Sleep duration (per 1 hour increase)	1.78 (0.1)	1.94 (0.09)	1.79 (0.01)

6572 Poster Session (Board #394), Mon, 1:15 PM-4:45 PM

What are patients' biggest concerns? A patient reported outcome case-management system. *First Author: Rahma M. Warsame, Mayo Clinic, Rochester, MN*

Background: Cancer patients (pts) receive complex care that may cause physical, emotional, & financial sequelae. Current practice limits clinician time to address patient concerns. The Patient Reported Outcome Quality Of Life (PROQOL) system was developed as a self-reported electronic questionnaire to assess symptoms, QOL and provide data about bothersome issues. Our aim was to determine if the PROQOL system improves QOL without negatively impacting routine clinic workflow. **Methods:** Eligible pts had multiple myeloma, amyloidosis, head & neck or gynecologic cancer seen in Hematology/Oncology clinics at Mayo Clinic, and were stratified by stem cell transplant and active treatment status. Pts were randomized 2:1 to PROQOL system or usual care. PROQOL system was offered prior to every visit. Pts select from various categories about their single biggest concern, and receive a printed list of actionable resources based on selected concern. Clinicians also receive the PROQOL results to review with pts. Providers and pts randomized to PROQOL completed a "was it worth it survey" (WIWI). An 8 item Linear Analogue Self-Assessment was used to assess QOL. The study was powered to detect a 0.5 standard deviation difference in QOL between groups. Herein we report the planned results of first 6 months. **Results:** Among the first 118 pts accrued, 55% were female, median age was 63 (32-86), & 93% were on therapy. Median time from diagnosis to PROQOL was 26 months. The PROQOL system took 3.6 minutes to complete. Baseline median QOL (range) was 7 (3-10) for both groups. The most common PROQOL issue selected was "cancer & diagnosis" (36.5%) followed by "physical health" (35.3%). Specific concerns were related to treatment plan, prognosis, fatigue, sleep, and neuropathy. WIWI showed: 71% of pts thought it was worthwhile, 83% would participate again, 80% would recommend it, & 65% used resources provided. 80% of providers reported the PROQOL did not interfere with care & 75% believed the pt wellbeing may improve. **Conclusions:** Notably treatment plan & prognosis remain pts' greatest concern despite being over 2 year from diagnosis. The PROQOL system demonstrates integrated PRO reporting in clinic is quick & worthwhile to pts & providers.

6573 Poster Session (Board #395), Mon, 1:15 PM-4:45 PM

Self-reported health and access to care among cancer caregivers: Analysis of the 2015 behavioral risk factor surveillance system (BRFSS). *First Author: Emily Castellanos, Vanderbilt University Medical Center, Nashville, TN*

Background: Caregivers play a vital role in the support and treatment of cancer patients. Caregiver well-being can impact patient-perceived quality of care. The study objectives were to compare self-reported health and access to care between cancer caregivers and non-caregivers, and to determine the relationship of caregiving burden to self-reported health and access to care. **Methods:** We used data from the Caregiver and Core Modules of the 2015 BRFSS, an annual federal survey of health-related behavior, health conditions, and preventive service use. Caregiver burden was assessed by time (hours per week and duration of caregiving) and task (personal care and household management tasks). Measures of self-reported health and access to care between cancer caregivers and non-caregivers were compared using *t*-test or Chi-Square testing. Associations of caregiver burden with self-reported health and access to care were assessed with linear and logistic regressions. **Results:** 1,910 cancer caregivers and 84,412 non-caregivers were included. Compared to non-caregivers, cancer caregivers were more likely to report inability to see a physician due to cost (15% vs 9%; $p < 0.001$), depression (25.0% vs 17.9%; $p < 0.001$), and poor mental health (mean days per month 5.7 vs 3.1; $p < 0.001$). Compared to caregivers with low task burden, those with moderate or high task burden reported both more poor mental health days (moderate ß = 1.8, 95% CI 0.5 – 3.1, p = 0.008; high ß = 2.0, 95% CI 0.6 – 3.3, p = 0.004) and increased likelihood of cost barriers (moderate OR 1.6, 95% CI 1.03 – 2.5, p = .035; high OR 1.8, 95% CI 1.2 – 2.9, p = .008). Increased time burden was associated with more poor mental health days (moderate ß = 1.5, 95% CI 0.2 – 2.7, p = .02; high ß = 4.4, 95% CI 3.3 – 5.6, $p < .001$) but not cost barriers. No differences in insurance, personal health provider, medical check-ups, or self-reported poor physical health were identified. **Conclusions:** Cancer caregivers are more likely than non-caregivers to report poor mental health, depression, and difficulty seeing a physician due to cost. Caregivers with high caregiving burden are at increased risk of experiencing poor mental health and cost barriers to medical care.

6574 Poster Session (Board #396), Mon, 1:15 PM-4:45 PM

Association between progression-free survival and health-related quality of life in oncology: A systematic review and regression analysis. *First Author: Bruno Kovic, Department of Health Research Methods, Evidence, and Impact, McMaster University, Hamilton, ON, Canada*

Background: The goal of cancer care is to improve not only survival duration but also health-related quality of life (HRQoL). Progression-free survival (PFS) has become an important surrogate outcome in assessing efficacy of new cancer drugs, but the relationship between improved PFS and HRQoL is not clear, particularly in the absence of an overall survival (OS) benefit. The objective of this study was to examine the relationship between PFS and HRQoL through a systematic review and analysis of published evidence. **Methods:** We searched MEDLINE, Embase, and Cochrane databases for randomized controlled human trials addressing oncology treatments published since 2000. We utilized the difference in median PFS time duration between treatment groups, with eligible trials being those reporting no significant OS benefit. We calculated and compared HRQoL between treatment groups using the difference in standardized mean incremental area under the curve adjusted to per month values. Weighted simple regressions were used to examine the PFS-HRQoL association, separately for physical, emotional, and global HRQoL domains. **Results:** 35,960 citations were identified, with 42 final articles reporting 30 clinical trials being eligible for inclusion. The 30 trials involved 10,731 patients across 12 types of cancer using 6 different instruments. 67% of all trials had improved PFS, and 56%, 54%, and 62% of trials had improved physical, global, and emotional HRQoL, respectively. The PFS with physical domain (n = 18) regression coefficient (slope) β = -0.205 (95% CI; -0.649 to 0.239), with emotional domain (n = 13) β = 0.775 (95% CI; -0.048 to 1.598), and with global domain (n = 24) β = 0.094 (95% CI; -0.271 to 0.459). **Conclusions:** Our systematic review and analyses revealed weak and non-significant association between PFS and HRQoL. In the absence of OS benefit, when longer PFS doesn't correspond to better HRQoL, using PFS as the proxy for efficacy for oncology drugs is problematic.

Understanding the non-curative potential of palliative chemotherapy: Do patients hear what they want to hear? *First Author: Andrea Catherine Enzinger, Dana-Farber Cancer Institute, Boston, MA*

Background: Misconceptions about the curative potential of PC are common, and may arise from gaps in informed consent. Another contributing factor could be patients' desire, or lack of desire, for information about prognosis and PC outcomes. **Methods:** We surveyed 137 patients with advanced colorectal (N = 102) or pancreatic cancer (N = 35) within 2 weeks of consultation about 1st or 2ndline PC, as part of randomized trial of a PC education intervention at 6 US sites. Patients rated how much information they wanted about PC risks/benefits, including impact on prognosis. Responses ranged from no information to as much as possible on a 5-point Likert scale. They reported decision-making preferences; whether a doctor discussed curability, and how likely they thought PC was to cure their cancer. Chi square and Wilcoxon tests examined whether information and decision-making preferences, or curability discussions were associated with expectations of cure. Multivariable logistic regressions evaluated whether associations were modified by age, race, gender, marital status, or cancer type. **Results:** Only 44.5% of patients accurately reported that their cancer was not at all likely to be cured by PC. Most patients wanted a lot, or as much information as possible about PC risks/benefits, including likelihood of cure (81.7%), cancer control (84.7%), and impact on length of life (80.3%). Most patients preferred shared (70.8%) versus active or passive decision-making. Neither decision-making nor prognostic information preferences were associated with expectations of cure. Patients (13.9%) who did not recall curability discussions were less likely to have accurate expectations (21% v 48%; OR, 0.29; 95% CI, 0.07-.97). Patient characteristics did not significantly confound this association. **Conclusions:** Most patients value shared decision-making and want maximal information about PC risks/benefits, including impact on prognosis. Despite wanting prognostic information and reporting curability discussions, many patients report inaccurate expectations about cure from PC. Future studies should examine whether these assertions reflect misunderstandings, differences in belief, or expressions of hope.

6576 Poster Session (Board #398), Mon, 1:15 PM-4:45 PM

Differences in mortality among patients with acute leukemia admitted on weekends as compared to weekdays. *First Author: Kaushal Parikh, New York Medical College, Valhalla, NY*

Background: The association between weekend admissions and patient outcomes has been widely reported for several acute illnesses. However, this is the first study using a nationwide database to focus on outcomes of weekend admissions for acute leukemia. **Methods:** We used the 2002-2012 Nationwide Inpatient Sample Databases to identify patients admitted with a diagnosis of acute leukemia. Admissions were identified as weekend or weekday admissions and rates of mortality, in-hospital complications, existing comorbidities, and demographic differences were assessed. Adjusted logistic regression models were used to analyze mortality and complication outcomes. **Results:** Out of a total of 71,392 patients included in the analysis, 12,234 (17.1%) patients were admitted over the weekend. While there has been a general decline in admissions and mortality in acute leukemia from 2002-2012, mortality was 18.8% for weekend admissions and 16.3% for weekday admissions ($p < 0.001$). Weekend admissions independently predicted higher mortality (adjusted odds ratio 1.128, 95% confidence interval, 1.06 to 1.20; $p < 0.001$). These patients were also less likely to receive an early bone marrow biopsy than their weekday counterparts (45% vs 26.5%; $p < 0.001$). Bone marrow biopsy was independently associated with a reduced in-hospital mortality (aOR 0.395, 95% CI 0.373 to 0.417; $p < 0.001$). Admissions to teaching hospital were also associated with a lower mortality (aOR 0.890, 95% CI 0.845 to 0.936; $p < 0.001$). Weekend admissions were also more likely to have in-hospital complications than weekday admissions (52.4% vs 50.5%; $p < 0.001$). **Conclusions:** There was a significantly increased mortality among acute leukemia patients admitted on a weekend. Our study suggests that patients admitted over the weekend may be clinically sicker or receive inferior care than weekday admissions. We also conclude that patients admitted to teaching hospitals have a better outcome and emphasize the importance of availability of resources and early presentation to tertiary care centers.

6577 Poster Session (Board #399), Mon, 1:15 PM-4:45 PM

Feasibility of wearable physical activity monitors in cancer patients (PAMCaP). *First Author: Muhammad Shaalan Beg, Division of Hematology/Oncology, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Wearable physical activity monitors (PAMs) provide a degree of functional assessment not possible with prior clinical instruments. Subjective assessments of functional status are prone to inaccuracy and current objective assessment techniques are limited to the research setting. The relevance of physical activity monitors (PAMs) to measure functional status in cancer patients is unclear. The feasibility of using these devices in cancer patients is not known. **Methods:** This is a prospective pilot trial of a commercially available PAM in cancer patients. Patients with Eastern Cooperative Group performance status (ECOG PS) 0-2 receiving systemic therapy at an NCI Designated Comprehensive Cancer Center were enrolled. (NCT02583815). The primary objective was to determine feasibility of PAM use, defined as device use of more than 50% of the study observation period. Secondary objectives were to correlate PAM-reported measures: median, minimum and maximum steps/day, minutes of activity/day, (light/ fairly active/ very active); with 1) clinician assessed ECOG PS and 2) quality of life tool scores (FACT-G, QIDS, PQSI and BFI). Patient experience with wearable PAMs was assessed at the end of study. **Results:** We enrolled 32 patients: median age = 56 years (range 23-72), female = 67%, and white = 78%. Most patients had gastrointestinal (52%) and breast (19%) primaries. Clinician assessed PS was ECOG 0 in 56%, 1 in 37% and 2 in 7%. Majority of patients (81%) met the primary end point. Mean PAM measured steps for ECOG 0 was 5911 steps/d, ECOG 1 was 1890 steps/d and ECOG 2 was 845 steps/d (p = 0.002). Minimum steps/day correlated with BFI (r = -0.56, p $<$ .01), FACT-G (r = 0.45, p 0.01) and QIDS (no vs mild vs moderate depression, p 0.01). Patients reported a positive experience with the devices (74%). **Conclusions:** Wearable PAMs are a feasible tool to measure physical activity in cancer patients receiving systemic therapy. PAM derived measures correlate with clinician assessments of performance status. Future work should develop methods to systematically incorporate PAMs in oncology clinical trials and practice. Clinical trial information: NCT02583815.

6578 Poster Session (Board #400), Mon, 1:15 PM-4:45 PM

Correlation of changes in disposition of geriatric (≥ 65 years) cancer patients receiving hematopoietic stem cell transplantation with an increase in healthcare costs. *First Author: Achuta Kumar Guddati, SUNY Downstate Medical Center, Brooklyn, NY*

Background: The increasing proportion of geriatric cancer patients in the general population has contributed to rising health care costs. The disposition of hematopoietic stem cell transplant (HSCT) recipients in the geriatric population is an important factor determining the cost of their health care. A database with nationwide representation for outcomes of HSCT over a 12 year period was analyzed. **Methods:** Data regarding patients who underwent HSCT was extracted from the Nationwide Inpatient Sample (NIS) from 2000 to 2011 using ICD-9-CM codes. HSCT hospitalizations were classified into allogeneic transplantation, autologous transplantation, subsequent hospitalization (s/p transplant) with graft versus host disease (GVHD) and subsequent hospitalization (s/p transplant) with other complications. NIS variables were used to identify in-hospital complications and discharge disposition. **Results:** The proportion of elderly patients (≥ 65 years) who received any type of transplant or were admitted with GVHD or other related complications who were discharged with additional support and to specialized facilities has increased over the past decade. The exception to this trend has been noted for allogeneic transplants and may be due to a more conservative approach towards their disposition (ie, higher level of care and longer length of stay). The trends from 2000 to 2011 are summarized in the table below. **Conclusions:** A higher percentage of geriatric cancer patients who receive HSCT are being discharged to nursing homes. These rates have significantly changed over the past decade ($p > 0.05$) and represents an additional contribution to the rising health care costs. This proportion of patients are expected to rise as increasingly older patients are being allowed to receive HSCT and represents a higher future demand for health care services.

	≥ 65 years			
	Autologous transplantation	Allogeneic transplantation	s/p Transplant with GVHD	s/p Transplant with other complications
Home	87 to 80%	77 to 69%	77 to 55%	71 to 66%
Home Healthcare	10 to 16%	16 to 27%	16 to 26%	17 to 20%
Nursing Home	3 to 4%	7 to 3%	6 to 19%	11 to 14%
Others	< 1%	< 1%	< 1%	0-1%

6579 Poster Session (Board #401), Mon, 1:15 PM-4:45 PM

Symptom burden and hospital length of stay among patients with curable cancer. *First Author: Sara D'Arpino, Massachusetts General Hospital, Boston, MA*

Background: Prolonged hospital admissions are often inconsistent with patients' preferences and incur significant costs. While patients' symptoms may result in hospitalizations, the relationship between patients' symptom burden and their hospital length-of-stay (LOS) has not been fully explored in patients with curable cancers. **Methods:** We prospectively enrolled patients with curable cancer and unplanned hospital admissions between 8/2015 and 12/2016. Within the first 5 days of admission, we assessed patients' physical (Edmonton Symptom Assessment System [ESAS]; scored 0-10 with higher scores indicating greater symptom burden) and psychological symptoms (Patient Health Questionnaire 4 [PHQ-4]; scored categorically and continuous with higher scores indicating greater distress). We created summated ESAS total and physical symptom variables. To assess the relationship between patients' symptom burden and their hospital LOS, we used separate linear regression models adjusted for age, sex, marital status, education level, time since cancer diagnosis, and cancer type. **Results:** We enrolled 452 of 497 (91%) approached patients (mean age = 61.9 years; 188 [42%] female). Over half had hematologic cancers (n = 249, 55%). Mean hospital LOS was 8.3 days. Over one-tenth of patients screened positive for PHQ-4 depression (n = 74, 16%) and anxiety (n = 60, 13%) symptoms. Mean ESAS symptom scores were highest for fatigue (6.6), drowsiness (5.4), pain (4.9), and lack of appetite (4.8). In multivariable regression analysis, patients' physical and psychological symptoms were associated with longer hospital LOS (table). **Conclusions:** Patients with curable cancer and unplanned hospital admissions experience a substantial symptom burden, which predicts for prolonged hospitalizations. Importantly, patients' symptoms are modifiable risk factors that, if properly addressed, can improve care delivery and may have the potential to help decrease prolonged hospitalizations.

Symptom burden associated with hospital LOS	B	95% Confidence Interval	Standard Error	P-value
ESAS Physical	0.10	0.04 to 0.17	0.03	**0.003**
ESAS Total	0.10	0.05 to 0.15	0.03	**< 0.001**
PHQ-4 Depression	0.68	0.15 to 1.20	0.27	**0.011**
PHQ-4 Anxiety	0.55	< 0.01 to 1.09	0.28	**0.0498**

6580 Poster Session (Board #402), Mon, 1:15 PM-4:45 PM

Inpatient hematology and oncology rehabilitation. *First Author: Leann Blankenship, Beaumont Health, Department of Hematology and Oncology, Oakland University William Beaumont School of Medicine, Royal Oak, MI*

Background: Functional decline in cancer patients impacts quality of life and overall survival. Increasing attention has been focused on cancer rehabilitation in survivors, largely in the outpatient setting. Beaumont Health System has shifted its focus to include the acute setting by developing an inpatient cancer rehabilitation unit (IPCR) to improve the comprehensive care of patients. **Methods:** We retrospectively reviewed the patients admitted to IPCR from January 1 - December 31, 2016 for the following: demographics, length of stay (LOS), function independence measure (FIM) gain and efficiency, discharge location, and primary tumor type. **Results:** IPCR had 117 inpatient admissions; 98 (83.7%) were solid malignancies while 19 (16.3%) were benign hematological disorders and hematological malignancies. Of the 98 patients with solid malignancies, 22 (22.4%) patients had breast cancer, 22 (22.4%) had gastrointestinal cancers, 5 (5.1%) had gynecological cancers, 23 (23.5%) had lung cancer, 8 (8.2%) had CNS malignancies, 11 (11.2%) had other cancers, and 7 (7.2%) had prostate cancer with 81.6% of patients having metastatic disease. Among the hematological malignancies, lymphoma was diagnosed in 11 (57.9%) patients while 3 (15.9%) each had multiple myeloma and leukemia. The mean age of the patients was 68 years and 59% were female. The average LOS was 8.6 days. The mean admission total FIM was 66.7 $\pm$12.8 and discharge total FIM was 87.3 $\pm$16.1. The total improvement in FIM was 20.6 $\pm$13.8 with FIM efficiency of 2.9. There were 21 (18%) patients transferred back to acute care units for decompensation, 7 (6%) went to subacute rehabilitation, 1 (0.85%) went to hospice while 87 (74.3%) were discharge to their homes upon completion of IPCR. **Conclusions:** Our focused rehabilitation was able to decrease the LOS, well above the 90th percentile Center for Medicare and Medicaid Services (CMS) benchmark and other prior studies, as well as enable patients to safely return home with improved FIM. Creating an IPCR unit proved to be beneficial, allowing for more comprehensive and individualized care, even in the setting of advanced malignancies.

6581 Poster Session (Board #403), Mon, 1:15 PM-4:45 PM

Prophylactic anticoagulation to benefit younger patients under 65 years of age with metastatic lung cancer: An analysis of the 2013 Healthcare Cost and Utilization Project (HCUP) data. *First Author: Arindam Bagchi, University Of Toledo, Toledo, OH*

Background: Cancer patients have increased risk of venous thromboses. Venous thromboembolism (VTE) is reported to be a leading cause of death in cancer patients. It has been hypothesized that prophylactic anticoagulation for VTE might improve prognosis and quality of life. Based on our analysis of the 2013 HCUP data, we propose that prophylactic anticoagulation should be considered for patients younger than 65 years with metastatic lung cancer. **Methods:** Patients were selected using ICD-9 diagnoses codes for metastatic lung cancer and VTE. Diagnoses were stratified by site including upper extremity, lower extremity, pulmonary, abdominal and nonpulmonary thoracic VTE. Patients were stratified by age, sex, race and ethnicity. Differences in incidence of VTE among groups were calculated by the Chi-Square method using the SAS software. **Results:** There were a total of 16,577 VTE events amongst 182,863 cases of metastatic lung cancer. Subgroup analyses showed that patients younger than 65 years of age had 356.82 more PE events per 100,000 individuals compared to those at or older than 65 years ($p < 0.0001$). The same age group also showed 374.83 more UE, 286.94 more nonpulmonary thoracic and 263.97 more abdominal (Abd) VTE events per 100,000 individuals (p-values, $p < 0.0001$). There was no statistically significant difference in the incidence of LE VTE's between the subgroups. **Conclusions:** Prophylactic anticoagulation should be considered in patients < 65 years of age with metastatic lung cancer. Increased incidence of VTE in these patients may contribute towards greater morbidity and mortality associated with metastatic lung cancer in this subgroup.

	Age < 65 y	Age > 65 y	
No. of patients	77415	105448	p value
PE	2928 3782.21 events per 100,000	3612 3425.38 events per 100,000	< 0.0001
UE VTE	912 1178.06 events per 100,000	847 803.23 events per 100,000	< 0.0001
LE VTE	2791 3605.24 events per 100,000	3913 3710.83 events per 100,000	0.2352
NonPulm Thoracic VTE	460 594.20 events per 100,000	324 307.26 events per 100,000	< 0.0001
Abd VTE	324 418.52 events per 100,000	163 154.57 events per 100,000	< 0.0001

6582 Poster Session (Board #404), Mon, 1:15 PM-4:45 PM

Patterns in provider types and cost of surveillance testing in early-stage breast cancer patients: A regional study. *First Author: Gary H. Lyman, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Although ASCO Choosing Wisely guidelines recommend against routine surveillance testing or imaging for asymptomatic individuals with early-stage breast cancer (ESBC) treated with curative intent, they are frequently performed. Physician specialty and costs associated with surveillance testing and imaging were examined in ESBC patients. **Methods:** Cancer registry patient records in Western Washington from 2007 to 2015 were linked with claims from two regional commercial insurers. Selected patients had been diagnosed with stage I/II breast cancer and treated with mastectomy or lumpectomy + radiation. Surveillance was considered from the first 4 month gap in treatment (surgery, chemo, radiation) through 13 months or restart of treatment. Evaluation and Management (E&M) and procedure codes for tumor marker (CEA, CA 15-3, CA 27.29) and advanced imaging (PET, CT, bone scan) were identified. Specialty codes were used to determine provider type. Physician visits were matched to tests using E&M codes in the +/- 7 days around each test. Cost included total reimbursed amount from insurers during the surveillance period. **Results:** During surveillance, 2,193 patients averaged 13.3 physician visits [median: 11, IQR: 8-17]. Oncologists (91%) and PCPs (83%) were the most common specialties with an average of 3.7 visits each. Overall, 37% of patients received tumor marker tests (avg = 2.8 tests/patient) and 17% received advanced imaging (avg = 1.5 images/patient). The mean total cost during the surveillance period was $18,403 (SD $26,640). Costs were higher for those patients who received tumor marker testing or advanced imaging. **Conclusions:** Patients frequently see oncologists and PCPs during early surveillance. Targeting oncologists to improve appropriate tumor marker testing could have the largest impact on aligning practice with Choosing Wisely recommendations and potentially reducing the financial burden on patients.

	Tumor Marker (n=2,302)	Advanced Imaging (n=531)
Med Onc	74 %	38%
Rad Onc	1%	4%
General Surgeon	3%	6%
PCP	14%	24%
Reconstructive Surgeon	2%	3%
Other	53%	50%
No office visit	7%	16%
Mean cost (std dev)	$24,380 ($29,392)	$29,998 ($34,922)

6583 Poster Session (Board #405), Mon, 1:15 PM-4:45 PM

Universal testing for hormonal status in breast cancer: Are we choosing wisely? *First Author: Taylor Maxwell Goller, University of Vermont Medical Center, Burlington, VT*

Background: Characterizing estrogen receptor (ER) and progesterone receptor (PR) status has long been standard practice with newly diagnosed breast cancers. ER and PR expression suggests a more favorable prognosis and predicts tumor responsiveness to hormonal therapy. However, this testing comes with considerable cost. At our institution, the Medicare reimbursement rate for a single ER/PR assay is $310. With over 300,000 newly diagnosed breast cancers in the US each year, the total cost of ER/PR testing is close to 100 million dollars. Furthermore, the 2010 American Society of Clinical Oncology (ASCO) and the College of American Pathologists (CAP) guidelines suggest that up to 20% of ER/PR testing worldwide may be inaccurate with potential for false negative results. A falsely negative result could lead clinicians to not offer treatment with hormonal therapies. The purpose of this study was to investigate whether nuclear grade could be used to predict ER status, thus saving cost and reducing the potential for false negative test results and the inappropriate withholding of beneficial treatment. **Methods:** A retrospective analysis of prospectively collected data from the University of Vermont Breast Cancer Database identified all newly diagnosed breast cancers of any histologic type with available data on nuclear grade and ER status (2/2008-10/2016). The relationship between nuclear grade and ER status was analyzed (Table). **Results:** Nuclear grades 1 and 2 were associated with a significantly higher proportion of ER positive results than high nuclear grades (chi-square test $p < .001$). **Conclusions:** Nuclear grade 1 and 2 breast cancers are nearly universally ER positive (99% and 97%, respectively). Thus, ER testing may be redundant in these tumors. Elimination of ER testing in nuclear grade 1 and 2 tumors could save tens of millions of dollars each year in the US alone. It could also reduce the potential for false negative test results and the inappropriate withholding of beneficial treatment.

Relationship between nuclear grade and ER expression status.

Nuclear Grade	ER Positive	%	ER Negative	%
3 (n: 1133) 37%	729	64%	404	36%
2 (n: 1642) 54%	1588	97%	54	3%
1 (n: 296) 9%	294	99%	2	1%
All (n: 3071)	2611	85%	460	15%

6584 Poster Session (Board #406), Mon, 1:15 PM-4:45 PM

CEASE: A novel patient directed electronic smoking cessation platform for cancer patients. *First Author: Jennifer M. Jones, Ontario Cancer Institute, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Continued smoking in cancer patients receiving treatment results in decreased efficacy, reduced survival, amd increased risk of recurrence. Despite ASCO and AACR policy statements, routine tobacco use screening and provision of smoking cessation treatment has not been widely implemented in the cancer setting. A paper-based tobacco use screening and clinician-dependent referral program for new ambulatory cancer patients was initiated at Princess Margaret Cancer Centre in 2013 resulting in moderate screen rates but low referral rates. In response, we developed and implemented a tailored patient directed electronic smoking cessation platform (CEASE) which included three elements:1) tobacco use assessment tool; 2) patient education on benefits of cessation; 3) a patient directed automatic referral system to smoking cessation programs. **Methods:** Interrupted time series design to examine the impact of CEASE on process of care (screening rates, referrals offered and accepted) and patient reported (quit attempts, smoking status, uptake of cessation programs) outcomes. Included 20 monthly intervals: 6 pre implementation (Apr-Sept 2015) (PRE), 8 gradual implementation across all tumour sites (Oct 2015-May 2016), and 6 postb implementation (Jun 2016-Nov 2016) (POST). A time series segmented linear regression was conducted to evaluate changes in process of care outcomes (excluding the implementation period). Pre-post self-report patient outcome data was also compared. **Results:** We assessed data from n = 3785 (PRE) and n = 4726 (POST) new patients. Screening rates increased from 44% using the paper-based approach to 65% with CEASE ($p = 0.0019$). Referrals offered to smokers who were willing to quit increased from 24% to 100% ($p < 0.0001$). Accepted referrals decreased from 45% to 26%; though the overall referral rate increased from 11% to 26% ($p = 0.0001$). The proportion of those using tobacco or attempting to quit did not differ at 3-months. However, engagement with the referral source increased from 4% to 62.5% ($p < 0.001$). **Conclusions:** CEASE was successfully implemented across all clinics and resulted in improvements in overall screening and referral rates and engagement with referral services.

6585 Poster Session (Board #407), Mon, 1:15 PM-4:45 PM

Transparency around disapproval reasons of early-phase trial proposals submitted to the National Cancer Institute (NCI). *First Author: Holly A. Massett, National Cancer Institute, Rockville, MD*

Background: NCI's ETCTN accepts Letters of Intent (LOI) for a new clinical trial either from a response to a solicitation for studies, or via unsolicited LOIs, where investigators independently propose novel studies. While the LOI approval rate for the first two years of the ETCTN was 100% for solicited LOI's, it was only 36% for unsolicited LOIs. Therefore, we analyzed all ETCTN LOI disapproval letters (DL) for unsolicited LOIs to identify the major reasons for disapproval. **Methods:** A content analysis was conducted on DLs issued between March 2014 and March 2016 (N = 50). Two coders independently scored disapproval reasons per letter using a code sheet with 22 categories identified from a sample of DLs (Intercoder Reliability = 97%). **Results:** All DLs were issued for unsolicited LOIs (44% = Ph 1; 26% = Ph 1/2; 30% = Ph 2); 271 reasons were identified across the 50 DLs (mean = 5.4/DL). High-level categories included concerns with study design, scientific rationale, feasibility, modality and administrative reasons. The top disapproval reasons were: Insufficient preclinical animal model data (54% of DLs); weak rationale/background (52%); inadequate information for biomarker correlative studies (46%); dose/scheduling plan absent or weak (36%); clinical data not adequately advanced (34%); and, patient population not described/inconsistent with treatment (34%). Top reasons for Phase 1 and 1/2 LOIs resembled the total but Phase 2 LOIs deviated slightly, with 'weak objective/endpoint' and 'biomarker correlative studies' as top DL reasons. Other common reasons were problems with combination study agents, company/drug collaboration, and competing trials. **Conclusions:** The reasons for LOI disapproval can be categorized and quantified. To increase transparency in the NCI ETCTN LOI review process, disapproval reasons for each DL are now collected on a standardized coding sheet, and will be reported quarterly to ETCTN PIs. NCI will also meet with all Grant PIs in Spring, 2017 to jointly discuss concerns and explore quality improvement solutions regarding the LOI submission process. The outcome of this meeting will be reported at ASCO as part of our findings.

6586 Poster Session (Board #408), Mon, 1:15 PM-4:45 PM

Does coaching goals of care discussion skills make a difference? *First Author: Nina A. Bickell, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Advanced cancer patients often have a poor understanding of their cancer prognosis. Goals of Care (GoC) discussions provide information about the cancer, its treatment & prognosis and elicit patient values. Little is known about the best ways to enhance patient understanding, clarify values and move GoC discussions earlier in the disease process. We report the effect of coaching oncologists on GoC discussions. **Methods:** We recruited oncologists & their advanced cancer patients with $<$ 2 year prognosis to a RCT testing a coaching model communication skills training. Patients were surveyed after their post-imaging visit. We define GoC discussions as patient report that their doctor talked about their cancer prognosis and clarified things most important to them given their disease. Outcome variables assess the impact of GoC on patients' knowledge on what to expect and clarity of values. **Results:** We enrolled 22/25 (88%) oncologists and 70% of eligible patients of whom 96 (55%) completed a survey. On average, doctors were 44 yrs old (32-66) and in practice 14.5 yrs (5-40). Patients' mean age was 62 yrs (20-95), 40% females, 58% white, 24% Latino & 22 % black. Overall, 2/3 of patients reported their treatment's goal was to cure their cancer; 14% reported cure to be unlikely. Patients felt more knowledgeable (79% vs 21%; p = 0.02) when their doctors discussed treatments, side effects & quality of life. When patients were asked about things important to them, they report being a bit clearer about their values (65% vs 35%; p = 0.16). Compared to controls, intervention patients felt more knowledgeable (78% v 63%; p = 0.17) but did not feel clearer about their values (60% v 54%; p = 0.59). Multivariate modeling found that poor health literacy (OR = 0.2; 95%CI: 0.07-0.82), having a GoC discussion (OR = 10.2; 1.7-63.1) and being in the intervention group (OR = 8.8; 1.4-55.2) significantly affected knowledge (model c = 0.88; p $<$ 0.01). However, discussing what's important to patients did not help patients feel clearer about their values (OR = 2.7; 0.6-12.2; model c = 0.82; p $<$ 0.05). **Conclusions:** Using a coaching model to teach oncologists communication skills may improve patients' understanding of what to expect with their cancer but does not impact their clarity of values. Clinical trial information: NCT02374255.

6587 Poster Session (Board #409), Mon, 1:15 PM-4:45 PM

Possible mechanisms of serotonin and aprepitant actions in chemotherapy induced nausea and vomiting (CINV): Insights into the mechanisms of serotonin and aprepitant actions in CINV—According to recent multi-institutional double-blind randomized clinical research on the AC regimen. *First Author: Michiko Tsuneizumi, Shizuoka General Hospital, Shizuoka, Japan*

Background: One of our interests has been whether palonosetron(P) would be superior to granisetron(G) when administering triplet antiemetic therapy for the prevention of CINV, since a prior trial demonstrated P to be superior to G for controlling CINV induced by highly emetogenic chemotherapy (HEC) in doublet therapy. In this study(TTT; trial for antiemetic therapy), we assessed the efficacies of P and G for use as triplet antiemetic therapy for AC, by monitoring CINV, focusing complete response (CR; no vomiting and no rescue medicine) in the delayed phase. The primary endpoint of TTT was a CR during the delayed phase with 5-HT3ra plus dexamethasone and aprepitant administration for AC. The purpose of gaining insights into the possible mechanism of action of aprepitant and P was to obtain ideas for the next strategy against CINV. **Methods:** Between 2012 and 2015, 491 breast cancer receiving AC were recruited from 11 institutions, and randomly assigned to either single-dose P(0.75mg) or G(40μg/kg) prior to AC on day 1, both with dexamethasone (9.9 mg) and aprepitant (125mg) on day 1 followed by additional doses (80mg) on days 2 and 3. Age, institution and habitual alcohol intake were used as stratification factors. The primary endpoint was a CR. **Results:** All 491 patients were included in efficacy analyses: 246 patients in the group P and 245 in the group G. The difference in CR during the delayed phase, i.e. 24 hrs after the administration of AC, did not reach statistical significance, however, there was a remarkable difference between 48 and 72 hrs in the day-to-day analysis(p $<$ 0.02). **Conclusions:** P showed better efficacy in controlling CINV between 48 to 72 hours after AC, than G as triplet antiemetic therapy for AC. We can reasonably speculate that the influence of serotonin has two peaks (0-24 hrs and 48-72 hrs). For controlling CINV in the delayed phase, not only an NK1 receptor antagonist but also administering a 5-HT3ra with long life should be considered until 72 hrs after HEC. Clinical trial information: UMIN 000007882.

6588 Poster Session (Board #410), Mon, 1:15 PM-4:45 PM

Phone call for chemotherapy validation in outpatient unit as a way to optimize health care without compromising patients' satisfaction and quality of life. *First Author: Patricia Marino, Institut Paoli-Calmettes, Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques and Sociales de la Santé and Traitement de l'Information Médicale, Marseille, France*

Background: Patients' satisfaction is known to be closely linked to the time spent with the physician. However, longer waiting times may be a source of dissatisfaction as well as organizational dysfunctions of the outpatient unit. Is a validation of chemotherapy by phone call instead of a medical consultation with a senior physician before chemotherapy (CT) is feasible without compromising patients' satisfaction and quality of life? **Methods:** Pts with OMS $<$ 1, able to respond to phone call, $<$ 76 years, receiving day 8 and or d15 of CT were included. We enrolled 343 pts in a before/after study between 2013 and 2016. In the "before" step (control arm), 168 pts had a systematic physician consultation the same day before CT administration. In the intervention arm 175 pts received a phone call by a junior physician the day preceding CT administration. A specific questionnaire for CT -related toxicity of the previous cycle was recorded and CT was validated or not by physician. The day after, pts received prepared CT without appointment with the oncologist and delay in administration for already prepared CT. At the end of CT protocol, socio demographics, patients' satisfaction (In-PatSat32) and health status (EQ-5D) questionnaires were completed by patients. **Results:** Questionnaires were completed by 83% and 74% in before and after step respectively, 241 questionnaires were analyzed. Satisfaction with care showed similar In-PatSat32 scores between arms, for satisfaction with: physician, nurse, organization and services. No differences of perceived health status and toxicity were observed between both groups, but patients' time spent in hospital was lower in the intervention group versus the control group, (p = 0.007). **Conclusions:** An alternative care pathway implementing phone calls before CT administration if feasible without compromising pts' satisfaction, quality of life and toxicity. We believe that saving time of pts, physicians and pharmacists is a way to optimize the model of care in outpatient unit, particularly in the immunotherapy area with more pts received intra venous treatment, probably for a long time.

6589 Poster Session (Board #411), Mon, 1:15 PM-4:45 PM

Concordance assessment of a cognitive computing system in Thailand. *First Author: Suthida Suwanvecho, Horizon Cancer Center, Bumrungrad International Hospital, Bangkok, Thailand*

Background: IBM Watson for Oncology (WFO) was trained by Memorial Sloan Kettering and is a cognitive computing system that uses natural language processing to ingest patient data in structured and unstructured formats. The system provides physicians with treatment options that are derived from established guidelines, the medical literature, and training from patient cases. In this study, we assessed the degree of concordance between treatment recommendations proposed by WFO and oncologists at Bumrungrad International Hospital (BIH). BIH is a 580-bed multispecialty hospital in Bangkok, Thailand. **Methods:** Data from breast, colorectal, gastric, and lung cancer patients treated at BIH were entered into WFO in 2015 and 2016. Retrospective cases were entered after a treatment plan had been determined, and prospective cases were entered during patients' treatment planning sessions. WFO recommendations were provided in 3 categories: "Recommended", "For Consideration", and "Not Recommended." Concordance was analyzed by comparing the decisions made by the oncologists to those proposed by WFO. Concordance was achieved when the oncologist's treatment suggestion was in the "Recommended" or "For Consideration" categories given by WFO. **Results:** A total of 211 cases were assessed, 92 were retrospective and 119 were prospective. The overall concordance rate was 83%; 89% for colorectal, 91% for lung, 76% for breast, and 78% for gastric cancer. Similar concordance rates were observed when retrospective and prospective cases were analyzed separately. Discordance was attributable in part to local oncologists' preferences for non-U.S. guidelines for certain cancers, especially gastric cancer. **Conclusions:** There was a high degree of concordance between WFO treatment options and the decisions made by local oncologists. Similar results were recently reported in a breast cancer concordance study conducted using WFO in India (San Antonio Breast Cancer Symposium 2016, Somashekhar et al). WFO's capabilities as a cognitive decision support tool can be further improved by incorporating regional guidelines. Future work will analyze reasons for discordance such as cost, insurance requirements, and patient and physician preference.

6590 Poster Session (Board #412), Mon, 1:15 PM-4:45 PM

Prevalence and estimated trend in chemotherapy use near death from population-based studies on cancer patients: A systematic review and meta-analysis. *First Author: Pei-Chun Chou, National Taiwan University Hospital Hsin-Chu Branch, Hsin-Chu, Taiwan*

Background: Chemotherapy (CMT) use near death, based on US national guidelines, is an indicator of aggressive treatment and poor quality of end-of-life (EOL) care. US law also decreased Medicare payments for outpatient CMT since 2005-2006. To evaluate the impact of US payment reform and guidelines on CMT use at EOL, we estimated and compared the overall prevalence of CMT use at EOL in the US and other countries as well as before and after 2007 in the US. **Methods:** Six databases were systematically searched to January 2017 for population-based studies of CMT use at EOL for patients in all cancer groups. Two reviewers independently extracted data.Overall CMT use prevalence was pooled by a random-effects model. Differences in prevalence of CMT use were compared by meta-regression between subgroups (US vs non-US countries; before and after 2007 in the US). **Results:** We identified 9 and 7 articles from the US and non-US countries, respectively. CMT was provided to 28.9% [95% confidence interval (CI) 26.2%-31.8%], 23.2% [95% CI 21.7%- 24.8%], 10.0% [95% CI 8.5%-11.8%], and 4.5% [95% CI 3.9%- 5.2%] of cancer patients in their last 6, 3, and 1 months as well as 14 days of life, respectively. CMT use in the last 6 months was more common in the US than in non-US countries (32.4% vs. 26.2%, p = 0.015) but similar to that of other countries in the last month (9.3% vs.11.2%, p = 0.179) and last 14 days (4.6% vs.5.6%, p = 0.683) of life. Prevalence of CMT use in the last 14 days of life in the US did not differ significantly before and after 2007 (5.1% vs. 5.2%, p = 0.967). **Conclusions:** Many cancer patients worldwide receive CMT at EOL, and the prevalence of CMT use in US patients' last 14 days of life was virtually unchanged over time. Effective interventions should be developed and provided to offset the trend of continuing CMT use at EOL.

6591 Poster Session (Board #413), Mon, 1:15 PM-4:45 PM

Estimating the optimal rate of adjuvant chemotherapy utilization in stage III colon cancer. *First Author: Safiya Karim, Cancer Care and Epidemiology, Queen's University, Kingston, ON, Canada*

Background: Identifying optimal chemotherapy utilization rates can drive improvements in quality of care. We report a benchmarking approach to estimate the optimal rate of adjuvant chemotherapy (ACT) for stage III colon cancer. **Methods:** The Ontario Cancer Registry was linked to electronic chemotherapy records to identify ACT utilization among a random 25% sample of patients with stage III colon cancer diagnosed during 2002-2008 in Ontario, Canada. We explored whether hospital factors (teaching status, regional cancer centre, medical oncologist on-site) were associated with ACT rates. The benchmark population included hospitals with the highest ACT rates that accounted for 10% of the patient population. Hospital ACT rates were adjusted for case mix in a multi-level model accounting for random variation at the hospital level. A Monte Carlo simulation was used to estimate the proportion of observed ACT rate variation that could be due to chance alone. **Results:** The study population included 2,801patients with stage III colon cancer; ACT was delivered to 66% (1861/2801) of patients. There was no difference in hospital ACT rate by teaching status (64% academic vs 67% non-academic, p = 0.107), comprehensive cancer centre status (65% cancer centre vs 67% non-cancer centre, p = 0.362), or having medical oncology on site (67% on site vs 66% not on site, p = 0.840). After excluding hospitals that had case volumes less than 10 (N = 150), unadjusted ACT rates varied across hospitals (range 44% to 91%, p = 0.017). The unadjusted benchmark ACT rate was 81% (95%CI 76%-86%); utilization rate in non-benchmark hospitals was 65% (95%CI 63%-66%). When using adjusted ACT rates in a multi-level model significant variation remained across hospitals ($p < 0.001$). The adjusted benchmark ACT rate was 74% (95%CI 63%-83%); non-benchmark hospital ACT rate was 65% (95%CI 53%-75%). The simulation analysis suggested that the non-random component of ACT rate variation across hospitals was 1.5%. **Conclusions:** There is significant variation in ACT rates across hospitals in routine practice. The estimated benchmark ACT rate is 74%. However, simulation analyses suggest that most of the variation in ACT utilization across hospitals may be due to chance alone.

6592 Poster Session (Board #414), Mon, 1:15 PM-4:45 PM

Code status transitions from full code to do-not-resuscitate (DNR) among hospitalized patients with advanced cancer. *First Author: Kelsey S. Lau-Min, Massachusetts General Hospital, Boston, MA*

Background: Code status discussions ensure the delivery of preference-concordant care. However, the processes by which hospitalized patients with advanced cancer change their code status from full code to DNR are unknown. **Methods:** We conducted a mixed-methods study on a prospective cohort of patients with advanced cancer who were hospitalized from 9/14-10/15. Two physicians used a consensus-driven medical record review to characterize processes leading to code status transitions from full code to DNR. We explored factors associated with these processes using $\chi 2$ and Kruskal-Wallis tests. **Results:** We reviewed 1,047 hospitalizations among 728 patients. Admitting physicians did not address code status in 52.1% of these hospitalizations, leading code status orders to be presumed full. 273 patients (37.5%) transitioned from full code to DNR; 132 (48.4%) of them had erroneous presumed full code status orders on admission. We identified three additional processes leading to transitions from full code to DNR: acute clinical deterioration (15.4%), discontinuation of cancer-directed therapy (17.2%), and hypothetical discussions regarding the futility of CPR (15.4%). Among these processes, code status transitions due to acute clinical deterioration were associated with less patient involvement, shorter time to death, and higher likelihood of inpatient death. Changes due to hypothetical discussions were more likely to involve palliative care. **Conclusions:** Half of code status transitions among hospitalized patients with advanced cancer were due to erroneous full code orders, underscoring a greater need to discuss patient CPR preferences. Transitions due to acute clinical deterioration were associated with less patient engagement and higher likelihood of inpatient death.

	Acute clinical deterioration (N = 42)	Therapy discontinuation (N = 47)	Hypothetical discussions (N = 42)	*p*
Patient involvement %	66.7	85.1	95.2	**0.002**

Physician volume and discontinuation of rituximab during lymphoma treatment. *First Author: Scott F. Huntington, Yale University, New Haven, CT*

Background: Despite the high complexity of cancer therapies, studies evaluating provider-level volume and outcomes of systemic treatments are lacking. As rituximab was the first approved monoclonal immunotherapy, and has the potential for severe infusion reactions, we hypothesize that low provider volume is associated with early rituximab discontinuation. **Methods:** We conducted a retrospective cohort study using Surveillance, Epidemiology, and End Results -Medicare data.Individuals 66+ years old with B cell non-Hodgkin lymphoma (NHL) diagnosed during 2004-2011 and 1+ rituximab claims were included. A provider was assigned to each patient-rituximab initiation using Medicare claims. We used a 12-month lookback from each initiation to categorize provider volume (0, 1-2, or 3+ rituximab initiations) in the prior year. Our primary outcome was early discontinuation, defined as receipt of 1-2 rituximab cycles within 180 days of initiation. We used a modified Poisson regression to account for provider level correlation and estimated the relative risk of early discontinuation in patients with 6+ months of follow up after rituximab initiation. A Cox proportional hazards model was used to measure the impact of discontinuation on overall survival. **Results:** A total of15,110 patients (median age: 75 years) initiated rituximab with 2,684 providers. The majority (70.4%) initiated rituximab in conjunction with chemotherapy and 1,146 (7.6%) experienced early rituximab discontinuation. Provider experience with rituximab during the previous 12 months was associated with early discontinuation in a dose-dependent manner (adjusted relative risk [aRR]: 1.57, [95% confidence interval [CI]:1.35-1.83], $p < .001$ for 0 vs 3+ initiations; aRR: 1.19 [95% CI:1.03-1.37], $p = .02$ for 1-2 vs. 3+ initiations). In addition, rituximab discontinuation was associated with a higher risk of death (adjusted hazard ratio: 1.39 [95% CI:1.28-1.52], $p < .001$). **Conclusions:** Lower physician volume is associated with increased risk of early discontinuation in older adults initiating rituximab for NHL. Due to the association between early discontinuation and mortality, physician volume may be an important factor in providing high quality NHL care.

6594 Poster Session (Board #416), Mon, 1:15 PM-4:45 PM

Patient safety: A progressive deprescribing model in patients with advanced solid tumors assisted at Instituto Oncológico Henry Moore (IOHM). *First Author: Ernesto Gil Deza, Instituto Oncológico Henry Moore, Buenos Aires, Argentina*

Background: "Deprescribing is the process of withdrawal of an inappropriate medication, supervised by a health care professional with the goal of managing polypharmacy and improving outcomes" (*Br J Clin Pharmacol* 80: 6, 1254. 2015). The aim of this paper is to present a model for deprescribing used at IOHM. **Methods:** Between 09/26/2012 and 09/26/2016, 10,053 pt filled out a Past Medical History Form, listing all the medications they were taking regularly. We selected all the pt. with advanced solid tumors (AST). In each pt the expected survival was established in order to evaluate the usefulness of the Tx. The drugs were classified in three groups: A) Green: Adequate (must be maintained); B) Yellow: Questionable (could be maintained or removed) or C) Red: Avoidable (must be removed). **Results:** We registered 2,103 pt who met the inclusion criteria. Sex F/M: 905 /1198. Median age 63 y (r = 19-99). A total of 1,629 pt. (77%) were taking medications on a regular basis. The total amount of medications was 5,679 . Median medications per patient: 3 (range: 1-14). Eighty percent of the pt (1,298 pt) were receiving questionable of avoidable medications. The following table shows the distribution of medications per group. **Conclusions:** A) In this cohort of 2,103 pt with AST, half of them had an average life expectancy of less than one year. B) 1,298 out of 1,629 pt (80%) were receiving a questionable medication C) 596/5,769 (10%) of the registered drugs, had to be suspended immediately and at least a thousand more could be eliminated. d) Obstacles to deprescribing were essentially medical ignorance, fear and inexperience.

Medication classification.

Measuring cancer care experiences: Introducing SEER-CAHPS. *First Author: Maria Andrea Rincon, National Cancer Institute, Bethesda, MD*

Background: Care experience ratings are recognized as measures of healthcare quality. Here we introduce a new, public data resource, SEER-CAHPS, which links cancer registry data from the National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) program with Medicare claims and the Medicare Consumer Assessment of Healthcare Providers and Systems (MCAHPS) survey. **Methods:** The SEER-CAHPS resource includes cancer registry data from 1973-2011 (diagnosis, incidence, mortality, and sociodemographic data), Medicare CAHPS survey data from 1998-2013 (sociodemographic, health status, and care experience ratings), and Medicare fee-for-service (FFS) claims data from 2002-2013. The survey includes global ratings of overall care, personal doctor, specialist, health plan, and prescription drug plans, and composite ratings of doctor communication, care coordination, getting needed care, and getting care quickly. Data also contain survey weights to account for the Medicare CAHPS sampling design. Cross-sectional and longitudinal analyses are possible. **Results:** Currently, SEER-CAHPS includes 205,339 individuals with a history of cancer documented in SEER (FFS: 26,802 with a survey before cancer diagnosis, and 55,231 with a survey after cancer diagnosis; Medicare Advantage [MA]: 57,227 with a survey before cancer diagnosis and 71,436 with a survey after cancer diagnosis). The data resource also includes 724,965 MCAHPS respondents without cancer in SEER regions (FFS: 282,592; MA: 447,358). The data provide insights on topics including experiences of cancer patients in their last year of life; experiences of cancer survivors; and the associations of guideline-concordant follow-up care with patient experiences among cancer survivors. We will demonstrate project sample-size estimation and present instructions for submitting data access applications. **Conclusions:** SEER-CAHPS, a new, publicly available resource, provides population-based, cancer-specific data on patient experiences, health outcomes and healthcare utilization.

6596 Poster Session (Board #418), Mon, 1:15 PM-4:45 PM

Identifying determinants of quality of life in patients undergoing systemic therapy for solid tumors. *First Author: Frank Po-Yen Lin, The Kinghorn Cancer Centre, Department of Oncology, St Vincent's Hospital, Sydney, Australia*

Background: Knowing which factors compromise quality of life (QoL) in patients undergoing cancer treatments can help oncologists provide more effective care. To identify these factors, we conducted a single-centered cross-sectional study examining the relationships between patient-reported QoL, adverse events (AE), and treatment characteristics. **Methods:** Consecutive patients attending an outpatient chemotherapy unit completed two questionnaires (EORTC QLQ-C30 and National Cancer Institute PRO-CTCAE) per visit to identify factors contributing to the lowest global QoL score [QLQ-C30 QL2, range 0 (worst)–100 (best)] over a 6-week period. QL2 was correlated to each PRO-CTCAE item and treatment characteristic (tumor type, drug class, number of cycles, and treatment intent) using multiple regression, adjusted for age, sex, and use of concurrent radiotherapy. To determine whether QoL can be reliably modeled by machine learning, ten algorithms were compared for performance in classifying patients into dichotomized QL2 subgroups. **Results:** One hundred and fifteen of 130 patients (157/244 visits) completed up to 6 sets of questionnaires (median QL2: 67, IQR: 50–83). No difference was found between QL2 and treatment characteristics (at $\alpha_{Bonferroni}=5\times10^{-4}$). However, QL2 was significantly associated with AE in gastrointestinal, respiratory, attention, pain, sleep/wake, and mood categories. Using AE as covariates, support vector machine with radial basis kernel was the best at classifying patients into QoL groups (mean bootstrapped area under ROC curve 0.812, 95% CI 0.700–0.925). **Conclusions:** Patient-reported QoL is associated with multiple AE, but not with characteristics of systemic therapy. Machine learning analysis suggests that a combined AE analysis may reliably characterize a patient's QoL.

Top PRO-CTCAE items associated with detriment of QoL.

Item	QL2 decrease per PRO-CTCAE grade	99% CI
Fatigue	12.5	(6.1–19.0)
Concentration	10.8	(1.3–20.3)
Anorexia	10.1	(2.7–17.5)
Feeling discouraged	10.1	(2.1–18.1)
Pain	9.9	(4.7–15.0)
Constipation	9.4	(2.0–16.8)
Nausea	9.2	(2.4–16.0)
Abdominal pain	9.2	(2.3–16.1)
Dry mouth	8.9	(1.8–16.0)
Dyspnea	8.9	(0.8–17.0)

6597 Poster Session (Board #419), Mon, 1:15 PM-4:45 PM

Implementing cost transparency in oncology: A qualitative study of barriers, facilitators, and patient preferences. *First Author: Erin Aakhus, Leonard Davis Institute for Health Economics, Philadelphia, PA*

Background: As cancer drug prices rise and insurance plans shift toward greater cost sharing, studies link patients' high out-of-pocket (OOP) costs to non-adherence and early discontinuation of treatment. Meanwhile, few oncologists routinely discuss OOP costs with their patients. Using qualitative methods, we explored barriers and facilitators of cost transparency (i.e., disclosure of financial risks of cancer treatment). **Methods:** We performed semi-structured interviews with cancer patients (n = 22) and providers (n = 19) at an academic medical center and three affiliated community practices between August, 2015 and May, 2016. Two analysts coded the transcribed interview data using textual thematic methods, and hypotheses were generated employing grounded theory method. **Results:** We grouped themes that emerged into three major domains: 1) barriers, 2) facilitators, and 3) patient preferences. Patients and providers both expressed a strong aversion to making tradeoffs between financial and physical health outcomes. While patients feared being "profiled" based on their ability to pay, providers feared that cost transparency might threaten the doctor-patient relationship by exposing personal or institutional financial conflicts of interest. Pragmatic barriers included time constraints and difficulty in providing accurate cost estimates. Important facilitators were strong doctor-patient relationships and availability of support staff with financial expertise. We detected substantial heterogeneity in patient preferences. While some patients wanted to discuss costs with their provider, others feared "distracting" providers from their primary roles as health advocates. **Conclusions:** With implementation of OOP cost transparency, oncology practices will need to consider patient/provider aversion to financial/health tradeoffs, patients' sensitivity to socioeconomic "profiling," provider- and practice-level financial incentives, time constraints, accuracy of cost estimates, and variability in patient preferences. Meanwhile, strong provider-patient relationships and availability of support staff will facilitate OOP cost transparency.

6598 Poster Session (Board #420), Mon, 1:15 PM-4:45 PM

Examining the relationship between cost of novel oncology drugs and their clinical benefit over time. *First Author: Ronak Saluja, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: The average launch price of oncology drugs has increased by 10% annually from 1995 to 2013. The purpose of this study was to determine if the clinical benefit of novel oncology drugs has increased proportionally over time and is correlated with launch price. **Methods:** Novel oncology drugs fromrandomized controlled trials (RCTs) cited for clinical efficacy evidence in drug approvals between January 2006 and August 2015 were identified. For each drug, only the first FDA approved indication was included. To determine clinical benefit, all included RCTs were scored using the ASCO Value Framework and the ESMO Magnitude of Clinical Benefit Scale. The launch price for the FDA approval year of each drug was extracted from RedBook. Each drug's 28-day cost was determined using the dosage schedule outlined in the respective RCT and was adjusted to 2015 USD using the consumer price index. The relationships between 28-day drug cost and FDA approval year, and between incremental drug cost (difference in total drug cost between experimental and control arms accounting for treatment duration) and FDA approval year were examined using generalized linear regression models (gamma distribution and log link). Ordinary least square models were used to evaluate the relationship between ASCO/ESMO scores and FDA approval year. Spearman's correlation coefficients between 28-day/incremental drug costs and ASCO/ESMO scores were also calculated. **Results:** Forty RCTs were included in this analysis. The 28-day drug cost was significantly associated with FDA approval year ($p = 0.04$), with an average increase of 8.5% per year. Incremental drug cost was also significantly associated with FDA approval year ($p < 0.001$) with an increase of 28.6% per year. The mean ASCO and ESMO scores were 26 and 3, respectively. Both scores were not statistically associated with FDA approval year ($p = 0.73$ and $p = 0.86$, respectively) and were also not correlated with 28-day or incremental drug costs (all rho $< = 0.2$). **Conclusions:** Novel oncology drugs are not priced according to their clinical benefit. The rising cost of novel oncology drugs over time is not associated with an increase in their clinical benefit, suggesting a decrease in their value over time.

6599 Poster Session (Board #421), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling (CGP) versus conventional molecular diagnostic testing of patients with advanced non-small cell lung cancer (NSCLC): Overall survival (OS) and cost in a U.S. health plan population. *First Author: James Signorovitch, Analysis Group, Inc., Boston, MA*

Background: Molecular diagnostic testing options in NSCLC include conventional testing (specific alterations in single genes or multi-gene panels), and CGP (all classes of genomic alterations—base pair substitutions, copy number, insertions/deletions, and rearrangements in multi-gene panels). Guidelines recommend broad molecular profiling to enable genomic matching with available compendia-based and investigational treatment options. This study estimated the incremental benefits and costs of CGP versus conventional testing of patients with advanced NSCLC. **Methods:** The impacts of increased use of CGP (via FoundationOne) versus conventional molecular testing on OS and on a commercial US health plan budget were estimated using a decision-analytic model. The number of patients needed to test with CGP to add 1 life year was also estimated. Model inputs were based on published literature (incidence rates, OS associated with drugs indicated for advanced NSCLC), real-world data (testing rates, and biopsy, conventional testing, and medical service costs from administrative claims data analyses), list price of FoundationOne, and assumptions for clinical trial participation. **Results:** Among 2 million covered lives, an estimated 532 had advanced NSCLC and 266 received molecular diagnostic testing. An increase in CGP use from 2% to 10% (+21 patients receiving CGP) was associated with +2 years in population OS and a budget impact of $0.018 per member per month (PMPM). The budget impact was primarily attributable to changes in drug use, longer treatment, and longer survival (collectively $0.013 PMPM) with the remainder due to CGP cost ($0.005 PMPM). Approximately 11 patients need to be tested with CGP versus conventional molecular diagnostic testing to add 1 life year. **Conclusions:** An increase in molecular diagnostic testing with CGP versus conventional testing to inform treatment decisions in patients with advanced NSCLC was associated with a gain in OS and a modest health plan budget impact, with most of the added costs attributable to increased use of effective treatments and prolonged survival.

6600 Poster Session (Board #422), Mon, 1:15 PM-4:45 PM

Are surrogate endpoints unbiased metrics compared to hazard ratio for death? An evaluation of clinical benefit scores (CBS) in the American Society of Clinical Oncology (ASCO) value framework. *First Author: Mahin Iqbal Qureshi, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*

Background: Clinical benefit scores (CBS) are a key element of the American Society of Clinical Oncology (ASCO) value framework's Net Health Benefit valuation of cancer therapies. CBS are assigned based on a hierarchy of efficacy endpoints, from hazard ratio for death (HR OS), to median overall survival (mOS), HR for disease progression (HR PFS), median progression-free survival (mPFS), and response rate (RR). When HR OS is unavailable, other endpoints in the hierarchy are used as "surrogates" to calculate CBS via their scaling factors. We aim to examine whether surrogate-derived CBS offer unbiased scoring of clinical benefit compared to HR OS-derived CBS. **Methods:** CBS for advanced-disease settings were computed for randomized clinical trials (RCTs) of oncology drug approvals by the Food and Drug Administration, European Medicines Agency, and Health Canada, between 2006 and August 2015. Spearman's correlation assessed association between CBS derived from surrogates and HR OS. Mean bias (surrogate-derived CBS minus HR OS-derived CBS) evaluated the tendency for surrogate-derived CBS to over- or under- estimate clinical benefit. Mean absolute error (MAE), a measure of average deviation, assessed precision of surrogate-derived CBS in relation to HR OS-derived CBS. **Results:** Scored RCTs (n=104) yielded 69, 93, 88, and 89 paired CBS between HR OS and mOS, HR PFS, mPFS, and RR, respectively. See table for results. Restricting to RCTs reporting all endpoints (n=59) and RCTs without OS as primary endpoint (n=68) showed similar results. **Conclusions:** Findings suggest HR PFS-, mPFS-, and RR-derived CBS are poor "surrogates" as they are imprecise and weakly correlated to HR OS-derived CBS. HR PFS and particularly mPFS exhibit bias to overestimate CBS.

Analysis of surrogate-derived CBS minus HR OS-derived CBS.

	Surrogates			
	mOS	HR PFS	mPFS	RR
Correlation Coefficient (95% CI)	0.75(0.62-0.84)	0.20(-0.01-0.39)	0.07(-0.14-0.27)	0.09(-0.12-0.29)
Mean Bias	2.43	12.35	42.30	4.96
MAE	9.81	16.19	46.59	18.32
Maximum Overestimation	107	57	324	48
% Overestimation (>0 Points)	52.5	74.2	85.2	59.6
% Overestimation (>20 Points)	8.7	25.8	60.9	27.3

Value frameworks for cancer care: Do they account for potential durable survival with immunotherapies? *First Author: Daniel A. Goldstein, Davidoff Cancer Center, Petah Tikva, Israel*

Background: Modern immuno-oncologic agents may have the potential to provide durable survival for some patients. Simultaneously, there is growing concern regarding the cost of cancer care, and multiple frameworks have been developed to assess value. The points based framework created by the American Society of Clinical Oncology (ASCO) has a specific threshold, and more points are awarded if substantial durable survival is demonstrated. The objective of this study was to assess if modern immuno-oncologic agents reach defined efficacy thresholds in this framework. **Methods:** We reviewedall FDA approvals for immuno-oncologic agents since the first approval in 2011. We collected data regarding study endpoints, specifically the parameters defined in the updated ASCO value framework: improvement in proportion of patients alive with the test regimen, and survival rate with standard. We assessed whether bonus points would be rewarded as per the updated ASCO value framework for durable responses demonstrated on the tails of the Kaplan-Meier curves. These parameters were used as an input to check whether each drug reaches the required achievement defined in the framework. **Results:** 17 indications for four immunotherapy active ingredients were approved by FDA between 2011-2016: ipilimumab, pembrolizumab, nivolumab and atezolizumab. 59% of the approvals rely on survival endpoints such as overall, progression-free, or relapse-free survival. 41% are based on objective response rates. Only one drug (nivolumab indicated for melanoma first-line treatment) was found to fulfill the threshold defined for the survival rate of standard care (above 20%). Six drugs achieved the required level of improvement in proportion of patients alive in the test regimen compared to the standard (above 50%). As there was no overlap between these two groups of drugs, no drug was found to gain the durable survival bonus points defined by the ASCO framework. **Conclusions:** Durable survival and responses of modern immuno-oncology agents are currently not recognized to be significant by the ASCO value framework. This may be due to insufficient demonstration of efficacy of such agents, or may be due to an inappropriately calibrated value framework.

6602 Poster Session (Board #424), Mon, 1:15 PM-4:45 PM

Total and out-of-pocket costs of different primary management strategies in ovarian cancer. *First Author: Rudy Sam Suidan, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Communicating healthcare costs to pts is an important component of delivering high-quality value-based care, yet cost data are lacking. This is especially relevant for epithelial ovarian cancer (OC), where no clinical consensus on optimal first-line treatment exists. Our objective was to generate cost estimates of different primary management strategies in OC. **Methods:** All women who underwent primary treatment for OC from 2006 – 2015 were identified from MarketScan, a claims database of commercially insured US pts (n = 12,761). Pts were classified based on: 1) whether they underwent primary debulking surgery followed by postoperative chemotherapy, or neoadjuvant chemotherapy followed by interval debulking; 2) type of chemotherapy regimen administered (intravenous [IV] every 3 weeks [Standard], IV every week [Dose-dense], or intraperitoneal [IP]/IV); and 3) if regimens included bevacizumab (Bev). Total and out-of-pocket (OOP) costs were calculated using all claims within 8 months from initial treatment and were normalized to 2015 US dollars. A generalized linear model was used to assess cost by strategy adjusting for clinical and demographic factors. **Results:** Mean adjusted total and OOP costs for the different treatment strategies/regimens are shown in the table. Among pts who did not receive Bev, 25% paid ≥$3964 and 10% paid ≥$5875. For pts who received Bev, 25% paid ≥$4201 and 10% paid ≥$6222. Among pts enrolled in high-deductible health plans, mean OOP costs were $4680, with 25% of pts paying ≥$6264 and 10% paying at least $9144. **Conclusions:** Costs vary across different treatment strategies and pts bear a significant OOP burden, especially those enrolled in high-deductible plans. As no consensus exists on optimal first-line management for OC, these data may help inform value-based discussions between providers and pts.

		Total Costs		OOP Costs	
	n	Adjusted Mean	p	Adjusted Mean	p
Primary Debulking	11,091	$100,483	< .001	$2791	< .001
Neoadjuvant Chemotherapy	1670	$106,614		$2362	
IV Standard Chemotherapy	9739	$98,516	< .001	$2661	< .001
IV Dose-dense Chemotherapy	1679	$107,929		$3193	
IP/IV Chemotherapy	1343	$114,166		$2707	
Regimens without Bev	11,912	$97,983	< .001	$2717	.02
Regimens with Bev	849	$160,781		$2931

Validity and reliability of four value frameworks for cancer drugs. *First Author: Tanya GK Bentley, Partnership for Health Analytic Research, LLC, Beverly Hills, CA*

Background: Little is known about the validity and reliability of value assessment frameworks. **Methods:** Eight panelists used the ASCO, ESMO, ICER, and NCCN frameworks to conduct value assessments of 15 drugs for advanced lung and breast cancers and castration refractory prostate cancer. Panelists received instructions and published clinical data to complete the assessments, assigning each drug a numeric or letter score. We used Kendall's *W* coefficient to measure convergent validity by cancer type among frameworks and intraclass correlation coefficients (ICC) to measure framework inter-rater reliability across cancers. Panelists were surveyed on their experiences. **Results:** Kendall's *W* for breast, lung, and prostate cancer drugs were 0.560 (p= 0.010), 0.562 (p= 0.010), and 0.920 (p< 0.001), respectively. Pairwise and subdomain *W* are shown in the table. ICC (95% CI) for ASCO, ESMO, ICER, and NCCN were 0.800 (0.660-0.913), 0.818 (0.686-0.921), 0.652 (0.466-0.834), and 0.153 (0.045-0.371), respectively. Panelists generally agreed the frameworks were logically organized and easy to use. **Conclusions:** Convergent validity among the frameworks was fair to excellent, increasing with clinical benefit subdomain concordance and simplicity of drug trial data. Inter-rater reliability, highest for ASCO and ESMO, improved with clarity of instructions and specificity of score definitions. Continued use, analyses, and refinements of the frameworks will bring us closer to using value-based treatment decisions to improve patient care and outcomes.

	High *W (p)*		Low *W (p)*	
Breast				
Pairwise	ESMO-ICER, ICER-NCCN	0.950 (0.019)	ASCO-NCCN	0.300 (0.748)
Subdomain	Certainty (ICER, NCCN)	0.908 (0.046)	Clinical benefit (ASCO, ESMO, NCCN)	0.345 (0.436)
Lung				
Pairwise	ESMO-ICER	0.974 (0.007)	ASCO-NCCN	0.218 (0.839)
Subdomain	Toxicity (ASCO, ESMO, NCCN)	0. 944 (< 0.001)	Certainty (ICER, NCCN)	0.230 (0.827)

6604 Poster Session (Board #426), Mon, 1:15 PM-4:45 PM

Challenges of diagnostic concordance of lung cancer cases in Qualified Clinical Data Registry (QCDR) measure collection by CMS in calculating MACRA's rewards and penalties. *First Author: Shawn Dana Glisson, Norton Healthcare's Norton Cancer Institute, Louisville, KY*

Background: QCDR was introduced for the Physician Quality Reporting System (PQRS) beginning in 2014. A QCDR is a CMS-approved entity that collects medical and/or clinical data for the purpose of patient and disease tracking to foster improvement in the quality of care provided to patients. Those who satisfactorily participate in PQRS through a QCDR may avoid the 2018 negative payment adjustment -2.0% of total Medicare payments. PQRS #396 is an example of a measurement by which oncologists may be evaluated. A physician's QCDR score is determined by his/her numerator and denominator per patient based on total data submitted by various healthcare providers. **Methods:** IRB approval was obtained for a retrospective review of 60 randomly selected NSCLC pathology reports that were diagnosed at UTMB. The Denominator was determined by CMS to be: The patients were between the ages of 18-75; the diagnosis of NSCLC was coded by the appropriate ICD and CPT codes. The Numerator was determined by CMS to be: Pathology reports with a diagnosis that included pT pN for NSCLC with histologic type vs those not documented for medical reasons vs those specimens that were not of lung origin, or were classified as NSCLC-NOS. **Results:** The study consisted of 60 NSCLC pathology reports of which 2 were determined in retrospect not to have been lung cancer cases. Another 10 were considered to be incomplete. A final 2 were diagnosed as a different histological lung cancer type. As [60 - (2+10+2)]/60 = 76.67%, adherence to the quality standard was less than perfect even though excellent medical care was delivered. This score puts the institution at risk of a 2% Medicare Payment Reduction in 2018 if a majority of other institutions score even slightly higher. **Conclusions:** Physician remuneration will be reduced by current information submitted to CMS. As the quality scores will be made public, reputations may be negatively impacted. Coding and billing operations may be hindered in their attempt to accurately submit data to CMS. Healthcare Systems may be less inclined to request outside consults (including NGS) that may provide a different diagnosis that could confuse the QCDR.

6605 Poster Session (Board #427), Mon, 1:15 PM-4:45 PM

Estimated cost of anticancer therapy directed by comprehensive genomic profiling (CGP) in a single-center study. *First Author: James Signorovitch, Analysis Group, Inc., Boston, MA*

Background: Accumulating evidence supports the clinical benefit of targeted therapies matched to cancer patients based on genomic alterations. CGP, which detects all classes of alterations (base pair substitutions, copy number, insertions/deletions, and rearrangements), can match more patients with available and investigational therapies. This study estimated anticancer drug costs and overall survival (OS) for matched vs. unmatched therapy. **Methods:** Costs were estimated for patients with complete data (N = 188/500) from a prospective, nonrandomized, phase I oncology center study of patients with diverse refractory cancers who underwent CGP and were treated with matched or unmatched therapy (PMID: 27197177). Average time to treatment failure and average OS were assessed during the observation period. Patient-specific drug and administration costs were imputed for the first regimen after CGP based on drug classes, unit costs, and times to treatment failure. **Results:** Patients onmatched (N = 122) vs. unmatched (N = 66) therapy had, on average, longer time on treatment (+1.5 mos), longer observed survival (+2.4 mos), and higher anti-cancer drug costs (+$38K) (all $p < 0.01$); 66% of increased drug costs were attributable to longer time on treatment as opposed to higher monthly drug costs. Combination therapy was used for 71% of matched and 53% of unmatched patients. Those undergoing CGP in earlier-line (1-3; N = 58) vs. later-line (4+; N = 130) therapy had numerically larger incremental increases in average times on treatment (+1.9 vs. +1.2 mos) and survival (+2.5 vs. +2.1 mos), and numerically lower incremental drug costs (+$27K vs. +$43K), with matched vs. unmatched therapy. **Conclusions:** For patients cared for in a phase I clinic, matched vs. unmatched therapy was associated with longer treatment durations, longer survival times, and manageable incremental costs. Despite frequent use of combination therapy, most of the increased costs of matched therapy were due to longer treatment times rather than higher monthly drug costs. Benefits of matching were numerically greater in earlier- vs. later-lines, consistent with the value of earlier-line use of CGP to guide treatment.

6606 Poster Session (Board #428), Mon, 1:15 PM-4:45 PM

Can we satisfactorily measure the clinical value of new oncology agents with a single summary measure? *First Author: Clare Frances Jones, PRMA Consulting Ltd, Fleet, Hampshire, United Kingdom*

Background: Current value frameworks (VFs) assess clinical value primarily through using clinical trial endpoints as survival metrics (e.g., median and hazard ratio (HR)). But, if key assumptions do not hold, the interpretation of these summary statistics can become problematic and fail to adequately capture the expected benefit to a patient. This has been observed with innovative oncology treatments. As a proof of concept analysis, we reviewed how two VFs (ASCO and ESMO) dealt with cases where the assumption of proportional hazards (PH) does not hold. **Methods:** Oncology agents approved by the FDA since 2011 were reviewed and three agents were identified with survival profiles where the assumption of PH was found not to hold because, on visual inspection, the survival curves displayed non-standard patterns: Divergence followed by convergence – panobinostat OS in RRMM; Curves initially track together then diverge – nivolumab OS in NSCLC; Curves diverge steadily then a plateau emerged in the active treatment curve – pembrolizumab PFS in refractory melanoma. We evaluated these agents to assess which measures of clinical benefit were most valued under each VF and how the issue of non-PH influenced the outcome. **Results:** Clinical benefit/value scores varied: ASCO: 14-27 (maximum 100), ESMO: grade 1-3. The ASCO VF uses a hierarchical approach (incorporating HR and median survival benefit, always prioritising the former) adding a bonus for survival benefit in the tail of the distribution. The combination of HR, median survival benefit 2 and 3 year survival rates in the ESMO non-curative VF can potentially capture aspects of clinical benefit in some cases of non-PH. Overall, the ASCO VF appears less flexible to accommodate non-PH than the ESMO VF. **Conclusions:** Despite VFs using summary statistics which cannot be easily interpreted under conditions of non-PH, the case of non-PH is not explicitly catered for. Additionally, both VFs may miss important interpretation where value is differentiated across patients groups with different response profiles which may underlie non-standard survival curves. In these situations, a more flexible approach to assessing clinical value may render VFs more relevant for clinical decision making.

6607 Poster Session (Board #429), Mon, 1:15 PM-4:45 PM

Impact of intravenous cancer drug wastage on economic evaluations. *First Author: Judy Truong, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Intravenous drugs administered through body-surface area (BSA) or weight-based dosing may cause wastage due to large and/or limited fixed vial sizes, and vial sharing restrictions. Drug wastage leads to incremental costs without incremental value to patients. Bach et al. (2016) estimated 10% of revenue ($1.8 billion) from cancer drugs would result from wastage in 2016. The pan-Canadian Oncology Drug Review (pCODR) committee provides recommendations on which drugs to publicly reimburse by reviewing clinical and economic evidence. There is considerable potential that drug wastage could impact the economic evaluations. We sought to determine the impact of modeling cancer drug wastage on the results of economic evaluations. **Methods:** Economic evaluations submitted by drug manufacturers and reviewed by the pCODR Economic Guidance Panel (EGP) were assessed for frequency of wastage reporting and modeling. Cost-effectiveness analyses and budget impact analyses were conducted for scenarios in which "no wastage" and "wastage" of drugs occurred. Sensitivity analyses were performed to determine the effects of BSA and weight variation. **Results:** 12 drugs for use in 17 indications were analyzed. Wastage was reported in 71% and incorporated in 53% of manufacturer's models, resulting in a mean incremental cost-effectiveness ratio (ICER) increase of 6.1% (range: 1.3% to 14.6%). EGP reported and incorporated wastage for 59% of models, resulting in a mean ICER increase of 15.0% (2.6% to 48.2%). When maximum wastage (i.e. the entire unused portion of each vial is discarded) was incorporated in our independent analysis, the mean ICER increased by 24.0% (0.0% to 97.2%) and the mean 3-year total incremental costs increased by 26.0% (0.0% to 83.1%). Over a 3-year period, wastage can increase the total incremental drug budget cost by CAD $102 million nationally. Changing the mean BSA or body weight caused 45% of the drugs to use a different vial size (if available) and/or quantity, resulting in further increased drug costs. **Conclusions:** Wastage can have an under-recognized and significant impact on economic evaluations of intravenous chemotherapy drugs. Guidelines are needed to promote uniform and optimal modeling of drug wastage in economic evaluations.

6608 Poster Session (Board #430), Mon, 1:15 PM-4:45 PM

Cost-effectiveness of ovarian cancer screening: An analysis of the UK Collaborative Trial of Ovarian Cancer Screening (UKCTOCS) from a U.S. health system perspective. *First Author: Haley Moss, Duke University Medical Center, Durham, NC*

Background: UKCTOCS is the largest randomized controlled trial to evaluate screening's impact on ovarian cancer mortality, assigning women to multimodal screening (MMS) with serum CA125 interpreted with a risk algorithm; annual transvaginal ultrasound; or no screening (NS). There was a non-statistically significant 15% reduction in mortality over 11 years in MMS group. As most of the potential benefit of screening was seen after 7 years, follow-up is ongoing to determine if an observed stage shift translates into significant mortality reduction. The current study estimates the cost-effectiveness of an MMS screening program in the US. **Methods:** A modified Markov model was constructed using data from UKCTOCS to compare MMS to NS. Published estimates of the long term effect of MMS screening on ovarian cancer mortality were used to simulate mortality over 40 years from the start of screening. Base case costs included CA125, ultrasounds, clinical evaluations and false-positive surgeries, with an annual weighted cost of $35 in addition to an estimated risk algorithm cost of $100. The utility and costs of ovarian cancer treatment were incorporated into the model. Incremental cost-effectiveness ratios (ICERs) were calculated in 2016 U.S. dollars per quality-adjusted year of life saved (QALY). Additional sensitivity analyses were performed. **Results:** MMS is both more expensive and more effective in reducing ovarian cancer mortality over a lifetime than NS. Screening women from age 50 to 75 with MMS reduced mortality by 24% with an ICER of $98,062/QALY. If screening begins at age 60, MMS reduces mortality by 12%, with ICER below the willingness to pay threshold of $100,000/QALY only if the algorithm costs $< $50. In probabilistic sensitivity analyses, the probability that screening from age 50-75 at an algorithm cost of $100 was less than $100,000/QALY was 41%. **Conclusions:** Ovarian cancer screening is potentially cost-effective in the US depending on final significance of mortality reduction and cost of the CA-125 risk algorithm. These results are limited by uncertainty around the effect of screening on ovarian cancer mortality beyond the 11 years of UKCTOCS.

6609 Poster Session (Board #431), Mon, 1:15 PM-4:45 PM

Delivery of meaningful cancer care: Evaluating benefit and cost of cancer therapies using ASCO and ESMO frameworks. *First Author: Joseph Del Paggio, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Background: ASCO and ESMO have developed frameworks to evaluate the benefit of cancer therapies. Here, we apply the frameworks to a cohort of contemporary randomized controlled trials (RCTs) to explore agreement and to evaluate the relationship between treatment benefit and cost. **Methods:** Characteristic and outcome data from RCTs evaluating systemic therapies in non-small cell lung cancer (NSCLC), breast cancer, colorectal cancer (CRC), and pancreatic cancer published and cited in *PubMed* between 2011-2015 were abstracted. Trial endpoints were evaluated using ASCO and ESMO frameworks. Cohen's kappa statistic was calculated to determine agreement between the two frameworks, using the median ASCO score as a benefit threshold. Differences in monthly drug cost between RCT experimental and control arms were derived from 2016 average wholesale prices. Analyses included Pearson chi-square tests, Fisher's Exact tests, independent samples t-tests, and Pearson correlation to assess the association between continuous variables. **Results:** Fifty percent (136/271) of published RCTs favoured the experimental arm; scoring rubrics were applicable to 109 RCTs (39% NSCLC, 33% breast, 23% CRC, 5% pancreas). ASCO scores ranged from 2 to 72; median score was 25. Thirty seven percent (40/109) of RCTs met benefit thresholds using the ESMO framework. Agreement between frameworks was fair at best ($\kappa = 0.28$, $p = 0.002$). When stratified by treatment intent (19 curative, 90 palliative RCTs), agreement remained poor ($\kappa = 0.23$, $p = 0.115$; $\kappa = 0.34$, $p < 0.001$). Major differences leading to limited agreement includes the relative weights each framework places on HR, endpoints, and toxicity/QOL analysis. Smaller RCT sample size was the only trial characteristic associated with higher ASCO scores ($p = 0.015$). Among the 100 RCTs for whom drug costing data were available, there was no association between ASCO benefit score and monthly drug costs ($r = -0.12$, $p = 0.22$); those meeting ESMO thresholds had a lower mean drug cost than those who did not ($p = 0.046$). **Conclusions:** There is only fair correlation between ASCO and ESMO clinical benefit frameworks. Drug costs are not associated with ESMO/ASCO measures of magnitude of clinical benefit.

6610 Poster Session (Board #432), Mon, 1:15 PM-4:45 PM

Cost of surveillance imaging in head and neck cancer patients treated with definitive radiotherapy. *First Author: Sweet Ping Ng, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The goal of surveillance is to detect potentially salvageable recurrence, allowing early salvage treatment and thereby improving clinical outcomes. Currently, there is limited data on the optimal frequency of imaging for head and neck cancer patients treated with definitive radiotherapy. This study aims to evaluate the cost-effectiveness of surveillance imaging in this group of patients. **Methods:** Eligible patients included those with a demonstrable disease free interval ($\geq$ 1 follow up scan without evidence of disease and a subsequent visit/scan) treated between 2000-2010. Age, tumor site and stage, induction chemotherapy use, dose/ fractionation, mode of detection of recurrence, salvage therapy, number and modality of scans were recorded. Deaths from disease recurrence or from other causes were also recorded. Imaging costs were calculated based on the 2016 Medicare fee schedule. **Results:** 1508 patients were included. Mean age was 55.8 years (range: 17-87). Median overall survival was 99 months (range: 6-199). Mean imaging follow up period was 70 months. 190 (12.6%) patients had disease recurrence – 107 locoregional (LR) and 83 distant. 119 (62.6%) of the relapsed group were symptomatic and/or had an adverse clinical finding associated with recurrence. 80.4% of LR relapses presented with a clinical finding, while 60.2% of distant relapses were detected via imaging alone in asymptomatic patients. There was no difference between the successful salvage rates and overall survival between those with relapses detected clinically or via imaging alone. 70% of relapses occurred within the first 2 years post-treatment. In those who relapsed after 2 years, the median time to relapse was 51 months (2 LR and 11 distant relapses). After 2 years, the average cost for detecting a salvageable recurrence for image-detected group was $741 447.41, and the cost for preventing 1 recurrence-related death for image-detected disease was $889 736.89. The number of scans required to detect a salvageable recurrence in an asymptomatic patient after 2 years was 3512. **Conclusions:** Surveillance imaging in asymptomatic patients without clinically suspicious findings beyond 2 years requires judicious consideration.

6611 Poster Session (Board #433), Mon, 1:15 PM-4:45 PM

Differences in medical care costs for recurrent versus de novo stage IV cancer by age at diagnosis. *First Author: Matthew P. Banegas, Kaiser Permanente Center for Health Research, Portland, OR*

Background: To address the paucity of data on costs of cancer recurrence, this study estimated medical care costs of patients diagnosed with recurrent breast, colorectal or lung cancer, and compared costs to patients diagnosed with de novo stage IV disease. **Methods:** Data from patients enrolled in three health plans who were diagnosed with de novo stage IV or recurrent breast ($n_{stage\ IV} = 352$; $n_{recurrent} = 765$), colorectal ($n_{stage\ IV} = 1072$ and $n_{recurrent} = 542$) and lung ($n_{stage\ IV} = 4042$ and $n_{recurrent} = 339$) cancers between 2000-2012 were used to estimate total medical care costs in the 12 months preceding (pre-index), month of index, and 12 months following (post-index) diagnosis/recurrence date. Cancer patients were identified using tumor registry data. Recurrent cancers were validated by medical record abstraction and the RECUR algorithms –innovative tools to detect recurrence using claims and electronic health record data. We used generalized linear repeated measures regression models controlling for demographic and comorbidity variables to estimate costs (2012 US$), stratified by age at diagnosis (ages $<$ 65, $\geq$65). **Results:** Medical care cost differences in the pre-index period indicate higher costs for recurrent cancer patients than for stage IV breast (Age $<$ 65:+$2550; Age $\geq$65: +$1254), colorectal (Age $<$ 65:+$3295; Age $\geq$65: +$1653), and lung cancer patients (Age $<$ 65: +$3232; Age $\geq$65: +$2340). Conversely, in the index and post-index periods, costs for stage IV cancers were higher than recurrent cancer costs. Specifically, post-index period cost differences indicate higher costs for stage IV patients than for recurrent breast (Age $<$ 65:+$683; Age $\geq$65: +$1172), colorectal (Age $<$ 65:+$3104; Age $\geq$65: +$1557), and lung cancer patients (Age $<$ 65:+$1136; Age $\geq$65: +$1103). **Conclusions:** Our study provides medical care cost estimates of recurrent and de novo stage IV cancers. Cost differences between recurrent and stage IV cancers reveal heterogeneity in care patterns that merits further investigation. The reported study costs, measured in capitated care systems using standardized fee-for-service reimbursement coefficients, may serve as a benchmark for stage-specific phase-of-care oncology episode payment models.

6612 Poster Session (Board #434), Mon, 1:15 PM-4:45 PM

Economic impact of immune checkpoint inhibitor therapy in Brazil and strategies to improve access. *First Author: Pedro Nazareth Aguiar, Federal University of São Paulo (UNIFESP), São Paulo, Brazil*

Background: Immunotherapy was elected by ASCO as the most important advance in Oncology for the last 2 consecutive years. Nevertheless, the costs of immune checkpoint inhibitors is a limitation to their incorporation in several countries, including Brazil. The objective of this study is to estimate the economic impact of immunotherapy and make suggestions in order to improve the access for patients who benefit the most from treatment. **Methods:** We assessed Brazilian cancer epidemiology data and the international literature to estimate the number of eligible patients each year. The authors estimated the economic impact according to the medication acquisition costs converted to US dollars. The median duration of the treatment was based upon the clinical trials. **Results:** We assessed 3 different agents (and one combo) for 7 indications. The results are summarized in the table below. **Conclusions:** The current cost of immune checkpoint inhibitors is prohibitive in the public health system in Brazil. While the country's GDP per capita is 78% lower than that of the US, immune checkpoint inhibitors have similar prices in both. Biomarker selection, posology, and lower cost drugs help decrease the total economic impact of therapy. Price discrimination and volume discounts would help improve access. Further studies and discussion with all stakeholders is needed to identify patients who would benefit the most and to implement strategies to increase access to these potentially life-saving therapies.

6613 Poster Session (Board #435), Mon, 1:15 PM-4:45 PM

Barriers to MACRA among a cohort of community oncologists. *First Author: Chadi Nabhan, Cardinal Health, Dublin, OH*

Background: Value Based Care (VBC) initiatives specifically the Medicare and CHIP Reauthorization Act (MACRA), which includes Medicare Incentive Payment System (MIPS) and Alternative Payment Models (APMs), present challenges for community oncologists. Understanding barriers associated with implementation and compliance are essential for optimal execution. **Methods:** Using audience response technology, 52 community oncologists and 26 practice managers (PMs) of diverse geography, practice type and affiliations were surveyed in November 2016. **Results:** Of the attendees, 43% were participating in commercial payer VBC while 33% were participating in the Oncology Care Model (OCM), an APM. Reasons for non-participation: Cost of drugs 58%; data transparency 42%; human resources 33%; technology 29%. The majority of attendees stated limited awareness of MACRA reporting requirements. Once reporting was explained, the stated challenges to MACRA implementation included: inability to measure and track costs 76%; problematic quality improvement activities 56%; lack of patient engagement tools 52%; concern about interpreting CMS reports 52%; meeting meaningful use requirements 33%. In regard to preparation: 52% had survivorship or palliative care plans, 39% made infrastructure investments, and 23% were utilizing clinical pathways. Although 54% stated use of data analytics to maximize efficiency and profitability, half of these were not satisfied with ease of data extraction or output. One third opined that patient satisfaction was irrelevant to quality of care. In the end, nearly half stated reporting requirements could be managed; but 98% stated they were unwilling to assume downside financial risks for hospital and emergency room visits. **Conclusions:** Identifying and eliminating barriers to MACRA (MIPS/APMs) implementation may be critical to program success. The main reasons for OCM non-participation were costs of drugs and data transparency. There is significant dissatisfaction with available reporting and data extraction tools. Willingness to assume 2-sided risk for total cost of care was identified as the greatest risk to APM adoption.

6614 Poster Session (Board #436), Mon, 1:15 PM-4:45 PM

Trends in aggressive care at the end-of-life for stage IV lung cancer patients. *First Author: Chebli Mrad, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, Icahn School of Medicine, New York, NY*

Background: Prior studies have demonstrated that high-intensity end-of-life care improves neither survival nor quality of life for cancer patients. The National Quality Forum endorses dying from cancer in an acute care setting, ICU admission in the last 30 days of life, and chemotherapy in the last 14 days of life as markers of poor quality care. **Methods:** Discharge data from the National Inpatient Sample database was analyzed for 3,030,866 acute care hospitalizations of metastatic lung cancer patients between 1998 and 2014. Longitudinal analysis was conducted to determine trends in aggressive care at the end-of-life and multivariate logistic regression was performed to determine associations with age, race, region, hospital characteristics, and aggressive care. **Results:** In-hospital mortality for metastatic lung cancer patients decreased from 17% to 11%. Among terminal hospitalizations, utilization of radiation therapy and chemotherapy decreased from 4.6% to 3.0% and from 4.8% to 3.0%, respectively. However, the proportion admitted to the ICU increased from 13.3% to 27.9% and invasive procedures increased from 1.2% to 2.0%. Reflecting this aggressive end-of-life care, mean total charges for a terminal hospitalization rose from $29,386 to $72,469, adjusted for inflation. Among patients who died in the inpatient setting, the ICU stay translated into higher total costs (+$16,962, CI: $15,859 to $18,064) compared to patients who avoided the ICU. Promisingly, palliative care encounters for terminal hospitalizations increased during this period from 8.7% to 53.0% and was correlated with a decrease in inpatient chemotherapy (OR = 0.56, CI: 0.47 to 0.68), radiotherapy (OR = 0.77, CI: 0.65 to 0.92), and ICU admissions (OR = 0.48, CI: 0.45 to 0.53) but had only a modest impact on terminal hospitalization cost (-$2,992, CI: -$3,710 to -$2,275). Multivariable analysis showed variation by patient and hospital characteristics in aggressive care utilization. **Conclusions:** Among patients with metastatic lung cancer there has been a substantial increase in ICU use during terminal hospitalizations, resulting in high cost for the health care system. Inpatient palliative care has the potential to reduce aggressive end-of-life interventions.

6615 Poster Session (Board #437), Mon, 1:15 PM-4:45 PM

Validation of a financial toxicity (FT) grading system. *First Author: Jonas A. De Souza, The University of Chicago Medicine, Chicago, IL*

Background: FT is an important adverse event (AE) that should be objectively measured in clinical practice. We previously developed an evidence-based FT grading system based on differences in HRQoL, analogous to the NCI-Common Terminology Criteria for Adverse Events (grade 1, mild AE; grade 2, moderate AE; grade 3, severe AE ,de Souza et al - ASCO 2015). We aimed to validate this grading system using a new sample of cancer patients (pts) and report its association with bankruptcy. **Methods:** FT was assessed by the COST (COmprehensive Score for financial Toxicity) in 2 sets of cancer pts. In the previously reported Development Set (DS), gradations of FT were determined by ROC analyses based on conventions for clinically meaningful small (0.2), medium (0.5) and large (0.8) effect sizes (e.s.) for independent FACT-G differences attributable to FT in pts with Stage IV cancers on chemotherapy. In the Validation Set (VS), differences in HRQoL and the odds ratio for a pt to have declared bankruptcy after the cancer diagnosis were assessed in a larger cohort of cancer pts on chemotherapy. **Results:** The grading system was developed in 888 cancer pts with cancer (233 pts in the DS and 655 in the VS). In the DS, ROC analyses produced 4 FT grades (G): G0, no FT, COST $\geq$26 (99 pts, 42%); G1, mild FT: $\geq$ 14-26 (71 pts, 31%); G2, moderate FT: $>$ 0-14 (58 pts, 25%); and G3, severe FT: COST = 0 (5 pts, 2%). Applying the FT grading to the 655 pts in VS, we had: G0, 146 pts (22%); G1, 281 (43%); G2, 215 (33%); and G3, 13 (2%). The decreases in FACT-G HRQoL measured in e.s. per FT grading in comparison with G0 were small for G1: -0.4 (95%CI: -0.6 – -0.25); large for G2: -0.9 (95%CI: -1.1 – -0.7); and even larger for G3: -1.5 (95%CI: -2.0 – -0.9), all with $p <$ 0.001. In the VS, 23 pts (4%) had declared bankruptcy after their cancer diagnosis. Compared to FT G0, the odds of having declared bankruptcy were 8.6 (95%CI: 1.1 – 67, p = 0.04) times higher for pts with FT G2, and 29 times higher (95% CI: 2.4 – 355, p = 0.008) for those with G3 FT. **Conclusions:** We developed a FT grading system anchored on independent differences in HRQoL. We applied the system in a different set of cancer pts and it retained its validity. We also found an larger incidence of bankruptcy after the cancer diagnosis in higher grades of FT, adding to the grading's meaningful use.

6616 Poster Session (Board #438), Mon, 1:15 PM-4:45 PM

Bias in valuation of health care benefits in metastatic prostate cancer: A contingent valuation of willingness to pay. *First Author: Nuno Sousa, Instituto Português de Oncologia de Lisboa, Senhora Da Hora, Portugal*

Background: Willingness to pay (WTP) studies assess societal valuation of healthcare interventions. Prostate cancer (PC) is the most common cancer diagnosis in men. We explore factors that may bias valuation of health care benefits through contingent valuation of WTP for therapeutic innovation in metastatic castration-resistant PC. **Methods:** Cross-sectional study of Portuguese Society (SOC) and Healthcare Providers (HCP). Monthly WTP assessed through biding and open-ended questions by standardized survey with 2 baseline scenarios: ScA 12-month median survival, ScB 30-month median survival. Respondents considered own financial resources and expenses and for each therapeutic scenario reported WTP, out-of-pocket, and expected National Healthcare System (NHCS) WTP. Impact of demographic, personal medical history and household income assessed by tweedie generalized linear model. **Results:** 1000 subjects on societal cohort and 100 physicians provided valid responses. Subjects reported higher WTP values when NHCS was to provide treatment compared to out-of-pocket cost. For NHCS perspective median WTP for ScA was 2,133€ for HCP vs 5,510€ for SOC and ScB 1 963€ for HCP vs 5,479€ for SOC. Overall, societal cohort's NHCS mean WTP was 2.6 (ScA) and 2.8 (ScB) times higher ($p < .001$) than healthcare providers, but with no difference for out-of-pocket WTP. This difference remained significant when adjusted for all other factors. Additionally, subjects with prior personal or familial history of cancer and subjects with higher household income provided higher WTP estimates. In HCP cohort, urologists reported higher WTP compared to Medical Oncologists. **Conclusions:** This study provides critical insight into differing valuation of cancer treatments between physicians and society and potential biases in individual valuation of healthcare benefits. Improvement of societal's perception and understanding of cost-benefit assessments is critical to designing an equitable healthcare system.

6617 Poster Session (Board #439), Mon, 1:15 PM-4:45 PM

Financial impact of flat dosed (FD) monoclonal antibodies (MABs) at a single institution in 2016. *First Author: Michael P. Kane, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Immuno-oncology (I/O) agents represent an important, accelerated breakthrough in cancer therapy. Like other MABs, these agents have been adjusted after FDA approval to have a flat-dose. Purportedly, flat dosing simplifies prescribing, dispensing, inventory and billing. Nivolumab (N) and Pembrolizumab (P) achieved FDA approval in several malignancies. Original studies determined the dosing of N @ 3 mg/kg q2-weeks and P @ 2 mg/kg q3-weeks. Based on simulations from population pharmacokinetics models, the FDA approved a FD of N 240 mg in melanoma, RCC and NSCLC. The financial impact of this FD methodology in our patient population was compared with weight based dosing (3mg/kg) of N with a cap of 240 mg versus flat dosing. The potential impact of this change was also evaluated for P, including if a 50 mg vial of P was still available. **Methods:** Applicable dispensed doses (N & P) and patients' weights for 2016 were mined from the electronic health record. Wholesale Acquisition Costs at end of year were used for financial comparison. **Results:** see table. **Conclusions:** Weight based dosing with a cap (N 240mg; P 200mg) versus flat dosing would have saved $198,567 and $80,037, respectively. Additionally, $760,351 would have been saved if 50 mg vials of P were available. With the current drug pricing structure, wide-scale adoption of flat dosing for I/O mABs may result in higher drug costs. Labeling I/O mABs with both weight-based and FD options and ensuring the availability of proper vial sizes, particularly multi-dose vials, to fit the population and dosing schema would restrain the costs of care.

N: 54 patients, 510 doses; (Mean 77.3kg, SD 16.15, (44.90-127.89kg)); 33 patients less than 80kg (302 doses).

2016 WAC of N	All weight based doses (3 mg/kg)	Flat Dose (240 mg)	Weight Based 3 mg/kg Capped at 240 mg
Cost	$3,147,460.20	$3,069,225.90	$2,870,628.51

P: 103 patients, 605 doses; (Mean 80.14kg, SD 19.89, (39.46-164.17kg)); 89 patient less than 100kg (528 doses).

2016 WAC of P	All weight based doses (2 mg/kg)	Weight Based If 50 mg vials were available	Flat Dose (200 mg)	Weight Based 2 mg/kg Capped at 200 mg	Weight Based Capped at 200 mg If 50 mg Vials Were Available
Cost	$5,615,929.50	$4,811,113.00	$5,380,265.00	$5,300,228.00	$4,619,913.50

6618 Poster Session (Board #440), Mon, 1:15 PM-4:45 PM

Spending on antineoplastic agents in the United States: 2011-2016. *First Author: Edward C. Li, University of New England College of Pharmacy, Portland, ME*

Background: Novel antineoplastic therapies confer advantages in efficacy and safety over traditional cytotoxic agents, but they are costly. There is little information on recent trends in actual antineoplastic expenditures representative of the overall U.S. health care system or by healthcare sector. The objective of this study was to describe antineoplastic expenditures by year and healthcare sector in the U.S. **Methods:** Quintiles IMS National Sales Perspective data for the period of Jan 1, 2011, to Dec 31, 2016, were evaluated to describe antineoplastic agent expenditures. Actual expenditures were totaled by health care sector and calendar year, and then adjusted for U.S. medical-cost inflation (part of the overall consumer price index) to 2016 dollars. Growth was calculated as the percentage increase from previous years. Descriptive statistical analysis was used. **Results:** Total antineoplastic expenditures increased from $26.8 billion in 2011 to $38.9 billion in 2016. Compared to the previous year, spending increased by 13.7%, 15.6%, 13.4%, 6.3%, and 0.4% in 2016, 2015, 2014, 2013, and 2012, respectively. In hospitals and clinics, spending on biologics grew by 80% from 2011 to 2016. Rituximab, bevacizumab, and trastuzumab expenditures continue to be high ($3.7, $3.0, and $2.6 billion in 2016, respectively) while nivolumab spending increased from $765 million in 2015 to $2.6 billion in 2016. Cytotoxic drug spending remained flat during the study period due to the availability of multiple generic products. Large percentage decreases in spending were seen for oxaliplatin (-97%), docetaxel (-98%), gemcitabine (-92%), bendamustine (-56%) and decitabine (-94%) in 2016 compared to 2011. **Conclusions:** Antineoplastic expenditures increased significantly since 2011 and are expected to continue to do so with the anticipated approval of additional novel but costly cancer therapies, and because of an aging population.

Top 5 antineoplastic expenditures by year (USD – in millions).

	2011	2012	2013	2014	2015	2016
Rituximab	$3,252	$3,372	$3,452	$3,519	$3,599	$3,737
Bevacizumab	$2,939	$2,829	$2,840	$2,948	$3,114	$2,965
Nivolumab				$0.85	$765	$2,586
Trastuzumab	$1,842	$1,999	$2,056	$2,256	$2,524	$2,586
Pertuzumab		$61	$244	$617	$854	$932

6619 Poster Session (Board #441), Mon, 1:15 PM-4:45 PM

Cost-effectiveness analysis of first-line treatments for early-stage, low-grade follicular lymphoma. *First Author: Joanna C. Yang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Low-grade follicular lymphoma (FL) can present as localized stage I to II disease in up to one-third of patients. Upfront involved-site radiation therapy (RT) to 24-30Gy is the preferred first-line management strategy for these patients. However, the National LymphoCare Study found that less than one quarter of patients with early-stage, low-grade FL received upfront RT, while more than half received either chemoimmunotherapy or observation. **Methods:** We performed a cost-effectiveness analysis using a Markov state-transition model to simulate the progression of early-stage, low-grade FL in a cohort of 60-year-old men. The following first-line treatments were compared: RT, observation, rituximab induction (RI), rituximab and bendamustine (BR), and rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (RCHOP). Patients who relapsed received second-line therapies that were dependent on their first-line treatment: RT for RI and observation, RCHOP for RT and BR, and BR for RCHOP. Disease-progression probabilities and other model inputs were from published trials. **Results:** First-line RT followed by RCHOP for relapses had a quality-adjusted life expectancy (QALE) of 11.4 years, superior to first-line observation, RI, BR, and RCHOP strategies. First-line RT strongly dominated observation, BR, and RCHOP. Compared with RI, first-line RT resulted in an incremental cost-effectiveness ratio of $2,740 per quality-adjusted life year. The probability of dying from other causes, the probability of a complete response to RT, and the probability of relapse had the greatest impact on both cost and effectiveness expected values. **Conclusions:** In contrast to current practice patterns, first-line RT is the most effective upfront treatment for patients with early-stage, low-grade FL. Further, first-line RT paired with RCHOP for relapses is a cost-effective treatment paradigm, relative to other strategies.

First-Line Treatment	Second-Line Treatment	Cost (2016 USD)	Effectiveness (Years)	Incremental Cost-Effectiveness Ratio
RI	RT	$585,430	7.3	
RT	RCHOP	$596,656	11.4	$2,740
Observation	RT	$750,548	5.3	Dominated
BR	RCHOP	$1,956,411	7.0	Dominated
RCHOP	BR	$2,017,066	8.6	Dominated

6620 Poster Session (Board #442), Mon, 1:15 PM-4:45 PM

Algorithmic matching of genomic profiles to precision cancer medicine clinical trials at DFCI. *First Author: James Lindsay, Dana-Farber Cancer Institute, Boston, MA*

Background: Genomic profiling and access to precision medicine clinical trials are now standard at leading cancer institutes and many community practices. Interpreting patient-specific genomic information and tracking the complex criteria for precision medicine trials requires specialized computational tools, especially for multi-institutional basket studies such as NCI-MATCH and TAPUR. **Methods:** To address this challenge we have developed an open source computational platform for patient-specific clinical trial matching at Dana-Farber Cancer Institute (DFCI) called MatchMiner, which aides in both patient recruitment to precision medicine trials, as well as decision support for oncologists. Trial matches are computed based on genomic criteria, including mutations, CNAs, and SVs, as well as clinical and demographic information, including cancer type, age, and gender. A formal standard called clinical trial markup language (CTML) to encode complex clinical trial eligibility criteria has also been created. **Results:** MatchMiner is now available at DFCI. Currently 123 precision medicine clinical trials have been transformed into CTML and 13,000 patient records are available, with over 88% of current patients having at least 1 match (average 2.6). A total of 103 genes are specified as criteria for at least 1 trial. KRAS, TP53, PTEN, PIK3CA and BRAF are the genes driving the most number of matches. General usage statistics and trial enrollment rates are currently being monitored to determine the system effectiveness. As this is an open source initiative, the software is also now publically available at https://github.com/dfci/matchminer. **Conclusions:** We have developed an open source computational platform that enables patient-specific matching and recruitment to precision medicine clinical trials at DFCI. We are actively seeking collaborators and plan to make CTML a multi-institution standard for encoding complex clinical trial eligibility in a computable form.

6621 Poster Session (Board #443), Mon, 1:15 PM-4:45 PM

Determinants of spending for metastatic breast, lung, and colorectal cancer in SEER-Medicare. *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: A substantial proportion of cancer spending is directed towards patients with metastatic disease. Past efforts to characterize spending for metastatic cancer have been limited, because they have not included patients with recurrent disease or analyzed spending across the entire episode of care. Spending for stage IV and recurrent metastatic cancer patients may differ. **Methods:** Using SEER-Medicare data from 2008-13, we identified breast (BC), colorectal (CRC), and lung (LC) cancer patients who were continuously enrolled in parts A, B and D, and had either stage IV or recurrent disease (i.e., return of cancer after resection of stage I-III disease). Mean total Medicare spending/patient per month and per year (2012$US) were estimated from 12 months prior to 12 months after diagnosis, and described for relevant patient sub-groups. **Results:** In a cohort of 27,847 patients, total spending for stage IV vs. recurrent cancer was 61-73% lower in the year before diagnosis ($11,339 vs. $28,796 for BC; $13,359 and $49,804 for CRC; $15,118 and $49,555 for LC), and 28-88% higher in the year after diagnosis ($68,787 and $42,091 for BC; $111,304 and $58,657 for CRC; $92,181 and $72,354 for LC). When considering the 2 year-period spanning the diagnosis, spending was similar (≤14%) between groups. The primary drivers of spending differences between patients with stage IV and recurrent disease were cancer type and time from diagnosis (Table). Younger age, higher comorbidity, and SEER region were also drivers of higher spending, especially after diagnosis. **Conclusions:** Spending patterns differ for patients with stage IV vs. recurrent cancer, suggesting different patterns of care that warrant further investigation. Spending differences after diagnosis were driven largely by part B spending, which was due in part to differential chemotherapy use.

Diff avg mo spending (2012 US$): Recur—stage IV

		Pre-advanced Dx		Post-advanced Dx	
	Medicare File	12 → 7 mos	6 → 1 mos	0 → 5 mos	6 → 11 mos

6622 Poster Session (Board #444), Mon, 1:15 PM-4:45 PM

Cost-effectiveness of front-line trials in metastatic colorectal cancer: Integrating the European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) with the costs of drugs. *First Author: Andrea Bonetti, Mater Salutis Hospital AULSS 9 of the Veneto Region, Legnago, Italy*

Background: In Western Countries, colorectal cancer (CRC) is the second most common cause of death from cancer. In light of the relevant expenses of drugs it might be interesting to make a balance between the cost of the drugs and clinical parameters of interest such as progression free survival (PFS). **Methods:** Phase III randomized clinical trials (RCTs) that compared at least two front-line chemotherapy regimens for mCRC patients were evaluated. Differences in PFS between the different arms were calculated and compared with the pharmacological costs (at the Pharmacy of our Hospital) needed to get one month of PFS. Subsequently we applied the ESMO-MCBS (a 1 to 5 scale) to the above phase III RCTs. **Results:** Overall 28 phase III RCTs, including 19 958 patients, were analyzed. The FOLFOX resulted the least expensive (56 € per month of PFS gained) while the addition of irinotecan to FOLFOX (FOLFOXIRI) increased only marginally the costs (90 € per month of PFS gained). Treatments including the monoclonal antibodies showed a cost per month of PFS gained of 2823 € (FOLFIRI with cetuximab in KRAS wild-type patients and liver-only metastases), of € 15 822 (FOLFOX with panitumumab in KRAS wild type) and of 13 383 € (FOLFOX with bevacizumab). According to the ESMO-MCBS the treatments including an EGFR-inhibitor (cetuximab or panitunumab) were associated with a score of 4 while the inclusion of bevacizumab reached a score of 3. The remaining phase III RCTs obtained a low (grade 1-2) score.Dividing the costs per month of PFS gained with the grade of ESMO-MCBS, for each RCTs, we obtained the costs of each point of ESMO-MCBS per month of PFS gained. FOLFOX was confirmed as being the least expensive (18.7 €) while among treatments including a targeted biological agent panitunumab in combination with FOLFOX in K-RAS wild type patients was less expensive (3955 €) than the combinations FOLFOX-bevacizumab (13 383 €) and FOLFIRI-cetuximab in K-RAS wild type patients (21 854.6 €). **Conclusions:** Our data demonstrate a huge difference in cost per month of PFS gained and per each point of the ESMO-MCBS in modern front line treatments in mCRC.

6623 Poster Session (Board #445), Mon, 1:15 PM-4:45 PM

Access and price of cancer drugs: What is happening in France? *First Author: Mathilde Grande, French National Authority for Health, La Plaine Saint-Denis, France*

Background: The French National Authority for Health (HAS) is responsible for health technology assessment (HTA), providing opinion on drugs for reimbursement and pricing purposes. For all indications with a positive opinion for reimbursement, HAS assesses the clinical added value (CAV) on a 5-point scale for pricing negotiations based on clinical data. A major to moderate CAV leads to the highest prices, a minor CAV leads to a higher price than the comparator, and no CAV leads to lower price than the cheapest comparator. Countries increasingly face the policy challenge of harnessing the benefits of cancer drugs while managing healthcare budgets. In this context, we aimed to analyze cancer drugs assessment by HAS. **Methods:** a retrospective and descriptive analysis comparing all new hematology/oncology cancer indications versus all others new indications assessed by HAS between 2010 and 2015 has been conducted. **Results:** 87 cancer indications (60 drugs) have been evaluated, representing 17% (87/510) of all new drugs indications assessed by HAS. Almost all cancer indications (92%) obtained a favorable opinion for reimbursement. Seven (8%) had an unfavorable opinion versus 20% in other therapeutic areas. However, 5 of these 7 indications were related to a drug included on the list of reimbursed drugs for another indication and consequently drugs are available. Overall, only 2 drugs were not reimbursed: nintedanib in non small cell lung cancer and tegafur/gimeracil/oteracil in gastric cancer (no impact on survival and lack of results transposability). Of the 80 indications with a favorable opinion, 20 had a major to moderate CAV (25%), 32 a minor CAV (40%) and 28 have no CAV (35%). Major to moderate CAV are mostly composed of hematology drugs (12, 60%). The proportion of major to moderate CAV assessment is higher in oncology than in other therapeutic areas (66% vs. 30%). **Conclusions:** France benefits from a universal healthcare system offering wide coverage and large access to drugs. Almost all of the new hematology/oncology cancer drugs assessed had a favorable opinion and are fully reimbursed (100%) by health insurance. A high proportion (66%) of CAV is recognized in oncology. Nevertheless, the over DRG list can inadvertently limit access to these new cancer drugs.

6624 Poster Session (Board #446), Mon, 1:15 PM-4:45 PM

Price trajectories assessment for Medicare Part B generic anti-cancer drugs. *First Author: Noa Gordon, Davidoff Cancer Center, Petah Tikva, Israel*

Background: Patented anti-cancer drugs launch prices have increased in recent years with subsequent increases after launch. Recently, large price increases of generic drugs were at the center of public attention in the United States. Our aim was to assess price changes with time for Medicare part B anti-cancer generic drugs and to understand how drug characteristics and market structure influence price trajectories. **Methods:** We included all Medicare part B anti-cancer drugs with price reported in both 2006 and 2016. Patent expiration dates were attached using the Medicare Drug Patent Expiration engine and drugs with a patent expiration date later than 2006 were excluded. Generic manufacturers' FDA approvals for each drug were extracted from the FDA Orange Book. For each drug we extracted the Average Sales Price (ASP) history from October 2006 to October 2016, published by the Center for Medicare and Medicaid services (CMS). Prices were adjusted for inflation, using information obtained from the United States Department of Labor. For each drug we calculated the cumulative ASP change during the follow-up period. Data were analyzed using IBM SPSS Statistics software. **Results:** We identified 31 anti-cancer generic drugs that met the inclusion and exclusion criteria. During the follow-up period, 15 (48%) drugs had increases in price (median 139%, range 18-2632%). Seven (23%) drugs increased by more than 200% (Table 1). Both gradual price and acute price increases were observed. Some of the drugs which had substantial price increases had no market competition market. **Conclusions:** Generic drug prices may change substantially with time. Gradual or rapid price increases may be due to lack of generic drug competition, substitution shortages or marketing reasons. New regulations may be needed to prevent further increases in generic drug costs, while balancing the need to maintain financial incentives for drug production and competition.

Top price increases.

TPS6625 Poster Session (Board #447a), Mon, 1:15 PM-4:45 PM

Biospecimen donors' views about biobank closure. *First Author: Rebecca D. Pentz, Emory University School of Medicine, Atlanta, GA*

Background: The future of biobanks is often uncertain due to sporadic funding. A survey of 456 biobank administrators found that they consider the loss of funding to be either a "massive (40%)" or "moderate (31%)" concern. Only 26% of biobanks reported having a plan in the event of closure (Cadigan et al., *Life Sciences, Society and Policy*, 2013). Biospecimen donors' views on how they want their tissue handled following biobank closure is unknown. Our study will be the first to determine how biospecimen donors want their data and biological materials handled if their biobanks were to close. We believe this report of 100 biospecimen donors' views will be useful to researchers and tissue bank administrators in creating contingency tissue bank closure plans that incorporate biospecimen donors' perspectives. **Methods:** We will complete accrual of 100 oncology biospecimen donors (current accrual is 65 patients) at one institution by interviewing them about their views of bank closure and preferences for the handling of their tissue post-closure. The interview asks participants if they have a preference for the handling of their tissue and information in the event of bank closure, and if so, if they prefer transfer of their materials to another tissue bank or destruction. Feelings about closure are captured in three categories: sad/disappointed, angry/frustrated, and other negative emotions. The effect of tissue bank closure upon trust in medical research is captured in three categories: decreases trust, does not decrease trust, and may decrease trust under certain circumstances. We ask the participants to rank the following options for transfer of their tissue and information: transfer to another local academic tissue bank, to a for-profit or pharmaceutical bank, to an international bank, or to a national bank. We also ask if any of these options are deemed absolutely unacceptable. Results: NA Conclusions: NA

TPS6626 Poster Session (Board #447b), Mon, 1:15 PM-4:45 PM

Objective assessment of physical activity during chemotherapy for breast cancer. *First Author: Michelle E. Melisko, University of California, San Francisco, San Francisco, CA*

Background: Exercise can alleviate side effects of chemotherapy, improve quality of life (QOL), and positively impact disease specific and overall survival. Despite the benefits of physical activity (PA), many patients' activity levels decrease during chemotherapy. Wearable devices, such as the Fitbit, can provide insight into patterns of activity, and help encourage behavior change. The aims of this study are: 1) determine the feasibility/acceptability of using a Fitbit to measure PA and sleep throughout chemotherapy for breast cancer; 2) describe patterns of PA, sedentary time, and sleep during chemotherapy; 3) explore associations of activity and sleep with QOL. **Methods:** Non-metastatic breast cancer patients from UCSF and UCSD will be enrolled prior to starting chemotherapy. Eligibility criteria include ability to speak/read English, walk unassisted, and access to internet or Fitbit compatible smart phone. Patients sign informed consent, receive a Fitbit Charge HR and guidance on how to use the device. Patients are instructed to wear the Fitbit throughout their adjuvant or neoadjuvant chemotherapy and 6 months post therapy and to sync the Fitbit at least weekly. Patients complete surveys at start, midpoint, end, and 6 months post chemotherapy. Questionnaires include PROMIS anxiety, depression, physical function, fatigue, cognitive function, social roles, comfort with technology and usefulness of the Fitbit. Fitabase database collects minute level activity, sleep, and heart rate. To assess feasibility, we will evaluate if a participant wears FitBit for at least 10 hour per day for $\geq$ 80% of the days during chemotherapy. We will use mixed effects regression models to assess patterns of PA and associations between activity and QOL. All models will include activity time and Fitbit wear time and will control for the potential confounding effects of age and other demographic or clinical variables. As of February 6 2017, 48 out of a planned 80 patients are enrolled. Acknowledgment: Athena Breast Health Network investigators and patients; support at UCSD by NCI (U54 CA155435-01) and by gift from Carol Vassiliadis and family; NCI grant K07CA181323 to SH; UCSF M Zion Health Fund Award, GBCTB unrestricted funding and TriValley SOCKS to MM. Clinical trial information: NCT03041545.

7000 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Phase 3 trial of momelotinib (MMB) vs ruxolitinib (RUX) in JAK inhibitor (JAKi) naive patients with myelofibrosis (MF). *First Author: Ruben A. Mesa, Mayo Clinic Cancer Center, Scottsdale, AZ*

Background: MMB, an oral JAKi, has been shown in early trials to reduce spleen volume, improve disease associated symptoms (Sx) and improve RBC transfusion (Tx) requirements in patients (pts) with MF. This study was designed to test non-inferiority of MMB vs RUX in splenic volume reduction and Sx amelioration, and superiority in Tx requirement, in JAKi naïve MF pts. **Methods:** Eligibility: MF, IPSS high risk, Int-2, or symptomatic Int-1; palpable spleen ≥5cm; platelets ≥ 50 K/μl, and no Gr ≥2 peripheral neuropathy (PN). Stratification by Tx dependency and platelets (<100, 100-200 and >200 K/μl). Pts were randomized 1:1 to 24 wks of MMB 200 mg qd + RUX placebo or RUX 20 mg bid (or modified per label) + MMB placebo, after which all pts could receive open label MMB. Assessments: spleen volume by MRI, and pt reported Sx using a daily eDiary of modified MPN-SAF Total Sx Score (TSS). Primary endpoint was splenic response rate (SRR; ≥35% reduction in volume from baseline) at 24 wks. Secondary endpoints, evaluated sequentially at 24 wks, were rates of TSS response (≥50% reduction from baseline), RBC Tx independence (TI), RBC Tx dependence (TD) and of RBC Tx. **Results:** 175 of 215 (81%) and 201 of 217 (93%) pts randomized to MMB and RUX, respectively, completed the 24 wk DB phase. Efficacy results are shown in Table. Most common Gr ≥3 AEs in the DB phase with MMB were thrombocytopenia (7%) and anemia (6%), and with RUX were anemia (23%), thrombocytopenia (5%) and neutropenia (5%). Gr ≥3 infections occurred in 7% of MMB and 3% of RUX pts. Treatment emergent PN occurred in 22 (10%) of MMB (all Gr ≤2) and 10 (5%) of RUX (9 Gr ≤2, 1 Gr 3) pts in DB phase, none discontinuing study drug for PN. Overall, AEs led to study drug D/C in 13% of MMB and 6% of RUX pts in DB phase. **Conclusions:** In pts with JAKi naive MF, 24 weeks of MMB is non-inferior to RUX for spleen response but not for symptom response. MMB treatment is associated with a reduced transfusion requirement. NCT01969838.

Endpoints	MMB	RUX	P-Value

7001 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Phase 3 randomized trial of momelotinib (MMB) versus best available therapy (BAT) in patients with myelofibrosis (MF) previously treated with ruxolitinib (RUX). *First Author: Claire N. Harrison, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: MMB, an oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease associated symptoms (Sx) and improve RBC transfusion requirements in patients (pts) with MF. This study of previously RUX treated pts with MF tested the superiority of MMB vs BAT in splenic volume reduction, Sx amelioration, and transfusion requirement at 24 weeks. **Methods:** Eligibility included primary or post-ET/PV MF; DIPSS high risk, Int-2, or symptomatic Int-1; prior RUX ≥4 weeks who either required transfusions or dose reduction to <20 mg BID with at least one of Gr ≥3 thrombocytopenia, anemia, or bleed; palpable spleen ≥5cm; and no Gr ≥2 peripheral neuropathy. Stratification was by transfusion dependency and baseline TSS (modified MPN-SAF Total Sx Score) <18 or ≥18. Pts were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported Sx using a daily eDiary for TSS. 1° endpoint was splenic response rate (SRR; ≥35% reduction in volume from baseline). 2° endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion, RBC transfusion independence (TI) and RBC transfusion dependence (TD). **Results:** 73 of 104 (70%) and 40 of 52 (77%) pts receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for 88% of pts included RUX, and 27% of pts were on RUX in combination with other drugs. Efficacy results are in Table. The most common Gr ≥3 adverse events in MMB pts were anemia (13%) and thrombocytopenia (7%), and in BAT pts, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%); treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Gr3) and in no BAT pts. **Conclusions:** In previously RUX-treated patients with MF, 24 weeks of MMB was not superior to BAT for SRR, but significantly better in improving disease related symptoms and transfusion independence. Clinical trial information: NCT02101268.

Bosutinib (BOS) versus imatinib (IM) for newly diagnosed chronic myeloid leukemia (CML): Initial results from the BFORE trial. *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BOS is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment (tx) of adults with Ph+ CML resistant/intolerant to prior therapy. We assessed the efficacy and safety of BOS vs IM for first-line tx of chronic phase (CP) CML. **Methods:** In this ongoing, multinational, phase 3, open-label study, 536 patients (pts) with newly diagnosed CP CML were randomized 1:1 to BOS 400 mg QD (n = 268) or IM 400 mg QD (n = 268 [3 not treated]). Per protocol, efficacy was assessed in a modified intent-to-treat (ITT) population of 487 Ph+ pts (BOS, n = 246; IM, n = 241) with e13a2/e14a2 transcripts; results in full ITT will also be presented. **Results:** After≥12 mo of follow-up, 78% of BOS and 73.2% of IM pts remain on tx with median tx durations of 14.1 and 13.8 mo, respectively. Major molecular response (MMR) rate at 12 mo (primary endpoint) was significantly higher with BOS vs IM (47.2% vs 36.9%; P= 0.02). Time to MMR was shorter for BOS (hazard ratio [HR] 1.34; P< 0.02). Rate of complete cytogenetic response (CCyR) by 12 mo was also significantly higher with BOS vs IM (77.2% vs 66.4%; P< 0.008), with time to CCyR shorter for BOS (HR 1.38; P≤0.001). Rates of BCR-ABL transcripts≤10% (Intl Scale) at 3 mo (75.2% vs 57.3%), MR^4 at 12 mo (20.7% vs 12%) and $MR^{4.5}$ at 12 mo (8.1% vs 3.3%) were higher with BOS vs IM, respectively (all P< 0.025). 1 BOS pt and 4 IM pts discontinued tx due to progression to accelerated or blast phase. There were no deaths within 28 d of last dose of BOS and 4 with IM. Safety data were consistent with known safety profiles of BOS and IM. 12.7% of BOS and 8.7% of IM pts discontinued due to drug-related toxicity. Gr≥3 diarrhea (7.8% vs 0.8%) and increased alanine (19% vs 1.5%) and aspartate (9.7% vs 1.9%) aminotransferase levels were more common with BOS. Cardio-, peripheral- and cerebrovascular events were infrequent (3%, 1.5% and 0% BOS vs 0.4%, 1.1% and 0.4% IM; gr≥3: 1.5%, 0% and 0% vs 0%, 0% and 0.4%). **Conclusions:** Pts on BOS had significantly higher rates of 12-mo MMR and CCyR and achieved responses faster than those on IM, but had higher incidence of gastrointestinal events and transaminase elevations. Results suggest BOS may be an important tx option for pts with newly diagnosed CP CML. Funding. Avillion, Pfizer. Clinical trial information: NCT02130557.

7003 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Deep molecular response to gilteritinib to improve survival in FLT3 mutation-positive relapsed/refractory acute myeloid leukemia. *First Author: Jessica K. Altman, Northwestern University, Chicago, IL*

Background: Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive ($FLT3^{mut+}$) relapsed/refractory (R/R) AML in the CHRYSALIS Phase I/II study (NCT02014558), specifically at doses ≥80 mg/d. This exploratory analysis assessed molecular response to gilteritinib in a CHRYSALIS subpopulation. **Methods:** Molecular response was assessed from bone marrow aspirates obtained at baseline and at ≥1 additional time point from $FLT3^{mut+}$ patients (≥18 y) treated with 120 or 200 mg/d gilteritinib. These doses were identified due to their ability to induce consistent, potent FLT3 inhibition and high clinical response rates. *FLT3-ITD* and total *FLT3* were quantified by NGS to assess molecular response. A Cox regression model of overall survival (OS) by Kaplan-Meier estimation established a *FLT3-ITD*:total *FLT3* ratio (ITD signal ratio) of 10^{-2}as the threshold for improved survival. **Results:** Of 147 $FLT3\text{-}ITD^{mut+}$ patients who received gilteritinib 120 or 200 mg/d, 80 were included in this analysis. Composite response rate for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of $\leq 10^{-2}$. Of these 20 patients, 18 had a ratio of $\leq 10^{-3}$ (major molecular response [MMR]) and 13 had a ratio of $\leq 10^{-4}$ (minimal residual disease [MRD] negative). Median time to achieve minimum signal ratio was 54 days. Elimination of morphologic leukemia was observed in 80% of patients with ITD signal ratios $<10^{-2}$. Patients who had a signal ratio $\leq 10^{-2}$, MMR, or were MRD negative had significantly longer median OS than those who did not (Table). **Conclusions:** Molecular responses to gilteritinib in $FLT3\text{-}ITD^{mut+}$ R/R AML correlated with clinical response and improved OS. This is the first demonstration of molecular response to a FLT3 inhibitor in AML. These data suggest ITD signal ratio may predict durable clinical benefit of gilteritinib. Clinical trial information: NCT02014558.

	Achieved a Molecular Response		Did not Achieve a Molecular Response		
Molecular Response	n	Median OS, Days (95% CI)	n	Median OS, Days (95% CI)	*P*-value
ITD signal ratio $\leq 10^{-2}$	20	417 (246–NA)	60	199 (142–234)	<.001
MMR	18	417 (228–NA)	62	213 (143–264)	.003
MRD negative	13	417 (228–NA)	67	213 (144–264)	.002

7004 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Enasidenib in mutant-*IDH2* relapsed or refractory acute myeloid leukemia (R/R AML): Results of a phase I dose-escalation and expansion study. *First Author: Eytan M. Stein, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: Recurrent mutations in *isocitrate dehydrogenase 2* (m*IDH2*) occur in 8-15% of AML pts. mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 protein. **Methods:** This phase 1/2 study assessed the maximum tolerated dose (MTD), pharmacokinetic and pharmacodynamic profiles, safety, and clinical activity of enasidenib in pts with m*IDH2* myeloid malignancies. Safety for all pts and efficacy outcomes for R/R AML pts from the phase 1 dose-escalation and expansion phases are reported. **Results:** In all, 239 pts received enasidenib. In the dose-escalation (n=113), the MTD was not reached at doses up to 650 mg daily. Median 2HG reductions from baseline were 92%, 90%, and 93% for pts receiving <100 mg, 100 mg, and >100 mg daily, respectively. Enasidenib 100 mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1–25). Grade 3-4 drug-related investigator reported AEs included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (ie, retinoic acid syndrome; 7%). For R/R AML pts, overall response rate (ORR) was 40.3%, including 34 (19.3%) complete remissions (CR; Table). Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) for R/R AML pts was 9.3 months (mos). For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML regimens (n=94; 53%) had median OS of 8.0 mos. **Conclusions:** Enasidenib was well tolerated, induced CRs, and was associated with OS of >9 mos in pts who had failed prior AML therapies. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. Clinical trial information: NCT01915498.

	R/R AML Pts

7005 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Distinct patterns of somatic mutation clearance and association with clinical outcome in patients with AML. *First Author: Koichi Takahashi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML. **Methods:** We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): MC2.5, persistent mutation with VAF<2.5%; MC1.0, persistent mutation with VAF<1%; and complete mutation clearance (CMC). **Results:** In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF≥2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of indeterminate potential (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 vs. 12.5 months, P = 0.04) or CMC (median 31.2 vs. 12.5 months, P = 0.049) had significantly better relapse-free survival (RFS). **Conclusions:** Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

Gene	MC2.5 (%)	MC1.0 (%)	CMC (%)	Pathway	MC2.5 (%)	MC1.0 (%)	CMC (%)

Allogeneic hematopoietic cell transplant (alloHCT) for hematologic malignancies in human immunodeficiency virus infected (HIV) patients (pts): Blood and Marrow Transplant Clinical Trials Network (BMT CTN 0903)/AIDS Malignancy Consortium (AMC-080) trial. *First Author: Richard F. Ambinder, Bunting Blaustein Cancer Research Building, Baltimore, MD*

Background: AlloHCT has been regarded as risky in HIV pts, with concern about fatal infection. We set out to assess feasibility and safety of alloHCT in this first prospective multicenter trial. **Methods:** The primary endpoint was 100-day non-relapse mortality (NRM). Pts had drug-susceptible HIV; age ≥ 15 yr; adequate organ function; acute myeloid leukemia (AML) or acute lymphocytic leukemia (ALL), high risk myelodysplastic syndrome (MDS), or Hodgkin (HL) or non-Hodgkin lymphoma (NHL) beyond first CR; an 8/8 HLA-matched related or at least a 7/8 unrelated donor. Pts received myeloablative (MA) or reduced intensity (RI) regimens. HIV outgrowth assays (VOA) were performed with resting CD4+T-cells in pts who had clinically undetectable HIV plasma RNA at 1 yr. **Results:** Between 5/2012 and 12/2015, 17 pts underwent alloHCT. Pts were: male (17); white (11), African American (3), Other/Unknown (3); median age 47 yrs (25-64). Associated malignancies were AML (9), ALL (2), MDS (2), HL (1), NHL (3). Median CD4 was 224 (55-833). Conditioning was MA (8) and RI (9). At 100 days there was no NRM, 13 pts were in CR, 4 pts had relapsed/progressive disease; and 8 pts achieved complete chimerism. The cumulative incidence of Grades (Gr) II-IV acute Graft vs Host Disease (GvHD) was 41 % (95%CI: 18 %, 64%). At 6 mo, OS was 82 % (95% confidence interval [CI]: 55%, 94%); 9 pts achieved complete chimerism. At 1 year, OS was 57 % (CI: 31%, 77 %); 8 deaths were from relapsed/progressive disease (5), acute GvHD (1), adult respiratory distress syndrome (1) and liver failure (1). Infections were reported in 11 pts (3 Gr 2, 8 Gr 3). Infectious HIV was detected by VOA in 2 of 3 pts who were mixed chimeras but 0 of 2 who were 100% donor. Median follow up of survivors is 24 mo (7 to 27). **Conclusions:** HIV pts with heme malignancies underwent MA or RI alloHCT without any100-day NRM and there were no infectious deaths at 1 year. AlloHCT should be considered the standard of care for HIV pts who meet usual eligibility criteria. Clinical trial information: NCT01410344.

7007 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Factors associated with allogeneic hematopoietic stem cell transplantation (HSCT) outcomes in patients (pts) with relapsed/refractory acute lymphoblastic leukemia (R/R ALL) treated with inotuzumab ozogamicin (InO) versus (v) conventional chemotherapy (C). *First Author: Partow Kebriaei, MD Anderson Cancer Center, Houston, TX*

Background: InO therapy in R/R ALL resulted in superior complete remission (CR)/CR with incomplete hematologic recovery (CRi) rates v C in the Phase 3 INO-VATE trial (NCT01564784; Kantarjian *NEJM* 2016). More InO v C pts proceeded to HSCT (41% [45/109] v 11% [12/109]; *P*<0.001). Factors associated with outcomes after HSCT are described. **Methods:** Full details have been published. Multivariate analyses (MVA) using Cox regression modeling were conducted to determine predictors of non-relapse mortality (NRM) and overall survival (OS). **Results:** As of 3/8/16, 108/326 pts underwent allogeneic HSCT (InO n=77; C n=31). Baseline characteristics were generally similar, except baseline platelet values were lower in InO v C pts. More InO v C pts achieved minimal residual disease negativity (MRD^{neg} [best status]; 71% v 26%; *P*<0.0001). Less InO v C pts received additional therapy before HSCT (14% v 55%, *P*<0.0001). NRM rates were higher in InO v C pts at 1 year (yr; 36% [95% CI 26–47] v 20% [8–36]) and 2 yrs (39% [27–51] v 31% [13–51]), but relapse rates were lower (1 yr, 23% [15–33] v 29% [13–48]; 2 yrs, 33% [22–44] v 46% [24–65]). No significant difference in post-HSCT survival was detected in InO v C pts; however, visual inspection of the curve suggested the survival probability varied before and after 15 months post-HSCT (1 yr, 44% [95% CI 33–55] v 65% [44–79]; 2 yr, 39% [28–50] v 34% [15–54]). Fatal veno-occlusive disease (VOD) was observed in 5 InO pts (all during the first 100 days from the date of HSCT) and no C pts. MVA showed that conditioning regimens without dual alkylators and thiotepa were associated (2-sided; *P*<0.05) with lower risk of NRM and post-HSCT survival, respectively. **Conclusions:** Compared with C, InO permitted more pts with R/R ALL to proceed to HSCT in CR/CRi with MRD^{neg} (best status). Despite increased NRM and fatal VOD, long-term survival was attainable in InO pts. In pts previously treated with InO, interventions to reduce NRM and improve OS after HSCT include avoiding dual alkylator conditioning regimens, especially those containing thiotepa. Funding: Pfizer Clinical trial information: NCT01564784.

Durable long-term survival of adult patients with relapsed B-ALL after CD19 CAR (19-28z) T-cell therapy. *First Author: Jae Hong Park, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined. Herein, we report the results from analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities. **Methods:** Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with $<$ 5% blasts were classified as minimal residual disease (MRD) cohort vs. patients $\geq$5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3). **Results:** 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the morphologic cohort. Complete remission (CR) rates were comparable (95% and 77%, respectively). However, median event-free and overall survivals widely diverged among the 42 patients who achieved MRD-negative CR: not reached (NR) (95% confidence interval [CI]: 4.2-NR) vs. 6.3 months (95% CI, 4.8-9.0) (p = 0.0005), and NR (95% CI, 15.3-NR) vs. 17 months (95% CI, 8.5 – 36.2) (p = 0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p = 0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, both correlating with peak CAR T cell expansion (p = 0.0326 and p = 0.0001, respectively). **Conclusions:** Despite comparable initial CR rates regardless of pre-treatment disease burden, durability of 19-28z CAR T cell mediated remissions and survival in adult patients with relapsed B-ALL positively correlated to a low disease burden and do not appear to be enhanced by allogeneic transplant. Our findings strongly support the early incorporation of CD19 CAR therapy before morphologic relapse in B-ALL. Clinical trial information: NCT01044069.

An antibody derived from a cured AML patient to identify a unique epitope on CD43 (CD43s) as a novel target for acute myeloid leukemia and myelodysplastic syndrome. *First Author: Mette D. Hazenberg, Academic Medical Center, Amsterdam, Netherlands*

Background: Immunotherapy for acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) is hampered by the lack of tumor-specific targets. **Methods:** We took advantage of the tumor-immunotherapeutic effect of allogeneic hematopoietic stem cell transplantation (HSCT) and searched the B cell repertoire of a patient with a lasting and potent graft versus AML response for AML-specific antibodies. **Results:** We identified a donor-derived B cell clone that produced an IgG1 antibody, AT1413, that specifically interacted with AML cell lines, with the patient's autologous AML blasts, but not with lymphocytes or with cells from liver, colon, skin and other tissues. AT1413 recognized a unique, not previously described, sialylated epitope on CD43 (CD43s). CD43s is overexpressed on all types of AML and MDS, as illustrated by its reactivity with freshly isolated blasts of each of more than 60 randomly selected AML and MDS patients in our clinic, representing all WHO 2008 AML and MDS classes. AT1413 induced antibody-dependent cell-mediated cytotoxicity (ADCC) and complement dependent cytotoxicity (CDC) of target cells in vitro. To investigate the effect of AT1413 *in vivo*we first generated mice populated with human effector cells (NK cells, CTL and myeloid cells) by injecting human hematopoietic stem cells into new born immunodeficient mice. After establishment of a human immune system in these mice we inoculated luciferase labeled AML cells via tail vein injection. Following engraftment of the tumor we dosed the mice biweekly with AT1413 or a control antibody. We observed strongly reduced numbers of AML cells in AT1413- but not in control antibody treated mice. Importantly, AT1413 treatment was tolerated well and did not affect numbers of non-malignant human myeloid cell in these mice. **Conclusions:** We have obtained an antibody from a cured AML patient which recognizes a unique sialylated epitope on CD43 (CD43s) that is selectively over-expressed on all WHO 2008 types of AML and MDS. This antibody was able to eliminate AML cells *in vivo* and therefore has high therapeutic potential.

A phase I trial of ipilimumab (ipi) in patients (pts) with myelodysplastic syndromes (MDS) after hypomethylating agent (HMAs) failure. *First Author: Amer M Zeidan, Yale School of Medicine, New Haven, CT*

Background: Pts with HR-MDS after HMA failure have a poor overall survival (OS) of $<$ 6 months. Immune escape is associated with resistance to HMAs in MDS. We hypothesized that CTLA-4 blockade in these pts would be tolerable and lead to clinical responses. **Methods:** This investigator-initiated, CTEP-sponsored, multi-center phase 1b study enrolled pts after failure of HMAs. In dose-escalation, ipi monotherapy was given at 2 dose levels (DL): 3 and 10mg/kg. Four doses (every 3 weeks) were administered followed by a maintenance phase (4 doses every 3 months) for non-porgressors. Toxicities and responses were evaluated with CTCAE4 and IWG2006 criteria, respectively. OS was estimated using the Kaplan-Meier method. The impact on T-cells were studied by flow cytometry and TCR sequencing. **Results:** 29 pts from 7 centers were enrolled. Mean age (SD) was 67 (8) years. Most had IPSS high/int-2 (55%), 45% had int-1. Three of 6 pts in DL1 and 4 of 5 pts in DL2 experienced grade [G]2-4 immune-related adverse events [IRAEs] that were reversible with drug discontinuation or systemic steroids. The DL1 (3mg/kg) was expanded with no G2-4 IRAEs reported in the 18 additional pts. A total of 15 deaths occurred due to disease progression or other complications but none attributed to ipilimumab. In total, 52% received all 4 induction doses, and 24% received $\geq$1 maintenance dose. Best objective responses were 2 marrow complete responses (mCR, 7%). Prolonged stable disease (PSD) for $\geq$46 weeks occurred in 6 pts (21%) and for $\geq$54 weeks in 3 pts (10%). Five pts (17%) subsequently underwent allogeneic transplantation (alloSCT) without evidence of excessive toxicity. Median OS (censoring at alloSCT) was 294 days (95%CI, 240-671+) and 400 days (95%CI, 240-671+) for those who received maintenance (n = 7). Pts who achieved PSD and mCR had significantly increased expression of ICOS, a marker of T-cell activation. **Conclusions:** Immune checkpoint blockade with ipi is tolerable and can lead to PSD/mCR in a proportion of pts. However, ipi monotherapy efficacy is limited after HMA failure and combination-based approaches should be considered. Increased frequencies of ICOS expression might predict clinical benefit. Clinical trial information: NCT01757639.

Immune-related gene expression deficit of leukemia stem cells (LSC) in AML. *First Author: Kamal Chamoun, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: AML LSC are believed to be responsible for residual and resistant leukemic disease leading to relapse. Understanding differences between bulk AML and the LSC subpopulation may allow the identification of novel LSC targets, especially for the most adverse risk AML where few patients are cured. Targeting LSC may be needed to eradicate AML, and immune-based therapies provide an approach for eliminating LSC. The transcriptional landscape of immune-related genes in LSC is not well understood. **Methods:** Samples were collected at diagnosis from 12 patients with high-risk AML prior to therapy. Bulk (CD45-dim blasts) and LSC (Lin-CD34+CD38-CD123+) AML marrow cells were FACS-sorted and analyzed using whole genome RNA-sequencing. Transcriptomes were analyzed using AltAnalyze software to identify differentially expressed genes in bulk AML cells and in AML LSC populations. These genes were further assessed by gene enrichment analysis using data from Gene Ontology (GO) and the Cancer Genome Atlas Project (CGAP). **Results:** Sixty-eight genes were identified with greater than 3-fold differential expression between bulk AML and LSC. GO enrichment analysis demonstrated more than 10-fold enrichment of genes involved in the molecular functions, biologic processes, and cell components related to the antigen presentation pathway, with the comparative down-regulation occurring in LSC. Among the top differentially expressed gene clusters, both the MHC class II and interferon-gamma signaling/response pathway gene expression was blunted in LSC. Additional expression analysis revealed that 42% of a CGAP-curated list of 201 antigen-processing and -presentation genes had significantly decreased expression in the LSC subpopulation compared to bulk AML. **Conclusions:** LSC from primary AML patient samples are characterized by reduction in expression of MHC class II receptor and antigen presentation genes compared to bulk AML. These results suggest that impairment in the presentation and/or processing of tumor associated antigens by MHC class II on LSC, along with tonic sponging of immune response cells and diversion away from LSC by bulk AML, may contribute to LSC evasion of immune surveillance and response.

Five-year results of the ponatinib phase II PACE trial in heavily pretreated CP-CML patients (pts). *First Author: Hagop M. Kantarjian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The tyrosine kinase inhibitor (TKI) ponatinib has potent activity against native and mutant BCR-ABL1 and is approved for use in pts with relapsed/intolerant CML or Ph+ ALL, or with BCR-ABL1/T315I. **Methods:** In the pivotal PACE study (NCT01207440), ponatinib (starting dose 45 mg/d) was assessed in pts with CML or Ph+ ALL resistant/intolerant to dasatinib or nilotinib, or with T315I. In Oct '13, dose reductions were implemented due to observed arterial occlusive events (AOEs). Efficacy and safety at 5 yrs (data as of 3 Oct '16) for CP-CML pts are reported. **Results:** Of 270 CP-CML pts in the safety population, 60% received ≥3 prior TKIs. At initiation of study closure, 99 pts were ongoing; among these pts, minimum follow-up was 52 months, and most (78%) had 15 mg/d as their last dose. In all CP-CML pts (n = 267, efficacy evaluable), cumulative response rates were: MCyR, 60%; CCyR, 54%; MMR, 40%; and $MR^{4.5}$, 24%. Among pts who achieved MCyR (n = 148) or MMR (n = 108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62 – 83) and 61% (95% CI, 51 – 70), respectively. Regardless of dose reduction in Oct '13, maintenance of response was high (Table). KM estimated 5-yr rate for PFS/OS was 49%/77%. TEAEs in ≥45% of CP-CML pts were rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first year. The incidence of any AOEs/serious AOEs for CP-CML pts was 29%/23%. Among CP-CML pts with no prior AOEs who had a prospective dose reduction, 17% (11/63) had a first AOE occurring after Oct '13. **Conclusions:** Long-term (5-yr) results from PACE demonstrate that ponatinib continues to show clinical benefit, irrespective of dose reductions, with deep and lasting responses in heavily pretreated CP-CML pts. Safety results were consistent with the safety profile across the ponatinib clinical program. Clinical trial information: NCT01207440.

Frontline hyper-CVAD plus ponatinib for patients with Philadelphia chromosome-positive acute lymphoblastic leukemia: Updated results of a phase II study. *First Author: Nicholas James Short, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The combination of chemotherapy plus a TKI is highly effective in Ph+ ALL. In this phase II study, we evaluated the safety and efficacy of HCVAD in combination with the third-generation pan-*BCR-ABL* inhibitor, ponatinib. **Methods:** Patients (pts) with newly diagnosed Ph+ ALL received 8 cycles of HCVAD alternating with high dose MTX/Ara-C every 21 days. Ponatinib was given at 45 mg daily for the first 14 days of cycle 1. Initially ponatinib 45 mg daily was given indefinitely beginning at cycle 2. Due to concern for vascular events, a protocol amendment was made in which, beginning in cycle 2, pts in CR received 30mg daily and pts in CMR received 15mg daily. Rituximab and IT chemotherapy were given with the first 4 courses. After 8 cycles of HCVAD, pts in CR received maintenance with ponatinib, vincristine and prednisone for 2 years followed by indefinite ponatinib. **Results:** 64 pts have been treated, 10 of whom had received prior treatment with another regimen (8 in CR, 2 not in CR). Median age was 48 years (range, 21-80) and median follow-up was 33 months (range, 2-62). Median cycles received was 6 (range, 2-8). 63 pts (98%) achieved CR after 1 cycle; 1 pt achieved CRp. CCyR was achieved in 98%, MMR in 97% and CMR in 77%. Median time to CMR was 10 weeks (range, 2-96). Median times to platelet and ANC recovery in cycle 1 were 22 and 18 days, respectively, and for subsequent cycles were 22 and 16 days, respectively. Grade ≥3 pancreatitis was observed in 12 pts (19%), thrombotic events in 4 (6%) and MI in 3 (5%). 8 pts have died, with 2 deaths attributed to ponatinib (both from MI). No grade ≥3 vascular events occurred after the protocol amendment. 38 pts continue to receive treatment (7 in consolidation, 14 in maintenance and 17 post-maintenance). 10 pts (16%) underwent allogeneic SCT in CR1. 7 pts have relapsed, 3 of whom were still receiving ponatinib. The 3-year continued remission and OS rates were 79% and 76%, respectively. In a landmark analysis at 4 months, CR duration and OS did not differ significantly in pts with or without allogeneic SCT. **Conclusions:** HCVAD plus ponatinib is highly effective in pts with newly diagnosed Ph+ ALL, resulting in high rates of CMR and promising long-term survival. Clinical trial information: NCT01424982.

Updated results of a phase I/II study of inotuzumab ozogamicin in combination with low-intensity chemotherapy (mini-hyper-CVD) as frontline therapy for older patients with acute lymphoblastic leukemia. *First Author: Nicholas James Short, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Inotuzumab ozogamicin (InO) is an anti-CD22 antibody-toxin conjugate that is effective in patients (pts) with relapsed/refractory ALL. Given the poor tolerance of elderly pts to intensive chemotherapy, we evaluated the safety and efficacy of low-intensity chemotherapy (mini-hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL. **Methods:** Pts ≥60 years of age with newly diagnosed Ph-negative pre-B ALL received mini-hyper-CVD (no anthracycline, dose reductions of cyclophosphamide, dexamethasone, MTX and Ara-C). Pts received InO 1.3-1.8 mg/m2 on day 3 of cycle 1 and 0.8-1.3 mg/m2 on day 3 of cycles 2-4. Rituximab (if CD20+) and prophylactic IT chemotherapy were given for the first 4 cycles. Responding pts received POMP maintenance for up to 3 years. **Results:** 47 pts have been treated, 4 of whom were in CR at enrollment. Median age was 68 years (range, 60-81) and median CD22 expression was 97% (range, 72-100%). Among 43 pts evaluable for response, 41 (95%) achieved CR or CRp (CR, n = 36, CRp, n = 5). 1 pt achieved CRi and 1 did not respond. MRD negativity by 6-color flow cytometry was achieved in 31/41 pts (76%) after 1 cycle and in 44/46 pts (96%) overall. Median times to platelet and ANC recovery in cycle 1 were 23 and 16 days, respectively, and for subsequent cycles were 22 and 17 days, respectively. Prolonged thrombocytopenia (> 6 weeks) occurred in 37 pts (79%). 4 pts (9%) developed VOD, 1 after allogeneic stem cell transplant (ASCT) and 3 unrelated to ASCT. Only 1 pt developed severe VOD. Among 46 responders, 6 (13%) relapsed, 3 (7%) underwent ASCT in CR1, 27 (59%) remain on treatment or have completed maintenance, and 10 (22%) died in CR/CRp. With a median follow-up of 24 months, the 3-year continued remission and OS rates were 72% and 54%, respectively. Compared to a historical cohort of older pts treated with hyper-CVAD ± rituximab (n = 79), mini-hyper-CVD + InO resulted in significantly higher 3-year OS (54% vs 31%; P = 0.007). **Conclusions:** Mini-hyper-CVD plus InO is safe and effective in elderly pts with newly diagnosed ALL and appears to improve outcomes compared to hyper-CVAD in this population. Clinical trial information: NCT01371630.

Differentiation syndrome associated with enasidenib, a selective inhibitor of mutant isocitrate dehydrogenase 2 (mIDH2). *First Author: Amir Tahmasb Fathi, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Enasidenib (AG-221), an oral mIDH2 inhibitor, promotes myeloid differentiation of leukemic blasts. Enasidenib treatment (Tx) can result in IDH-inhibitor-associated differentiation syndrome (IDH-DS), with manifestations akin to retinoic acid syndrome seen during acute promyelocytic leukemia Tx. **Methods:** A phase 1 dose-escalation/expansion study (N = 239) (NCT01915498) included 109 pts with relapsed/refractory AML who received enasidenib 100 mg /day. An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential IDH-DS cases. The DSRC identified and agreed on signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. Of the 109 pts, the DSRC identified and retrospectively reviewed 27 cases (8 investigator reported IDH-DS cases and 19 cases suggestive of IDH-DS) to determine consistency with IDH-DS. **Results:** The DSRC found 13 of the 27 cases to be consistent with IDH-DS (11.9% of 109 pts). Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in > 2 pts were dyspnea (n = 10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4 cases and hydroxyurea was used for cytoreduction. Enasidenib was interrupted for 9 pts (median 7 days) but dose reductions or discontinuation were not required. Six of 13 pts had clinical responses (2 complete remission [CR], 2 CR with incomplete hematologic recovery, 1 partial remission, 1 morphologic leukemia-free state), 6 had stable disease and 1 had progressive disease. **Conclusions:** Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective management strategies, should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in m*IDH2* AML treated with enasidenib, and is likely due to its suggested mechanism of action, differentiation. Clinical trial information: NCT01915498.

7016 Poster Discussion Session; Displayed in Poster Session (Board #216), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Effect of cytarabine/anthracycline/crenolanib induction on minimal residual disease (MRD) in newly diagnosed FLT3 mutant AML. *First Author: Richard M. Stone, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Baseline characteristics such as age >60, WBC>100,000/μL and *FLT3/NPM1/DNMT3A*+ve are known to be associated with a poor prognosis in AML. Ivey et al. (NEJM 2016) reported that *FLT3-ITD+ve* patients (pts) who were MRD+ve after 2 cycles of induction chemotherapy were more likely to relapse as compared to those who became MRD-ve (92% vs 35%). Eradication of *FLT3+ve*clones may lead to reduced relapse rates. Crenolanib is a type I FLT3 TKI, which inhibits both FLT3-ITD and TKD mutations. We here report that a single induction cycle of cytarabine/anthracycline/crenolanib leads to MRD negativity by multiparameter flow cytometry (MPF), and low rate of early relapse in pts with newly diagnosed *FLT3+ve*AML. **Methods:** This abstract includes 29 consecutively treated, newly diagnosed, *FLT3+ve* AML pts, who achieved CR1 after one course of cytarabine/anthracycline/crenolanib. Pts received 7+3 induction with cytarabine 100 mg/m^2/d for 7d and either daunorubicin (<60 y: 90 mg/m^2; ≥60 y: 60 mg/m^2) or idarubicin 12 mg/m^2 for 3d. Crenolanib (100 mg TID) was started on day 9 until 72 h prior to next chemotherapy. **Results:** 29 pts (15M, 14F), median age 55y (10pts ≥60y) are included. MRD at time of count recovery was assessed by MPF in 25/29 pts. 20/25 (80%) became MRD–ve. With a median follow up of 7mth, 4/25 pts have relapsed (2/5 MRD+ve, 2/20 MRD-ve).Age ≥60 was a risk factor for MRD+ve and relapse. All 4 pts with WBC>100K as well as 5 pts with *FLT3/NPM1/DNMT3A+ve* AML became MRD-ve after one induction cycle and none have relapsed. **Conclusions:** These data suggest, in the context of an ongoing trial (NCT02283177), crenolanib in combination with standard induction is associated with a high rate of achieving an MRD negative state by MPF and a low rate of relapse in previously untreated adults with mutant *FLT3*. Longer follow-up and comparison of MRD data with similar pts treated with standard chemo alone will be necessary to reach more definitive conclusions. Clinical trial information: NCT02283177.

Sub-group	MRD-ve	Relapse free
Total	20/25 (80%)	21/25 (84%)
MRD-ve at CR1	20	18/20 (90%)
MRD+ve at CR1	5	3/5 (60%)
<60y	14/15 (93%)	14/15 (93%)
≥60y	6/10 (60%)	7/10 (70%)
WBC >100,000/μL	4/4 (100%)	4/4 (100%)
FLT3/NPM1/DNMT3A+ve	5/5 (100%)	5/5 (100%)

Outcomes with lower intensity therapy in TP53-mutated AML. *First Author: Tapan M. Kadia, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: *TP53* mutations confer an adverse prognosis in patients (pts) with AML treated with standard chemotherapy. A recent study reported high response rates using a 10-day regimen of decitabine (DAC10) in pts with *TP53*-mutated (*TP53*-MUT) AML. The question remains whether this benefit is unique to DAC10 or whether the same benefit among *TP53*-MUT AML applies to other low intensity therapy (Rx). **Methods:** We reviewed our own experience of pts treated with low intensity Rx from 2012 - 2016. Mutation testing was performed using a whole-exome sequencing panel. We reviewed the clinico-pathologic characteristics of these pts, and compared their outcomes based on the presence/absence of a *TP53*mutation and by the type of Rx they received. **Results:** There were 131 pts in our cohort of which 33 (25%) had *TP53*-MUT. Pt characteristics are outlined in Table 1A. All pts were treated with low intensity Rx and were divided into the following groups: DAC10 [n=34, 26%]; 5-day decitabine, or 7-day azacytidine (DAC5) [n=39, 30%]; or cladribine+low dose araC (CLAD/LDAC) [n=58, 44%]. Response rates and OS by Rx and *TP53*-MUT status are summarized in Table 1B. While there was no significant difference in response rates or OS by *TP53*-MUT status within any of the treatment approaches, there was a trend for inferior response rates and OS among pts with *TP53*-MUT who received either DAC-5 or CLAD/LDAC ; this was not seen in pts receiving DAC10. **Conclusions:** The presence of a *TP53*-MUT was associated with a nonsignificant trend towards inferior outcomes among pts receiving DAC5 or CLAD/LDAC, but not among those receiving DAC10. Comparing across groups, the CLAD/LDAC combination was associated with the longest OS, and DAC10 was associated with superior outcomes compared to DAC5, in *TP53*-MUT cohort.

Charac. Median (range) or N, [%]	*TP53* – Mut	*TP53* – WT
N	33	98
Age	75 (62-90)	72 (61-91)
WBC	3.2 (0.5-26.9)	3 (0.2-77.8)

Achievement of a negative minimal residual disease state after hypomethylating agent therapy in older patients with AML to reduce risk of relapse. *First Author: Prajwal Boddu, MD Anderson Cancer Center, Houston, TX*

Background: Persistence of minimal residual disease (MRD) post therapy is a powerful predictor of outcome in patients with AML treated with traditional cytarabine and anthracycline based regimens. The clinical relevance of MRD in the context of hypomethylating agents has not been evaluated extensively. **Methods:** Among 194 patients with AML treated with single agent azacytidine, decitabine, or gaudecitabine, 116 (median age 76, range 60 - 92) had MRD analysis performed on bone marrow specimens obtained at time of assessment of response or thereafter; among them 69 (59%) achieved either morphologic complete remission (CR) or CR with incomplete recovery of platelets (CRp) or counts (CRi), and 61 (53%) had evaluable MRD data; MRD was assessed using an 8-color flow panel, with a detection sensitivity of 0.01%. **Results:** Median cycles to achieving response was 2 (range, 1-6). Sixty one patients had evaluable MRD data at the time of response, of whom 19 (28%) became MRD negative (-). This was associated with a reduced cumulative risk of relapse (p = 0.012) but did not translate to an improved relapse-free survival (RFS; p = 0.17) or overall survival (OS; p = 0.79) due to high frequency of non-relapse deaths (attributable to comorbidities and infections) in the MRD- group. Patients who achieved a MRD- state at the time of achieving response had a higher mortality [5/8 (62%)] when compared with those who achieved a MRD- state in subsequent cycles [1/13 (7.6%); p = 0.01], resulting in an inferior OS (6.2 months (mo) vs 20 mo, p = 0.012). Similarly, achieving negative MRD at CR and at any time up to 3 months post response was not associated with improved RFS or OS despite a lower cumulative risk of relapse (p = 0.045). There was no impact of MRD, on OS, whether the MRD- state was achieved after 1st, 3rd or 6thcycle of therapy. Association between depth of MRD response at time of remission and RFS was borderline significant (p = 0.08). On multivariate analysis, response (CR vs CRi/CRp), but not a negative MRD, was predictive for RFS or OS. **Conclusions:** In this cohort of older AML patients treated with hypomethylating agents, achieving a MRD- state was associated with a reduced risk of relapse but not improved RFS or OS.

7019 Poster Discussion Session; Displayed in Poster Session (Board #219), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

A Bayesian randomized phase II study of guadecitabine (SGI-110) based regimens comparing guadecitabine 5 days (SGI5), 10 days (SGI10), 5 days + idarubicin (SGI5 + Ida), 5 days + cladribine (SGI5 + Clad), in untreated patients ≥ 70 years with acute myeloid leukemia (AML). *First Author: Kiran Naqvi, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Guadecitabine is a next generation hypomethylating dinucleotide of decitabine and deoxyguanosine resistant to degradation by cytidine deaminase. This allows prolonged exposure of leukemia cells to its active metabolite, decitabine. We aimed to compare the efficacy and safety profile of guadecitabine in untreated ≥ 70 years AML patients. **Methods:** Untreated patients ≥ 70 years with AML were randomized in a phase 2 Bayesian design in one of the 4 arms: guadecitabine 60mg/m^2/daily x 5 (SGI5), guadecitabine 60mg/m^2/daily x 10 (SGI10), SGI5 + Ida (6mg/m^2/daily x 2), or SGI5 + Clad (3mg/m^2/daily x 5). The Bayesian design evaluated response and toxicities simultaneously. Primary objective was complete remission (CR) rate and remission duration. Survival was estimated using the Kaplan-Meier method. **Results:** Between June 2014 and Nov 2016, we treated 34 patients: 8 in SGI5; 9 in SGI10; 8 in SGI5 + Ida and 9 in SGI5 + Clad. Median age was 75 years. 38% had complex karyotype. Median follow-up was 8.3 months. Overall response rate (ORR= CR + CRi) was 53%, shown in the table below. Median remission duration was 7.4 months. 4 week mortality was 3%. Median survival is 13.1 months. A trend for superior survival was observed with SGI5 + Ida (median survival not reached; p=0.22). Common G3/4 toxicity included febrile neutropenia (48%), thrombocytopenia (26%), leukopenia (22%) and anemia (11%). **Conclusions:** Guadecitabine is clinically active and safe as single agent and in combination in elderly patients with untreated AML. A separate previously reported multicenter study showed no difference between SGI5 vs SGI10 in 103 treatment naïve elderly AML patients (Kantarjian et al. Blood 2015 126:458). CR and ORR were lower with SGI5 + Clad. Based on these findings, the study continues now comparing SGI5 vs SGI5 + Ida.

Response no. (%)	SGI5 (n=8)	SGI 10 (n=9)	SGI5+Clad (n=9)	SGI5+Ida (n=8)	Total (n=34)
CR	1 (13)	5 (56)	0	6 (75)	12 (35)
CRi	2 (25)	1 (11)	1 (11)	2 (25)	6 (18)
PR	0	0	1 (11)	0	1 (3)
Early death (4 weeks)	0	1 (11)	0	0	1 (3)
CR+CRi	3 (38)	6 (67)	1 (11)	8 (100)	18 (53)

7020 Poster Discussion Session; Displayed in Poster Session (Board #220), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Updated results from phase II study of guadecitabine for patients with higher risk myelodysplastic syndromes or chronic myelomonocytic leukemia. *First Author: Guillermo Montalban-Bravo, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Improving the current response and survival outcomes of patients with higher risk MDS and CMML is fundamental. Guadecitabine is a next generation hypomethylating agent with increased length of exposure compared to decitabine and clinical activity in patients with MDS. **Methods:** Single arm phase 2 clinical trial of guadecitabine at a dose of 60mg/m^2 sc daily for 5 days (days 1-5) every 28 days for patients with newly diagnosed MDS or CMML classified as Intermediate-2 or High risk by IPSS. Primary endpoint is complete response (CR). Responses were evaluated following the revised 2006 International Working Group criteria. Sequencing data was obtained at the time of pre-treatment evaluation by the use of a 28-gene next generation sequencing platform. Study included stopping rules for response and toxicity. Overall survival (OS) was censored at the time of transplant. **Results:** A total of 53 patients have been enrolled: 50 (94%) are evaluable for toxicity and 44 (83%) for response. Median age is 67 years (49-87). A total of 43 (86%) patients have MDS and 7 (14%) have CMML. A total of 21 (42%) have complex karyotype. Sequencing data was available in 48 (96%) patients with *TP53* mutations being the most frequently detected in 36% patients. After a median of 6 treatment cycles (1-20), the ORR is 71% including 32% CR. Median best response occurred by 3 cycles (1-6). Seven (21%) out of 33 evaluable patients achieved a complete cytogenetic response. Ten (20%) subjects proceed to allogeneic stem cell transplantation. Median follow up was 6.3 months (0-23). Median OS is 14.1 months (CI 13.3-14.9 months) and median EFS is 8.4 months (CI 5.6-11.2 months). Forty-five (90%) patients experienced at least one AE during therapy. Most common grade 1-2 AEs included fatigue (66%), nausea (38%) and dyspnea (26%). Dose reductions due to cytopenias were required in 17 (34%) patients. Early 8-week mortality occurred in 3 (6%) patients. **Conclusions:** Guadecitabine is well-tolerated and active in patients with higher-risk MDS and CMML even in the presence of adverse biological features such as high frequency of complex karyotype, therapy related disease and *TP53* mutations. Clinical trial information: NCT02131597.

7021 Poster Session (Board #221), Mon, 8:00 AM-11:30 AM

Creating a synthetic control arm from previous clinical trials: Application to establishing early end points as indicators of overall survival in acute myeloid leukemia (AML). *First Author: Donald A. Berry, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clinical trials of experimental drugs require controls. Concurrently randomized controls are the gold standard for judging drug effect. Historical controls are not ideal but are much more efficient and economical. Historical controls derived from a single clinical trial have the biases of that trial. Using many trials with comparable end points and eligibility minimizes such bias. Medidata's archive contains >3000 trials with clinical data rights for deidentified aggregated analyses. We used this resource to develop a synthetic control arm (SCA) for a particular phase I/II single-arm trial in AML. We demonstrate the utility of this approach by addressing a different but equally important issue: establishing early end points as predictors of long term clinical outcomes. **Methods:** We built an SCA from 7 relapsed/refractory AML trials completed in last 5 yrs. They had similar eligibility criteria as a particular phase I/II trial for an investigational agent. We selected subjects for the SCA who had baseline covariates matching the subjects in the tri.al. Data cleaning and standardization ensured consistency of data fields. The primary outcomes were CR (complete remission) and CRi (CR without hematologic recovery) at 56 days, and overall survival (OS) subsequent to 56 days. Non-CR/non-CRi deaths before 56 days were set to OS=0. We used a landmark analysis to correlate CR and CRi with OS, calculating the hazard ratio (HR) of OS of CR and CRi vs its comparison group. **Results:** The SCA included 340 subjects (median age 63 yrs, 55% male, 77% White Non-Hispanic, 28% ECOG 0). Results are in this table. **Conclusions:** The Medidata trial archive is a resource for creating SCAs. The example SCA we created identified well-defined subjects for whom a CR or CRi is associated with longer OS. Investigations of SCAs for other drugs could aid in addressing the types of subjects and drug categories for which CR or CR/CRi predict longer OS. Such information can help build more efficient and more informative adaptive clinical trials.

	N	Median OS (wks)	Com-parison	HR	p value
CR	35	64	CRi	0.22	<0.001
CRi	51	23	Other	0.44	<0.001
CR/CRi	86	30	Other	0.28	<0.001
Other	254	11	–	–	–

7022 Poster Session (Board #222), Mon, 8:00 AM-11:30 AM

Molecular genetic testing patterns for patients with newly diagnosed acute myeloid leukemia (AML) enrolled in the CONNECT MDS/AML disease registry. *First Author: Daniel Aaron Pollyea, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previously the CONNECT MDS/AML Disease Registry (George et al. ASH 2016. Abstract 3548) showed suboptimal adherence to WHO 2008 recommendations for AML in a cohort of newly diagnosed (ND) AML patients (pts) in clinical practice. Here we report a detailed analysis of patterns of molecular genetic testing in pts with ND AML in community and academic settings. **Methods:** The CONNECT MDS/AML Disease Registry (NCT01688011) is a US prospective, observational cohort study of pts with ND AML (≥55 years) or MDS. Enrollment is ongoing. All clinical decisions are made by study clinicians. The current analysis evaluated the percentage of pts with AML with molecular genetic testing recommended by NCCN guidelines (*NPM1*, *FLT3-ITD*, *CEBPA*, *IDH1*, *IDH2*, *DNMT3A*, and *KIT*). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing. **Results:** Between 12 Dec 2013, and 8 Dec 2016 (data cutoff), 259 AML pts were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of pts. Likelihood of testing varied, respectively, for academic vs community sites (76% [70/92] vs 62% [103/167], P= .018), normal vs abnormal karyotype (77% [79/103] vs 59% [79/133], P= .006), age < 65 vs ≥65 (83% [65/78] vs 60% [108/181], P= .0003), and Medicare vs other insurance (61% [83/137] vs 74% [90/122], P= .025). In pts with molecular genetic testing (n = 173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of pts, including 8% (6/79) of those with normal karyotype. Of the 7 NCCN-recommended tests, *NPM1* (77%) and *FLT3-ITD* (76%) were most often reported and *DNMT3A* least often (16%). **Conclusions:** Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of ND AML pts, a majority do not receive guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

7023 Poster Session (Board #223), Mon, 8:00 AM-11:30 AM

Genomic landscape of adult mixed phenotype acute leukemia (MPAL). *First Author: Kiyomi Morita, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MPAL is a rare subgroup of acute leukemia characterized by both myeloid and lymphoid phenotypes. Genetic basis of MPAL is not well understood. **Methods:** We studied 31 patients (pts) with MPAL (median age 53) that met 2008 WHO criteria. Bone marrow samples were studied by targeted capture sequencing of 295 genes (median 393x), RNA sequencing, and Infinium methylation EPIC array (Illumina). Mutational landscape was compared to 194 AML, 71 B-ALL, and 6 T-ALL cases. Promoter methylation pattern was compared to the data from 194 AML (TCGA), 505 B-ALL and 101 T-ALL cases (Nordlund et al. Genome Biology. 2013). **Results:** Eighteen (58%) pts had myeloid-T and 13 (42%) had myeloid-B phenotype. Four pts had t(9;22), 1 had 11q23 rarrangement, and 8 had complex karyotype. MPAL had similar number of mutations with AML but had higher number of mutations than B-ALL or T-ALL. Both AML-type and ALL-type mutations were detected in MPAL, supporting the mixed phenotypic features. However, *NPM1*, *CEBPA* and *GATA2* mutations were specific to AML and were not found in MPAL. Myeloid-T and myeloid-B showed distinct patterns of mutations, in which *DNMT3A*, *IDH2, NOTCH1, IL7R,* and *FBXW7* mutations were enriched in myeloid-T whereas *RUNX1* mutations were enriched in myeloid-B. Myeloid-T and myeloid-B also showed distinct patterns of promoter methylation. Overall, myeloid-T had more hypermethylated CpG loci than myeloid-B. Genes that have essential role in T-cell receptor (TCR) pathway (*CD3D*, *CD7*, *CD247*, *LCK*, *PRKCQ, CCR9, and TCL1A*) were differentially methylated and differentially expressed between myeloid-T and myeloid-B. RNA sequencing revealed several known translocations such as, *NSD1-NUP98*, and *KMT2A-MLLT4,* in addition to the novel fusion proteins such as *FOXP1-DNAJC15*, *RUNX1-NAP1L1*, and *BCL2-TM9SF3*. Unbiased hierarchical clustering of MPAL, AML, B-ALL and T-ALL by promoter methylation revealed that myeloid-T had consistent similarity with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML. **Conclusions:** MPAL is genetically heterogeneous and myeloid-T and myeloid-B shows distinct patterns of mutations, methylation and gene expressions. Therapy for MPAL may need to be tailored based on the genetic profiles.

7024 Poster Session (Board #224), Mon, 8:00 AM-11:30 AM

Baseline and early post-treatment clinical and laboratory factors associated with severe neurotoxicity following 19-28z CAR T cells in adult patients with relapsed B-ALL. *First Author: Jae Hong Park, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CD19-specific chimeric antigen receptor (CAR) modified T cells produce high anti-tumor activity in relapsed or refractory (R/R) ALL, but can be associated with cytokine release syndrome (CRS) and neurotoxicity (NTX). Herein, we report baseline and post-treatment clinical and laboratory factors associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069). **Methods:** 51 adult pts with R/R B-ALL were treated with 19-28z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (sNTX), we examined demographic, treatment, and clinical blood parameters as well as in vivo CAR T expansion and serum cytokines, and performed univariate and multivariate analysis. **Results:** In this cohort of ALL pts, 20, 8, 2, 18 and 3 pts experienced Gr 0, 1, 2, 3, and 4 NTX, respectively. No pt developed grade 5 NTX. Disease burden (≥50% blasts) at the time of T cell infusion ($p = 0.0045$) and post-treatment ≥Gr3 CRS ($p = 0.0010$) were significantly associated with sNTX, but we found no association with age, weight, T cell dose, choice of conditioning chemotherapy (Flu/Cy s. Cy), and prior lines of treatment. Among the clinical and blood parameters, fever, low PLT, high ferritin and MCHC as well as elevated GM-CSF, IFNγ, IL-15, IL-5, IL-10, IL-2 at day 3 of T cell infusion at day 3 of T cell infusion were significantly associated with sNTX (all $p < 0.01$). While some of these cytokines were also elevated in severe CRS cases, IL-5 and IL-2 at day 3 were unique to sNTX. Furthermore, in vivo peak CAR T expansion at day 7 ($p = 0.0001$) significantly correlated with sNTX ($p < 0.01$). Lastly, multivariate analysis revealed baseline PLT < 60 or MCHC > 33.2% and morphologic disease (> 5% blasts) has 95% sensitivity and 70% specificity of identifying sNTX pts. **Conclusions:** These data provide a characterization of early clinical and serum biomarkers of sNTX in adult pts receiving 19-28z CAR T cells and should help identify appropriate pts for early intervention strategy to mitigate NTX. Clinical trial information: NCT01044069.

7025 Poster Session (Board #225), Mon, 8:00 AM-11:30 AM

Inotuzumab ozogamicin (IO) combined with mini-hyper-CVD as salvage therapy for patients (pts) with R/R acute lymphoblastic leukemia (ALL). *First Author: Rita Assi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Outcome of pts with R/R ALL is poor. IO, a CD22 monoclonal antibody bound to a toxin, calicheamicin, has single-agent activity in R/R ALL with response rate of 80% and median survival of 7.7 months. Adding IO to low-intensity chemotherapy might further improve clinical outcomes. **Methods:** Pts ≥18 years with R/R ALL were eligible. Chemotherapy was of lower intensity than standard hyper-CVAD and referred to as mini-hyper-CVD (cyclophosphamide and dexamethasone at 50% dose reduction (DR), no anthracycline, methotrexate at 75% DR, cytarabine at 0.5 g/m^2 x 4 doses). Rituximab (if CD20+ blasts) and intrathecal chemotherapy were given for first 4 courses. IO was given on day 3 of each of the first 4 courses at a dose of 1.8 mg/m2 for cycle 1 then 1.3 mg/m2 for subsequent cycles. After the occurrence of veno-occlusive disease (VOD), IO was modified to 1.3 mg/m2 for cycle 1 followed by 1.0 mg/m2 for subsequent cycles. **Results:** Sixty pts with a median age of 35 years (range 18-87) were treated. Overall, 47 pts (80%) responded, 32 of them (54%) achieving complete response. The overall minimal residual disease negativity rate among responders was 82%. Grade 3-4 toxicities included prolonged thrombocytopenia (79%), infections during induction and consolidations (52%, and 73% respectively), and hyperbilirubinemia (13%). VOD of any grade occurred in 9 patients (15%). At a median follow-up of 19 months, the median relapse-free survival (RFS) and overall survival (OS) were 9 and 11 months, respectively. The 2-year RFS and OS rates were 33% and 38%. The 2-year OS rates for patients treated in salvage (S)1, S2, and S3 and beyond were 53%, 0%, and 34%, respectively ($p = 0.005$). When compared to IO monotherapy in a similar pts population, a significant improvement in OS was observed (11 and 6 months, respectively; $p = 0.003$). **Conclusions:** The combination of IO with low-intensity mini-hyper-CVD chemotherapy is effective in pts with R/R ALL. Results are encouraging and appear superior to those obtained with IO alone, particularly in pts treated in S1. The risk of VOD should be considered carefully for transplant candidates and pts with previous liver damage. Lower dose of weekly schedules of IO are being explored Clinical trial information: NCT01371630.

7026 Poster Session (Board #226), Mon, 8:00 AM-11:30 AM

Phase IB/II study of nivolumab with azacytidine (AZA) in patients (pts) with relapsed AML. *First Author: Naval Guastad Daver, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Blocking PD-1/PD-L1 pathways enhances anti-leukemia responses in murine AML (Zhang et al, Blood 2009). PD-1 positive CD8 T-cells are increased in bone marrow (BM) of pts with AML (Daver et al, ASH 2016). AZA up-regulates PD-1 in AML (Yang et al., Leukemia 2013). **Methods:** Pts were eligible if they had AML and failed prior therapy, had adequate performance status (ECOG ≤ 2), and organ function. AZA 75mg/m^{2}Days 1-7 with nivolumab 3mg/kg on Day 1 and 14 was established as the recommended phase II dose. Courses were repeated every 4-5 weeks indefinitely. Responses were evaluated at the end of 3 courses. **Results:** 53 pts with med age 68 years (range, 44 – 90), secondary AML (43%), poor risk cytogenetics (43%), med prior regimens 2 (range, 1-7) have been enrolled. Common mutations included *DNMT3A* (n = 11), *TP53* (n = 11), *TET2* (N = 8), *CEBPA* (n = 8), *ASXL1* (n = 8). All 53 pts are evaluable for response: 11 (21%) achieved CR/CRi and 7 (14%) had hematologic improvement (HI) for an overall response rate of 35%. Additionally, 14 (26%) had ≥50% BM blast reduction, 3 (6%) had stable disease > 6 months, and 12 (23%) had progression. The CR/CRi have been durable with 9 of 11 (82%) pts with CR/CRi alive at 1 year, after censoring for SCT. Med survival for the 53 evaluable pts was 5.7 months (range, 0.9 – 16.2) and in the 27 salvage 1 pts was 9.3 months (range, 1.6 – 16.2). These compare favorably to historical survival with AZA-based salvage protocols at MDACC. Grade 3/4 and Grade 2 immune toxicities were observed in 7 (14%) and 6 (12%) pts, respectively. These responded rapidly to steroids and 12 of 13 pts were successfully rechallenged with nivolumab. Multicolor flow-cytometry data were available on pretherapy, end of cycle 1, and end of cycle 2 BM aspirates in 9 CR/CRi and 22 non-responders. Pts who achieved CR/CRi had higher pre-therapy total CD3 ($P = 0.02$) and higher CD8$^+$ T-cells ($P = 0.07$) infiltrate in the BM. Responders demonstrated progressive increase in BM CD8$^+$ and CD4$^+$ infiltrate. Both responders and non-responders had increase in CTLA4$^+$ CD8$^+$ cells on therapy. **Conclusions:** Full dose AZA and nivolumab are tolerable and may produce durable responses in relapsed AML. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML. Clinical trial information: NCT02397720.

7027 Poster Session (Board #227), Mon, 8:00 AM-11:30 AM

Dose escalation results of a phase 1b study of the MDM2 inhibitor AMG 232 with or without trametinib in patients (Pts) with relapsed/refractory (r/r) acute myeloid leukemia (AML). *First Author: Harry Paul Erba, University of Alabama at Birmingham, Birmingham, AL*

Background: The ubiquitin ligase MDM2 inhibits the tumor suppressor p53. In preclinical AML models, MDM2 inhibitors have antitumor activity as monotherapy that is synergistic when combined with MEK inhibitors. This open-label phase 1b study assessed the maximum tolerated dose (MTD), pharmacokinetics (PK), and preliminary antitumor activity of the investigational oral, selective MDM2 inhibitor AMG 232 as monotherapy or combined with the MEK kinase inhibitor trametinib in pts with r/r AML. **Methods:** Pts with r/r AML received AMG 232 for 7 days every 2 weeks (7 days on/7 days off) at 60, 120, 240, 480, and 960 mg PO QD as monotherapy (Arm 1) or combined with trametinib 2 mg PO QD (Arm 2). Primary endpoints were the incidence of adverse events (AEs), dose-limiting toxicities (DLTs), and PK. Additional endpoints included best response (revised IWG) and serum MIC-1 level (increased MIC-1 suggests p53 activation). p53 target gene (*P21*, *BAX*, and *PUMA*) expression in bone marrow was assessed by microarray. **Results:** In total, 35 pts (Arm 1, n = 26; Arm 2, n = 9; median age, 68 y; range, 26–86) were treated. Arm 1 enrolled AMG 232 at 60 mg (n = 4), 90 mg (n = 4), 180 mg (n = 5), 240 mg (n = 3), and 360 (n = 10). Twenty-two (85%) pts in Arm 1 had treatment-related AEs; the most common were nausea (n = 14), diarrhea (n = 14), and vomiting (n = 6). No DLTs occurred; one pt is still on treatment. The MTD was determined as 360 mg based on tolerance of gastrointestinal toxicity. Arm 2 enrollment is ongoing at a fixed AMG 232 dose of 60 mg plus trametinib (n = 9). AMG 232 plasma exposure increased with dose escalation; PK was unaffected by trametinib. Trametinib PK was as expected. Increases from baseline (BL) to day 10 in serum MIC-1 were dose dependent. Evidence of increased *P21*, *BAX*, and *PUMA* expression (BL to day 7 or 8) was seen (n = 3). One pt (Arm 2) had complete remission (CR); three pts (Arm 1) achieved CRi/MLFS. Median response duration was 66 days [range, 21–377+]). **Conclusions:** AMG 232 monotherapy was tolerable in pts with r/r AML at doses up to 360 mg on a 7 days on/7 days off schedule with expected PK, on-target biological effects, and early evidence of antileukemia activity. Clinical trial information: NCT02016729.

7028 Poster Session (Board #228), Mon, 8:00 AM-11:30 AM

Efficacy of anti-CD19 chimeric antigen receptor modified T(CAR-T) cell therapy in Chinese patients with relapsed/refractory acute lymphocytic leukemia in a multicenter trial. *First Author: Lei Xiao, Innovative Cellular Therapeutics Co., LTD., Shanghai, China*

Background: r/r B-ALL was reported as the most-threatening disease because of the low disease free survival even treatment with allogeneic hematopoietic stem cell transplantation. For overcoming conventional therapies limitation, autologous CD19CAR-T was performed in our clinical trials to induce remission in patients with r/r disease. 30 patients (from 7 clinical centers, in China) as volunteers with r/r B-ALL were treated by autologous CD19 CAR-T. **Methods:** 5 juveniles and 25 adults with r/r ALL received autologous CD19 targeted CAR-T, the doses between 1.03×10^6 CAR-T cells/kg and 10.09×10^6CAR-T cells/kg. These 30 cases(from 7 clinical centers, in China) were treated with CAR-T cells from May. 8 2015 to January. 4 2017 (Table1). Patients were monitored for a response. Highly standardized CAR T cell preparation protocol and manageable CRS in most were kept for no significant difference in 7 clinical centers. **Results:** After treated with CAR-T, a total of 30 cases (5 juveniles and 25 adults coming from 7 clinical centers, in China) with r/r B-ALL were all detected the CAR-T cells proliferated in the blood and bone marrow. The results showed that complete remission (CR) is 26/30(86.67%) between day7-14 after CD19 CART cell infusion, and 25/30(83.33%) cases arrived at MRD negative. There is about 1/3 of the total cases receiving a repeat infusions following initial ones since these patients have no safety concerns. Additionaly, the severe Cytokine release syndrome (CRS) was 8/30(26.67%) of cases and 24/30(80%) of cases was seen CRS. The anti-IL6R agent tocilizumab and Methylprednisolone were effective confrontation Severe CRS. **Conclusions:** This is the first multicentre report to our knowledge of successful treatment of r/r ALL with anti-CD19 CAR T cells in China. Even r/r B-ALL with high-burden leukemia patients also was effective and associated with a high remission rate after infused autologous CD19 CAR-T).(NCT 02813837).

7029 Poster Session (Board #229), Mon, 8:00 AM-11:30 AM

Sorafenib plus 5-azacytidine (AZA) in older untreated *FLT3*-ITD mutated AML. *First Author: Maro Ohanian, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Sorafenib plus 5-azacytidine (AZA) is observed to be safe and effective in relapsed / refractory *FLT3*-ITD mutated acute myeloid leukemia (AML) patients (pts). **Hypothesis:** Combining sorafenib with AZA is safe and effective in older untreated *FLT3*-ITD mutated AML pts. **Methods:** Eligibility included: untreated *FLT3*-ITD mutated AML (≥10% mutation burden), age ≥60 yrs, adequate organ function, and ECOG performance status ≤ 2. The regimen was: AZA 75 mg/m^{2}daily x 7 days and sorafenib 400 mg twice daily for 28 days. **Results:** 26 pts with untreated AML [median age 73 (61-86)] were enrolled: 16 (62%) pts had normal karyotype, 2 (8%) complex karyotype, 4 (15%) other miscellaneous abnormalities, and 4 (15%) with insufficient metaphases. Prior to the initiation of treatment, *FLT3*-ITD was detected in all pts with a median allelic ratio of 0.3735 (0.009-0.885). The overall response rate (ORR) in 25 evaluable pts was (76%) [7 (28%) with CR, 10 (40%) CRi/CRp, and 2 (8%) PR]. Pts underwent a median of 3 (1-35) treatment cycles. The median number of cycles to response was 2 (1-4), and the median time to achieve response, 1.77 months (mos) (0.689-4.271 mos). The median duration of CR/CRp/CRi is 14.5 mos (1.18—28.74). Three (18%) responding pts (CR, CRp, CRi) have proceeded to allogeneic stem cell transplant. With a median follow-up of 6.8 mos (0.2-18.8), 6 pts are alive, 3 in remission (CR/CRP/CRi). The median overall survival (OS) for the entire group is 8.3 mos; 9.2 mos in 17 responders. Evaluable pts treated with AZA + sorafenib (n = 25) were compared to a matched cohort of historical FLT3-ITD mutated pts > 60 yrs, but treated with hypomethylator-based (HMA) therapy without sorafenib (n = 20); the respective ORR (CR, CRp, CRi, PR) (76% vs. 70%, p = 0.653) and median OS (8.3 and 9.4 mos, p = 0.69) were similar. The remission duration for the responding pts treated with AZA+sorafenib was significantly longer (14.5 mos) than those on other HMA regimens without sorafenib (3.8 mos) (p = 0.01). Adverse events possibly attributable to the regimen included: grade (Gr) 1/2 nausea (n = 3), Gr 1/2 diarrhea (n = 2), Gr 1 dyspnea (n = 1), and Gr 1 breast pain (n = 1). **Conclusions:** The combination of AZA and Sorafenib is both well tolerated and effective in older untreated *FLT3*-ITD mutated AML. Clinical trial information: NCT02196857;NCT01254890.

7030 Poster Session (Board #230), Mon, 8:00 AM-11:30 AM

Clinical observations of AML expressing mutant RUNX1 and pre-clinical studies of RUNX1-targeted novel therapy of AML. *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Runt-related transcription factor 1 (*RUNX1*) is critically involved in normal and malignant hematopoiesis. Somatic mutations in *RUNX1* occur in ~10% of AML, especially in older patients with history of radiation or antecedent hematologic disorder. Presence of mRUNX1 is reported to confer relative resistance to therapy and poorer prognosis in AML, and there are no mRUNX1-targeted or specific therapies available. **Methods:** We retrospectively analyzed outcomes of 94 *mRUNX1* and 444 wild-type *RUNX1* AML patients treated at our institution from 9/2013 to 12/2016. We also determined the pre-clinical efficacy of a targeted therapy against cultured and primary AML cells expressing mRUNX1. **Results:** 67% of mRUNX1 patients were > 65 years of age. Co-occurring mutations with mRUNX1 were *ASXL1* (33%), *N/KRAS* (20%), *FLT3* (20%), *IDH2* (18%), *IDH1* (13%) and *TET2* (10%). In patients > 65 years treated with hypomethylating agent-based therapy, the presence or absence of *mRUNX1* did not impact response rate (42% vs 46% CR/CRp, p = 0.67), median event-free survival (3.4 vs 4.7 mo, p = 0.82) or overall survival (11.5 vs 9.3 mo, p = 0.97). In mRUNX1 expressing AML OCI-AML5 and MonoMac1 cells, knockdown of RUNX1 by shRNA repressed its targets, e.g., MYC and PU.1, inhibited growth and induced apoptosis. Ex vivo knockdown of RUNX1 abrogated in vivo leukemia initiation by OCI-AML5 cells. After engraftment, inducible shRNA-mediated in vivo knockdown of RUNX1 restored survival of immune-depleted NSG mice engrafted with OCI-AML5 cells. RUNX1 transcription is driven by a super enhancer occupied by the bromodomain extraterminal protein (BETP), BRD4. Accordingly, BRD4 knockdown by shRNA or treatment with the BRD4-inhibitor OTX015 depleted RUNX1 and its targets, and induced apoptosis of AML cells. Treatment of OCI-AML5 cell-engrafted NSG mice with OTX015 (50 mg/Kg/day X 5, for 3 wks) reduced AML burden and improved survival ($p < 0.01$). Co-treatment with the BETi and BCL2 inhibitor venetoclax or CDK4/6 antagonist palbociclib or decitabine synergistically induced apoptosis of OCI-AML5 and primary AML blasts. **Conclusions:** These findings highlight a novel, promising, BETP antagonist-based therapy of AML expressing mtRUNX1.

7031 Poster Session (Board #231), Mon, 8:00 AM-11:30 AM

Outcomes in AML patients age ≥70: A very large single institution experience. *First Author: Jeffrey E. Lancet, Moffitt Cancer Center, Tampa, FL*

Background: AML in older adults is associated with poor outcomes. The Moffitt Cancer Center AML Database was used to evaluate a very large cohort of patients (pts) age ≥ 70 with untreated AML to identify key prognostic variables affecting outcome. **Methods:** Overall survival (OS): Kaplan-Meier method and was compared across groups using the log-rank test. Association between OS and predictors: Cox regression model. Impact of participation of initial clinical trial on OS: Propensity score with stratified log-rank test. A predictive model for 12 month OS was developed using multiple logistic regression with backward elimination method. **Results:** Nine hundred eighty (980) pts were identified. M/F(%): 66/34. Median age at diagnosis: 75.7 years (range 70 – 95.7 years). De novo/secondary (%): 43/57. Fifty two % of pts had prior hematologic disease (AHD). Baseline karyotype at AML diagnosis: adverse in 31% and non-adverse in 58%. Baseline ECOG PS: 0-1 in 79%; ≥2 in 19%. Median OS was 7.1 months (95% CI 6.4 – 7.9) for the entire cohort. In the univariable model, factors associated with inferior survival included: secondary AML (sAML) status, poor-risk karyotype, ECOG ≥2, non HMA therapy (including clinical trials), Charlson Comorbidity Index ≥3, older age, increased WBC, decreased platelets (plts), and decreased hemoglobin (hgb). Independent negative predictors for OS in the multivariate model included sAML, poor-risk karyotype, ECOG ≥2, non-HMA initial therapy, older age, increased WBC, decreased plts, and decreased hgb. Propensity score matching revealed no significant difference in OS amongst pts receiving initial treatment on a clinical trial (median 7.8 months, 95% CI 6.4 – 10.4) vs not (median 7.0 months, 95% CI 6 –7.9). A model to predict OS at 12 month was developed in a subset of 446 pts. Independent predictive variables included karyotype, ECOG PS, AML type (de novo vs sAML), age, and WBC, with AUC of 0.78, indicating strong discriminatory capacity. **Conclusions:** In this largest reported cohort of AML pts age ≥ 70, prognostic modeling identifies differences in longer-term survival with conventional therapies, discriminating the highest risk subsets. Decision modeling to further assist choice of optimal therapies for these pts is in progress.

7032 Poster Session (Board #232), Mon, 8:00 AM-11:30 AM

Exposure-adjusted adverse events (AEs) comparing blinatumomab to standard of care (SOC) chemotherapy in patients (pts) with relapsed/refractory B-precursor acute lymphoblastic leukemia (r/r ALL) from a randomized phase III study. *First Author: Anthony Selwyn Stein, Department of Hematology and Hematopietic Cell Transplantation, City of Hope, Duarte, CA*

Background: Blinatumomab (blin), a bispecific T-cell engaging antibody construct, has shown improved overall survival vs SOC in pts with r/r ALL in a randomized phase 3 study (*Haematologica* 2016;101:S129). To better evaluate safety, we compared AEs of blin vs SOC after adjusting for varying treatment exposure times. **Methods:** Adults $\geq$ 18 yrs with r/r ALL (refractory, 1st relapse $<$ 1 yr, $\geq$ 2 relapses or relapse after transplant) were randomized to receive blin or SOC (1 of 4 predefined regimens). Blin was dosed by continuous infusion (4 wks on/2 wks off) for up to 5 cycles (9 μg/d on d1−7 in cycle 1, then 28 μg/d); up to 4 maintenance cycles (4 wks on/8 wks off) were allowed for $\leq$ 12 mo. Exposure-adjusted (exp-adj) event rates were calculated as no. of events*100/total exposure time (Table). **Results:** Median (range) no. of cycles were 1 (1−4) for SOC and 2 (1−9) for blin. The highest exp-adj rates (per 100 pt-yrs) were for pyrexia (507 SOC vs 376 blin), anemia (987 vs 229), thrombocytopenia (750 vs 126) and neutropenia (351 vs 121), all lower in blin. Febrile neutropenia (365 vs 93) and infections (1216 vs 436) were also both lower in blin ($p < 0.0001$). Exp-adj rates for neurologic events were 743 SOC vs 472 blin, with median time (range) to onset of 7 (1−43) d and 7 (1−190) d, respectively, and gr $\geq$ 3 cytokine release syndrome (CRS) rates were 0 SOC vs 10 blin. The most frequent AEs in both cycles 1 and 2 were pyrexia, nausea and anemia in both arms; CRS events decreased in the blin arm between cycles 1 and 2 (14% vs 2%). Most fatal AEs were related to infection in both arms. **Conclusions:** Here blin showed an AE profile consistent with that previously reported for r/r ALL, including similar rates of manageable CRS and neurologic events. Exp-adj AE rates were generally higher in SOC vs blin, including for cytopenias and infections. Clinical trial information: NCT02013167.

Updated results of frontline ofatumumab-hyper-CVAD in adults with CD20+ acute lymphoblastic leukemia. *First Author: Abhishek Maiti, The University of Texas Health Science Center at Houston, Department of Internal Medicine, Houston, TX*

Background: Chemoimmunotherapy is an effective frontline therapy for acute lymphoblastic leukemia (ALL). Ofatumumab (O) binds to a proximal small-loop epitope on CD20 and is more potent *in vitro* than rituximab. Here we report interim results of its combination with hyper-CVAD (HCVAD) in adult patients (pts) with CD20+ ALL. **Methods:** Since 7/2011, we have enrolled 63 pts with Ph-negative CD20+ ALL (59 newly diagnosed, 4 previously treated). For the intensive phase, pts received 4 cycles (cy) of HCVAD (odd cy 1, 3, 5, 7) alternating with 4 cy of methotrexate-cytarabine (MTX-Ara-C, even cy 2, 4, 6, 8), and ofatumumab during cy 1-4. For maintenance, pts received POMP for ~30 months (mos), and intensification with MTX/PEGylated asparaginase on mos 6 and 18, and O-HCVAD on mos 7 and 19. Intrathecal MTX-Ara-C was used for CNS prophylaxis. Bulky mediastinal disease was irradiated when indicated. **Results:** Median age was 41 years (range: 18-71) and median WBC count was 4.6 x10^9/L (range: 0.6-201 x10^9/L). 22 pts (35%) had diploid cytogenetics and 8/35 pts (23%) had TP53 mutation. CD20 expression was $>$ 20% in 38 pts (60%), 10-20% in 6 pts (10%) and 1-10% in 16 pts (25%). Median follow-up was 20 mos (range: 1-58) and median number of cy was 8 (range: 1-8). 3 pts (5%) were in CR at the time of enrollment. Of 60 pts evaluable for response, 58 pts (97%) achieved CR; 1 pt achieved CRp and 1 pt died during cy 1 from sepsis. Flow cytometric minimal residual disease (MRD) was negative in 57/62 pts (92%) overall, and in 36/57 pts (57%) at CR. Median time to negative MRD was 0.7 mos. Median time to platelet and neutrophil recovery in cy 1 was 21 and 18 days, respectively. The most common grade 3/4 non-hematological toxicities were infections during induction (49%) and consolidation (72%), elevated transaminases (35%), and hyperbilirubinemia (21%). 5 pts (7%) experienced a grade 3/4 transfusion reaction. 8 pts (13%) received stem cell transplantation in CR1. 10 pts (16%) have relapsed (8 morphological, 2 MRD only). Overall survival and 2-year CR duration rates were 80% and 81%, respectively. Survival outcomes were independent of percentage of CD20 expression. **Conclusions:** O-HCVAD is safe, effective and results in durable responses in pts with CD20+ ALL. Clinical trial information: NCT01363128.

7034 Poster Session (Board #234), Mon, 8:00 AM-11:30 AM

Correlation between mutation clearance and clinical response in elderly patients with acute myeloid leukemia (AML) treated with azacitidine and pracinostat. *First Author: Koichi Takahashi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In a phase II study in 50 elderly patients (pts) with AML who were not eligible for intensive chemotherapy, treatment with pracinostat + azacitidine (AZA) was well tolerated, led to 42% complete remission (CR) rate and a median overall survival (OS) of 19.1 months (Blood 2016: 128;100). Here we investigate the impact of somatic mutations and their clearance on disease response and patient outcomes. **Methods:** 88 samples from 41 study pts were sequenced. All 41 pts were analyzed pre-treatment, and a median of 3 longitudinal samples were analyzed from 19 pts between Cycle 2 and 9. Mutations were assayed by SureSelect targeted capture exon sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies. Longitudinal mutation clearance was analyzed by plotting variant allele frequency (VAF). **Results:** At baseline, 96 mutations in 28 genes were detected in 38 pts, with the most frequent being in *SRSF2* (27%), *DNMT3A* (20%), *IDH2* (17%), *RUNX1* (17%), and *TET2*(17%). Mutations associated with CR rate and OS are indicated in the Table. A CR was achieved in 10/19 pts that had longitudinal sequencing analysis and at the time of CR, 9 (90%) had persistently detectable mutations in their bone marrow. In 7 of them, continued exposure to pracinostat + AZA lowered the VAF or cleared residual mutations. In 2 pts, relapsed samples showed re-expansion of the founder clone. **Conclusions:** Mutations in *NPM1*, and DNA methylation pathway were associated with a better response to pracinostat + AZA, while *TP53* mutation was associated with a poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat + AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR. Clinical trial information: NCT01912274.

7035 Poster Session (Board #235), Mon, 8:00 AM-11:30 AM

Overall survival (OS) with CPX-351 versus 7+3 in older adults with newly diagnosed, therapy-related acute myeloid leukemia (tAML): Subgroup analysis of a phase III study. *First Author: Jeffrey E. Lancet, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: tAML may occur as a late complication of cytotoxic therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine (C) and daunorubicin (D). In a randomized, open-label, controlled phase III trial in patients (pts) aged 60-75 years with newly diagnosed, secondary AML (tAML or after MDS), CPX-351 significantly improved OS versus 7+3. The current analysis of this phase III study evaluated outcomes in the subgroup of pts with tAML. **Methods:** Pts were randomized 1:1 to induction with 1-2 cycles of CPX-351 (100 u/m^2 [C 100 mg/m^2 + D 44 mg/m^2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3]) or 7+3 (C 100 mg/m^2/day x 7 days [2nd induction: x 5 days] + D 60 mg/m^{2}on Days 1, 2, and 3 [2nd induction: Days 1 and 2]). Pts with complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. The study was not powered for this subgroup analysis. **Results:** 304 pts were enrolled and received study treatment, including 62 (20%) pts with tAML; demographics of tAML pts were similar between study arms. Pts with tAML had typically received prior non-anthracycline chemotherapy alone (25%), radiation alone (25%), or non-anthracycline chemotherapy + radiation (32%). CPX-351 was associated with an OS benefit versus 7+3 in older tAML pts and numerically longer event-free survival (EFS) and remission duration (Table). A greater proportion of tAML pts achieved CR+CRi (47% vs 36%, respectively) and proceeded to stem cell transplantation (37% vs 27%) with CPX-351. The safety profile of CPX-351 was comparable to that of 7+3. **Conclusions:** CPX-351 is associated with improved outcomes in older pts with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population. Clinical trial information: NCT01696084.

	CPX-351 (n = 30)	7+3 (n = 32)	HR (95% CI)
Median OS	12.17 mo	6.64 mo	0.49 (0.27, 0.88)
Median EFS	2.50 mo	1.64 mo	0.66 (0.38, 1.17)
Remission duration	10.87 mo	6.11 mo	0.50 (0.17, 1.50)

7036 Poster Session (Board #236), Mon, 8:00 AM-11:30 AM

Efficacy by consolidation administration site: Subgroup analysis of a phase III study of CPX-351 versus 7+3 in older adults with newly diagnosed, high-risk acute myeloid leukemia (AML). *First Author: Jonathan E. Kolitz, Hofstra Northwell School of Medicine, Hempstead, NY*

Background: The CPX-351 liposomal formulation delivers a synergistic 5:1 molar ratio of cytarabine (C) and daunorubicin (D) preferentially to leukemia cells. CPX-351 has demonstrated significantly improved overall survival (OS) versus 7+3 in a randomized, open-label, phase III study in patients (pts) aged 60-75 years with newly diagnosed, high-risk AML. In contrast to 7+3, which includes C continuous infusion, CPX-351 is administered as a 90-minute infusion and has the potential to be given in the outpatient setting. The current analysis of the phase III trial assessed the setting of consolidation therapy. **Methods:** Pts were randomized 1:1 to 1-2 induction cycles of CPX-351 or 7+3; pts with complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles (CPX-351: 65 u/m^2 [C 65 mg/m^2 + D 28.6 mg/m^2] on Days 1 and 3; 7+3: C 100 mg/m^2/day x 5 days + D 60 mg/m^2 on Days 1 and 2). Site of administration was not protocol defined. **Results:** Few pts received induction as outpatient therapy (CPX-351 n = 3/153 and 7+3 n = 1/151 in each cycle). 49/153 CPX-351 pts and 32/151 7+3 pts received consolidation, with a substantial proportion of pts receiving CPX-351 as outpatients (consolidation 1: 51%; consolidation 2: 61%). CPX-351 consolidation was associated with substantial improvement in median OS versus 7+3 irrespective of inpatient/outpatient status (Table). Median OS was not diminished with CPX-351 administration in the outpatient versus inpatient setting (consolidation 1: 25.43 and 14.72, respectively; consolidation 2: 26.32 and not reached). **Conclusions:** Some pts can successfully receive CPX-351 consolidation as outpatients without diminished efficacy, potentially reducing hospitalizations associated with treatment administration. Clinical trial information: NCT01696084.

7037 Poster Session (Board #237), Mon, 8:00 AM-11:30 AM

Idarubicin and cytarabine with clofarabine or fludarabine in adults with newly diagnosed acute myeloid leukemia: Updated results of a randomized phase II study. *First Author: Ghayas C. Issa, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The purine nucleoside analogues fludarabine and clofarabine are effective agents in the treatment of acute myeloid leukemia (AML). This study evaluated the efficacy and safety of combining idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. **Methods:** Using a Bayesian adaptive design, patients (pts) deemed suitable for intensive chemotherapy were randomized to receive CIA (n = 106) or FIA (n = 76). All pts received idarubicin 10 mg/m^2 IV daily on Days 1-3 and cytarabine 1 g/m^2 IV daily on Days 1-5. Clofarabine and fludarabine were given at 15 mg/m^2 and 30 mg/m^2, respectively, IV daily on Days 1-5. Pts with FLT3 mutations could receive sorafenib. Up to 6 cycles of consolidation were allowed for responding pts. **Results:** Baseline characteristics were similar comparing CIA to FIA with a median age of 53 years (range, 20-66) vs 49 years (range, 18-66) respectively and ELN risk intermediate-2/adverse of 57% and 58% respectively. With a median follow-up of 27 months (range, 1-58), the CIA and FIA arms had a similar CR/CRp rate (80% and 82%, respectively). MRD negativity rate by multiparameter flow cytometry at the time of CR/CRp was higher comparing CIA to FIA (80% vs. 65%, respectively, P = 0.07). The median EFS were 13 months and 12 months, respectively (P = 0.91), and the median OS were 24 months and not reached, respectively (P = 0.23). There were more adverse events (all grades) associated with CIA, particularly AST/ALT elevation (29% vs 4%), hyperbilirubinemia (26% vs 9%) and rash (31% vs 9%). Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P = 0.32). Comparing the 2 arms to a historical cohort of pts treated with IA showed similar response rates, EFS and OS excluding pts with FLT3 mutations from this analysis. However, in pts < 50 years of age, FIA was associated with improved survival compared with IA (2-year EFS rate: 58% vs 30%, P = 0.05; 2-year OS rate: 72% vs 36%; P = 0.009). **Conclusions:** CIA and FIA have similar efficacy in younger pts with newly diagnosed AML. FIA is associated with a better toxicity profile and may improve survival compared to IA in pts < 50 years of age. Clinical trial information: NCT01289457.

7038 Poster Session (Board #238), Mon, 8:00 AM-11:30 AM

Prognostic significance of alterations of pathways regulating autophagy in acute myeloid leukemia. *First Author: Giovanni Marconi, Istituto Seragnoli, DIMES, University of Bologna, Bologna, Italy*

Background: Nowadays, science is debating if autophagy in cancer can lead to therapy resistance or it can favor apoptosis. Autophagy pathways are involved pro-apoptotic mechanism, or they can improve stresses survival eliminating damaged mitochondria and proteins. Levels and activity of pro-apoptotic and anti-apoptotic proteins (eg. bcl-2 and p53), high levels of cAMP, and a pink/park complex could play as fulcrum on this lever. Our study aims to define the role of autophagy in AML. **Methods:** We analyzed 148 consecutive non M3 AML with Affymetrix SNP array. We screened all patients for TP53, FLT3, NMP1 mutations. Patients was treated with intensive induction chemotherapy regimens. Survival data were collected prospectively, with a median follow-up of 18 months. **Results:** Autophagy alteration (gene group 1: *ULK1 CHR11; ULK1 CHR17; BECN1; ATG14; AMBRA1; UVRAG; ATG9A; ATG9B; PIK3C3; PIK3R4*) was related to lower Complete Remission rate (CR%) after induction in univariate ($p < .001$) and multivariable regression model with age, karyotype, secondary AML, TP53 mutation ($p = .014$); autophagy alteration shown to confer worst Overal Survival (OS) ($p < .001$) and was significantly associated with complex karyotype and TP53 mutation ($p < .001$). We detected significant differences in term of survival independently both in gain and loss in group 1 genes ($p < .001$). Alterations in genes in cAMP pathway (group 2: *SESN1; PRKAA1 CHR 3; PRKAB1: PRKAA1 CHR 1: PRKAG1 CHR11; PRKAG1 CHR 7; PRKAG3; PRKAB1*) and in genes that could be related to a switch from a physiological role of autophagy to a resiliency mechanism (group 3: *CCND1; BCL2; PINK1; PARK2; TP53; MDM1; MDM4*) showed to confer worst OS ($p < .001$ in both groups); Alteration in group 2 and group 3 were related to lower CR% after induction ($p < .001$ in both groups). Whole Exome Sequencing on 56 patients in our set did not found any significant mutation in genes we analyzed with the exception of TP53. **Conclusions:** Alterations in autophagy regulator genes are associated with poor prognosis and therapy resistance. A loss in autophagy could block apoptosis, a gain could confer cell resiliency. Acknowledgements: *ELN, AIL, AIRC, Progetto Regione-Università 2010-12,FP7 NGS-PTL, HARMONY*

7039 Poster Session (Board #239), Mon, 8:00 AM-11:30 AM

Response and survival rates with frontline hypomethylating agent (HMAs) in favorable risk AML. *First Author: Michael Richard Grunwald, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC*

Background: HMAs are an accepted frontline therapy for AML patients (pts) who are unfit for intensive induction therapy (IIT), particularly pts with unfavorable cytogenetics and/or p53 mutations. However, little is known about the response of favorable risk AML to HMAs. We previously reported that NPM1 mutated and/or CD34- AML status were predictors of response to HMAs. Here, we evaluated responses to frontline HMAs in AML. **Methods:** A total of 117 patients with *de novo* AML diagnosed between 7/2013 and 9/2016 were evaluated based on pt and disease related variables, overall response rate (ORR = CR + CR with incomplete count recovery + hematologic remission (ANC > 1000/μL, Hgb > 10g/dL, Plts > 100,000/μL, & no circulating blasts)), and overall survival (OS). Categorical variables were compared using Fisher's exact test. Kaplan Meier methods estimated survival outcomes, and log rank tests compared survival between groups. Multivariable analyses were performed using Cox proportional hazards models. **Results:** 51 pts, considered unfit for IIT, received frontline HMAs. ORR and OS were highest in the ELN favorable risk AML pts (n = 13; ORR = 92%, p = .009; median OS = 17.5 months, p = .022). Among 41 NPM1 mutated pts, 15 received HMAs; and 26 received intensive induction. ORRs were 73% and 84%, respectively (p = .434). No difference was found in OS distributions between the HMA and IIT groups in univariate and multivariate (adjusted for age and FLT3 status) models (p = .329 and .241, respectively). Interestingly, ORR was 100% among 9 HMA-treated pts with NPM1 mutated, CD34-, FLT3/ITD-, cytogenetically normal AML. **Conclusions:** HMA therapy is highly effective frontline treatment in favorable risk AML pts considered unfit for IIT. Survival results with HMAs in NPM1 mutated AML are comparable to those of fitter pts treated with IIT. In selected favorable risk pts considered unfit for standard induction, HMAs can be a successful bridge to potentially curative therapy, including more intensive therapy or transplant. Cytogenetically normal AML with an isolated NPM1 mutation and CD34- status appears to be exceptionally responsive to frontline treatment with HMAs. Prospective validation of these findings is necessary.

7040 Poster Session (Board #240), Mon, 8:00 AM-11:30 AM

CyFi: A phase I study exploring the role of cMET pathway inhibition with ficlatuzumab (Fi) combined with high-dose cytarabine (Cy) in patients with high risk relapsed or refractory acute myeloid leukemia (AML). *First Author: Victoria Wang, University of California, San Francisco, San Francisco, CA*

Background: Pts with AML who are refractory to induction therapy or relapse within 1 year have poor outcomes. Elevated serum HGF level is an adverse prognostic factor in AML (Verstovsek, et al. 2001; Kim, et al. 2005). Preclinical models have shown that myeloid blasts produce HGF in an autocrine fashion and pharmacologic blockade of the HGF/c-Met axis sensitizes blasts to cell death (Kentsis, et al. 2012). **Methods:** We initiated a phase I study to assess the safety and tolerability of Fi combined with Cy in patients with AML who are refractory to 7+3 or have relapsed within 1 year of induction. Fi is given in escalated dosing of 10, 15, or 20 mg/Kg for 4 doses every 2 weeks, starting on day 0, and Cy at a fixed dose of 2g/m2 on days 2-7, using a 3x3 design. PBMCs, BM and serum are collected at defined time points to assess HGF levels and activation of the c-Met pathway. **Results:** Dose escalation is complete and there were no protocol-defined DLTs identified in 9 evaluable pts. All pts treated to date were refractory to induction. Four had de novo AML; 2 had undifferentiated leukemia; 2 prior MDS; 1 prior MPN. Most frequent grade 3/4 TEAEs were febrile neutropenia (56%), LFT abnormalities (11%), and electrolyte disturbance (11%). There was 1 death (11%) from sepsis and multi-organ failure on day 23, following ANC recovery. Of the 7 evaluable pts, 3 achieved a CR (43%), all in the 2nddose cohort. Two of the 3 CRs are long lasting 11 and 12 months following AlloHCT. All patients had detectable circulating HGF levels at baseline compared to control subjects without AML. HGF levels increased following exposure to Fi by an average of 193%. Baseline HGF levels or change from baseline were not associated with treatment response. **Conclusions:** Ficlatuzumab can be safely combined with HiDAC in this high-risk AML population and produce durable clinical responses. Circulating HGF levels were detectable at baseline and uniformly increased with treatment suggestive of a feedback response or immune complex stabilization. Dose expansion is ongoing. Clinical trial information: NCT02109627.

7041 Poster Session (Board #241), Mon, 8:00 AM-11:30 AM

Emotion and Symptom-focused Engagement (EASE): A randomized pilot trial of an integrated psychosocial and palliative care intervention for individuals with acute leukemia (AL). *First Author: Gary Rodin, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Individuals diagnosed with AL may experience severe physical and psychological distress due to the illness and its treatment, the threat of relapse and treatment failure, and a high risk of mortality. To alleviate psychological and physical distress in this population, we developed a novel, 8-week, manualized intervention called EASE. This includes: 1) EASE-psy-a tailored psychotherapeutic component to reduce psychological distress; and 2) EASE-phys-symptom screening, with moderate to severe physical symptoms triggering early palliative care. **Methods:** To assess the feasibility and preliminary efficacy of EASE, patients were recruited within 2 weeks of admission to a comprehensive cancer center and randomized to receive either EASE or usual care (UC). Physical and psychological symptoms were assessed at baseline, 4, 8 (primary endpoint), and 12 weeks. Intervention patients received 6-10 psychotherapy sessions over 8 weeks, weekly assessment of physical symptoms, and consultation and follow-up by palliative care, when needed. One-way ANOVA was performed to assess mean change scores over time between groups. **Results:** Forty-two patients were randomized to EASE (n = 22) or UC (n = 20). Predefined feasibility outcomes were all met: $>$ 86% (19/22) of EASE participants (goal $>$ 64%) completed $>$ 50% of proposed EASE-psy sessions; 64% (14/22) completed symptom screenings (goal $>$ 50%); and 100% of those with moderate to severe symptoms had $>$ 1 meeting with the EASE-phys team (goal 100%). There were statistically significant findings favoring EASE vs. UC for satisfaction with care at 8 and 12 weeks (Δ: -3.12 vs 7.39, $p < 0.04$; -6.1910 vs 0.0125 $p < 0.03$). There were trends favoring EASE vs. UC for traumatic stress symptoms, depressive symptoms, quality of life, attachment security, and number, severity, and distress related to physical symptoms at 4, 8, and 12 weeks. **Conclusions:** Although not powered for statistical significance, this randomized pilot trial of EASE for AL showed promising reductions in psychological and physical distress and supports the feasibility and need for a larger randomized controlled trial. Clinical trial information: NCT02353559.

7042 Poster Session (Board #242), Mon, 8:00 AM-11:30 AM

Unsupervised hierarchical clustering of surface antigen expression to identify normal karyotype AML patients with distinct disease characteristics and poor outcome. *First Author: Madlen Jentzsch, Department of Hematology and Oncology, University of Leipzig, Leipzig, Germany*

Background: Surface antigen expression evaluation is part of the standard work-up at acute myeloid leukemia (AML) diagnosis. The biological & prognostic implications of surface antigen expression patterns in normal karyotype (NK) AML patients (pts) remain unknown. **Methods:** The diagnostic antigen expression patterns of mononuclear cells in bone marrow (BM) of 111 NK-AML pts were assessed using a standard flow cytometric panel. At diagnosis common AML gene mutations (mut) & expression levels were analyzed. Pts received stem cell transplantation (SCT, 98% allogeneic, 2% autologous; median age 63 years [y, range 26-74y]) after induction therapy at our institution. Median follow up was 3.3y. With R's gplot package unsupervised hierarchical clustering of surface antigens was performed & revealed 4 distinct clusters. **Results:** Pts in cluster 1 (n = 36) had higher expression of immature, in cluster 2 (n = 31) of thrombocytic/T-cell/erythroid, in cluster 3 (n = 24) of monocytic & in cluster 4 (n = 20) of myeloid surface antigens. All 4 clusters associated with distinct clinical & molecular features. At diagnosis, compared to all others, pts in cluster 1 had a higher CD34+/CD38- cell burden ($P<$ .001), higher blood blasts ($P<$ .03) & BM blasts ($P<$ .06) by trend. They had less *NPM1* mut ($P<$ .001) & *DNMT3A* mut ($P=$ .02), were more likely to be *EVI1* positive ($P=$ .03) & had higher *EZH2* ($P=$ .02), *RUNX1* ($P=$ .009), *BAALC* ($P<$ .001), *ERG* ($P=$ .02) & *MN1* ($P<$ .001) expression. Compared to all others, pts in cluster 1 had a higher cumulative incidence of relapse (CIR, $P=$ .002, at 1y 41% vs 15%) & shorter event-free survival (EFS, $P=$ .02, at 1y 50% vs 69%). In multivariate analysis, cluster 1 pts had a significantly higher CIR (Hazard Ratio [HR] 5.4, $P=$ .01) after adjustment for *FLT3*-ITD & shorter EFS (HR 2.1, $P=$ .02) after adjustment for *FLT3*-ITD, age & disease status at SCT. **Conclusions:** Pts in cluster 1 had high expression of immature surface antigens (eg CD34, CD117, CD13), genes involved in stem cell renewal & worse outcome. Our data indicate a relationship between easily accessible surface antigen expression patterns at diagnosis, molecular disease features & aggressiveness of the NK-AML phenotype.

7043 Poster Session (Board #243), Mon, 8:00 AM-11:30 AM

A phase 1b dose escalation study to evaluate safety, tolerability and pharmacokinetics of oral monotherapy with KX2-391 in elderly subjects with acute myeloid leukemia who are refractory to or have declined standard induction therapy. *First Author: Margaret T. Kasner, Thomas Jefferson University, Philadelphia, PA*

Background: Treatment of elderly AML patients is complicated by poor tolerance to standard therapies and multi-drug resistance. It is imperative to explore novel agents which are tolerable and target alternative pathways. KX2-391 is an oral non-ATP-competitive inhibitor of Src kinase and tubulin polymerase. We conducted a phase I open-label safety and activity study in elderly subjects with AML who were refractory to or declined standard induction chemotherapy. Five dose levels were tested from 40 to 160 mg daily. **Methods:** 24 subjects were recruited from 3 institutions with an average age of 74 years (range 63-86). The majority had previously received HMAs. 1 subject was treated at 40 mg, 2 at 80 mg, 8 at 120 mg, 12 at 140 mg, and 1 at 160 mg. Of the 24 subjects enrolled, 7 (29%) were on treatment for 12 days or less; 9 (38%) from 15 to 29 days, 5 (21%) from 33 to 58 days and 3 (13%) from 77 to 165 days. One subject treated at 120 mg for 165 days had a reduction in splenomegaly from 16 cm to 4 cm BLCM, and survived 373 days. A second subject was treated at 120 mg for 154 days until disease progression. One subject was dosed at 160 mg for 12 days and remained treatment-free for about 18 months. **Results:** DLTs occurred in 8 subjects at: 120mg (AST/ALT, elevated bilirubin); 140 mg (Mucositis, Allergic Reaction, 2 elevated LFTs, acute kidney injury) and 160 mg (Mucositis). The most common ($\geq$ 25%) treatment-related adverse events were nausea/vomiting; diarrhea; anorexia; fatigue/weakness; increase ALT/AST; hypokalemia; hypotension; febrile neutropenia; dyspnoea; abdominal pain; constipation; dizziness. The RPTD for KX2-391 is 120 mg given once daily. KX2-391 bone marrow concentrations are similar to the target IC50 of 142 ng/mL. **Conclusions:** This is the first study conducted to determine whether KX01 can be safely given to this high risk, frail AML patient population. The data from this study support proceeding with further studies including alternative dosing phase 1 studies (higher dose, shorter course followed by drug-free intervals) and phase 2 studies to assess efficacy. Clinical trial information: NCT01397799.

7044 Poster Session (Board #244), Mon, 8:00 AM-11:30 AM

The effect of donor source on outcomes after second allogeneic hematopoietic cell transplantation for relapsed leukemia. *First Author: Eric Huselton, Washington University in St. Louis, St. Louis, MO*

Background: There is no standard treatment for patients with leukemia who relapse after allogeneic stem cell transplant (HCT). A second HCT (HCT2) may be the only possibly curable option; however, this is performed in few patients. We hypothesized that patient and transplant characteristics, such as donor source will affect outcomes. **Methods:** We retrospectively evaluated adult patients who received a HCT2 for relapsed leukemia or MDS at a single institution between 2000-2016. 85 patients underwent a HCT2 with an unmanipulated graft from a matched related (MRD, n = 21), matched unrelated (MUD, n = 40), or haploidentical (haplo, n = 24) donor, preceded by either a reduced intensity (RIC) or myeloablative conditioning (MAC) regimen. **Results:** The median age at HCT2 was 50 yrs and the median time between transplants was 448 days. Patients had relapsed AML (n = 62), ALL (n = 12), and MDS (n = 10). The median length of follow up for survivors was 22.3 months (range 3.9-131) with 20 patients alive in June 2016. 65 patients died; 32 from relapse, 21 from infection, 7 from GvHD, and 5 from organ failure. 1-year OS from HCT2 was 38.6%. For patients with MRD, MUD, haplo donors, 1 year OS was 52.3%, 33.3%, and 34.6% (p = 0.72). 1-year DFS in the entire cohort, MRD, MUD, and haplo groups was 26.4%, 14.3%, 34.8%, and 25.3% (p = 0.45). 1-year TRM was 36.2% and not different across these groups (p = 0.80). Univariate analyses of OS, DFS, and TRM based on patient, disease, and transplant characteristics showed an association with RIC and worse OS and DFS (HR 2.0, 95% CI 1.2-3.3; and HR 1.9, 1.2-3.1). Having $>$ 1 year between transplants was associated with lower TRM (HR 0.38, 0.19-0.77). Traditional risk factors like age, presence of active disease at HCT2, shorter time between transplants, and using the same donor from the first HCT were not otherwise significantly associated with OS, DFS, or TRM. **Conclusions:** Outcomes after HCT2 did not differ based on donor source. MAC is associated with better OS relative to RIC (1yr OS 51% vs 23%, $p < 0.01$), DFS (1yr DFS 37% vs 12%, $p < 0.01$), with similar TRM (1yr TRM 30% vs 47%, p = 0.12). Based on these data, serious consideration is necessary before using RIC regimens for HCT2 in patients with relapsed leukemia.

7045 Poster Session (Board #245), Mon, 8:00 AM-11:30 AM

Allogeneic stem cell transplant (AHCT) in the eighth decade: Age is just a number. *First Author: Ravi Kishore Narra, Medical College of Wisconsin, Milwaukee, WI*

Background: Allogeneic hematopoietic cell transplant (AHCT) is a curative treatment for hematological malignancies but older adults ($>$ 70 years) have been historically excluded due to age-related comorbidities and concern for increased non-relapse mortality (NRM). Reduced intensity conditioning (RIC) regimens, and improvements in supportive measures have broadened AHCT to older adults. Limited data exist regarding AHCT in their eighth decade ($>$ 70). **Methods:** We evaluated 24 consecutive pts aged $>$ 70 years receiving AHCT for various hematological malignancies between 2012 and 2016 at the Medical College of Wisconsin. **Results:** Median age was 72 (range, 70-76), and 62% were male. Disease indications included 11 AML, 6 CMML, 1 MDS, 1 NHL, 1 MM with only 11 patients (46%) in CR at transplant. 15 patients (62%) had normal karyotype, while other 9 had complex karyotype (n = 4), trisomy 11 (n = 1), trisomy 8 (n = 1). 6 patients (26%) had low-risk DRI score, 9 (39%) intermediate and 8 (35%) had high-risk score. Median HCT-CI score was 1.5 (range, 0-5) and 79% patients had a score of $\leq$2. Donors were related in 50% cases (3 haploidentical, 7 matched siblings and 2 syngeneic). Conditioning was RIC in 23 pts and all peripheral blood grafts. Median follow up was 14.2 months (range, 1.5-42.3). At day 28, 92% had neutrophil engraftment and 87% platelet engraftment. 2 patients had primary graft failure. 4 patients had acute GVHD, 4 had chronic GVHD,1 had both. Median CD3 chimerism was 99% (range, 74-100), CD33 was 100% (range, 78-100). Median of hospital-free days in the first 100 days was 80 and 160 days in the first 6 months after AHCT. 4 pts (17%) underwent AHCT entirely in outpatient setting. 6 patients relapsed at a median of 145 days (range 40-195). Survival at 2 years was 67% with relapse-free survival of 56% and NRM of 14%. Causes of death included sepsis (n = 1), fungal pneumonia (n = 1), cardiac (1), IPS (1), relapse (3). **Conclusions:** This experience with septuagenarians undergoing AHCT demonstrated an excellent 2 yr survival of 67% and that they can receive AHCT in the outpatient setting with a median hospital-free period of 80 days within the first 100 days. In carefully selected patients NRM with AHCT is manageable. Age alone should not determine eligibility for AHCT.

7046 Poster Session (Board #246), Mon, 8:00 AM-11:30 AM

Better survival with fludarabine and timed sequential busulfan regimen in older patients with AML/MDS. *First Author: Uday R. Popat, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We previously reported 6% 100 day NRM with a MA fludarabine (Flu) and busulfan (Bu) in older patients with a median age of 60 years. MA dose of Bu in this timed sequential (TS) regimen was administered over a longer period of time. To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) or the RIC Flu/Bu regimen, which is used as standard (ST) for older patients at our center (ST cohort). **Methods:** Patients in the TS cohort received IV Bu 80 mg/m^2/d on day -13 and -12 and Flu 40 mg/m^2/d followed by IV Bu on day -6 to -3, dose adjusted to achieve a total Bu course AUC of 20,000 μmol-min based on PK studies. Patients in the ST cohort received Flu 40 mg/m^{2}day followed by IV Bu daily for 4 days (day -6 to -3) dosed to achieve AUC of 16,000 μmol-min. Patients with AML or MDS were eligible for the study if they had adequate organ function, had matched related or unrelated donor and were treated between Jan 2012 and Sept 2016. **Results:** 162 patients, 50 with MDS and 112 with AML, were included in this study. Patient characteristics including age, sex, disease status, cytogenetic risk group, donor type, graft source CMV status and comorbidity were well balanced and without any significant difference in the two cohorts. Median age was 66 and 65 years in ST and TS cohorts, respectively. Overall survival (OS) and progression free survival (PFS) were significantly better in the TS cohort (see Table). This was due to a reduction in the disease progression without any increase in the non-relapse mortality (NRM). After adjusting for other covariates, the multivariate analysis for PFS confirmed longer PFS with TS Bu regimen (HR: 0.36; P=0.003). The benefit was mainly seen in patients with a comorbidity score $\leq$ 3. **Conclusions:** The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS. Clinical trial information: NCT01572662.

	Standard Cohort		TS Cohort		TS vs STD

7047 Poster Session (Board #247), Mon, 8:00 AM-11:30 AM

Timing of initiation of defibrotide (DF) post-diagnosis of hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) after hematopoietic stem cell transplantation (HSCT): Final data from an expanded-access protocol. *First Author: Stephan A. Grupp, Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: VOD/SOS is an unpredictable, potentially life-threatening complication of HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with $>$ 80% mortality. DF is approved to treat hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the US and to treat severe hepatic VOD/SOS post-HSCT in the European Union. **Methods:** In an expanded-access study, VOD/SOS patients (pts) with or without renal/pulmonary MOD after HSCT or chemotherapy received DF 25 mg/kg/d (6.25 mg/kg q6h) for a recommended $\geq$21 days. For these exploratory analyses, D*ay +100* survival rates in HSCT pts were examined *post hoc* by time from diagnosis to start of DF for (1) all pts before/after days 1, 2, 3, 4, 7, and 14, using Fisher's exact test and (2) pts starting DF on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and $\geq$15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed. **Results:** In the final dataset, timing of initiation was available for 1000 HSCT pts (512 with MOD) who received $\geq$1 dose of DF. In 31.0% of pts, DF was started the day of diagnosis; in 92.9%, by Day 7. In the analysis of initiation before/after days 1, 2, 3, 4, 7, and 14 post-diagnosis, earlier initiation was associated with significantly higher Day +100 survival rates for all days ($P \leq .001$), except Day 14 (2.6% of pts started DF after Day 14). The trend test for particular initiation days also showed a significant trend over time for higher Day +100 survival with earlier DF initiation post-diagnosis ($P < .001$). Adverse events (AEs) and serious AEs occurred in 70.8% and 53.4% of pts. Other than VOD/SOS and MOD, the most common AE was hypotension (11.7%) and most common serious AE was respiratory failure (7.3%). **Conclusions:** In this exploratory analysis of final study data, earlier DF initiation post-VOD/SOS diagnosis improved Day +100 survival, confirmed by the Cochran-Armitage test ($P < .001$). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed. *Support:* Jazz Pharmaceuticals. Clinical trial information: NCT00628498.

7048 Poster Session (Board #248), Mon, 8:00 AM-11:30 AM

Allogeneic transplant leads to markedly improved survival in older patients with AML. *First Author: Curtis Andrew Lachowiez, Oregon Health & Science University, Portland, OR*

Background: AML is a disease of the elderly, and outcomes with standard treatment are dismal. Allogeneic transplant is the only curative therapy for most patients with AML. Recent work has shown age is not a factor in transplant outcomes, and should not be a limiting factor for transplant. The treatment pathway for older patients with AML should take into account their disease risk, comorbidities, and treatments with a proven survival advantage. We investigated our institutional experience to help guide the establishment of optimal pathways for patients. **Methods:** We conducted a retrospective analysis of 118 patients over age 65 with AML treated at our institution between 2010-2015. Patients receiving therapy (n = 90) were categorized into two groups: intensive induction therapy (7+3 based) or induction therapy with a hypomethylating agent. The groups were well matched in regard to comorbidities. **Results:** In poor risk patients, complete remission (CR) was achieved in 42% (n = 30/71). Select patients up to age 75 proceeded to allogeneic transplant if they achieved CR. Survival in CR1 was higher in the transplant (n = 22, median 719 days, 95% CI: 366-1071 days), than in the non-transplant group (n = 8, median 257 days, 95% CI: 92-421 days, p-value $<$ .001). In analyzing all risk groups, overall survival was superior in transplant (median 1188 days) versus non-transplant recipients (median 185 days) (see 1, 2, and 3 year survival in table). No difference in median survival occurred based on age at induction (older than 70: n = 9, younger than 70: n = 16, p-value = 0.316). There was no difference in median survival based on chemotherapy regimen without transplant: intensive induction (n = 24, survival 250 days, p-value 0.179) compared to hypomethylating agents (n = 22, survival 139 days). **Conclusions:** We confirm that transplant can be safely performed in patients over 70 years of age, and highlight the survival advantage of transplant to chemotherapy alone. Additionally, our data found no survival benefit of hypomethylating agents in elderly patients with poor risk AML.

Overall Survival (all risk groups)	Transplant	No transplant
1 year	76% (23/30)	23% (14/60)
2 year	40% (12/30)	6% (4/60)
3 year	20% (6/30	5% (3/60)

7049 Poster Session (Board #249), Mon, 8:00 AM-11:30 AM

Ten-year survival after randomized comparison of imatinib (IM) 400 mg vs. IM 800 mg vs. IM + IFN vs. IM + Ara C vs. IM after IFN in chronic myeloid leukemia (CML). *First Author: Ruediger Hehlmann, Medizinische Fakultaet Mannheim Universitaet Heidelberg, Mannheim, Germany*

Background: It is unclear whether IM 400 mg is the optimum choice for the successful treatment of CML. Treatment optimization was therefore attempted. **Methods:** From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) were randomized into a 5-arm study to analyze 2 IM doses and 3 combinations. 1536 patients were evaluable, 400 for IM 400 mg, 420 for IM 800 mg, 430 for IM + Interferon (IFN), 158 for IM + Ara C and 128 for IM after IFN. Recruitment to the latter two arms was stopped after a pilot phase. **Results:** 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival (PFS) 80%. 10-year OS was 80% with IM 400 mg, 79% with IM 800 mg, 84% with IM + IFN, 84% with IM + Ara C and 79% with IM after IFN. The differences were not significant. 10-year PFS was 80% with IM 400mg, 77% with IM 800mg, 83% with IM + IFN, 82% with IM + Ara C and 75% with IM after IFN. The differences were not significant either. Survival with any treatment was not significantly different from IM 400mg at any risk level by any risk score (Euro Sokal, EUTOS, ELTS). 87 patients progressed to blast crisis (BC). The 10-year cumulative incidence of BC was 5.8% (95% CI: 4.7%; 7.1%) equally distributed across treatment arms. Most BC occurred in the first 2 years. Median survival after BC was 7.9 months across treatment arms. 275 patients have died, 23 after stem cell transplantation in first CP. Two thirds of deaths were unrelated to CML. Incidence of death due to CML by competing risk analysis with death unrelated to CML as competing risk was not different between the 5-treatment arms. 10-year relative survival probability was 92% when compared to matched general population data. Patients reaching the cytogenetic or molecular response landmarks according to European LeukemiaNet criteria ($<$ 10% BCR-ABL IS at 3 months, $<$ 1% BCR-ABL IS or complete cytogenetic remission at 6 months, $<$ 0.1% BCR-ABL IS (MMR) at 12 months) had a significantly better survival than those not reaching the landmarks regardless of therapy. **Conclusions:** In conclusion, outcome of CML is currently more determined by prognostic markers than by choice of therapy. IM400 mg remains an excellent choice for initial therapy of CP-CML. Clinical trial information: NCT00055874.

7050 Poster Session (Board #250), Mon, 8:00 AM-11:30 AM

Impact of early landmark responses with ponatinib on 4-yr outcomes in CP-CML patients (pts) in PACE, a pivotal phase II trial. *First Author: Martin Mueller, Universitätsmedizin Mannheim, Mannheim, Germany*

Background: Ponatinib is approved for pts with refractory CML or Ph+ ALL for whom no other TKI therapy is indicated, or for patients with T315I. Previously (Mueller ASCO '16), we reported the positive association of early landmark responses with ponatinib on survival at 3 yrs in heavily pretreated pts with CP-CML in PACE (NCT01207440). Here, we provide an update with survival outcomes at 4 yrs. **Methods:** The association of molecular (assessed in a central lab) and cytogenetic responses (CyR) at 3, 6 and 12 mo with 4-yr post-landmark PFS and OS was evaluated in CP-CML pts (n = 267). *P* values: calculated using log-rank test. Data cutoff: 3 Oct '16. **Results:** At baseline, median time from diagnosis: 7 (range, 0.5–27) yrs; median age: 60 (18–94) yrs; median %Ph+: 100% (3–100), ≤10% Ph+: 19 pts (7%); 61% of pts had ≥3 prior TKIs. Among evaluable pts at 3, 6 and 12 mo, MCyR/CCyR was achieved in 48%/39%, 62%/52% and 71%/56% and MMR in 14%, 29% and 39% of pts, respectively. Greater reductions in BCR-ABL1 levels (Table) and CyR at most landmark time points were associated with improved 4-yr post-landmark PFS and OS. Deeper responses at all landmark time points were associated with achievement of $MR^{4.5}$ over time. **Conclusions:** As with the 3-yr landmark analysis, CyR and deep reductions in BCR-ABL1 transcripts at early time points correlated with improved 4-yr post-landmark survival in this refractory population. These data continue to demonstrate the prognostic value of early cytogenetic and molecular responses with ponatinib in heavily pretreated pts with CP-CML. Clinical trial information: NCT01207440.

Estimated PFS and OS at 4 yrs past landmark by BCR-ABL1 level.

Landmark time	Response	n	PFS	*p–value	n	OS	*p–value
3 mo	BCR-ABL1						
	≤ 0.1%	32	97%	–	33	97%	–
	> 0.1–1%	47	57%	.32	48	85%	.54

7051 Poster Session (Board #251), Mon, 8:00 AM-11:30 AM

Impact of dose reductions on 5-year efficacy in newly diagnosed patients with chronic myeloid leukemia in chronic phase (CML-CP) from DASISION. *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Dasatinib (DAS) dose modifications generally mitigate adverse events (AEs) without affecting efficacy for responding patients (pts). A 2-year retrospective analysis of DASISION showed that rates of cytogenetic and molecular responses remained higher for pts given DAS vs imatinib (IM), even when daily doses were modified (Jabbour ASH 2011). Efficacy was not compromised due to dose reductions to manage DAS-related AEs. Here, we report results from a 5-year analysis evaluating the impact of dose reductions on efficacy in pts from DASISION. **Methods:** In DASISION (NCT00481247), pts with treatment-naïve CML-CP were randomized to receive either DAS (100 mg once/day; N = 259) or IM (400 mg once/day; N = 260). Up to 2 dose reductions were permitted for AEs (DAS: 80 mg, then 50 mg; IM: 300 mg, then 200 mg). Efficacy in all pts was evaluated retrospectively by 5 years. **Results:** Molecular response rates remained higher for DAS than IM, independent of dose reductions, and were comparable in pts with and without dose modifications in each arm (table). Overall, 95 (37%) DAS- and 44 (17%) IM-treated pts had dose reductions at any time due to AEs. Median average daily dose was 83 mg DAS and 328 mg IM for pts with reductions for any cause and 82 mg DAS for pts with reductions due to pleural effusion. The most common AEs resulting in dose reduction were hematological toxicity for IM (9%) and pleural effusion for DAS (12%). **Conclusions:** A 5-year retrospective analysis of DASISION showed molecular responses remained higher for DAS vs IM when daily doses were modified due to AEs. Dose reductions for any cause, including pleural effusion, did not affect efficacy (MMR rates were not reduced). In this analysis, for pts who experienced AEs, DAS dose reductions to 80 mg or 50 mg were safe and effective treatment options. Clinical trial information: NCT00481247.

Molecular responses by 5 years, % (95% confidence interval).

Dose reductions		DAS	IM
Any AE		n = 95	n = 44
	MMR	75 (65, 83)	64 (48, 78)
	MR^4	50 (39, 60)	46 (30, 61)
Pleural effusion		n = 30	n = 0
	MMR	83 (65, 94)	-
	MR^4	57 (37, 75)	-
None		n = 164	n = 216
	MMR	77 (70, 83)	64 (57, 70)
	MR^4	56 (48, 64)	44 (37, 50)

MMR, major molecular response; MR^4, 4-log reduction in *BCR-ABL1* transcripts.

7052 Poster Session (Board #252), Mon, 8:00 AM-11:30 AM

Tyrosine kinase inhibitor (TKI) therapy discontinuation in patients with CML in chronic phase: A US clinical practice perspective. *First Author: Ellen K. Ritchie, Weill Cornell Medical College, New York, NY*

Background: This study assessed TKI discontinuation practice in the US before the publication of new practice guidelines in November 2016 including recommendations on TKI discontinuation for patients (pts) with CML in chronic phase (CML-CP). **Methods:** From 10/12/2016 to 11/9/2016, 300 US oncologists/hematologists completed a survey on the reasons for TKI discontinuation in pts with CML-CP, their perspective on adequate response pts should achieve before considering TKI discontinuation (minimum response to TKI, response duration, and TKI therapy duration), and post-discontinuation CML monitoring. **Results:** One third of participating physicians reported having attempted TKI discontinuation (102 of 300); 66 did so outside of a clinical trial. Physicians who reported TKI discontinuation were more likely to practice in academic centers; were more experienced clinicians ($>$ 10 years in practice); and followed a larger number of CML pts vs those who did not. Among the 66 physicians, the majority would consider TKI discontinuation for medical reasons (76% adverse events, 47% pregnancy planning), with fewer for economic reasons (35%); 12% reported they would consider it for all of their pts who achieve an adequate response. There was no consensus on the minimum response achieved (56% consider a decrease in BCR-ABL of $\geq$4.5 log, 21% 3 log, and 11% 1 log), the minimum response duration (29% 3 yrs, 24% 2 yrs, and 20% 1 yr), and the minimum TKI therapy duration (44% 3yrs, 20% 2 yrs, 19% 1 yr) before TKI discontinuation. There was no consensus on the frequency of CML monitoring post-discontinuation with $<$ 10% of physicians considering monthly molecular monitoring in the first year. **Conclusions:** TKI discontinuation in pts with CML-CP responding to TKI was attempted outside of clinical trials without clear guidelines. Conditions under which TKI therapy was discontinued differed from new recommended practice guidelines, which may have resulted in discontinuation where deep response may not be achieved and disease not adequately monitored. The recommended practice guidelines need to be communicated to physicians as TKI discontinuation is likely to be conducted in a broader population.

7053 Poster Session (Board #253), Mon, 8:00 AM-11:30 AM

Clinical relevance of mutations in patients with myelodysplastic syndromes and myelodysplastic/myeloproliferative neoplasms with normal karyotype. *First Author: Guillermo Montalban-Bravo, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Clinical outcomes of patients with myelodysplastic syndromes (MDS) and myelodysplastic/myeloproliferative neoplasms (MDS/MPN) are heterogeneous. Specific mutations and mutation patterns are known to define prognostic groups in normal karyotype acute myeloid leukemia. Whether this is the case in MDS and MDS/MPN remains unknown. **Methods:** We evaluated 325 previously untreated patients with MDS or MDS/MPN with normal karyotype evaluated from 2012 to 2016. Next generation sequencing (NGS) on whole bone marrow DNA analyzing a panel of 28 or 53 genes was performed at the time of diagnosis. **Results:** A total of 225 (69%) patients had MDS and 100 (31%) had MDS/MPN including 77 (24%) patients with chronic myelomonocytic leukemia (CMML). Median age was 69 years (31-92). Among patients with MDS, 189 (84%) had lower-risk and 36 (16%) had higher-risk based on IPSS. NGS data was obtained by 53-gene panel in 93 (29%) patients and by 28-gene panel in 232 (71%). A total of 202 (62%) patients had detectable mutations. Median number of mutations was 1 (range 0-6). Detected mutations are detailed in Table 1. A total of 111 (34%) patients, 70 with MDS and 41 with MDS/MPN, received therapy with hypomethylating agents. Median follow up was 12 months (0-167). By univariate analysis, *NRAS* (HR 3.28, CI 1.25-8.62, p=0.016) and *TP53* (HR 4.9, CI 1.44-16.67, p=0.011) predicted for shorter overall survival (OS) among MDS patients. After multivariate analysis including IPSS-R, only *TP53* retained its impact in OS (HR 5.25, CI 1.44-19.13, p=0.012). Among MDS/MPN patients, no mutation was found to significantly impact OS. **Conclusions:** With the exception of *TP53* mutations, no other identified mutation seemed to independently define prognosis of patients with MDS or MDS/MPN with normal karyotype. In view of the high proportion of lower-risk patients, longer follow up is required to better define prognostic impact of mutations in this population.

7054 Poster Session (Board #254), Mon, 8:00 AM-11:30 AM

Prevalence and complications associated with off-label use of lenalidomide in older patients with myelodysplastic syndromes (MDS). *First Author: Andrew Mark Brunner, Massachusetts General Hospital, Boston, MA*

Background: Lenalidomide (LEN) is approved for patients with lower-risk MDS with del5q who are transfusion-dependent (TD). We aimed to assess the prevalence and complications associated with LEN use in non-TD older patients with MDS. **Methods:** Using the SEER-Medicare database we identified Medicare enrollees diagnosed with MDS from 2007-2011. Medicare part D claims were analyzed for evidence of LEN use. CPT, HCPCS, and ICD-9 codes were used to characterize TD MDS (claims for $\geq$ 2 RBC transfusions within 8 weeks prior to LEN), complications, and baseline risk per SEER-Medicare MDS Risk Score (SMMRS; Uno, *Leuk Res* 2014). Incident complications during LEN were noted if there were no prior claims for the same within a 1-yr look-back window. **Results:** Among 469 patients initiating LEN (median age 78 years), 77% received it first-line, and 23% after a hypomethylating agent. Among all, 19% had del5q, 37% had non-del5q MDS, and 44% no histology specified (MDS NOS). SMMRS risk was evenly distributed between low (36%), intermediate (30%), and high (34%). Only 42% of patients were TD at the time of first LEN prescription, and 26% had not been transfused within six months prior to LEN. Non-TD patients receiving LEN were more likely to have lower-risk disease (p = .004), and less likely to have pre-treatment thrombocytopenia (p = .005) or neutropenia (p = .003); they did not differ significantly in age (p = .85), documentation of del5q (p = .51), comorbidity (p = .65) or treatment center volume (p = .80). Median days on LEN for the non-TD was 121. Incident complications post-LEN among the non-TD are shown. **Conclusions:** These data suggest there is widespread off-label use of LEN in older patients with MDS, as many receive the drug who are not TD. Moreover, off-label exposure to LEN in these patients is associated with a sizable risk of incident complications, which is difficult to justify given they are already living free of transfusion dependence.

New complication during LEN among non-TD	Prevalence (%)
Dyspnea	24.4

7055 Poster Session (Board #255), Mon, 8:00 AM-11:30 AM

Implementation of a screening program for identification of unrecognized inherited marrow failure syndromes. *First Author: Curtis Andrew Lachowiez, Oregon Health & Science University, Portland, OR*

Background: Inherited marrow failure syndromes (IMFS) are considered diseases of childhood, but testing adults with atypical presentations of diseases associated with IMFS is critical for establishing an optimal treatment protocol. The most common IMFS, Fanconi Anemia and Telomere Biology Diseases, are associated with MDS and aplastic anemia (AA), head and neck cancers, skin, and cervical cancer. Such patients can have profound toxicity with standard chemotherapy regimens. **Methods:** We implemented a screening protocol in patients at highest risk of an undiagnosed IMFS (MDS under age 60, AA patients under age 65, and head and neck cancers under age 60) with chromosome breakage analysis and telomere length testing. **Results:** Our protocol diagnosed nine patients (estimated ~10% of patients $<$ age 60 with these diseases) with IMFS. The features of these patients are described in the table. Only three (33%) patients had the classic physical characteristics of IMFS. Three patients were over age 50 when diagnosed with an inherited disorder. Most importantly, in all patients the treatment approach was modified significantly, including minimizing conditioning for BMT, utilizing danazol as first line treatment for AA, as well as aggressive cancer and endocrinopathy screening. Outcomes with modified treatment have been favorable, and occult malignancies were detected through screening in two patients. **Conclusions:** Inherited marrow failure syndromes are uncommon yet under recognized disorders that significantly impact treatment decisions in addition to implementation of surveillance programs for both the affected individual and their relatives alike. Through this approach of thoughtful screening of patients presenting to our institution with marrow failure we identified an unrecognized IMFS in an estimated 10% of patients.

Age	Hematological Findings	Additional Findings	Diagnosis
28	MDS	No	FA
22	AA	Café au lait spots, Cervical cancer	FA
37	MDS	No	FA
30	MDS	Nail dystrophy, skin changes	Dyskeratosis Congenita
43	AA	No	Telomere Disease
44	MDS	No	Telomere Disease
59	MDS	Cirrhosis	Telomere Disease
52	AA	Nail dystrophy, skin changes	Dyskeratosis Congenita
57	MDS	No	Telomere Disease

7056 Poster Session (Board #256), Mon, 8:00 AM-11:30 AM

Relationship of bone marrow blast (BMBL) response to overall survival (OS) in a multicenter study of rigosertib (Rigo) in patients (pts) with myelodysplastic syndrome (MDS) with excess blasts progressing on or after treatment with a hypomethylating agent (HMA). *First Author: Aref Al-Kali, Mayo Clinic, Rochester, MN*

Background: No therapies are approved for MDS after HMA failure. 04-24 was a single-arm study to evaluate best BMBL response as a potential surrogate for OS in higher-risk (HR) MDS pts who progressed on or after an HMA. Rigo is a Ras-mimetic that inhibits the RAS-RAF-MEK pathway, which is frequently activated in HR MDS (Athuluri-Divakar *Cell* 2016; Gil-Bazo *Cancer Biol Ther* 2016). **Methods:** Eligible MDS pts had 5-30% BMBL confirmed within 6 wks pre-study and progression per International Working Group (IWG) 2006 criteria on or after HMAs within 2 yrs. Rigo 1800 mg/24 hrs was continuously infused over 72 hrs q 2 wks × 8 cycles, then q 4 wks until progression or unacceptable toxicity. Primary endpoint was relationship of best BMBL IWG response to OS by Kaplan Meier method. **Results:** 64 pts were treated (median 5 cycles, range 1-32+), with 61% male, median age 73 (range 47-87), median prior HMA duration 10.8 mos (range 1.2-70.2). Revised International Prognostic Scoring System scores were low 2%, intermediate 11%, high 27%, very high 53%, and unknown 8%. ≥Grade 3 adverse events in ≥10% of pts were anemia 19%, thrombocytopenia 19%, and febrile neutropenia 16%. At the analysis time 40 pts (63%) had died. Best BMBL IWG response was marrow complete response (mCR) 14 pts (22%), stable disease (SD) 30 (47%), progressive disease (PD) 15 (23%), and failure (early death/withdrawal) 5 (8%); 2 mCR pts had transplant. Median OS was 7.0 mos (95% confidence interval 4.8-10.8). Landmark median OS (from day of best BMBL response) was mCR not reached; SD 6.3 mos; PD 3.3 mos. Median OS of mCR+SD was 8.5 mos, with log-rank p = 0.011 (mCR+SD OS to PD OS). **Conclusions:** BMBL response is a predictor of survival for MDS pts receiving Rigo after HMA failure, confirming findings in earlier Phase 1/2 studies (Silverman ASCO 2015 Abstr 7017). Based on earlier results identifying an MDS subset benefitting from Rigo (Garcia-Manero *Lancet Oncol* 2016; ASCO 2016 Abstr 165681), a randomized Phase 3 trial of Rigo vs physician's choice (INSPIRE) is ongoing to determine if Rigo improves survival after HMA failure within 9 cycles. Clinical trial information: NCTO 1928537.

7057 Poster Session (Board #257), Mon, 8:00 AM-11:30 AM

Hypomethylating agent (HMA) therapy use and survival in older patients with higher risk myelodysplastic syndromes (HR-MDS) in the United States (USA): A large population-based study. *First Author: Amer M Zeidan, Yale School of Medicine, New Haven, CT*

Background: The HMA azacitidine improved overall survival (OS) compared to conventional care in patients with HR-MDS in the landmark randomized clinical trial AZA-001 by a median of 9.5 months compared to conventional care regimens. However recent registry data from USA (Zeidan et al, 2016) and Spain (Bernal et al, 2015) did not show substantial population-level gains in OS. We used HMA market entry in the US (2004-06) as a natural experiment to assess the effect of HMA on OS. **Methods:** We conducted a retrospective cohort study using Surveillance, Epidemiology, and End Results-Medicare data.Individuals were included if they were 66 years or older in age, had refractory anemia with excess blasts (RAEB, considered to have HR-MDS), and were diagnosed in 2001-11.We performed 2-stage residual inclusion instrumental variable (IV) analysis, using diagnosis year as the IV. Residuals from the first stage model were added to the second stage regression to control for effects of unobserved factors between HMA treatment and OS. We also adjusted for demographic characteristics, comorbidity, disability status and transfusion receipt. **Results:** Among 2,581 patients with RAEB, the median OS from diagnosis was 9 months, and 35.8% received HMAs. In the first stage model, diagnosis year was a strong predictor of HMA (2001-06 vs. 2011, Odds Ratio = 0.004-0.56, P-value < .01). In IV analysis, patients who received HMAs showed no gain in OS (Hazard Ratio (HR) = 0.93, 95% Confidence Interval (CI) = 0.76-1.14), while there was a strongly protective effect of unobservable characteristics on OS (HR = 0.58, 95% CI = 0.47-0.73). **Conclusions:** In our US population-based analysis,HMA use was not associated with survival prolongation in older adults with HR-MDS. It is unclear if this is related to suboptimal use of HMAs (alternate schedules, doses, number of cycles), use of decitabine (which did not show survival benefit in randomized studies), or the unselected nature (compared to strict eligibility in clinical trials) of patients receiving HMAs at the community level. Better understanding of these issues is vital for optimal HMA patient selection and administration.

7058 Poster Session (Board #258), Mon, 8:00 AM-11:30 AM

Prognostic and therapeutic impact of cytogenetic abnormalities in patients with myelodysplastic/myeloproliferative neoplasms, unclassifiable. *First Author: Abhishek Avinash Mangaonkar, Mayo Clinic, Rochester, MN*

Background: The 2016 WHO classification includes myelodysplastic/myeloproliferative neoplasms, unclassifiable (MDS/MPN-U), as an MDS/MPN overlap syndrome not meeting criteria for well-defined entities such as CMML. No standard prognostication or treatment guidelines exist for such patients. **Methods:** We retrospectively identified MDS/MPN-U cases from 1990-2016 through our myeloid malignancies database. All bone marrow reports were reviewed to ensure compliance with 2016 WHO criteria. Clinical & cytogenetic parameters at diagnosis were assessed & compared with treatment outcomes. **Results:** Eighty nine patients met study criteria, with a median age of 69 years (range: 37-93); 58 (65%) males. Median follow-up was 22.2 months (range: 0-172), with 41 (46%) deaths & 13 (15%) leukemic transformations. Median OS was 24.8 months (range: 0-172). 43 (53%) patients had an abnormal karyotype, with common abnormalities being trisomy 8 (12%), complex karyotype (9%) & del (20q) (6%). Given the fewer types of abnormalities identified, the IPSS cytogenetic stratification was more effective than IPSS-R, with risk categorization including; 45 good (55%), 20 intermediate (25%) & 16 high risk (20%) respectively (8 unavailable). On univariate analysis, increased age (p = 0.05), decreased hemoglobin (p = 0.02), higher ANC (p = 0.03), circulating immature myeloid cells (p = 0.02), higher LDH (p = 0.009), absence of bone marrow ring sideroblasts (p = 0.001) & higher risk (intermediate & high) IPSS cytogenetic categories (p = 0.01) adversely impacted OS. In a multivariate model that included the aforementioned variables, higher risk IPSS cytogenetics retained a negative prognostic impact (p = 0.04). 28 patients received a median of 6 cycles (range: 1-21) of hypomethylating agent therapy (HMA), with an overall response rate of 18% (CR-3, PR-2). All responders had an abnormal karyotype (p = 0.01). However, HMA did not affect either OS or LFS. **Conclusions:** Intermediate & high risk IPSS cytogenetic categories independently & adversely impact survival in WHO defined MDS/MPN-U patients. HMA use did not impact OS; however, patients with abnormal karyotypes were more likely to respond.

7059 Poster Session (Board #259), Mon, 8:00 AM-11:30 AM

Axl blockade in vitro and in patients with high-risk MDS by the small molecule inhibitor BGB324. *First Author: Sonja Loges, Department of Oncology, Hematology, BMT with Section Pneumology and Institute of Tumor Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The interplay with bone marrow stroma plays an important role in the pathobiology of MDS. Gas6 is secreted by mesenchymal bone marrow stroma cells and promotes survival and therapy resistance of AML cells expressing the Axl receptor. We hypothesized that inhibiting Axl by the small molecule inhibitor BGB324 might hold therapeutic potential in MDS. **Methods:** We investigated the inhibitory effect of BGB324 on primary bone marrow mononucleated cells (BMMNC) and mesenchymal stroma cells (MSC) from MDS patients in comparison to healthy donors. In the ongoing first-in-patient Phase 1a/b trial BGBC003 A standard 3 + 3 dose escalation study was performed to identify the maximum tolerated dose of BGB324 in patients with previously treated high risk MDS or AML. BGB324 was administered as an oral loading dose on days one and two followed by a reduced daily maintenance. Three dose levels were explored 400/100mg, 600/200mg and 900/300mg. **Results:** We found that BGB324 inhibited BMMNC from low- and high-risk MDS patients with an IC50 of 2.1 μM and 3.8 μM, respectively (n = 5). In comparison, BMNNC from healthy donors were resistant to BGB324 (IC50 9.4 μM, p < 0.05, n = 10). Axl expression was present in MSC isolated from the BM of MDS patients and BGB324 inhibited the proliferation of MSC from low- and high-risk MDS patients (IC50 2.5 μM and 2.7 μM, respectively; n = 7/5).To date, 3 patients with MDS were treated with 400 mg loading dose and 100 mg maintenance dose of BGB324. Therapy has been well-tolerated and the MTD has not yet been reached. The majority of adverse events reported have been Grade 1 and 2. The most common related adverse events are diarrhea and fatigue. One patient with MDS was treated for 80 weeks and experienced a PR. Evidence of target inhibition was demonstrated by almost complete inhibition of Axl phosphorylation accompanied by reduction in phosphoErk and phosphoAkt signalling at day 21 of treatment. **Conclusions:** BGB324 is well-tolerated and might represent a promising novel treatment approach in MDS. Safety and efficacy of BGB324 will be explored further in clinical trials. Clinical trial information: NCT02488408.

7060 Poster Session (Board #260), Mon, 8:00 AM-11:30 AM

Does supplemental interphase FISH analysis to standard chromosom analysis improve the detection of myelodysplastic syndrome? *First Author: Benjamin Joseph Lang, Baylor University Medical Center, Dallas, TX*

Background: Our objective was to evaluate whether the addition of interphase FISH analysis to standard chromosome analysis (CA) improves the detection of chromosomal abnormalities in patients with work up for myelodysplastic syndromes (MDS), acute myeloid leukemia, and myelodysplastic/myeloproliferative disorders and thereby increases diagnostic and prognostic information. We performed a retrospective data review of all MDS orders between January and September 2015 at our institution and evaluated concurrent tests for discrepancies between CA and FISH results. Our aim was to evaluate best practices with regard to diagnostic test utilization, specifically to assess the diagnostic and prognostic value of FISH in addition to CA for patients with potential and known MDS. **Methods:** Retrospective data review of concurrent test orders of CA and myelodysplastic FISH panel were reviewed. The myelodysplastic FISH panel consists of screening for monosomy 5/deletion 5q, monosomy 7/deletion 7q, CEP7, trisomy 8, and D20S108 (20q12). The results of CA and FISH results were analyzed using a chi-square test to evaluate statistical significance. **Results:** A total of 1121 samples were queried, of which 55 were excluded due to inability to perform CA and limited diagnostic value of accompanying standalone FISH data on the 4 markers tested in this study. Analysis of the eligible 1066 samples showed that the standalone CA had significantly higher sensitivity ($p < 0.0001$) in detecting abnormal cases (N = 247, 23.17%) as compared to standalone FISH analysis (N = 180, 16.89%). Overall, 173 (16.23%) cases were determined to be abnormal by both methods. CA correctly interpreted 1059 of 1066 cases (99.34%).Only 7 samples were interpreted as normal by CA but were found to be abnormal by FISH. This results in overall 0.66% (2.76% of the abnormal cases) of abnormalities that would have been missed by CA only. **Conclusions:** These findings suggest that FISH studies with 4 markers used in this study provide limited additional utility in cases with a complete CA.

7061 Poster Session (Board #261), Mon, 8:00 AM-11:30 AM

Phase I/II trial of glasdegib in patients with primary or secondary myelofibrosis. *First Author: Aaron Thomas Gerds, Leukemia Program, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland, OH*

Background: Glasdegib is a small molecule inhibitor of the Sonic Hedgehog pathway, and data from the single arm, lead-in cohort of a phase 1b/2 trial in myelofibrosis (MF) are shown. **Methods:** Patients (age ≥18 yrs) with primary/secondary MF previously-treated with ≥1 Janus Kinase inhibitor (JAKi) were enrolled and received glasdegib 100 mg QD orally in 28 day cycles. AEs and laboratory abnormalities were assessed. Key efficacy endpoints were proportion of patients with spleen volume reduction (SVR) ≥35% and ≥50% reduction in total symptom score (TSS) measured by the MPN Symptom Assessment Diary (MPN-SAD) at Week 24. **Results:** 21 patients were enrolled between Oct '14-Oct '15 in this ongoing study. Mean age was 69.3 yrs (range 58-83). Median duration of treatment was 85 days (22-343). 52% were refractory patients with inadequate response to prior JAKi. Baseline symptoms were mostly mild (1-4), except fatigue (>4). No patients achieved SVR ≥35%, 5 patients had some SVR (maximum 2.3-21.4% reduction from baseline), and no progressive disease prior to Day 71. At week 24, 1 patient had ≥50% reduction in TSS, but 3/21 and 4/21, respectively showed 30% and 20% TSS reduction. Of 14 patients with severe baseline symptoms (1 with ≥5, or ≥2 with ≥3), 1, 1, and 2 achieved 50%, 30%, and 20% TSS reduction, respectively at week 24. TSS, spleen-related, and constitutional symptom scores showed a trend of reduction over 24 weeks with spleen-related symptoms, inactivity, and fatigue showing greatest improvement (52%, 58%, and 36%, respectively). Dysgeusia (N=13), muscle spasms (N=12), alopecia (N=8), decreased appetite (N=7), fatigue (N=7), lipase increase (N=5), and weight decrease (N=5) occurred in ≥20% patients. None, except 1 episode of fatigue, were considered serious AEs. Glasdegib steady state PK was consistent with previous single agent data. **Conclusions:** Glasdegib has an acceptable toxicity profile in patients with primary/secondary MF previously treated with JAKi. Symptom responder definition for refractory patients may not be the same as for JAKi naïve patients. Patient reported symptom improvement may be a more sensitive indicator of treatment benefit vs SVR. Further study of glasdegib may be warranted. Clinical Trial Information: NCT02226172.

7062 Poster Session (Board #262), Mon, 8:00 AM-11:30 AM

Allogeneic hematopoietic cell transplantation for myelofibrosis (MF) in high risk patients. *First Author: Swapna Narayana, Froedtert Hospital and Medical College of Wisconsin, Milwaukee, WI*

Background: Although allogeneic transplantation(alloHCT) is the only curative treatment modality for MF, given the median age of MF, most patients are not candidates for alloHCT due to concerns for treatment-related mortality(TRM), age and comorbidities. **Methods:** We reviewed the outcomes of 24 recipients of matched related/unrelated donor alloHCT for MF at the Medical College of Wisconsin. All patients with JAK2 mutation(62%) and/or constitutional symptoms recieved Roxulitinib atleast 4 months prior to alloHCT with discontinuation of Ruxolitinib 48 hrs prior to the start of conditioning. Majority (91%) received conditioning with Fludarabine and Busulfan(Flu/Bu4, Flu/Bu3, Flu/Bu4). Only 2 patients received TBI based regimen; Flu/TBI(2-4Gy). Those with splenomegaly > 22cm received pre-transplant splenic radiation(n = 11; 49%). Survival outcomes were analyzed using Kaplan-Meier curves and compared between groups using log-rank test. **Results:** Median age was 57 years(range,40-67) with 29% > 60 years. A 46% had primary ET or PV that evolved to MF and 17% had MDS cytogenetics. Majority(74%) patients MF-3 grade. More than 80% recieved Ruxolitinib and 25% were treated with hypomethylating/cytotoxic chemotherapy. HCT-CI score was≥3 in 62%. Four patients had cirrhosis and portal hypertension(PHTN), and another 3 had PHTN without Cirrhosis.At median follow up of 36months, 3-year overall survival(OS) and relapse-free survival were(RFS) 70%. Marrow fibrosis improved post HCT with only 15% grade 3. One patient relapsed and died from AML 15 months post-HCT. TRM was 25% at 3 years; causes of death were sepsis(n = 3), alveolar hemorrhage(n = 1) and myocardial infarction(n = 1). Variables such as type of donor, DIPSS scoring, MF grade and age of the patient were not significantly associated with OS/RFS on univariate analysis. **Conclusions:** Despite advanced age and 62% with HCT CI≥3, we report excellent survival outcomes compared to other prior data. Careful patient selection, use of Ruxolitinib pre-HCT, splenic irradiation pre-HCT and Flu/Bu based conditioning regimen all contributed to the remarkable results in this series.

7063 Poster Session (Board #263), Mon, 8:00 AM-11:30 AM

Phase 2 study of ruxolitinib in combination with 5-azacitidine in patients with myelofibrosis. *First Author: Lucia Masarova, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Ruxolitinib (RUX) is effective in controlling symptoms and organomegaly in patients with myelofibrosis (MF). Combination with azacitidine (AZA) may further improve its efficacy. **Methods:** RUX 15 or 20 mg orally twice daily was given continuously since cycle 1. AZA 25 to 75 mg/m2 on days 1-5 of each 28-day cycle was added starting cycle 4. Responses were assessed per International Working Group for Myelofibrosis Research and Treatment 2013 criteria (IWG-MRT). **Results:** Among 44 pts enrolled between 03/2013 and 06/2016, 39 patients (89%) were evaluable for response. After median (med) follow-up of 20.4+ months (range, 0.5-37+); 24 pts (54%) are on study with a med overall survival of 39+ months. Med age was 66 years (range, 48-87), 36 pts (82%) had int-2/high IPSS score, 29 (66%) had spleen ≥5cm, and 24 (55%) were $JAK2^{V617F}$ positive. Twenty five pts (57%) were previously treated. Twenty eight (72%) pts had objective response regardless of previous therapy (Table). Med time to response was 1.0 months. 7 (25%) responses occurred after the addition of AZA with med time to response of 4.2 months. In total, 23 pts (79%) had palpable spleen reduction by > 50%, which occurred after AZA was added in 6 (28%) of them. $JAK2^{V617F}$ allele reduction was noted in 13 (87%) evaluable pts, including > 50% reduction in 3 pts (13%). A reduction in bone marrow fibrosis grade was observed in 12 (31%) responders, including ≥2 and 1 grade reduction in 2 and 9 pts, respectively. Grade 3/4 non-hematological and hematological toxicities occurred in 4 and 16 pts, respectively. The most common reasons for therapy discontinuation (n=17) were stem cell transplantation (n=6), lack of response (n=3) and progression to AML (n=2). **Conclusions:** Concomitant RUX with AZA was feasible with overall IWG-MRT response rate of 72%, including >50% spleen reduction in 79% of patients, which compares favorably to single RUX. Clinical trial information: NCT01787487.

IWG-MRT 2013	N (%)
Overall response	28 (72)
Partial remission (PR)	2 (7)
Clinical improvement (CI) spleen + total symptom score (TSS)	7 (25)
CI TSS + CI hemoglobin	2 (7)
CI spleen + complete cytogenetic remission (CCyR)	2 (7)
CI TSS + CCyR	1 (4)
CI spleen + TSS + molecular PR (JAK2)	2 (7)
CI TSS only	8 (28)

7064 Poster Session (Board #264), Mon, 8:00 AM-11:30 AM

Ruxolitinib (RUX) in combination with azacytidine (AZA) in patients (pts) with myelodysplastic/myeloproliferative neoplasms (MDS/MPNs). *First Author: Rita Assi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clinical trials exclusively focusing on pts with MDS/MPNs are lacking. Combining RUX and AZA may target distinct manifestations of MDS/MPNs. **Methods:** Pts were treated with single-agent RUX 15 mg or 25 mg (based on platelets count) orally twice daily continuously in 28-day cycles for the first 3 cycles. AZA 25 mg/m^2 (day 1-5) was added on each cycle starting cycle 4 and could be increased to 75 mg/m^2 (maximum) or started earlier than cycle 4 and/or at higher dose in pts with proliferative features or high blasts. **Results:** 35 pts with med age 70 years (range, 43-79) were enrolled (MDS/MPN-U, n = 14; CMML, n = 17; atypical CM (aCML), n = 4), 28 (80%) were Int-2/High per MF DIPSS, 14 (41%) had splenomegaly > 5 cm, and 12 (34%) had EUMNET MF-2/MF-3 fibrosis. Common mutations on a 28-gene sequencing panel included JAK2 (29%), RAS (27%), ASXL1 (21%), TET2 (18%), and DNMT3A (12%). All 35 pts were evaluable for response per MDS/MPN IWG criteria and 17 (49%) responded. 6/17 (35%) IWG responses occurred after the addition of AZA (med time after AZA = 1.8 months). JAK2 mutated pts had a trend to higher responses vs those with non-mutated pts (8/10 vs 9/25, P = 0.19). Ten pts had > 5% pretreatment BM blasts and 7 achieved a reduction in blasts to < 5% (70%). A > 50% reduction in palpable spleen length reduction at 24 weeks was seen in 9/12 (75%) pts. New grade 3/4 anemia and thrombocytopenia occurred in 18 pts (51%) and 19 (54%) pts but were manageable with dose modifications. Only one pt discontinued therapy due to cytopenias. At a med follow-up of 17.4 mo (range, 1.2-36.8+), 14 (40%) pts died: pneumonia (n = 4), sepsis (n = 4), progression to AML (n = 4), and cardiac arrest (n = 1). The med survival for all pts was 16.6 mo (1.0 - 36.8). Compared to CMML and aCML, MDS/MPN-U pts had significantly better med survival (26.4+ vs 15.0+ vs 1.5+ mo, respectively; p = 0.01). **Conclusions:** The combination of RUX and AZA showed an IWG-response rate of 49% in pts with MDS/MPNs, and was well-tolerated. The benefit appears more profound in pts with MDS/MPN-U. This study is ongoing. (ClinicalTrials.gov Identifier: NCT01787487).

7065 Poster Session (Board #265), Mon, 8:00 AM-11:30 AM

Identification of effective therapy in Langerhans cell histiocytosis in the adult population. *First Author: Jennifer Ma, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Langerhans cell histiocytosis (LCH) is a rare disorder of histiocytic proliferation most commonly observed in children. LCH in adults is less characterized and a standard of care has not been established. Here we review clinical outcomes of adult LCH patients (pts) treated with various therapies at a large referral center. **Methods:** We identified 108 pts over 18 years of age with histologically confirmed LCH presenting to our center between 1990-2015. Clinical and treatment characteristics were examined and classified by single or multi-system involvement (SSI or MSI, respectively) and risk-organ involvement (ROI; liver, spleen, hematopoietic system and CNS). Overall survival (OS) and freedom from first progression (FFFP) were calculated by the Kaplan-Meier method. Univariate analysis was performed with the Cox proportional hazards model. **Results:** Median age at diagnosis was 44 years (range 18-89) with a median follow-up of 3.9 years (0.1-9.1). Median OS was 16.1 years and FFFP was 5.6 years, with 94 (87%) pts alive at last follow-up. Eighty-three (77%) had SSI and 13 (12%) had ROI. The most common sites of disease were bone (52 pts; 48%), lung (28; 26%), and skin (24; 22%). Only 11 pts (9%) experienced progression of disease (POD) after first treatment. Twenty-four (22%) received radiotherapy, 42 (39%) underwent excision, and 26 (24%) received systemic therapy at any point during treatment. The most common systemic agents were vinblastine, 6-mercaptopurine (6-MP), methotrexate (MTX), and cladribine. Eight received combination vinblastine, 6-MP, and MTX (VMM), 4 of which had MSI. Median progression-free survival (PFS) of VMM pts was 6 months, compared with 2.8 for all other systemic agents (p = 0.1). For OS, lack of ROI was the only significant variable upon univariate analysis (HR .22, 95%CI 0.06-0.75, p = 0.016). No variables were significant for PFS. **Conclusions:** Effective therapy for adult LCH has not been clearly identified. In our cohort of both low and high risk patients, the low POD rate observed is encouraging. VMM, a regimen previously studied in pediatric pts, is also effective in adults and may be considered the combination of choice for treatment of adult LCH. Further prospective study is warranted.

TPS7066 Poster Session (Board #266a), Mon, 8:00 AM-11:30 AM

CASCADE: A phase 3, randomized, double-blind study of vadastuximab talirine (33A) versus placebo in combination with azacitidine or decitabine in the treatment of older patients with newly diagnosed acute myeloid leukemia (AML). *First Author: Eunice S. Wang, Department of Medicine, Roswell Park Cancer Institute, Buffalo, NY*

Background: AML is associated with poor survival rates in patients (pts) who are not eligible for intensive chemotherapy or allogeneic stem cell transplant (allo-SCT) due to advanced age, comorbidities, and/or disease risk factors. Non-intensive therapies, such as the hypomethylating agents (HMAs) azacitidine and decitabine, are frequently employed in this setting; however, response rates and survival remain suboptimal in this pt population. Vadastuximab talirine (33A) is a CD33-directed antibody conjugated to pyrrolobenzodiazepine (PBD) dimers. Upon binding, 33A is internalized and transported to the lysosomes where PBD is released via proteolytic cleavage of the linker, leading to DNA crosslinking and cell death. In preclinical studies, HMA priming followed by 33A exposure upregulated CD33 expression, increased DNA incorporation of the PBD dimer, and enhanced cytotoxicity. In a phase 1 study, 33A plus HMA was generally well tolerated without a significant pattern of off-target toxicity. Activity of the combination was markedly improved compared to historical data of HMA monotherapy, with a high MRD-negative remission rate and activity maintained in the highest risk subgroups (Fathi et al, ASH 2016). **Methods:** This phase 3, randomized, double-blind, placebo-controlled global study was designed to compare overall survival between pts treated with 33A plus HMA vs. pts treated with placebo plus HMA (NCT02785900). Secondary endpoints include composite complete remission rate (CR/CRi), event-free survival, and safety. Approximately 500 pts will be randomized in a 1:1 manner to one of the study arms. Investigators may select either HMA (azacitidine or decitabine). Eligible pts are adults with newly diagnosed, previously untreated, de novo or secondary AML, and have intermediate or adverse cytogenetic risk. Pts must not have AML associated with favorable risk karyotype or be a candidate for allo-SCT. Combination treatment may be repeated every 4 weeks until disease progression, leukemic recurrence, or unacceptable toxicity. Study enrollment began in June 2016.

TPS7067 Poster Session (Board #266b), Mon, 8:00 AM-11:30 AM

An open-label, randomized phase III study of gilteritinib versus salvage chemotherapy in relapsed or refractory FLT3 mutation-positive acute myeloid leukemia. *First Author: Alexander E. Perl, University of Pennsylvania, Philadelphia, PA*

Background: *FLT3* mutations occur in 30% of patients with acute myeloid leukemia (AML), most often as internal tandem duplications (FLT3-ITD) or point mutations at codon D835. FLT3-ITDs are associated with high relapse rates, short remission duration, and poor overall survival (OS); FLT3-D835 can confer resistance to other tyrosine kinase inhibitors (TKIs). Gilteritinib is a highly selective FLT3/AXL TKI with activity against both FLT3-ITD and FLT3-D835 mutations. A recent phase 1/2 study of gilteritinib (20–450 mg/d) in relapsed/refractory (R/R) AML showed favorable tolerability at doses ≤300 mg/d, and consistent, potent FLT3 inhibition at doses ≥80 mg/d. Patients with FLT3 mutation-positive (FLT3^{mut+}) AML receiving doses ≥80 mg/d had an ORR of 52% (CR/CRp/CRi = 41%, PR = 11%) and longer OS than historic experience in R/R AML with combination cytotoxic chemotherapy or other FLT3 TKIs as monotherapy. Given these results, we initiated a phase 3 trial of once-daily (QD) 120 mg gilteritinib. **Methods:** This randomized, open-label phase 3 study (NCT02421939) will enroll 369 adults with FLT3^{mut+} AML in first relapse or refractory to front-line therapy. Patients who have not previously received FLT3 inhibitors, except sorafenib and midostaurin, will be randomized 2:1 to either 120 mg gilteritinib QD or the investigator's pre-randomization specified salvage chemotherapy choice (LoDAC, Aza, MEC, FLAG-IDA), and stratified by prior chemotherapy response and salvage chemotherapy intensity. Gilteritinib or low-intensity chemotherapy cohorts will receive continuous 28-day treatment cycles until a discontinuation event occurs; the high-intensity chemotherapy cohort will receive ≤2 treatment cycles before response measurement. Primary objective is OS; key secondary objectives are event-free survival and CR rate. Other secondary objectives: leukemia-free survival, remission duration, composite CR rate, subsequent transplantation rate, patient-reported fatigue, and safety. A formal interim analysis is planned when ~50% of planned death events have occurred. Study enrollment began on Oct 23, 2015; as of Jan 20, 2017, 167 subjects have been randomized. Clinical trial information: NCT02421939.

TPS7068 Poster Session (Board #267a), Mon, 8:00 AM-11:30 AM

A phase II/III, multicenter, open-label, 3-arm study of gilteritinib, gilteritinib plus azacitidine, or azacitidine alone in the treatment of newly diagnosed FLT3 mutation-positive acute myeloid leukemia (AML) patients ineligible for intensive induction chemotherapy. *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Gilteritinib, a highly selective, potent FLT3/AXL inhibitor, showed antileukemic activity with favorable tolerability in a Phase 1/2 trial of FLT3 mutation-positive ($FLT3^{mut+}$) relapsed/refractory AML. In $FLT3^{mut+}$ AML cell lines, gilteritinib plus azacitidine (AZA) inhibited growth, and induced apoptosis and differentiation. This ongoing Phase 2/3 trial will examine the efficacy, safety, and tolerability of gilteritinib alone, gilteritinib plus AZA or AZA alone in newly diagnosed $FLT3^{mut+}$AML patients ineligible for intensive induction chemotherapy. **Methods:** This open-label, 3-arm, 2-stage randomized trial (NCT02752035) will enroll ~540 newly diagnosed adults with $FLT3^{mut+}$ (FLT3-ITD or -TKD) AML; those with APL, BCR-ABL^{+}, or active CNS leukemia will be excluded. Before initiation, the safety and tolerability of gilteritinib plus AZA will be assessed in a Safety Cohort to establish the appropriate gilteritinib dose for combination therapy. Subjects will then be randomized 1:1:1 to receive oral gilteritinib alone (120 mg daily; Days 1–28), AZA alone (75 mg/m^2 by subcutaneous injection or intravenous infusion on Days 1–7), or AZA (75 mg/m^2; Days 1–7) plus oral gilteritinib (daily on Days 1–28 at the dose determined from the Safety Cohort), and stratified by age (< 75 vs ≥ 75 years). Subjects will continue treatment until a discontinuation event occurs. The primary endpoint is overall survival of subjects receiving gilteritinib or gilteritinib plus AZA versus AZA alone; the key secondary endpoint is event-free survival. Additional secondary endpoints: complete remission rate, leukemia-free survival, remission duration, composite remission rate, tolerability, and fatigue. Dose changes and interruptions are allowed in all treatment arms. A formal interim futility analysis by an Independent Data Monitoring Committee is planned when ~50 subjects in each treatment arm have either discontinued therapy or completed 2 treatment cycles. Enrollment began on November 21, 2016; as of January 31, 2017, the Safety Cohort is ongoing. Clinical trial information: NCT02752035.

TPS7069 Poster Session (Board #267b), Mon, 8:00 AM-11:30 AM

Phase 3, randomized, double-blind, placebo-controlled study of venetoclax combined with azacitidine versus azacitidine in treatment-naïve patients with acute myeloid leukemia. *First Author: Jalaja Potluri, AbbVie Inc., Chicago, IL*

Background: Elderly acute myeloid leukemia (AML) is a biologically and clinically distinct disease with a diminished response to chemotherapy, low remission rates, and short disease-free and overall survival. Venetoclax (VEN) is a potent, selective small-molecular inhibitor of BCL-2. In preclinical models, venetoclax has been shown to kill AML cells as a single agent with demonstrated synergistic activity in combination with the DNA methyltransferase inhibitor azacitidine (AZA). Early clinical data from a phase 1b study (NCT02203773) showed that VEN plus AZA had an acceptable safety profile and promising efficacy in treatment-naïve elderly patients with AML. The current phase 3 study continues to evaluate the combination for this AML population. **Methods:** This phase 3, randomized, double-blind, placebo-controlled study (NCT02993523) is designed to assess VEN plus AZA compared with placebo plus AZA in treatment-naïve elderly and adult patients with AML who are not eligible for standard induction therapy due to age or comorbidities. Primary objectives of the study are to evaluate if VEN with AZA will improve overall survival (OS) and composite complete remission rate (CR +CRi) versus placebo with AZA. Secondary objectives include event-free survival, CR+CRi rate at the end of Cycle 1, and if combining VEN plus AZA reduces fatigue and improves global health status/quality of life based on patient reported outcomes versus placebo with AZA. Exploratory objectives are to evaluate biomarkers predictive of VEN activity including minimal residual disease negativity rate, and BCL-2 expression and outcome measures of overall survival and complete remission rate, as well as the impact of VEN on additional quality of life measures. Patients will be randomized 2:1 to VEN plus AZA (arm A) or placebo plus AZA (arm B). Patients on arm A will receive once daily 400 mg VEN orally on days 1–28 plus daily 75 mg/m^2 SC or IV AZA for 7 days in a 28-day cycle. Patients on arm B will receive once daily placebo orally on days 1–28 plus daily 75 mg/m^2 SC or IV AZA for 7 days on a 28-day cycle. Study recruitment began in February 2017, with target enrollment of 400 patients. Clinical trial information: NCT02993523.

TPS7070 Poster Session (Board #268a), Mon, 8:00 AM-11:30 AM

A phase I, first-in-human study of MGD006/S80880 (CD123 x CD3 DART) in AML/MDS. *First Author: Norbert Vey, Institut Paoli-Calmettes, Centre Régional de Lutte Contre le Cancer, Marseille, France*

Background: MGD006/S80880 is a novel CD123 x CD3 DART molecule designed to target CD123-positive cells for recognition and elimination by CD3-expressing T lymphocytes as effector cells. CD123, the alpha chain of the interleukin 3 receptor (IL-3Ra) is known to be highly expressed in $>$ 90% of AML patients and at least 50% of MDS patients. Based on these observations, targeting CD123 could be a promising strategy in the preferential ablation of AML and MDS cells. **Methods:** MGD006 is currently being evaluated in a Phase 1 dose-escalation and cohort expansion study in relapsed/refractory (R/R) AML or intermediate-2/high risk MDS. The objectives of the study are to determine the MTDS and safety profile, and describe the pharmacokinetics and preliminary activity of MGD006. Patients are dosed in 28-day cycles. All patients start with a lead-in continuous IV infusion of 30ng/kg/day for 3 days followed by 100ng/kg/day for 4 days. Subsequent weeks (2-4) are dosed in two different schedules. One arm receives MGD006 for 4 days on/3 days off and the second arm receives MGD006 for 7 days continuously at the maximal dose assigned to each cohort (up to 1000ng/kg/day). Beginning with the second cycle, all patients are administered MGD006 for 4 days on/3 days off at the maximal dose/cohort. Patients can continue on treatment until 2 cycles (8 weeks) after the attainment of a CR, maximum of 12 cycles of MGD006, DLT or treatment failure. Once the MTDS is identified, two cohorts of 24 patients each, one in AML and one in MDS, will be enrolled. Response is assessed by IWG or IPSS criteria for AML and MDS, respectively. Signs and symptoms of cytokine release syndrome (CRS), a common AE, are graded according to Lee criteria. The study continues to enroll patients with open sites in the US, France, Germany, Italy, and The Netherlands. ClinicalTrials.gov #NCT02152956. EudraCT #2015-003813-11.

TPS7071 Poster Session (Board #268b), Mon, 8:00 AM-11:30 AM

A biomarker-directed phase 2 trial of SY-1425, a selective retinoic acid receptor alpha agonist, in adult patients with acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS). *First Author: Rachel J. Cook, Oregon Health & Science University, Portland, OR*

Background: SY-1425 (tamibarotene) is an orally available, synthetic retinoid approved in Japan for the treatment of relapsed/refractory (R/R) APL. SY-1425 is a more potent and selective retinoic acid receptor alpha (RARα) agonist with improved pharmacologic properties compared to all-trans retinoic acid (ATRA) including increased half-life and lack of metabolism by CYP26A1 resulting in extended relative exposures. SY-1425 binding to RARα relieves pathogenic repression of myeloid differentiation. Super-enhancers associated with *RARA* and upregulation of *RARA* expression correlate with increased sensitivity to SY-1425 *in vitro* and predict for response to SY-1425 with induced differentiation and reduced proliferation in RARA-high PDX AML models, but not in RARA-low models. SY-1425 also induces the RARα target gene *DHRS3* in RARA-high AML cell lines. This study is designed to demonstrate pharmacodynamic (PD) and clinical effects of SY-1425 in non-APL AML and MDS patients (pts) positive for the *RARA* super-enhancer associated biomarker or exploratory *RARA* pathway biomarker, IRF8. **Methods:** This study is enrolling pts with R/R AML, R/R higher-risk MDS, newly-diagnosed AML $\geq$60 yrs unlikely to respond to or tolerate standard therapy, and transfusion dependent lower-risk MDS pts without del 5q who are unlikely to respond to or have failed ESAs. Pts must be biomarker positive based on centralized testing of tumor cells from blood. All pts receive SY-1425 at 6 mg/m^2/day PO with continuous twice daily dosing. Primary objectives are to characterize the activity of SY-1425 by ORR in AML and higher-risk MDS pts or transfusion independence in lower-risk MDS pts. Secondary objectives include event-free and relapse-free survival, duration of response, overall survival, hematologic improvement and safety. PD evaluation includes induction of *DHRS3* and expression of myeloid differentiation markers. Target enrollment is 80 pts. This trial opened in September 2016. Through a protocol amendment, SY-1425 treatment in combination with azacitidine will also be evaluated. ClinicalTrials.gov identifier: NCT02807558.

TPS7072 Poster Session (Board #269a), Mon, 8:00 AM-11:30 AM

A randomized, double-blind phase III study of ibrutinib versus placebo in combination with corticosteroids in patients with new onset chronic graft versus host disease. *First Author: David Bernard Miklos, Stanford University Medical Center, Stanford, CA*

Background: Chronic graft versus host disease (cGVHD) is a common complication of allogeneic stem cell transplantation, with pathophysiology involving alloreactive and dysregulated T and B cells and innate immune populations. Ibrutinib, a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase, is indicated by the US FDA for the treatment of patients (pts) with CLL/SLL. Ibrutinib recently received breakthrough therapy and orphan drug designation for the treatment of pts with cGVHD who did not respond to one or more lines of systemic therapy. Ibrutinib reduces severity of cGVHD in murine models and recently was shown to achieve an NIH-defined overall response rate of 67% in pts with steroid relapsed/refractory cGVHD (Miklos *Blood* 2016). **Methods:** The primary objective of this Phase 3, multicenter, international, randomized, controlled, double-blind study is to evaluate the 24-week response rate of ibrutinib versus placebo in combination with prednisone. Pts with newly diagnosed moderate or severe cGVHD, as per NIH Consensus Development Project Criteria (2014), will be randomized in a 1:1 ratio to receive either oral ibrutinib (arm A) or placebo (arm B) in combination with oral prednisone. Ibrutinib or placebo will be given until unacceptable toxicity, relapse of underlying disease, death, or the need for a new systemic treatment for progressive cGVHD. Eligible study pts (age ≥12 yrs) must require systemic treatment with corticosteroids and have no prior systemic treatment for cGVHD. The primary endpoint is response rate (complete or partial response) at 24 weeks, as per NIH Consensus Development Project Criteria, and must occur in the absence of both new therapy for cGVHD and relapse/return of the underlying disease that was the indication for transplant. Secondary endpoints will assess for additional clinical benefit including corticosteroid dose reduction, improvement of Lee cGVHD Symptom Scale scores, withdrawal of all immunosuppressants, and overall survival. This study is currently enrolling pts. Funding source: Pharmacyclics LLC, an AbbVie Company. Clinical trial information: NCT02959944.

TPS7073 Poster Session (Board #269b), Mon, 8:00 AM-11:30 AM

The OMNI patient registry: A prospective observational registry to assess vascular safety in patients with CML and Ph+ ALL treated with ponatinib. *First Author: Annette Stemhagen, United BioSource, LLC (UBC), Blue Bell, PA*

Background: Ponatinib is an oral TKI with potent activity against BCR-ABL1. The pivotal PACE study (NCT01207440) formed the basis for approval of ponatinib in the US for the treatment of patients with resistant/intolerant CML or Ph+ ALL, or those with the T315I mutation. Long-term follow-up of PACE showed a higher cumulative incidence of vascular occlusive events (VOEs) than reported at the time of approval — dose reductions were later implemented to mitigate VOEs. VOEs comprise arterial occlusive events (AOE) and venous thromboembolic events. The exposure-adjusted incidence of AOEs has not increased over time in PACE; in patients with a history of ischemic disease, the relative risk of serious AOEs was 2.6 in those with ≥2 vs 0 risk factors. The primary objective of this patient registry is to assess VOEs occurring during ponatinib use in routine clinical practice in the US. **Methods:** OMNI (NCT02455024) is a prospective observational registry of eligible patients (Table) with CML or Ph+ ALL for whom the decision to initiate treatment with ponatinib has already been made for the approved US indications. Patients voluntarily enroll into the registry, which is non-interventional with no protocol-mandated tests/procedures — all treatment decisions are made at the discretion of the health care practitioner in consultation with their patient. Study duration is anticipated as ~30 mo (~18-mo enrollment followed by 12 mo of data collection, which will occur every 3 mo). The primary analysis will be performed 12 mo after last patient enrolled and will estimate the incidence of VOEs by duration of ponatinib exposure. To understand differences between those with and without VOEs, exploratory analyses will be performed, considering factors such as patient demographics, risk factors for developing VOEs, dose and duration of ponatinib treatment, and concomitant medications. VOE outcomes also will be assessed. Enrollment will begin in 2017, with a target of ≥300 patients. Clinical trial information: NCT02455024.

Key inclusion criteria	CP-CML, AP-CML, BP-CML, or Ph+ ALL With/without anticoagulant and/or antiplatelet agents ≥18 yrs
Key exclusion criteria	Concomitant TKI therapy

TPS7074 Poster Session (Board #270a), Mon, 8:00 AM-11:30 AM

A randomized, open-label, phase II study of azacitidine (AZA) in combination with durvalumab in patients (pts) with previously untreated higher-risk myelodysplastic syndromes (MDS) or acute myeloid leukemia (AML) ineligible for hematopoietic stem cell transplantation (HSCT). *First Author: Lewis R. Silverman, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Hypomethylating agents (HMAs) induce hematologic response in ~ 50% of higher-risk MDS pts; however, there are few treatment options for nonresponding pts at increased risk of AML progression and death. While older AML pts ineligible for HSCT have similar overall survival (OS) with AZA and chemotherapy (13.3 vs 12.2 months) (Döhner et al. Haematologica 2015;100: P566), there is an opportunity to further improve responses and OS in these pts. Blockade of the programmed cell death-1 (PD-1)/PD-ligand 1 (PD-L1) pathway with immune checkpoint inhibitors is an emerging paradigm in anticancer therapy. PD-L1 is expressed on cells from AML and MDS pts; expression is upregulated on myeloblasts following HMA therapy (Yang et al. Leukemia 2014; 28:1280) and during MDS transformation to AML (Ogata et al. Leuk Res 2012; 36:1229). Durvalumab (MEDI-4736), a human anti-PD-L1 monoclonal antibody, is well tolerated and induces durable responses in pts with solid tumors (Lutzky et al. JCO 2014;32:3001). This randomized, open-label, phase 2 study evaluates efficacy and safety of subcutaneous (SC) AZA ± durvalumab in pts with higher-risk MDS and older pts with AML. **Methods:** Eligible MDS pts (< 20% blasts) aged ≥ 18 years, with IPSS intermediate- or high-risk MDS, and AML pts (≥ 20% blasts) aged ≥ 65 years, are randomized 1:1 to receive either AZA 75 mg/m^2 SC for 7/28 days or AZA 75 mg/m^2 SC for 7/28 days plus durvalumab 1500 mg IV on day 1 of 28-day cycles. Pts are stratified by cytogenetic risk: intermediate- vs poor-risk AML, and intermediate- vs poor-/very-poor-risk MDS. Primary endpoint is overall response rate per IWG 2006 criteria in MDS pts, and proportion of pts achieving complete response (CR) or CR with incomplete blood count recovery (CRi) per modified IWG 2003 criteria in AML pts. Other endpoints include safety, time to response, overall survival and PD-1/PD-L1 activity. Pts will be followed every 3 months until discontinuation. Target enrollment is 182 pts: 72 MDS pts and 110 AML pts. Enrollment began in June 2016 (ClinicalTrials.gov NCT02775903).

TPS7075 Poster Session (Board #270b), Mon, 8:00 AM-11:30 AM

H3B-8800-G0001-101: A first in human phase I study of a splicing modulator in patients with advanced myeloid malignancies. *First Author: David P. Steensma, Dana-Farber Cancer Institute, Boston, MA*

Background: Dysregulated mRNA splicing is important in tumorigenesis and in resistance to cancer therapy. Somatic heterozygous mutations in core spliceosome genes (e.g. *SF3B1, SRSF2, U2AF1*) have been reported at high frequencies in patients with myelodysplastic syndromes (MDS), acute myeloid leukemia (AML), and chronic myelomonocytic leukemia (CMML). These mutations confer a change of function resulting in aberrant mRNA splicing that, in preclinical models, results in defects in hematopoietic cell development and myelodysplasia. Recurrent mutations in the spliceosome of patients with malignancies suggests importance in disease pathogenesis. Cells bearing splicing mutations depend on wild-type spliceosome function, suggesting the spliceosome as a therapeutic target. In vitro data indicate preferential induction of apoptosis (measured by caspase 3/7 activation) in SF3B1-mutant cells following treatment with the SF3B1 modulator H3B-8800. H3B-8800 inhibits growth in human AML cell lines, including those with mutations in U2AF1, SRSF2 or SF3B1. Oral administration of H3B-8800 modulates splicing and induces antitumor activity in xenograft leukemia models expressing mutant core spliceosome components. **Methods:** This study explores the safety of H3B-8800 in patients with myeloid cancers. Dose escalation (Cohort A) follows a 3+3 design with a starting dose of 1 mg daily for 5 consecutive days every 14 days in a 28 day cycle. Cohort A is open to patients with MDS, AML or CMML, irrespective of spliceosome mutations. In parallel to dose escalation, up to 6 patients with mutations of interest may be enrolled at doses determined to be safe in Cohort A (Cohort B). After determining the recommended phase 2 dose, 4 expansion cohorts will enroll patients with: (1) International Prognostic Scoring System (IPSS) low/int-1 risk MDS with SF3B1 mutations, (2) IPSS low/intermediate risk-1 MDS with mutations in SRSF2, U2AF1, or ZRSR2, (3) high/intermediate risk-2 MDS or AML, and (4) CMML; 3 and 4 having mutations in SF3B1, SRSF2, U2AF1, or ZRSR2. The first cohort enrolled 3 patients and the trial is currently enrolling patients at the second dose level. Clinical trial information: NCT02841540.

7500 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

First-line treatment of iNHL or MCL patients with BR or R-CHOP/R-CVP: Results of the BRIGHT 5-year follow-up study. *First Author: Ian Flinn, Tennessee Onc, Nashville, TN*

Background: BRIGHT, a phase 3, open-label, noninferiority study comparing efficacy and safety of bendamustine plus rituximab (BR) vs rituximab plus cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP) or rituximab with cyclophosphamide, vincristine and prednisone (R-CVP) in treatment-naive patients (pts) with indolent non-Hodgkin lymphoma (iNHL) or mantle cell lymphoma (MCL), showed that the complete response rate for first-line BR was statistically noninferior to R-CHOP/R-CVP (*Blood* 2014). Pts were monitored for ≥5 years (yr) to assess the overall effect of BR or R-CHOP/R-CVP in a controlled clinical setting. This analysis reports the time-to-event variables of the 5-yr follow-up (FU) study. **Methods:** Pts with iNHL or MCL randomized to 6-8 cycles of BR or R-CHOP/R-CVP underwent complete assessments at end of treatment, then were monitored regularly. Progression-free survival (PFS), event-free survival (EFS), duration of response (DOR) and overall survival (OS) were compared using a stratified log-rank test. **Results:** Of 447 randomized pts, 224 received BR, 104 R-CHOP, and 119 R-CVP; 419 entered the FU. The median FU time was 65.0 and 64.1 months for BR and R-CHOP/R-CVP, respectively. The 5-yr PFS rate was 65.5% (95% CI 58.5-71.6) and 55.8% (48.4-62.5), and OS was 81.7% (75.7-86.3) and 85% (79.3-89.3) for BR and R-CHOP/R-CVP, respectively. The hazard ratio (95% CI) for PFS was 0.61 (0.45-0.85; *P*= .0025), EFS 0.63 (0.46-0.84; *P*= .0020), DOR 0.66 (0.47-0.92; *P*= .0134), and OS 1.15 (0.72-1.84; *P*= .5461) comparing BR vs R-CHOP/R-CVP. Similar results were found in iNHL [PFS 0.70 (0.49-1.01; *P*= .0582)] and MCL [PFS 0.40 (0.21-0.75; *P*= .0035)], with the strongest effect in MCL. Use of R maintenance was similar, 43% in BR and 45% in R-CHOP/R-CVP. B was included as second-line in 27 (36%) of the 75 pts requiring therapy who originally received R-CHOP/R-CVP. Comparable safety profiles with expected adverse events were observed in the FU study in BR vs R-CHOP/R-CVP. **Conclusions:** The long-term FU of the BRIGHT study has confirmed that PFS, EFS, and DOR were significantly better for BR, and OS was not statistically different between BR and R-CHOP/R-CVP. The safety profile was as previously reported. Clinical trial information: NCT00877006.

7501 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Bendamustine plus rituximab (B-R) versus CHOP plus rituximab (CHOP-R) as first-line treatment in patients with indolent lymphomas: Nine-year updated results from the StiL NHL1 study. *First Author: Mathias J. Rummel, Department of Haematology and Oncology, Justus-Liebig Universität, Giessen, Germany*

Background: This multicenter, randomized, phase III study compared B-R and CHOP-R as first-line treatment in patients (pts) with indolent lymphomas or mantle cell lymphoma and was first published in The Lancet in 2013. The final analysis demonstrated a significantly prolonged progression-free survival (PFS) in the B-R group compared to the CHOP-R group, with a median PFS of 69.5 vs. 31.2 months, respectively. In the current analysis, we present updated results for overall survival (OS), time-to-next-treatment (TTNT), and secondary malignancies (sNPL) with a median follow-up of 113 months for patients with indolent lymphomas (excluding MCL). **Methods:** 447 pts with indolent lymphomas were randomized to receive B-R or CHOP-R for a maximum of 6 cycles. The primary endpoint was PFS; secondary endpoints included OS, TTNT, and sNPL. **Results:** Patient characteristics were well balanced between arms; median age was 64 years. The difference in OS between the two treatment arms was not statistically significant, with 60 deaths in the B-R group vs 68 deaths with CHOP-R (HR 0.82, 95% CI 0.58 – 1.15, p = 0.249). The estimated 10-year survival rates were 71% for B-R and 66% for CHOP-R. TTNT was significantly prolonged with B-R compared with CHOP-R (HR 0.52, 95% CI 0.38 – 0.69, p < 0.001). Median TTNT was not yet reached in the B-R group (95% CI 124.9 – n.y.r) vs. 56 months in the CHOP-R group (95% CI 39.1 – 82.0). Patients treated initially with B-R needed fewer second-line treatments due to disease progression compared to CHOP-R treated pts: 73 pts (34%) in the B-R group received salvage treatment compared with 106 pts (52%) in the CHOP-R group. For B-R pts, CHOP-R was used as second-line therapy 26 times (36%), whereas B-R was used for pts initially treated with CHOP-R 49 times (46%). 36 pts with sNPL were observed in the B-R group compared with 39 in the CHOP-R group, with 7 hematological malignancies in both groups to date. **Conclusions:** In pts with previously untreated indolent lymphomas, B-R demonstrates a PFS and TTNT benefit over CHOP-R. Clinical trial information: NCT00991211.

7502 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Phase IIIb randomized study of lenalidomide plus rituximab (R^2) followed by maintenance in relapsed/refractory NHL: Analysis of patients with double-refractory or early relapsed follicular lymphoma (FL). *First Author: David Jacob Andorsky, Rocky Mountain Cancer Centers/US Oncology Research, Boulder, CO*

Background: Chemoresistant patients with FL and those who progress within 2 y after initial diagnosis have poor outcomes (Casulo. *JCO.* 2015) and highlight an unmet need. **Methods:** MAGNIFY (NCT01996865) is a phase IIIb, multicenter, open-label study of relapsed/refractory (R/R) NHL patients, including grades 1-3b or transformed FL (tFL). Patients receive 12 cycles of lenalidomide plus rituximab (R^2); those with stable disease or better are randomized 1:1 to maintenance R^2 or rituximab alone. The primary endpoint is progression-free survival (PFS). This analysis focuses on FL: double-refractory (DR) patients are refractory to both rituximab (as monotherapy or combination) and an alkylating agent, and early relapse (ER) patients progressed or relapsed within 2 y of initial diagnosis. **Results:** As of July 19, 2016, the R/R FL population (N = 117) included 32 (27%) DR and 43 (37%) ER patients, median ages of 64 and 65 y, respectively, mostly grade 1-3a FL (94%; 91%) and 2 tFL (1 DR; 1 ER); 72% and 49% were stage IV at study entry. Patients had a median of 2 prior regimens (DR 3; ER 2). Of ER patients, 31 had first-line R-chemo vs 12 with R-mono/other. Response rates are in Table 1. Median time to response was 2.8 mo for DR and 2.7 mo for ER patients, with median duration not reached. 1-y PFS for FL patients was 66% (DR 66%; ER 45%); 1-y PFS for ER patients with first-line R-chemo was 50% vs 27% in others. Common grade ≥3 treatment-emergent AEs for DR and ER patients were neutropenia (53%; 33%), leukopenia (9%; 12%), and lymphopenia (9%; 5%). **Conclusions:** R^2 followed by maintenance showed favorable activity and tolerable safety profiles in FL patients who are double-refractory or had early relapse (< 2 years) after initial diagnosis. Enrollment in MAGNIFY is ongoing. Clinical trial information: NCT01996865.

Best response for evaluable patients in induction and maintenance.

Response status, n (%)	DR (n = 28)	ER (n = 33)	All FL (N = 91)
ORR	13 (46)	16 (48)	61 (67)
95% CI	28%-61%	31%-67%	56%-77%
CR/CRu	6 (21)	4 (12)	33 (36)
PR	7 (25)	12 (36)	28 (31)
SD	10 (36)	13 (39)	21 (23)
PD*	5 (18)	4 (12)	9 (10)

*Includes PD and/or death prior to response evaluation completion.

7503 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

A genetic risk-stratified, randomized phase 2 intergroup study of fludarabine/antibody combinations in symptomatic, untreated chronic lymphocytic leukemia (CLL): Results from Cancer and Leukemia Group B (CALGB) 10404 (Alliance). *First Author: Amy S. Ruppert, The Ohio State University, Columbus, OH*

Background: Prior to use of novel targeted agents for CLL, debate existed regarding the best chemoimmunotherapy regimen to build upon in patients (pts) with non-del(11q) disease. The role of lenalidomide (L) was also not defined. CALGB 10404 was a randomized phase 2 study addressing these questions. **Methods:** Pts with untreated CLL requiring therapy were randomized to treatment with fludarabine + rituximab (FR), FR + 6 monthly consolidative treatments of L (5 mg days 1-21/28 x 1 then 10 mg days 1-21/28 x 5) (FR+L), or FR + cyclophosphamide (FCR). Based on pretreatment central interphase cytogenetic screening, pts with del(11q22.3) in at least 20% of cells were excluded from the primary analysis, testing whether 2-year progression-free survival (PFS) rate was improved in non-del(11q) pts within each arm. A target accrual of 103 non-del(11q) pts per arm provided at least 84% power to detect an increase in 2-year PFS rate from 60% to 73%; the critical value was 69% using a single stage design and type I error rate of 4%. **Results:** A total of 342 non-del(11q) CLL pts were randomized to treatment with FR (n = 123), FR+L (n = 109), or FCR (n = 110). Baseline characteristics were similar across arms. Two-year PFS rates with exact 90% CIs were 64% (57-71%) (FR), 71% (63-78%) (FR+L), and 74% (66-80%) (FCR). Median PFS was significantly shorter with FR compared to FR+L (p = 0.03) and FCR (p < 0.01): 43 (95% CI: 33-50), 66 (95% CI: 45-not reached), and 78 (95% CI: 58-not reached) months respectively. Median overall survival (OS) has not been reached for any arm. OS at 1, 2, and 3 years was similar across arms, although there was a plateau in OS with no events beyond 41 months in the FR+L arm, different from FR/FCR where events continued to occur. The most common adverse events were cytopenias and infections. **Conclusions:** FR+L and FCR met the protocol defined primary endpoint. FR+L extended PFS relative to FR and a plateau in survival differentiated this arm from the FR/FCR arms. Future studies comparing FR+L to FCR or incorporating L into other novel treatment regimens are justified. Support: U10CA180821, U10CA180882, Celgene. Clinical trial information: NCT00602459.

7504 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Ublituximab and ibrutinib for previously treated genetically high-risk chronic lymphocytic leukemia: Results of the GENUINE phase 3 study. *First Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, OR*

Background: Patients (pts) with high-risk chronic lymphocytic leukemia (CLL) defined by interruptions in TP53 (either by mutation or deletion) or loss of chromosome 11q experience inferior outcomes with ibrutinib (IB) monotherapy (O'Brien ASH 2016). Ublituximab (UTX) is a novel glycoengineered mAb with enhanced ADCC targeting a unique epitope on the CD20 antigen. GENUINE is the first randomized Ph 3 trial conducted assessing the addition of a novel agent to ibrutinib in high-risk rel/ref CLL, and evaluates IB monotherapy vs. UTX + IB. **Methods:** Eligible pts with rel/ref CLL and centrally confirmed del17p, del11q, and/or a TP53 mutation were randomized 1:1 to receive IB (420 mg QD) alone or with UTX (900 mg on D1, 8, 15 of Cycle 1, D1 of Cycle 2-6, and Q3 Cycles thereafter). There was no limit on number of prior therapies. Prior IB exposure was excluded. The primary endpoint was overall response rate (ORR) per iwCLL 2008 criteria, with secondary endpoints including CR rate, MRD negativity, PFS, time to response (TTR) and safety. **Results:** 126 pts were randomized at sites in the US and Israel, with 117 pts treated (59 on UTX + IB, 58 on IB alone). Median age 67, median 3 prior therapies (range 1-8), > 70% of were male. High-risk cytogenetics were relatively balanced with ~ 50% of pts having del17p. UTX+IB was well tolerated, with infusion reactions the most prevalent AE (44%, GR3/4 5%). Neutropenia was comparable with the combination (17%, Gr3/4 7% vs. 10%, Gr3/4 9%), and other AE's were similar or lower with UTX+IB vs. IB alone (all grades), including fatigue (17% vs. 31%), dizziness (12% vs. 21%), contusion (12% vs. 26%), anemia (10% vs. 16%), and myalgia (9% vs. 14%). At median follow-up of 12 mo, best ORR per independent central review was 80% for UTX + IB vs. 47% for IB alone ($p < 0.001$). While not powered for secondary endpoints, observed advantages were seen in PFS and radiographic CR rate in the UTX + IB arm. CR and MRD confirmation is ongoing. Median TTR for the combo was 1.97 mo vs. 3.8 mo for IB alone. Both arms have responses pending confirmatory assessments. **Conclusions:** The addition of UTX to IB demonstrated a superior response rate compared to IB alone without additional clinically significant toxicity. Clinical trial information: NCT02301156.

7505 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Richter's syndrome (RS) in patients with chronic lymphocytic leukemia (CLL) on novel agent therapy. *First Author: Matthew Steven Davids, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: Novel agents (NA) targeting B cell receptor kinases and Bcl-2 have substantially improved outcomes in CLL; however, the development of RS in CLL patients (pts) on NAs has been observed, and has not been systematically evaluated. **Methods:** We retrospectively reviewed pts at 9 academic centers diagnosed with pathologically-confirmed RS from 2011-16. Informed consent was provided through IRB-approved protocols. Descriptive statistics were utilized and overall survival (OS) was calculated from RS diagnosis (dx) to death or last follow-up by Kaplan-Meier. **Results:** 71 pts who developed RS on NAs for CLL were identified. Median age at CLL dx was 55 yrs (range 21-82), median of 3 therapies (range 0-12) prior to the NA. 68% pts were fludarabine-refractory, and 5 pts (7%) had relapsed post alloHCT. Median time from CLL dx to initiation of NA was 68.5 mo. (range 1.1-246.2). FISH at NA initiation: del(17p) 30/61 (49%), del(11q) 15/61 (25%), trisomy 12 15/61 (25%). Complex karyotype was present in 40/53 (75%). 46/52 (88%) were *IGHV* unmutated, VH1-69 10/43 (23%), VH4-39 4/43 (9%). 59 (83%) pts were on a BTK inhibitor, 6 (8%) PI3K inhibitor, 6 (8%) venetoclax. RS histology: DLBCL (87%), plasmablastic (6%), Hodgkin (4%), 3% other. RS Ki-67%: >90 (23%), 75-90 (25%), 50-75% (25%), <50% (28%). Median time from start of NA to RS dx was 9.1 mo (range 0.9-48.2), with 65% developing RS within 12 mo. of starting NA. In 56 pts, 19 different regimens were used as initial RS therapy, including: R-EPOCH (36%), R-CHOP (20%), checkpoint blockade (9%), OFAR (7%), or a different NA (7%). Of the 48 pts evaluable for response, ORR was 42% (15% CR, 27% PR). In 29 evaluable pts receiving R-EPOCH/CHOP, ORR was 48% (21% CR). With a median follow-up of 10.6 mo., median OS was only 3.3 mo. (95%CI 2.2-6.0), though none of the 7 pts who achieved CR has died. **Conclusions:** We report to our knowledge the largest series of CLL pts developing RS on NAs. Pts often had high risk CLL, particularly complex cytogenetics, and RS frequently developed within the first year of NA therapy. Substantial variation exists in treatment, and outcomes are poor for those who do not achieve CR. Identification of molecular drivers of RS and development of novel treatment strategies are urgently needed.

Radiotherapy to bulky disease PET-negative after immunochemotherapy in elderly DLBCL patients: Results of a planned interim analysis of the first 187 patients with bulky disease treated in the OPTIMAL>60 study of the DSHNHL. *First Author: Michael Pfreundschuh, University Saarland Medical Schoolý, Homburg Saar, Germany*

Background: RT to bulky sites improves outcome of elderly DLBCL patients [Lancet Oncol 2008; 9: 105-116; J Clin Oncol 2014; 32:112-1118]. Whether RT can be spared in PET-negative pts. after R-CHOP was prospectively addressed in OPTIMAL >60. **Methods:** 61 to 80 y-old pts. were randomized in a 2x2 factorial design to 6xCHOP-14 or 6xCHLIP-14 (liposomal instead of conventional vincristine) plus 8 x rituximab 375 mg/m^2(R) q 2 wks. or 12xR (days -4,-1,1,4,14,28,42,56,91,126,175, 238). Pts. with bulk (>=7.5 cm) PET-positive after 6 cycles chemotherapy were assigned to RT (39.6 Gy), while PET-negative bulks were observed. **Results:** 187/505 (37%) had bulky disease and were compared to 117/306 (38%) RICOVER-60 pts. (38%) who had received 6xCHOP-14+8R. OPTIMAL>60 pts. were older (70 vs. 68 years) and had more IPI=3 (33% vs. 29%) and IPI=4,5 (34% vs. 23%) compared to RICOVER-60. PET was performed in 166/187 OPTIMAL>60 bulk pts. (reasons for no PET: early death: 5; excessive toxicity: 3; protocol violation: 1, non-compliance: 4, change of diagnosis: 6, others: 2). 80/166 (48%) bulks remained PET-positive after 6 cycles of chemotherapy and 62/80 (78%) were irradiated (reasons for no RT: progression: 8; medical reasons: 9; negative biopsy: 1), reducing RT from 67/117 (57%) in RICOVER-60 by 42% to 62/187 (33%) in OPTIMAL>60. Despite the unfavorable demographics, outcome of the 187 bulk pts. in OPTIMAL>60 was non-inferior to RICOVER-60, not even in the least intensive of the 4 OPTIMAL>60 treatment arms consisting of 47 pts. who received 6xCHOP-14+8R as in RICOVER-60. 2-year PFS and OS in OPTIMAL>60 was 79% and 88%, respectively, compared to 75% and 78% of the 117 RICOVER-60 pts. In a multivariable analysis adjusting for the IPI risk factors, the hazard ratio of the OPTIMAL>60 compared to the RICOVER-60 bulk pts. was 0.7 (95% CI: 03.; 1.5; p=0.345) for PFS and 0.5 (95% CI: 02.; 1.3; p=0.154) for OS. **Conclusions:** RT can be spared in bulky disease PET-negative after chemotherapy. This strategy results in a 42% reduction of RT without compromising the outcome of these patients. Supported by Amgen, Roche, Spectrum. Clinical trial information: NCT01478542.

7507 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Noninvasive detection of clinically relevant copy number alterations in diffuse large B-cell lymphoma. *First Author: Michael C. Jin, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Somatic copy number alterations (SCNAs) are common and clinically important genomic events in lymphomas. For example, *MYC* and *BCL2* amplifications are associated with adverse outcomes (Quesada, ASH 2016), while *PD-L1* (*CD274*) amplifications are associated with improved response to checkpoint inhibitors (Ansell, NEJM 2015). However, noninvasive detection of these events from circulating tumor DNA (ctDNA) remains difficult. Using CAPP-Seq, a targeted high-throughput sequencing platform, we developed a method to profile both focal and broad SCNAs from plasma. **Methods:** We profiled plasmas from a cohort of 75 pretreatment diffuse large B-cell lymphoma patients and 48 healthy controls. Focal SCNAs were evaluated at ultra-high depths (~10,000x), allowing for detection of lesions at ~1% ctDNA fraction. Thresholds were tuned to allow a false positive rate of 1%, which was empirically validated in an independent healthy cohort (n = 15), yielding a panel-wide false discovery rate of ~2.3% (0% in our genes of interest). Sequencing reads outside the targeted regions were separately pooled and analyzed to evaluate arm and chromosome level SCNAs. **Results:** We detected SCNAs in clinically relevant genes at the frequencies reported in literature, including amplifications in *MYC* (8.0%), *BCL2* (24.0%), and *BCL6* (14.7%) and deletions in *TP53* (13.3%) and *CDKN2A* (9.3%). Remarkably, 26.7% of the cohort demonstrated amplification of both *PD-L1* and *PD-L2* (*PDCD1LG2*). Furthermore, we discovered amplifications in *PD-L2*, but not *PD-L1*, in 13.3% of our patients. Interestingly, *PD-L1* amplifications were more common in patients with relapsed lymphoma than in those with treatment-naïve disease (43.5% vs 19.2%, p = 0.02). Most *PD-L1* amplifications were focal (65%) while the remainder typically involved > 80% of Chr9p. Corresponding tissue profiling data is in progress and will also be presented. **Conclusions:** Noninvasive sampling of lymphoma ctDNA enables detection of both focal and broad SCNAs, including amplifications of *MYC*, *BCL2*, and *PD-L1*. The ability to noninvasively profile copy number altered regions allows for biopsy-free discovery of clinically significant structural alterations in lymphoma patients.

7508 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Autologous (auto) versus matched sibling donor (MSD) or matched unrelated donor (MUD) allogeneic (allo) hematopoietic cell transplantation (HCT) in follicular lymphoma (FL) patients (pts) with early chemoimmunotherapy failure (ECF): A Center for International Blood and Marrow Transplant Research (CIBMTR) analysis. *First Author: James K. Godfrey, University of Chicago, Chicago, IL*

Background: Contrary to most FL, high-risk FL pts with ECF (i.e. relapse within 2 yrs of frontline chemoimmunotherapy) have a 5 yr OS of only 50%. (Casulo, JCO 2015). We used the CIBMTR database to compare autoHCT versus either MSD or MUD alloHCT as the first transplant approach in FL pts with ECF. **Methods:** Adult FL pts (age ≥18) undergoing autoHCT or alloHCT between 2002-2014 and receiving first line rituximab-based chemoimmunotherapies with evidence of ECF (defined as disease relapse or progression within 2 yrs of treatment initiation) were included. The primary endpoint was OS; secondary endpoints were progression-free survival (PFS), relapse and non-relapse mortality (NRM). **Results:** 440 pts had ECF (auto = 240, MSD = 105, MUD = 95) (Table 1). The 5 yr adjusted probabilities (AjP) of NRM were significantly lower with autoHCT (5%), versus MSD (17%) or MUD (33%) HCT ($p<0.0001$). 5 yr AjP of relapse were significantly lower with MSD (31%) or MUD HCT (23%), versus autoHCT (58%; $p<0.0001$). AjP of 5 yr PFS following auto, MSD and MUD HCT were 38%, 52% and 43% (p=.006) respectively. The AjP of 5 yr OS was significantly higher following autoHCT (70%) or MSD HCT (73%) versus MUD HCT (49%; p=0.004). **Conclusions:** AutoHCT for FL pts with ECF has low NRM and 5 yr OS rates (70%) that are provocatively higher than historical data (~50%). MSD HCT had the lowest relapse rate with similar survival. A prospective trial confirming the role of HCT in ECF FL is warranted.

CD19 CAR-T cells combined with ibrutinib to induce complete remission in CLL. *First Author: Saar Gill, University of Pennsylvania, Philadelphia, PA*

Background: Immunotherapy with anti-CD19 CART cells induces complete remission (CR) in the minority of patients with CLL, but where CRs occur they tend to be durable. Based on preclinical evidence of synergy, we combined anti-CD19 CAR T cells with ibrutinib to test the hypothesis that pre- and concurrent treatment would enhance the CR rate. **Methods:** This is a pilot trial of anti-CD19 CAR T cells in adults with CLL/SLL who were not in CR despite at least 6 months of ibrutinib. Pts must have failed at least 1 regimen before ibrutinib, unless they had del(17)(p13.1) or a *TP53* mutation. T cells were lentivirally transduced to express a CAR comprising CD3z, 4-1BB, and humanized anti-CD19 scFv (CTL119). Pts were lymphodepleted 1 week before infusion. Ibrutinib was continued throughout the trial. **Results:** Manufacturing was successful in all pts. Ten pts (9M, 1F; ages 47-77; 0-12 regimens prior to ibrutinib) have been infused. All had abnormalities of *TP53* or *ATM* and two pts had increasing *BTK* C481S clones. Median marrow CLL burden was 10% (range 10-50%). The median follow-up is 6 months (range 0.5-9). Cytokine release syndrome (CRS) developed in 9 pts; gr1 in 2, gr2 in 6 and gr3 in 1 pt. One pt developed gr4 tumor lysis syndrome. Treatment of CRS with the IL-6 receptor antagonist tocilizumab was not required. At 3 months, 8 evaluable pts had achieved an MRD-ve marrow CR (89%) by 9-color flow, and all remain in marrow CR at last F/U. There was modest residual splenomegaly in 3/5 patients, and adenopathy resolved in 4/6 subjects with progression in 1/6. MRD assessment by deep sequencing will be presented. **Conclusions:** We observed 89% MRD-ve marrow CR in pts with high-risk CLL using a well-tolerated combination of CART cells and ibrutinib. Longer follow-up will reveal the durability of these results and could support evaluation of a first-line combination approach in an attempt to obviate the need for chronic therapy. Clinical trial information: NCT02640209.

Long-term efficacy and safety with ibrutinib (ibr) in previously treated chronic lymphocytic leukemia (CLL): Up to four years follow-up of the RESONATE study. *First Author: John C. Byrd, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Ibr, a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase, is FDA-approved for all pts with CLL/SLL. We report updated safety and efficacy results with up to 4 y follow-up from the ph III RESONATE trial of ibr vs ofatumumab (ofa). **Methods:** Pts had ≥1 prior therapy. Pts received 420 mg ibr PO until PD or ofa up to 24 wks. At interim analysis (median 9 mo follow-up), the DMC declared superiority of ibr vs ofa for PFS and OS, and ibr access was recommended for all ofa pts. Long-term follow-up efficacy endpoints are per investigator assessment. Ofa pts were censored at crossover for OS. **Results:** 391 pts were randomized to receive ibr (n = 195) or ofa (n = 196). Median age was 67 y (40% ≥70 y); 57% had Rai stage III/IV. With median follow-up of 44 mo (53 mo max) for ibr arm, PFS was significantly longer for ibr vs ofa (median NR vs 8 mo, [HR 0.133; $P<0.0001$]; 3-y PFS 59% vs 3%) with significant benefit across subgroups. PFS with ibr for del11q subgroup trended to have the most favorable outcome; however, PFS was not statistically different for pts with del17p or del11q or without these FISH abnormalities. At analysis, with the majority of pts (68%) randomized to ofa crossing over to ibr, OS was longer for ibr vs ofa (median OS NR for either arm). The OS rate for ibr at 3 y was 74%. ORR for ibr was 91% with CR/CRi rates (now 9%) increasing over time. Baseline cytopenias improved with extended ibr therapy for hemoglobin (85%), platelet (95%), and absolute neutrophil counts (95%). AE profile of ibr was consistent with previous reports. Major hemorrhage, Gr ≥3 atrial fibrillation, and Gr ≥3 hypertension occurred in 6%, 6%, and 8% of pts, respectively, over a follow-up of up to 4 y. Incidence of most Gr ≥3 AEs decreased from y 1 vs y 2-3: neutropenia- 18% vs 8%; pneumonia- 11% vs 4%; atrial fibrillation- 4% vs 2%, respectively. Discontinuations were most frequently PD (27%) and AE (12%). At analysis, 90 ibr pts (46%) continue ibr on study. **Conclusions:** Long-term treatment with ibr in this international ph III RESONATE study is tolerable and continues to show sustained PFS and OS regardless of high-risk cytogenetics. Ph III results in relapsed del17p and del11q pts compare favorably to prior ph II reports. Clinical trial information: NCT01578707.

7511 Poster Discussion Session; Displayed in Poster Session (Board #273), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Tolerability and activity of chemo-free triplet combination of TGR-1202, ublituximab, and ibrutinib in patients with advanced CLL and NHL. *First Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Novel targeted agents are emerging for B-cell malignancies, but few studies have safely combined these agents. Ublituximab (UTX) is a novel glyco-engineered mAb targeting a unique epitope on the CD20 antigen. TGR-1202 is a next generation, once daily PI3Kδ inhibitor, demonstrating a favorable safety profile compared to prior inhibitors, including in long-term follow up (Burris, 2016). This Ph 1 trial evaluates the safety/efficacy of the triplet combination of a novel anti-CD20 mAb + PI3Kδ + BTK inhibitor (ibrutinib) in pts with B-cell malignancies. **Methods:** Eligible pts had CLL or rel/ref NHL w/o limit to prior therapies, including those ref to prior PI3Kδ or BTK inhibitors. UTX dosed on D1, 8, 15 of C1; D1 of C2-6, and C9 & 12. TGR-1202 dose escalated (400/600/800mg QD), ibrutinib dosed at 420mg (CLL) or 560mg (NHL), both on C1D1. **Results:** 38 pts were enrolled: 20 CLL/SLL and 18 NHL, including 6 follicular (FL), 6 DLBCL, 4 mantle cell (MCL) and 2 marginal zone (MZL). Med age 65 yrs (range 32-85); 29 M/9 F; med prior tx = 3 (range 0-6). 2 pts were ref to prior PI3Kδ and 2 were prev treated with ibrutinib (1 ref/1 rel). MTD was not reached. Most common (> 20%) all causality AE's were fatigue (42%), diarrhea (39%), dizziness (34%), nausea (32%), neutropenia, pyrexia, rash, infusion reaction, insomnia (each at 29%), thrombocytopenia, cough (each at 26%), anemia (24%) and sinusitis (21%). GR 3/4 AE's were minimal, the only event > 10% was neutropenia (16%). ORR amongst 36 evaluable pts is shown in the table below. 53% of evaluable CLL pts had high-risk cytogenetics and 4/6 DLBCL pts were non-GCB. One CLL pt (17p/11q del) ref to both PI3Kδ and ibrutinib achieved a CR. Med time on study is 10 mos (range 1 – 27+ mos). Med DOR not reached (range 3 – 24+ mos). **Conclusions:** This is the first known triple combination of an anti-CD20 mAb + PI3Kδ + BTK inhibitor. The combination of UTX, TGR-1202, and ibrutinib has been well tolerated with activity observed across heavily pre-treated and high-risk B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202 + full dose ibrutinib) are underway. Future trials for the triplet are warranted. Clinical trial information: NCT02006485.

Subtype	N	CR	PR	ORR
CLL/SLL	19	3	16	100%
FL/MZL	7	2	4	86%
DLBCL	6	0	1	17%
MCL	4	1	3	100%

Clinical and biologic covariates of outcomes in ZUMA-1: A pivotal trial of axicabtagene ciloleucel (axi-cel; KTE-C19) in patients with refractory aggressive non-Hodgkin lymphoma (r-NHL). *First Author: Frederick Lundry Locke, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Outcomes in activated B cell subtype diffuse large B cell lymphoma (ABC-DLBCL) and r-NHL are poor (Sehn *Blood* 2015, Crump ASCO 2016). ZUMA-1 is the first, multicenter trial of anti-CD19 chimeric antigen receptor (CAR) T cells, axi-cel, in r-NHL. **Methods:** Dosing and eligibility were per Neelapu ASH 2016. The primary endpoint was objective response rate (ORR); secondary endpoints were duration of response (DOR), overall survival (OS), and safety. Cell of origin (COO) and CD19 status were assessed centrally using Lymphoma Subtyping Test NanoString (Wallden *JCO* 2015) and a validated immunohistochemistry assay, respectively. **Results:** As of Jan 27, 2017, 111 patients (pts) were enrolled; the manufacturing success rate was 99% with an average 17-d turnaround time; 101 pts (modified intent-to-treat [mITT] population) received axi-cel. In the mITT population, the ORR was 82% (complete response [CR], 54%). With 8.7 m median follow-up, 44% remain in response and 39% in CR. The median DOR was 8.1 m and not reached (NR) for pts with CR. Median OS was NR. Results for clinical and biologic covariates are listed in the table. In pts who received tocilizumab (n = 43) and/or steroids (n = 27) for cytokine release syndrome (CRS) and/or neurologic events (NE), ORR was 84% and 78%, respectively. Most common grade ≥3 adverse events (AEs) were neutropenia (66%), leukopenia (44%), anemia (43%), febrile neutropenia (31%), thrombocytopenia (24%), and encephalopathy (21%). Rates of grade ≥3 CRS and NE were 13% and 28%, respectively. There were 3 grade 5 AEs (Neelapu ASH 2016). **Conclusions:** Axi-cel induced an ORR of 82% in pts with r-NHL, response is ongoing in 44% of pts at 8.7 m. Similar clinical responses were observed in pts with r-ABC-DLBCL. AEs were manageable and the use of tocilizumab/steroids did not appear to impact ORR. Drs Locke and Neelapu contributed equally. Funding source: Kite Pharma and Leukemia & Lymphoma Society Therapy Acceleration Program Clinical trial information: NCT02348216.

Group (n = samples evaluable)	% Positive for Marker in Evaluable Samples	ORR/CR
mITT (n = 101)	N/A	82%/54%
GCB (n = 69)	71%	88%/57%
ABC (n = 69)	25%	76%/59%
CD19+ (n = 82)	90%	85%/57%
CD19- (n = 82)	10%	75%/50%

CR rates in relapsed/refractory (R/R) aggressive B-NHL treated with the CD19-directed CAR T-cell product JCAR017 (TRANSCEND NHL 001). *First Author: Jeremy S. Abramson, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: JCAR017 is a second-generation, CD19-directed, 4-1BB CAR T cell product comprising CD8 and CD4 CAR T cells in a 1:1 ratio. A multicenter phase 1 trial of JCAR017 in R/R B-cell NHL (NCT02631044) is underway. **Methods:** Patients with R/R DLBCL, PMBCL, FL grade 3B, or MCL and adequate organ function are eligible. There was no minimum ALC requirement for apheresis; no test expansion was required. Treatment includes lymphodepletion with fludarabine and cyclophosphamide, followed by JCAR017. Multiple dose levels (DLs)/administration schedules of JCAR017 are being evaluated. Study objectives include safety, PK, and antitumor response. **Results:** As of November 23, 2016, 28 patients have been treated and are evaluable for safety and efficacy. Nineteen were male, 9 female; 25 DLBCL, 2 MCL, and 1 FL grade 3B. Median age was 63 years (range 37-79), median number of prior therapies was 4 (range 1-8), 23 (82%) were refractory to their last chemotherapy, and 16 (57%) had prior transplant. No severe cytokine release syndrome (sCRS) was observed; 10 patients had grade 1-2 CRS (1 received tocilizumab). Five patients developed neurotoxicity, including 4 grade 3-4; all events resolved in the 4 patients who had adequate follow up. Median onset of CRS and neurotoxicity were 5 and 11 days, respectively. Four deaths after disease progression occurred, none related to JCAR017. In 20 patients treated at DL1 (5×10^7 cells), the RR was 80% with 60% achieving CR. One patient with secondary CNS involvement achieved CR without neurotoxicity. JCAR017 was detected at 3 and 6 months in responding patients, including some who relapsed; higher mean peak levels were detected in patients with durable response at 3 months. Data on patients treated at DL2 (1×10^8 cells), alternative dose schedules, tumor biopsy, and additional biomarkers will be presented. **Conclusions:** Treatment with JCAR017 results in high CR rate in patients with heavily pretreated R/R DLBCL. Relapses can occur despite persistence of JCAR017, suggesting tumor immune evasion mechanisms may contribute to relapse. Observed toxicities are manageable and occurred at rates lower than those reported for other CD19-directed CAR T cell products. Clinical trial information: NCT02631044.

7514 Poster Discussion Session; Displayed in Poster Session (Board #276), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

L-mind: MOR208 combined with lenalidomide (LEN) in patients with relapsed or refractory diffuse large b-cell lymphoma (R-R DLBCL)—A single-arm phase II study. *First Author: Kami J. Maddocks, Division of Hematology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: The Fc-enhanced CD19 antibody MOR208 and the immunomodulatory drug LEN have demonstrated single agent activity in patients (pts) with R-R DLBCL. MOR208 and LEN have shown synergy in vitro and in vivo in preclinical lymphoma models. This ongoing phase II study assesses the safety and efficacy of MOR208 + LEN in pts with R-R DLBCL. **Methods:** Pts >18 years old with R-R DLBCL, ECOG 0–2, adequate organ function, having previously received ≥1 but not more than 3 prior therapies, including ≥1 CD20-targeting regimen and who are not candidates for autologous stem cell transplant (ASCT), are eligible. Treatment comprises up to 12, 28-day (d) cycles (C) of MOR208 12 mg/kg IV, weekly during C1–3 (loading dose d4 of C1); every second week C4–12 + LEN 25 mg po d1–21, C1–12. Pts progression-free after 12 cycles receive up to 12 additional cycles of MOR208 (every second week). The primary endpoint is the overall response rate (ORR) by central radiology assessment. Secondary endpoints include disease control, duration of response, progression-free and overall survival, safety, and response by cell of origin and other biomarkers. A preplanned safety evaluation was undertaken. **Results:** 31 of 80 planned pts were enrolled prior to data cutoff (3 January 2017). Median age was 74 years (range 47–82); 45% of pts received ≥2 prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage ≥III disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3-5). The most common treatment-emergent adverse events (any grade/grade ≥3 [% pts]) were neutropenia (39/26), anemia (23/0) thrombocytopenia (16/6), infections (26/10) diarrhea (13/0), pyrexia (13/0), and rashes (13/6). Of 26 response evaluable pts (median follow-up 3.3 months), ORR (investigator assessed) was 58% (15 pts), with 7 (27%) complete responses. Median time to response was 1.8 months. **Conclusions:** The combination of MOR208 + LEN is well tolerated and shows promising activity in pts with R-R DLBCL. Accrual and follow-up of pts is ongoing, as are cell of origin and other biomarker analyses. Clinical trial information: NCT02399085.

Updated results of single-agent ibrutinib in recurrent/refractory primary (PCNSL) and secondary CNS lymphoma (SCNSL). *First Author: Christian Grommes, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: PCNSL is an aggressive primary brain tumor with median progression free survival (PFS) after upfront methotrexate-based chemotherapy of 2-3 years. Outcome and treatment options are poor for recurrent/refractory (r/r) disease. Ibrutinib has shown promising clinical response in Mantle cell lymphoma, CLL, Marginal Zone, and Waldenström. This trial investigates Ibrutinib in patients with r/r PCNSL and SCNSL. **Methods:** Eligible patients had r/r PCNSL or SCNSL, age≥18, ECOG≤2, normal end-organ function, and unrestricted number of CNS directed prior therapies. In patients with SCNSL disease, systemic disease needed to be absent. **Results:** Twenty-five patients were enrolled (3 at 560 mg; 22 at 840 mg). Median age was 68 (range 21-85); 15 were women. Median ECOG was 1 (0: 2, 1: 15, 2: 8). 64% had PCNSL and 36% SCNSL; 68% had recurrent disease. Seventeen had parenchymal disease, 3 isolated cerebrospinal fluid (CSF) involvement and 5 both. Seven grade 4 adverse events were observed in 7 patients neutropenia (in 3 patients), lymphopenia (2), sepsis (1), and ALT elevation (1). Fourteen patients developed 20 grade 3 toxicities, including lymphopenia in 5 patients, hyperglycemia in 3, ALT elevation in 2, thrombocytopenia in 2, lung infection in 2, AST elevation in 1, neutropenia in 1, urinary tract infection in 1, colitis in 1, febrile neutropenia in 1 and fungal encephalitis in 1. The most common toxicities at any grade were hyperglycemia, thrombocytopenia and anemia of which most were grade 1/2. No grade 5 events have been observed. After a median follow-up of 414 days (range 289-674), 22/25 patients were evaluated for response (3 did not complete at least 15 days of drug treatment). Over all response was 68% (17/22; 77% (17/22) in patient that completed at least 15 days of drug treatment) with 10 CR, 7 PR, 2 SD and 3 PD as best response. The median PFS is 4.6 months (5.4 months in patients that completed at least 15 days of drug treatment; longest: 15.3 months). The median overall survival has not been reached. **Conclusions:** Patients with CNS lymphoma tolerate Ibrutinib with manageable adverse events. Clinical response was seen in 68% of CNS lymphoma patients. Clinical trial information: NCT02315326.

Phase I clinical trial on pomalidomide and dexamethasone in treating patients with relapsed/refractory primary central nervous system lymphoma (PCNSL) or primary vitreoretinal lymphoma (PVRL). *First Author: Han W. Tun, Mayo Clinic, Jacksonville, FL*

Background: PCNSL is a diffuse large B cell lymphoma confined to the CNS. Pomalidomide (POM) is a novel immunomodulatory agent with excellent CNS penetration (~40%) based on CNS PK analysis in rats and pre-clinical therapeutic activity against CNS lymphoma. **Methods:** A Phase I clinical trial was undertaken to determine the maximal tolerated dose (MTD) of POM, safety profile and overall response rate (ORR). Treatment consists of POM daily for 21 days every 28 days in combination with dexamethasone 40 mg PO weekly for two cycles followed by POM alone in subsequent cycles until progression or intolerance. 4 dose escalation levels of POM (3mg, 5mg, 7mg, and 10 mg) were planned. Thromboprophylaxis with oral anticoagulant or aspirin was required. MTD determination has been completed and expansion of the MTD cohort is ongoing. Therapeutic responses were evaluated per the international PCNSL collaborative group (IPCG) criteria after 2 cycles of treatment. The trial is registered with ClinicalTrials.gov (#NCT01722305). **Results:** 21 of 25 patients accrued were eligible for assessment. The MTD was determined to be 5 mg qd for 21 days every 28 days. Two DLTs were seen at dose level 3 (Grade 3 dyspnea and grade 4 thrombocytopenia). One DLT was seen in the expanded MTD cohort (Grade 4 neutropenia and lymphocytopenia). ORR for the study (9/21) was 43% (95% CI- 22%, 66%) with 4 CR, 1 CRu and 4 PR. 3 responders completed 2, 4, and 6 cycles before progression. 6 responders have completed 4, 5, 6, 10, 12, and 32 cycles and remain on treatment. ORR for the MTD dose level was (5/12) 42% (95% CI-15%, 72%) with 3 CR and 2 PR. 2 patients had stable disease (SD). Pseudoprogression was seen in 1 patient. Overall, grade 3/4 toxicity was hematologic (neutropenia, anemia, and thrombocytopenia) in 38.1% and non-hematologic in 33.3% (fatigue, pneumonia, sepsis, syncope, dyspnea, hypoxia, respiratory failure and maculo-papular rash). Percent CSF/blood ratio of POM was determined to be 19% in 1 patient. **Conclusions:** Pomalidomide treatment is feasible with therapeutic activity against relapsed/refractory PCNSL and should be further developed. Clinical trial information: NCT01722305.

Outcomes by CD30 expression in patients with CTCL receiving brentuximab vedotin (BV) vs physician's choice (PC) in the Phase 3 ALCANZA study. *First Author: Youn H. Kim, Department of Dermatology, Stanford University School of Medicine and Stanford Cancer Institute, Stanford, CA*

Background: The Phase 3 ALCANZA study showed significant, durable responses with CD30-directed antibody-drug conjugate BV vs PC of methotrexate (MTX) or bexarotene (Bex) for CD30-positive (CD30+) cutaneous T cell lymphoma (CTCL). Uniform CD30 expression is characteristic of primary cutaneous anaplastic large cell lymphoma (pcALCL), but is variable among other subtypes including mycosis fungoides (MF). We examined activity of BV and MTX / Bex by CD30 expression in pts treated on the ALCANZA study. **Methods:** Adults with previously treated CD30+ MF or pcALCL were enrolled. MF pts had ≥2 skin biopsies from separate lesions, pcALCL had ≥1. Patients were scored CD30+ if ≥1 biopsy had ≥10% CD30+ lymphoid cells using an investigational Ventana diagnostic test, centrally assessed by one pathologist. We compared the proportion of MF subgroup pts (n=50 per treatment arm) with objective response lasting ≥4 months (ORR4; ALCANZA primary endpoint) and PFS in pts with all biopsies ≥10% CD30+ ($CD30_{min}$ ≥10%) vs ≥1 biopsy <10% CD30+ ($CD30_{min}$ <10%). Pts were randomized 1:1 to BV 1.8 mg/kg IV, Q3W, or PC for up to 16 three-week cycles. **Results:** 125/184 (68%) MF and 44/47 (94%) pcALCL pts were screened and scored CD30+. High inter-lesional variability in CD30 expression was seen in MF pts; 55/125 CD30+ MF pts (44%) had ≥1 biopsy with low (<10%) or undetectable CD30. 100/125 CD30+ MF pts were eligible and enrolled. In the BV arm, ORR4 was higher in MF pts with $CD30_{min}$ ≥10% vs <10%; median PFS with BV was higher in the $CD30_{min}$ <10% group (Table). ORR4 with BV was greater than PC over all CD30 expression ranges ($CD30_{min}$ <5%, 38% vs 13%; CD30 ≥5–≤20%, 35% vs 10%; CD30 >20%, 76% vs 7%, respectively). **Conclusions:** Notable inter-patient or inter-lesional variability in CD30 expression was seen in MF pts. Highly superior ORR4 and PFS endpoints were seen with BV over PC regardless of $CD30_{min}$ expression level. Clinical trial information: NCT01578499.

	BV	PC	Difference, % [95% CI]
ORR4, n/N (%)			
$CD30_{min}$ <10%	9/22 (40.9)	2/21 (9.5)	31.4 [2.8, 58.1]
$CD30_{min}$ ≥10%	16/28 (57.1)	3/29 (10.3)	46.8 [20.6, 67.0]
Median PFS (months) [95% CI]			Hazard ratio [95% CI]
$CD30_{min}$ <10%	27.9 [8.6, 27.9]	2.3 [1.6, 3.5]	0.125 [0.044,0.355]
$CD30_{min}$ ≥10%	17.2 [9.8, NE]	3.5 [2.1, 4.6]	0.176 [0.072,0.432]

Preliminary results of a phase Ib study of GS-4059 in combination with entospletinib in patients with B-cell malignancies. *First Author: Christopher Fegan, Cardiff CLL Research Group, School of Medicine, Heath Park, Cardiff, United Kingdom*

Background: GS-4059 (ONO-4059) selectively and irreversibly inhibits Bruton's tyrosine kinase (BTK) and entospletinib selectively inhibits spleen tyrosine kinase (SYK). **Methods:** This ongoing phase 1b study is evaluating the safety and tolerability of GS-4059 combined with entospletinib in patients with previously treated CLL, FL, SLL, MCL, MZL, WM, or non-GCB DLBCL. The study design uses 3+3 dose escalation (Table) withexpansion cohorts at potential phase 2 doses. **Results:** With a median duration of treatment of 22 weeks (range 3-56), 26/32 enrolled patients continue on treatment. The median age was 70 (43–85) years and 59% were men. Patients had the following diseases: CLL (n = 9), non-GCB DLBCL (7), FL (6), WM (5), MCL (2), SLL (2), and MZL (1). The median number of prior therapies was 2 (1–5). Five patients discontinued all study treatment, 4 due to disease progression (DLBCL x 2, MCL, MZL) and one due to withdrawal of consent. There has been 1 death on study due to progressive disease. The maximum tolerated dose was not reached. 90% of patients treated reported a treatment-emergent AE (TEAE) of which 48% were grade ≥3. Grade ≥3 TEAEs that were present in more than 1 patient were neutropenia (4), anemia, thrombocytopenia, pneumonia and AST/ALT elevation (2 each). The TEAEs present in >10% of patients were fatigue (7), petechiae (5), asthenia, constipation, contusion, dyspepsia, neutropenia and rash (4 each). No patients discontinued treatment due to AEs and all 5 patients with interruption of treatment for an AE successfully re-initiated therapy. 17 patients were evaluable for best overall response with the results as follows: 11 with partial responses (2 each with CLL, DLBCL, FL, SLL, WM, 1 with MCL); 4 with stable disease; 2 with progressive disease. **Conclusions:** GS-4059 at up to 160 mg in combination with entospletinib up to 400 mg daily was safe and well tolerated, supporting the continued clinical evaluation of the combination for the treatment of B-cell malignancies. Clinical trial information: NCT02457598 Clinical trial information: NCT02457598.

Response rates with pembrolizumab in combination with rituximab in patients with relapsed follicular lymphoma: Interim results of an on open-label, phase II study. *First Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Follicular lymphoma (FL) tumors are infiltrated with antitumor T cells, however, their function is impaired by immune checkpoints such as PD-1/PD-ligand pathway. Blocking PD-1 enhances the function of antitumor T cells in FL. In addition, blocking PD-1 on NK cells has been shown to enhance the ADCC effect of NK cells. We reasoned that the combination of pembrolizumab (P), an anti-PD-1 antibody (ab), and rituximab (R), an anti-CD20 ab that induces ADCC, is likely to be synergistic through activation of both the innate and adaptive immune systems and result in enhanced clinical activity in FL. **Methods:** We evaluated P and R in an open-label, non-randomized, single institution, phase II trial (N=30). Key inclusion criteria included adult (age ≥ 18 years), FL grade 1-3a, ECOG 0-1, in relapse after ≥1 prior therapy (tx) and R sensitive disease, defined as a complete (CR) or partial response lasting at least 6 months (mos) after most recent R-containing therapy. Pts received R (375 mg/m^2 IV) on days 1, 8, 15, and 22 of cycle 1 and P (200mg IV) q 3 weeks for up to 16 cycles starting on day 2 of cycle 1. Primary endpoint was overall response rate (ORR). **Results:** 27 pts have initiated therapy, median age 65 (range 42-79), 52% male, 76% had intermediate or high risk FLIPI, 56% met GELF criteria. Median prior tx =1 (range 1-4). Adverse events (AE) regardless of causality were mild, most grade 1-2. Grade 3 AE's included nausea (N=2), infusion reaction (N=2), aseptic meningitis (N=1), pneumonia (N=1). Immune-related AEs included grade 2 diarrhea (N=2), grade 2 pneumonitis (N=1), grade 2 skin rash (N=1). At the pre-planned interim analysis (N=15), ORR was 80%, CR rate was 60%. With a median follow up of 7 mos (range 0.5-17), median DOR, PFS, and OS has not been reached. PD-L1 expression was tested in 8 baseline tumor samples using PD-L1 22C3 IHC pharmDx and was detected in histiocytes in all 8 tumors, present in only 1-8% of tumor cells in 5 tumors. Additional biomarker analyses are ongoing. **Conclusions:** The combination of P and R is well tolerated in relapsed FL and is associated with high overall and CR rate. These interim results warrant further investigation of this combination in FL. Clinical trial information: NCT02446457.

7520 Poster Discussion Session; Displayed in Poster Session (Board #282), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Combination ibrutinib (Ibr) and venetoclax (Ven) for the treatment of mantle cell lymphoma (MCL): Primary endpoint assessment of the phase 2 AIM study. *First Author: Constantine Si Lun Tam, Peter MacCallum Cancer Centre; St Vincent's Hospital; University of Melbourne, Melbourne, Australia*

Background: Both ibr and ven have activity in relapsed/refractory (R/R) MCL, but complete remissions (CR) are attained in <25% with either. We sought to determine the activity of the combination in an investigator-initiated, phase 2 study. **Methods:** Enrolment of 24 patients (pts) with R/R (n=23) or frontline (n=1) MCL completed in 09/16. Pts received 4 weeks of ibr (560mg/d), followed by introduction of ven (weekly ramp-up to target 400mg/d). The primary endpoint was CR rate at week 16, as assessed by PET/CT, BMAT, flow & molecular MRD, and endoscopy (if baseline gut involvement). Response was calculated separately with and without knowledge of the PET result by IWG criteria (Cheson JCO 2007), in order to compare with published studies (ibr, 9% CR at wk16; ven, best CR rate 21%). **Results:** Median age of pts was 68 (range, 47-81) years. For the R/R pts (n=23), median lines of prior therapy was 2 (1-6), 48% were refractory to last treatment, and 30% had failed previous autologous SCT. As of data cutoff on Jan 11 2017, 18 pts remain on therapy, and 6 stopped treatment due to progressive disease (4), adverse event (1) or unrelated death (1). At week 16, ORR was 71% (63% CR) and 80% of complete responders were flow-cytometry negative in the marrow (sensitivity 10^{-3} to 10^{-4}). Using CT without PET, the comparison responses were CR 42%, CRu 17%, PR 17% (ORR 78%). After a median follow-up of 8.3 (range 1.4-17.7) months, the 8-month estimates of PFS and OS months are 74% and 81%. Adverse events ≥20%, irrespective of attribution, were fatigue (71%), diarrhea (67%), nausea (50%), URTI (38%), gastro-esophageal reflux (33%), neutropenia (33%), cough (25%) and bruising (21%); with the exception of neutropenia (25% grade 3-4), these were predominantly grade 1-2 in severity. Tumour lysis syndrome occurred in 2 pts with high tumour burden, leading to revision of the protocol ven starting dose from 50mg, to 20mg/d. **Conclusions:** The combination of ibr and ven was tolerable and achieved CR rate of 63% at week 16 in pts with MCL. The efficacy results compare favorably with historical results, and warrant further phase III investigation. Clinical trial information: NCT02471391.

7521 Poster Session (Board #283), Mon, 8:00 AM-11:30 AM

Innovative approach to determine overall survival (OS) benefit for orphan diseases using case match control analyses (CMCA): The PROPEL experience of pralatrexate in patients with relapsed/refractory (R/R) peripheral T-cell lymphoma (PTCL). *First Author: Owen A. O'Connor, Columbia University Medical Center, New York-Presbyterian Hospital, New York, NY*

Background: The challenges in conducting randomized studies in orphan diseases poses limitations on our ability to identify the most promising treatments. Randomized studies in this setting can take protracted periods of time to complete, can be very expensive while not offering the promise of significant commercial return, and could become irrelevant as the pace of scientific advancement continues. The majority of drugs approved in this setting are often approved on surrogate end-points like progression free survival (PFS) or complete response (CR) rates in single arm studies. CMCA are statistically stronger than single arm studies, and can be highly informative in this setting. **Methods:** We established an integrated international database of patients with R/R PTCL to clarify the OS advantage of pralatrexate using original data from the PROPEL study, an international, multicenter phase II study in patients with R/R PTCL. The propensity score was used to match cases and controls. Cases were matched based on histology, number of previous treatments received, age at diagnosis and sex. **Results:** With 1:1 ratio match, we identified 83 cases and 83 controls. In total, 83 patients out of 109 treated on the PROPEL study were successfully matched. OS was plotted for each of the two study populations. The survival curves for the control population were found to be nearly identical to that reported for this population from other datasets. The overall survival was 4.04 months (95% CI 2.83, 5.78), which is consistent with historical controls describing this population. The median OS in for the pralatrexate treated cohort in this analysis was 16.6 months (95% CI: 11.99-25.56). The OS was a highly statistically significant difference between these two populations, with a hazard ratio of 0.426 (95% CI: 0.296-0/61). This difference held up for each of the major histologic subsets, including PTCL-NO and angioimmunoblastic PTCL. **Conclusions:** This approach can be used to better understand how new drugs in orphan diseases perform in heterogeneous patient populations. Clinical trial information: NCT00364923.

7522 Poster Session (Board #284), Mon, 8:00 AM-11:30 AM

Ibrutinib, fludarabine, cyclophosphamide, and obinutuzumab (GA101) (iFCG) for previously untreated patients with chronic lymphocytic leukemia (CLL) with mutated IGHV and non-del (17p). *First Author: Nitin Jain, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts with mutated *IGHV* (*IGHV*-M) have favorable long-term outcomes after FCR. **Methods:** We designed an investigator-initiated phase II trial with ibrutinib, fludarabine, cyclophosphamide, and obinutuzumab (iFCG) for previously untreated pts with *IGHV*-M CLL (NCT02629809). The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through addition of ibrutinib and obinutuzumab. Key eligibility included age ≥18, *IGHV*-M, no del17p. Pts received 3 courses of iFCG. G-CSF was not mandated. Primary endpoint: CR/CRi with bone marrow (BM) MRD-neg (4-color flow-cytometry) after 3 courses of iFCG. Pts meeting primary endpoint received ibrutinib with obinutuzumab (iG) for C3-6, then ibrutinib C7-12. Pts not achieving primary endpoint received iG (C4-12). All pts who are MRD neg at 1 year will stop all therapy, including ibrutinib. Pts MRD+ at 1 year may continue ibrutinib. Historic C3 BM MRD-neg with FCR in *IGHV*-M 26% (Strati, Blood 2014). Target BM MRD-neg after iFCG x3 is 45%. Sample size 45. **Results:** 23 pts started treatment. Median age 59 yrs (25-71). Prognostic markers [del13q (n=17), negative (n=3); trisomy 12 (n=3)]. 18 pts completed 3 courses of iFCG and had initial response assessment (the remaining 5 pts too early). All 18 pts had a response; 14/18 (78%) achieved MRD-neg in BM at 3 month with 7/18 achieving CR/CRi (all MRD neg). No pt has progressed, and all but one continue to receive treatment. Of the 23 pts, 11 pts had G3-4 neutropenia and 5 pts had G3-4 thrombocytopenia. 4 pt had neutropenic fever. 1 pt who achieved MRD-neg CR developed pulmonary MAC infection, and declined further therapy. 1 pt had atrial fibrillation. G3 ALT developed in 3 pts. FC was dose reduced in 10 pts; ibrutinib dose-reduced in 2 pts. **Conclusions:** iFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the ASCO meeting. Clinical trial information: NCT02629809.

	Response at 3 Month		Best Response	
	N=18	Marrow MRD	N=18	Marrow MRD
ORR	18/18 (100)	14/18 (78) neg	18/18 (100)	16/18 (89) neg
CR/CRi	7 (39)	7/7 (100) neg	9 (50)	9/9 (100) neg
PR	11 (61)	7/11 (64) neg	9 (50)	7/9 (78) neg

7523 Poster Session (Board #285), Mon, 8:00 AM-11:30 AM

Results of a phase II multicenter study of obinutuzumab plus bendamustine in pts with previously untreated chronic lymphocytic leukemia (CLL). *First Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, OR*

Background: Bendamustine (B) + rituximab (R; BR) is a commonly used 1L treatment for CLL. The CLL10 study reported an ORR of 96% and CR of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti-CD20 monoclonal antibody. A randomized Phase III trial in 1L CLL pts showed that G significantly improved PFS and CR rate compared with R, when used in combination with chlorambucil (Goede 2014). B + G (BG) was evaluated in a subgroup of CLL pts in the GREEN study (Stilgenbauer 2015). We present results of a Phase II study (NCT02320487) evaluating the efficacy and safety of BG as 1L treatment for CLL pts. **Methods:** 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100mg day (D) 1, 900mg D2, 1000mg D8 and D15; C2–6: 1000mg D1) and B (90mg/m^2: C1, D2 and D3; C2–6, D1 and D2). Each cycle was 28 days. Primary endpoint was CR assessed using iwCLL criteria. Secondary endpoints included ORR, PFS, OS, and MRD. Median follow-up at the time of analysis was 11.0 months. **Results:** Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluated pts, IgVH status was 32.9% mutated and 67.1% unmutated. The incidences of trisomy 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity (MRD-) in blood, as measured by 4-color flow cytometry, was achieved in 42.7% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD- in bone marrow (BM) was 60.8% in pts with BM samples. The most common AEs (all grades [Gr]) were infusion reactions (72.5%), nausea (52.0%), pyrexia (36.3%), neutropenia (34.3%), fatigue (34.3%), constipation (26.5%), and rash (26.5%). The most common Gr 3–4 AE was neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of TLS was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators. **Conclusions:** BG is an effective regimen for 1L treatment of CLL pts, inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed. Clinical trial information: NCT02320487.

7524 Poster Session (Board #286), Mon, 8:00 AM-11:30 AM

Ibrutinib vs chlorambucil: Immunophenotypic and quantitative impacts on circulating immune cells in chronic lymphocytic leukemia (CLL). *First Author: Isabelle Solman, Pharmacyclics LLC, an AbbVie Company, Sunnyvale, CA*

Background: Ibrutinib (ibr), a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase, is indicated by FDA for treatment (Tx) of patients (pts) with CLL. Following the outcome of the RESONATE-2 trial, ibr was approved as the first chemotherapy-free Tx option for treatment-naïve (TN) pts. In this study, ibr reduced the risk of progression or death by 84% compared with chlorambucil (chl). To assess the impact of ibrutinib vs this traditional chemotherapeutic agent on the immune system, quantitative changes in circulating cells were studied throughout the first year of Tx. **Methods:** Immunophenotypic analyses were performed by flow cytometry on peripheral blood to assess lymphoid and myeloid cells of TN CLL pts who received 420 mg ibr once daily (n=50) or 0.5-0.8 mg/kg chl twice a month (n=30). Medians of statistically significant changes ($p<0.05$, Wilcoxon test) in absolute counts of 1-year paired samples (pre-dose vs 1-year) are reported. **Results:** Chl progressively reduced circulating B, T, NK, NKT cells, myeloid derived suppressor cells (MDSC), and monocytes by 69%-99%. All development stages of $CD4^+$ and $CD8^+$ T cells, except stem cell memory T cells (T_{SCM}), decreased by 51%-90%. Regulatory T cells (Treg) and $PD1^+$ T cells also decreased similarly; however, long-term activated T cells (T_{LA}) were not impacted. On the other hand, ibr mainly reduced B cells (90%), MDSC (61%) and some T cells, specifically T_{LA}, $PD1^+$ T cells, Treg and effector T cells (27-52%). Naïve T cells, T_{SCM}, central memory T cells and NK cells were spared throughout the full year of Tx. Classical monocytes were increased (+187%), while non-classical monocytes and intermediate monocytes remained relatively steady. **Conclusions:** Chl, a traditional chemotherapy, affected non-specifically most immune cell subsets in circulation, although surprisingly it did not affect T_{LA} which have been reported as dysfunctional in CLL. Ibr represents a more targeted Tx approach than cytotoxic chemotherapy; essentially B cells, abnormal T subsets (T_{LA}, $PD1^+$T, Treg) and pro-tumor MDSCs were reduced. However, ibr preserved naïve T cells, NK cells and monocytes, which are important for mounting anti-tumor responses. Clinical trial information: NCT01722487.

7525 Poster Session (Board #287), Mon, 8:00 AM-11:30 AM

Persistence of ibrutinib-associated hypertension in CLL pts treated in a real-world experience. *First Author: Lisa M. Gashonia, Abramson Cancer Center, Philadelphia, PA*

Background: Cardiovascular (CV) complications associated with ibrutinib (Ibr) include hypertension (HTN) and atrial fibrillation (AFIB) (incidence 26% and 9%, OBrien, ASH 2016). Unlike clinical trials, Ibr toxicities are the most common reasons for its discontinuation in clinical practice. The incidence of HTN in pts treated with Ibr outside of clinical trial setting and its impact on outcomes is unknown. **Methods:** Retrospective, cohort study of Ibr-treated CLL pts to estimate HTN incidence. Baseline CLL characteristics and co-morbidities were recorded. Blood pressure (BP) measurements were recorded prior to Ibr and sequentially following exposure at specific time points. CV meds were reviewed during a 12 mo follow-up period. The association between Ibr exposure and BP was tested. **Results:** 153 consecutive CLL pts treated with Ibr at a dose of 420 mg/day were identified. Med age was 57 yr (range: 34-87), relapsed CLL (69%), follow-up 14.5 mo. CV pre-Ibr characteristics included: smoking hx (49%), HTN (42%), hyperlipidemia (39%), diabetes (17%), CAD (12%), AFIB (6.8%). Proportion of pts on $\geq$1 anti-HTN med increased from 44% pre-Ibr (20% $\geq$ 2) to 57% during Ibr (30% $\geq$ 2). Med pre-Ibr BP was 127/70 mmHg (range 90-182/48-95mmHg). At 1, 3, 6, 9, 12 mo, med BPs were 137/73, 141/75, 143/76, 140/75, 142/77 (7 mo to peak BP). There was a significant association between Ibr exposure and increased BP ($p<.01$). New HTN was observed in 40% of pts and 36% HTN pts had BP increased above baseline (med baseline 135/70 vs peak 161/80). Incidence of new AFIB was 8.1%. In UV analyses, predictive clinical factors for HTN were not identified. Pre-Ibr HTN (OR 3.0, p .05), CAD (OR 4.3, p .03), prior AFIB event (OR 10.8, p.001), hyperlipidemia (OR 3.4, p.05) were associated with post-Ibr AFIB. **Conclusions:** In the largest real-world series focused on BP in Ibr treated pts, we demonstrate a clear association between Ibr and HTN. Nearly 40% of pts developed HTN within 12 mo of Ibr exposure (vs. 26% in clinical trials over 5 yr). Despite aggressive management (multiple agents), Ibr associated HTN was persistent. These data underscore the critical need for monitoring and management strategies for HTN and follow-up data on future CV events.

7526 Poster Session (Board #288), Mon, 8:00 AM-11:30 AM

Cytogenetic and fluorescence in situ hybridization testing in veterans with chronic lymphocytic leukemia. *First Author: Ahmad Sami Halwani, Huntsman Cancer Institute at the University of Utah, Division of Hematology and Hematological Malignancies, SLC VA IDEAS Center, Salt Lake City, UT*

Background: The presence of deletion 17p (del17), determined by chromosome analysis and/or fluorescence in situ hybridization (FISH), is a strong negative prognostic marker in chronic lymphocytic leukemia (CLL). Prior to the introduction of novel agents (ibrutinib, venetoclax), the clinical utility of cytogenetics/FISH was limited by the absence of chemoimmunotherapy regimens that were proven effective in patients with del17. Testing practices for chromosomal aberrations since the introduction of novel agents have not been reported. We report cytogenetic/FISH trends in a nationwide cohort of veterans diagnosed with CLL. **Methods:** CLL patients diagnosed 2008-2015 and receiving care at VA were identified through the VA Clinical Cancer Registry. Electronic medical records were used to determine cytogenetic/FISH testing (lab records), treatment histories (pharmacy dispensation records), and evidence of system use (heme-onc notes). Cytogenetic/FISH testing was identified by presence of specific keywords in the test name or Logical Observation Identifiers Names and Codes (LOINC) descriptions, then validated by human annotation. The testing rates are reported for the entire cohort, at time of diagnosis, time of regimen initiation (including the 12 months preceding initiation), during the novel era (2014 – 2015) and prior (2008–2013). **Results:** From 2008 to 2015, 3,638 CLL patients were diagnosed and received care at VA. Documented records of treatment regimens were available for 1,562 patients who received a total of 2,929 treatment regimens. Only 24% (998) of patients were tested at any point in time during their care at the VA, 17% (622) were tested at time of diagnosis, and 19% (542) of treatment courses were preceded by cytogenetic/FISH testing. No testing differences existed following the introduction of the novel agents at diagnosis (both ~ 17%), or prior to regimen initiation (20% vs 16%). **Conclusions:** Our study suggests CLL patients diagnosed and receiving care at the VA are not routinely undergoing cytogenetics/FISH testing at diagnosis or prior to treatment. Changing this practice pattern will personalize treatments so that del17 CLL patients receive less toxic and more effective therapies.

7527 Poster Session (Board #289), Mon, 8:00 AM-11:30 AM

Phase 2 trial of brentuximab vedotin and gemcitabine for pediatric and young adult patients with relapsed or refractory Hodgkin lymphoma (HL): A Children's Oncology Group (COG) report. *First Author: Peter D. Cole, The Children's Hospital at Montefiore, Bronx, NY*

Background: AHOD1221 (NCT01780662) tested Brentuximab vedotin (Bv) with gemcitabine (GEM) in children or young adults with HL. The primary objective was to describe the complete response (CR) rate within 4 cycles of therapy. **Methods:** Eligibility criteria included age $\leq$30 years; no prior Bv exposure; and primary refractory HL or advanced stage disease with early relapse. Each 21-day cycle consisted of Bv on day 1 at the recommended phase 2 dose (RP2D), 1.8 mg/kg and GEM 1000mg/m^2 on days 1 and 8. Patients were evaluable for response if they completed 4 cycles of Bv+GEM, had a CR after 2 cycles, or progressive disease at any time. Response was assessed after even cycles, and confirmed by central review. CR was defined by FDG-PET negativity (Deauville 1-2) regardless of residual lesion size. **Results:** 42 patients were treated with Bv+GEM. Median age was 17.4 years (range 5.4-28.7), and 23 (55%) were female. The majority (n=35; 83%) had primary refractory disease or early relapse $<$6 months after completion of primary treatment. Common ($>$10%) adverse events included maculopapular rash (36% in cycle 1), neutropenia (33%) and elevated serum transaminases (21%). GCSF-stimulated peripheral blood stem cell (PBSC) collection was successful in all patients (n=23) for whom it was attempted, with median total collection of 9.4x10^{6}CD34+ cells/kg (range 3.5-36.8). 23 of 40 evaluable patients experienced a CR (58%; 95% CI 42-73%) within four cycles, and 6 had a partial response (PR), for an ORR of 73% (95% CI, 59-86%). For 4 patients with PR or stable disease, all target lesions were Deauville 3 or less after cycle 4, considered a CR by modern response criteria (Cheson et al. Blood 2016;128(21): 2489). **Conclusions:** Bv+GEM is a highly active combination for primary refractory or high-risk relapse of HL, with a CR rate exceeding that seen after either Bv (34%) or GEM (9%) alone. PBSCs can be collected successfully following Bv+GEM, making this an effective reinduction regimen when autologous stem cell transplantation is indicated. Compared to alternate retrieval regimens, Bv+GEM offers the advantage of avoiding agents associated with late treatment sequelae. Clinical trial information: NCT01780662.

7528 Poster Session (Board #290), Mon, 8:00 AM-11:30 AM

Digital sorting and copy number profiling of purified, PD-L1 positive, Reed Sternberg cells in classical Hodgkin lymphoma. *First Author: Chiara Mangano, Menarini Silicon Biosystems, Inc., Bologna, Italy*

Background: Classical Hodgkin Lymphoma (cHL) is one of the disease in which the check-point inhibitors have been demonstrated to be more successful. Lately, it has been reported that in malignant Reed-Sternberg Cells (RSCs), PD-1 ligands (PD-Ls) are overexpressed and that chr.9 amplification correlates with advanced stages of the disease, when the standard therapy have already failed. Unfortunately, the detection of the genetic alterations in RSCs is challenging, as one of the hallmark of cHL is the presence of a small number of malignant cells sparse in an abundant and heterogeneous immune infiltrate. Here we present a method for the isolation and the genetic characterization of purified RSCs, which overcomes the limitations posed by the low-cellularity of cHL biopsies, and could be helpful for earlier detection of genetic alterations and adoption of immunotherapy. **Methods:** FFPE tissue sections from cHL patients were dissociated down to single-cell suspension and stained using anti-CD30 and anti-PD-L1 antibodies. Beyond the positivity to CD30 and PD-L1, RSCs were selected according to morphological criteria such as cell size and the presence of polylobate nuclei compared to surrounding lymphocytes. Target cells were isolated using the DEPArray™ cell sorter, as single cells or in small pools of cells. Recovered cells were whole genome amplified (*Ampli*1™ WGA), and genome-wide copy-number aberrations (CNAs) profiles were obtained using *Ampli*1™ LowPass kit on IonTorrent platform. **Results:** After the dissociation, RSCs maintained cell morphology and therefore, we were able to discriminate them from the heterogeneous immune infiltrate. RSCs appeared as large multinucleated cells with a big central nucleolus surrounded by a clear halo; cell diameter and ploidy were computed from the images. Pools of lymphocytes and pools of CD30+/ PD-L1+ RSCs were isolated. Sequencing results confirmed the expected flat profile for lymphocytes, while RSCs showed an aberrant profile with multiple losses and gains. **Conclusions:** The analysis of purified RSCs, could offer a valuable tool to uncover genetic alterations hidden by cHL immune infiltrate, for earlier adoption of more effective treatment regimens.

7529 Poster Session (Board #291), Mon, 8:00 AM-11:30 AM

Single institution experience of allogeneic stem cell transplantation for Hodgkin lymphoma. *First Author: Mauricio Pineda-Roman, Mount Sinai Hospital, New York, NY*

Background: Hodgkin lymphoma (HL) is curable in the majority of cases without stem cell transplantation (SCT). However, patients(pts) who relapse after chemotherapy require autologousSCT, and about half of those pts relapse. For over 3 decades, allogeneic SCT has been implemented in more refractory HL pts. We present the long term follow up of a group of pts from a our institution who underwent alloSCT for HL. **Methods:** 21 pts with HL transplanted from 2008 to 2015 and disease characteristics (HL type, status at SCT, chemosensitivity), treatment(graft source, donor type, auto and allo SCTdates, GVHD prophylaxis) and outcomes (maximum grade of acute and chronic GVHD, survival (OS) and causes of death) were analyzed. **Results:** 13 males and 8 females received an alloSCT from 2008 to 2015, 11 pts had Nodular sclerosis HL, 6 NOS, 2 mixed cellularity, 1 lymphocyte predominant and 1 lymphocyte depleted. Performance status was 60 to 100, median of 90. 16 grafts were unrelated and 5 HLA identical. 18 pts received PBSC, 2 bone marrow and one double cord transplant. Most pts, 19, had a prior autoSCT, one had 2 prior autoSCT and for one , the allo was the first SCT. One patient was transplanted in unconfirmed first CR, 2 in confirmed CR, 4 in PR without prior CR, 3 in 1strelapse, 5 in 2nd relapse, 5 in 3rd relapse, and one in primary induction failure. All patients had a reduce intensity conditioning: 14 Flu/Mel, 4 Flu/Mel ATG, and one each Flu/TBI/ATG, Flu/TBI, Flu/Cy. Acute GVHD happened in 11 pts: max grade I in 1 , II in 7, III in 1 and IV in 2. 6 pts had extensive chronic GVHD. 12 pts (57.1%) have died (survival range 0.65-43.45 months, mean 13.1, median 6.12). Causes of death were primary disease in 4, infection in 3 pts, GVHD and infection in 2, ARDS, organ failure, pulmonary toxicity in 1 each. 9 pts (42.8%) are alive (survival range 1.63-8.44 years, mean 4.97, median 4.47) **Conclusions:** AlloSCT for pts with relapsed HL is a feasible treatment modality that can lead to long term OS in a significant proportion of pts. Our data is comparable with other published studies for HL alloSCT. The utility of alloSCT should not be dismissed even in the age of Brentuximab and checkpoint inhibitors.

7530 Poster Session (Board #292), Mon, 8:00 AM-11:30 AM

Ongoing phase 1/2 study of INCB050465 for relapsed/refractory (R/R) B-cell malignancies (CITADEL-101). *First Author: Rod Ramchandren, Karmanos Cancer Institute, Detroit, MI*

Background: INCB050465 is a selective PI3Kδ inhibitor with no preclinical hepatotoxicity at clinically relevant doses. We report emerging safety and efficacy data from a phase 1/2 study of INCB050465 in patients (pts) with r/r B-cell malignancies (NCT02018861). **Methods:** The protocol was initiated with a single patient cohort, treated with INCB050465 5 mg QD PO. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45 mg QD. Based on PK/PD, the 20 and 30 mg QD cohorts were expanded. Responses were assessed Q9W by the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria. **Results:** As of the data cutoff (Nov 1, 2016), 52 pts were treated (median age, 65 y [range, 30–88]; baseline tumors: diffuse large B-cell lymphoma [DLBCL], n=14; follicular lymphoma [FL], n=10; Hodgkin lymphoma [HL], n=9; marginal zone lymphoma [MZL], n=8; CLL, n=6; mantle cell lymphoma [MCL], n=5; 62% had >3 prior systemic regimens). Median duration of therapy was 3.3 mo (range, 0.6–13.4); no DLTs were identified. 67% of pts discontinued therapy (disease progression, 31%; AEs, 25%); 33% had dose interruption; 4% had reduction. Most common nonhematologic AEs (all grade [Gr]; Gr ≥3): nausea (38%; 0%), diarrhea (31%; 6%), vomiting (25%; 0%); Gr ≥3 hematologic AEs: neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), anemia (4%). 40% of pts had serious AEs, most frequently colitis, diarrhea, hypotension (all n=3). 1 pt had Gr 3 pneumonitis; none had *Pneumocystis jirovecii* pneumonia (PJP) or Gr ≥2 elevated transaminase. Objective responses (ORs) occurred at all doses (Table), except 5 mg QD; 90% were observed at first assessment. **Conclusions:** INCB050465 demonstrated manageable toxicities with no clinically meaningful transaminitis/PJP. OR rates were generally high, with 90% observed at first assessment. Different dosing regimens/ schedules, long-term safety, and disease-specific cohorts are being evaluated. Clinical trial information: NCT02018861.

	N[a]	OR, n (%)	CR,[b] n	PR,[b] n
All pts	45	22 (49)	10	12
NHL	31	19 (61)	10	9
DLBCL	14	5 (36)	3	2
FL	9	7 (78)	2	5
MZL	4	4 (100)	2	2
MCL	4[c]	3 (75)	3	0
CLL	6[c]	2 (33)	0	2
HL	8	1 (13)	0	1

[a] Evaluable pts. [b] Radiologic/metabolic.[c] One MCL and 3 CLL pts had received ibrutinib, of whom 1 CLL pt had a best OR of PR in this study.

7531 Poster Session (Board #293), Mon, 8:00 AM-11:30 AM

Activity of the immunologic doublet of lenalidomide plus obinutuzumab in relapsed follicular lymphoma: Results of a phase I/II study. *First Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Relapsed follicular lymphoma (FL) remains a challenge and salvage regimens are associated with toxicity and limited control. Outcomes are linked to the immune microenvironment and lenalidomide and rituximab are highly active in FL. Obinutuzumab has increased ADCC compared to rituximab in preclinical models and is approved for relapsed FL. We hypothesized that the immunologic properties of obinutuzumab and lenalidomide would be synergistic. The study objective was to determine the MTD of lenalidomide with obinutuzumab in relapsed FL and describe the efficacy of the combination. **Methods:** This open label phase I/II study enrolled Gr 1-3a FL. Transformation was excluded. Lenalidomide was given on D 2-22 with 1000mg obinutuzumab on D1, 8, 15, and 22 of cycle 1 and on D1 for up to 12 cycles (28 days/cycle). Obinutuzumab was given every 2 months thereafter for up to 30 months in pts who responded following doublet therapy. During dose escalation, 3 cohorts were planned with 10, 15 and 20mg of lenalidomide. Phase II planned to enroll 30 pts at MTD with efficacy and safety as primary endpoints. **Results:** All 36 pts with FL enrolled (6 in dose escalation and 30 at MTD), and are eligible for efficacy and safety analysis. The median age was 65 with a median of 2 prior therapies. No DLTs were observed in phase I, and 20 mg of lenalidomide was used for phase II. To date, the most common all grade non-heme toxicities were fatigue(83%), diarrhea(67%) and rash(53%). Grade 3+ toxicities included neutropenia (23%), infection (11%) and fatigue (8%). The overall response rate was 100% with 78% (95%CI 60.85-89.88%) of pts attaining complete response (CR/Cru). All pts with rituximab refractory FL (13) responded. At a median follow up of 14 months, 10 pts progressed. The estimated 24 month PFS is 61% (95% CI 43-87%). **Conclusions:** Lenalidomide and obinutuzumab is highly active with durable remissions in relapsed FL, with all pts responding and 78% achieving CR. The majority of pts remain on therapy and the combination appeared safe. Correlatives are ongoing to identify biomarkers of response and frontline studies of the combination are currently enrolling. Clinical trial information: NCT01995669.

7532 Poster Session (Board #294), Mon, 8:00 AM-11:30 AM

Double-blind, randomized phase 3 study to compare efficacy and safety of the biosimilar CT-P10 to rituximab combined with CVP therapy in patients with previously untreated advanced-stage follicular lymphoma. *First Author: Won Seog Kim, Samsung Medical Center, Seoul, Republic of Korea*

Background: CT-P10 is a biosimilar candidate to the innovator rituximab (RTX). In patients with rheumatoid arthritis, CT-P10 has demonstrated equivalence in pharmacokinetics (PK) and efficacy (Yoo, ACR 2016). This study aimed to demonstrate non-inferiority of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT02162771). PK equivalence was confirmed (Coiffier, ASH 2016). **Methods:** A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375 mg/m^2 i.v) plus CVP (cyclophosphamide, vincristine, and prednisone) every 3 weeks over 8 cycles. Overall response rate (ORR) according to the 1999 IWG criteria over 24 weeks was assessed by the independent review committee. **Results:** Noninferiority of CT-P10 to RTX was shown for the primary efficacy endpoint of ORR. The ORR difference was 4.3% (Table) and the lower bound of the 95% confidence interval was -4.25%. B-cell depleted after the 1st infusion and remained as depleted over 8 cycles in both groups. Overall safety profile of CT-P10 was consistent with that of RTX and the proportion of patients with positive anti-drug antibody was similar in both groups (4.3% and 2.9%) for 24 weeks. Neither progressive multifocal leukoencephalopathy nor Hepatitis B virus reactivation was reported in each group. **Conclusions:** This study demonstrates noninferiority of efficacy of CT-P10 to RTX combined with CVP in previously untreated AFL. CT-P10 was well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles of induction period. Clinical trial information: NCT02162771.

Summary of efficacy and safety (number [%] of patient).

	CT-P10	RTX
	(N=66)	(N=68)
ORR (CR+CRu+PR)	64 (97.0)	63 (92.6)
Complete response (CR)	20 (30.3)	15 (22.1)
Unconfirmed CR (CRu)	6 (9.1)	8 (11.8)
Partial response (PR)	38 (57.6)	40 (58.8)
	(N=70)	(N=70)
TEAE related to the study drug		
Treatment-emergent adverse event (TEAE)*	37 (52.9)	34 (48.6)
Serious TEAE*	6 (8.6)	4 (5.7)
Infusion-related reaction*	15 (21.4)	17 (24.3)
Infection*	6 (8.6)	9 (12.9)

7533 Poster Session (Board #295), Mon, 8:00 AM-11:30 AM

Phase 1B of ibrutinib and high-dose methotrexate for recurrent/refractory CNS lymphoma. *First Author: Christian Grommes, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Primary CNS Lymphoma (PCNSL) is an aggressive primary brain tumor. Outcome and treatment options for patients with recurrent/refractory (r/r) disease are poor. We have observed promising efficacy of single agent ibrutinib in r/r PCNSL and secondary CNS lymphoma (SCNSL). In this phase 1B trial, we investigate the toxicity of ibrutinib in combination with high-dose methotrexate (HD-MTX) in r/r PCNSL/SCNSL. **Methods:** Eligible patients had r/r PCNSL/SCNSL or newly diagnosed SCNSL, age≥18, ECOG≤2, normal end-organ function, and with any number and type of prior therapies. In patients with SCNSL disease, systemic disease needed to be absent. HD-MTX was given at 3.5g/m2 every 2 weeks for a total of 8 doses. To minimize adverse events, ibrutinib was stopped on days of HD-MTX infusion and was restarted 5 days after MTX infusion or after completion of MTX-clearance, if clearance of MTX required more than 5 days. Ibrutinib was continued daily after completion of 8 doses of MTX. **Results:** Six patients have been enrolled; 3 received 560mg and 3 received 840mg ibrutinib in combination with HD-MTX. Median age was 62 (range 43-74); median ECOG 1 (0:2; 1:3; 2:1). Two had r/r PCNSL and 4 SCNSL. Three had brain disease, one isolated cerebrospinal fluid (CSF) involvement and two parenchymal and CSF involvement. Three patients had recurrent (2 PCNSL; 1 SCNSL), two refractory (both SCNSL), and one newly diagnosed disease (SCNSL). There were no grade 4 adverse events. Grade 3 events were observed in 5 patients (lymphopenia in 3, ALT elevation in 2, diarrhea in 1, electrolyte changes in 1, hypertension in 1). The most common adverse events were hypokalemia, low WBC, hyperglycemia, ALT and AST elevation. There was no dose reduction of methotrexate or ibrutinib in any patient. After a median follow-up of 130 days, all patients were evaluated for response after 4 doses of HD-MTX, with 4/6 (67%) showing a response: 2 CR, 2 PR, and 1 SD, 1 PD; both non-responders were refractory SCNSL. Ibrutinib concentrations were measured in plasma and CSF. **Conclusions:** Patients with CNS lymphoma tolerate the combination of HD-MTX and Ibrutinib (at 560 and 840mg) well. Continued enrollment into a combination arm that includes rituximab, methotrexate and ibrutinib is ongoing. Clinical trial information: NCT02315326.

7534 Poster Session (Board #296), Mon, 8:00 AM-11:30 AM

Whole body diffusion-weighted MRI to predict treatment outcome after one cycle of immunochemotherapy in aggressive non-Hodgkin lymphoma. *First Author: Katja De Paepe, University Hospitals Leuven, Leuven, Belgium*

Background: Treatment adaptation based on early identification of non-Hodgkin lymphoma (NHL) patients not responding to therapy might improve survival. The role of interim fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) after 2-4 cycles of immunochemotherapy (ICT) herein is experimental as it renders false positive results, due to a rituximab-induced inflammatory response. Whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) was evaluated as a radiation-free imaging technique to predict treatment outcome in NHL after one cycle ICT (2-3 weeks). **Methods:** 47 patients with aggressive NHL (35 DLBCL,2 primary mediastinal BCL,3 unclassifiable BCL, 2 Burkitt,2 MCL, 2 peripheral TCL and 1 extranodal NK-TCL) were enrolled. All had baseline and interim WB-DWI/MRI, and end-of-treatment PET/CT; 39/47 had interim PET/CT. International prognostic index (IPI), immunohistochemical (IHC) markers Ki-67, Bcl-6 and Bcl-2 were evaluated for their predictive value. WB-DWI/MRI was assessed quantitatively with histogram analysis (high b-value signal intensity (SI) and apparent diffusion coefficient (ADC)). Patients were categorized as non-responder when lesions had decreased ADC or insufficient SI decrease between scans. Kaplan-Meier survival analysis was performed with log rank, Cox hazard ratio calculation and multivariate analysis. Outcome measure was disease-free-survival (DFS). **Results:** Median follow-up time was 43 months (4-70 months). 33 patients had complete remission (CR), 5 progression and 9 recurrent disease. WB-DWI/MRI predicted DFS correctly in 45/47 (96%) [log rank p<0.001; hazard ratio (HR) 52, (CI 95% 6-401)]; end-of-treatment PET/CT was correct in 37/47 (79%) [p=0.003;HR 4.3, (1.5-12.4)], and interim PET/CT in 28/39 (72%) [p=0.016;HR 3.9, (1.2-12.5)]. IPI score and IHC parameters were not significantly predictive. Multivariate analysis showed WB-DWI/MRI as the only independent prognostic factor (p<0.001). **Conclusions:** WB-DWI/MRI can accurately predict treatment outcome in aggressive NHL after only one cycle of immunochemotherapy without the burden of radiation exposure. Clinical trial information: NCT01231269.

7535 Poster Session (Board #297), Mon, 8:00 AM-11:30 AM

Copanlisib in patients with relapsed or refractory follicular lymphoma. *First Author: Martin H. Dreyling, University Hospital of LMU, Munich, Germany*

Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (iNHL) subtype, yet treatment options in the relapsed/refractory (r/r) setting are limited. Copanlisib is a pan-Class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant PI3K-α and PI3K-δ activity. We report results from the FL subset of a large phase II study (n=141) in iNHL patients (pts) (NCT01660451, part B). **Methods:** A total of 104 pts with indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (60 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle. The primary endpoint was objective tumor response rate (ORR) per independent radiologic review (Cheson et al., JCO 20:579, 2007). **Results:** Of the 104 pts treated, 62% were refractory; median prior lines 3 (range 2-8), median time from progression 8 wks (range 1-73 wks). 52% were male, 83% white, median age 62 yrs, and 62% ECOG 0. At the time of primary analysis the ORR was 58.7%, comprising 15 pts (14.4%) with complete response (CR) and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) pts and progression of disease as best response in 2 pts. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 wks (range 1-105); 33 (32%) pts remained on treatment. For all pts, the most common treatment-emergent AEs occurring in >25% of pts included (all grade/grade 3 +): diarrhea (34%/5%), reduced neutrophil count (30%/24%), fatigue (30%/2%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/1.4%), hepatic enzymopathy (AST 28%/1.4%; ALT 23%/1.4%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event. **Conclusions:** Copanlisib was highly active as a single agent in heavily pretreated r/r FL pts and resulted in durable responses in the majority of pts. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzymopathy, opportunistic infections, and colitis. Clinical trial information: NCT01660451.

7536 Poster Session (Board #298), Mon, 8:00 AM-11:30 AM

Phase II study of single-agent copanlisib in patients with relapsed or refractory diffuse large B-cell lymphoma (DLBCL). *First Author: Georg Lenz, Translational Oncology Medical Clinic, Münster University Clinic, Münster, Germany*

Background: Relapsed/refractory (r/r) DLBCL patients (pts) are characterized by poor prognosis. Copanlisib is a pan-Class I phosphatidylinositol 3-kinase (PI3K) inhibitor, with modest single-agent activity in unselected DLBCL pts. Here we report the treatment effect of copanlisib in r/r DLBCL pts with regards to cell of origin (COO) and molecular biomarker profiles (NCT02391116). **Methods:** Patients with r/r DLBCL and ≥1 prior lines of therapy were eligible. Copanlisib (60 mg IV infusion) was administered on days 1, 8 and 15 of a 28-day cycle. Tumor samples were evaluated for COO, CD79B mutations and > 400 genes by next generation sequencing (NGS). The primary endpoint was objective tumor response rate (ORR; per Lugano Classification, 2014) by COO and CD79B status. **Results:** The full-analysis (FAS) and per-protocol sets (PPS; ≥3 doses, post-baseline scans and NGS/COO data) included 67 and 40 pts, respectively. Pts were 58% male, median age 69 (range 25-93), ECOG status 0/1/2 22%/57%/21%, and heavily pretreated (median prior lines = 3, range 1-13). In the PPS, COO (and mutant CD79B status) analysis identified 22 GCB DLBCL (2 mutant), 16 ABC DLBCL (6 mutant), and 2 unclassifiable. The ORR in the PPS was 25% (10 of 40), with 5 complete responses (CR) and 5 partial responses (PR); stable disease in 12 pts. The ORR was 13.6% with 1 CR in GCB pts and 37.5% with 4 CRs (25%) in ABC pts. Response to copanlisib was 25% in pts with (2/8) and without (8/32) CD79B mutations. Five of 10 ABC DLBCL-wtCD79B pts and one GCB DLBCL-mCD79B responded (ongoing > 17 cycles). NGS analysis in 54 pts detected 348 mutations; BCL2 (54% of pts), TP53 (41%), BCL6 (30%), MYC (22%), CD79B (19%)/A (6%), MYD88 (19%), TNFAIP3 (17%), CARD11 (13%), and NFKBIA (9%). Response to copanlisib was not significantly different based on BCL2, BCL6, MYC, and MYD88 mutations. With a median of 6 cycles (range 1-29), the most common AEs (% all grade/gr3+4) were diarrhea (36/2), nausea (31/2), fatigue (31/3), fever (21/2) and transient hypertension (40/33) and hyperglycemia (34/31). There were 14 gr5 AEs (none drug-related). **Conclusions:** Copanlisib treatment of r/r DLBCL pts resulted in encouraging responses, especially in the ABC subtype, with a manageable toxicity. Clinical trial information: NCT02391116.

7537 Poster Session (Board #299), Mon, 8:00 AM-11:30 AM

Intratumoral G100 to induce systemic immune responses and abscopal tumor regression in patients with follicular lymphoma. *First Author: Christopher Flowers, Winship Cancer Institute, Atlanta, GA*

Background: Follicular lymphoma (FL) is an incurable malignancy with patients (pts) ultimately relapsing following standard therapies. Active immunotherapy has the potential to induce life-long host anti-tumor immunity and disease control. G100 consists of glucopyranosyl lipid-A (GLA), a TLR-4 agonist in a specific formulation. Preclinically, G100 activates dendritic cells, T cells and NK cells, and triggers systemic anti-tumor immunity. In Merkel Cell carcinoma pts, G100 administered intratumorally (IT) induced tumor inflammation and responses including a CR after G100 alone. This is the first study of G100 IT in pts with NHL. **Methods:** Previously treated or naïve pts with FL with an injectable tumor site and distal sites of disease were eligible. In Part 1, G100 cohorts of 5 or 10μg were enrolled in a 3+3 design, followed by a large tumor (> 4cm) cohort at 20μg. Pts received 6-9 doses of G100 IT ~qwk after radiation (RT, 2 Gy x2 doses) to the lesion. A 2nd course of G100 could be given without RT to an additional site. **Results:** As of 31Dec16, all 9 pts in Part 1 dose escalation (3 pts each at 5, 10, or 20 μg/dose) were evaluable for safety and efficacy. An additional 13 pts at 10μg/dose were included in the safety analysis only. No G100-related DLTs or SAEs were observed at any dose level. Of 22 safety pts, all G100 related AEs were grade 1/2 and none occurred in > 2 pts. Tumor biopsies following G100 demonstrated diffuse infiltration of CD8+ T cells in 5/5 pts and T cell repertoire analyses indicated an increased frequency of clonal tumor infiltrating lymphocytes (TILs). Best responses include: 4 PRs (45%), 3 SDs (33%) and 2 pending (22%). Of the 4 PR pts, tumor regression ranged 58-89% including up to 56% shrinkage of abscopal (distal) sites. **Conclusions:** G100 IT was safe, well-tolerated, induced CD8+ T cell infiltration and expansion of TIL clones. G100/RT treated and abscopal lesion regressions were observed signifying the induction or boosting of systemic anti-tumor immunity. The induction of immune responses, favorable safety profile and clinical activity indicate that G100 IT is an active agent that warrants further investigation. Part 2 enrollment continues with randomization to G100/RT ± pembrolizumab. Clinical trial information: NCT02501473.

7538 Poster Session (Board #300), Mon, 8:00 AM-11:30 AM

Elucidation of distinct mutational patterns between diffuse large B cell lymphoma subtypes utilizing circulating tumor DNA. *First Author: Joanne Soo, Duke University School of Medicine, Durham, NC*

Background: Patients with diffuse large B cell lymphoma (DLBCL) exhibit significant differences in clinical outcome based on cell-of-origin (COO). Patients are categorized as having germinal-center-like (GCB) or activated-B-cell-like (ABC) disease based on RNA microarray and histopathological analyses of tumor biopsies. We recently described an accurate sequencing-based method for determination of COO in DLBCL utilizing stereotyped differences in mutations (Scherer et al., 2016). Here, we further explore the mutational patterns in patients with differing molecular subtypes of DLBCL based on sequencing of circulating tumor DNA. **Methods:** We applied cancer personalized profiling by deep sequencing (CAPP-Seq) to pretreatment plasma samples and matched germline from a cohort of 115 patients with DLBCL. We then identified somatic alterations, which were used to determine COO molecular subtypes as previously described. Finally, we compared mutational patterns in patients with GCB and non-GCB DLBCL. **Results:** We detected a significantly greater number of total mutations (GCB: 1766 ± 160 mutations per Mb of targeted sequencing; non-GCB: 1364 ± 150 mutations per Mb of targeted sequencing; $p < 0.05$) and coding mutations (GCB: 145 ± 21 mutations per Mb of targeted sequencing; non-GCB: 28 ± 8.5 mutations per Mb of targeted sequencing; $p < 0.001$), particularly in immunoglobulin (Ig) regions ($p < 0.05$). In addition, GCB and non-GCB samples exhibited distinct mutational patterns within Ig regions. GCB samples were enriched for mutations in regions of switch mu (Sμ) ($p < 0.01$) and IGHV2-70 ($p < 0.01$), while non-GCB samples were enriched for mutations in regions of IGHG3 ($p < 0.03$), IGHV4-34 ($p < 0.03$), and IGLL5 ($p < 0.05$). GCB samples were also significantly enriched for coding mutations in SOCS1 ($p < 0.01$), a gene not included in our original COO classifier. **Conclusions:** Patients with GCB and non-GCB DLBCL exhibit distinct mutational patterns across both Ig and non-Ig loci of the genome. These differences in mutational patterns can be used to classify molecular subtypes noninvasively, potentially providing further utility to noninvasive genotyping and liquid biopsies.

7539 Poster Session (Board #301), Mon, 8:00 AM-11:30 AM

Anti-infective prophylaxis with aciclovir and cotrimoxazole to reduce the rate of infections and therapy-associated deaths in elderly patients with DLBCL undergoing R-CHOP immunochemotherapy. *First Author: Niels Murawski, Saarland University Medical School, Homburg, Germany*

Background: To study if anti-infective prophylaxis with aciclovir and cotrimoxazole is effective in preventing infections in pts. receiving R-CHOP, we compared infections and treatment-related deaths in two prospective DSHNHL trials with different anti-infective strategies. **Methods:** 61-80-yo. pts. in RICOVER-60 study [Lancet Oncol 2008; 9:105-116] received 6 or 8 cycles of CHOP-14 with or without 8 applications of rituximab. Anti-infective prophylaxis consisted of ciprofloxazine (500 mg/d) during days of severe leukocytopenia ($< 1000/mm^3$). In OPTIMAL > 60, pts. were randomized to 6xCHOP-14 or 6xCHLIP-14 (conventional substituted by liposomal vincristine) in combination with rituximab, 8 applications q 2 wks. or 12 applications between days -4 and 238 /2x2 factorial design). In OPTIMAL > 60, anti-infective prophylaxis consisted of cotrimoxazole (2 double strength doses twice every week p. o.) and aciclovir (4 x 400 mg/d p.o.) in addition to ciprofloxazine. **Results:** In RICOVER-60, grade 3&4 infections in 232 patients (IPI = 1 and bulky disease or IPI > 1) receiving 6xCHOP-14+8R were 6% (76/1200) per cycle and 28% (60/218) per patient. With intensified anti-infective prophylaxis in OPTIMAL > 60 there were no differences with respect to infections between the 4 treatment arms. Grade 3&4 infections were 4% (83/1987) per cycle ($p = 0.007$) and 18% (64/365 pts. with toxicity documentation) per patient ($p = 0.004$). Treatment-related deaths (defined as all non-lymphoma associated deaths during and within 2 months after the end of chemotherapy) went down from 15/232 (7%) in RICOVER-60 to 7/385 (2%; $p = 0.003$) in OPTIMAL > 60. **Conclusions:** Anti-infective prophylaxis with cotrimoxazole and aciclovir in addition to ciprofloxazine significantly reduced the rates of severe infections and treatment-related deaths in elderly patients receiving R-CHOP supporting the use of this anti-infective strategy in all DLBCL patients receiving R-CHOP. Clinical trial information: NCT01478542.

7540 Poster Session (Board #302), Mon, 8:00 AM-11:30 AM

Phase II clinical trial of first-line combination of radiation followed by gemcitabine, dexamethasone, and cisplatin (GDP) chemotherapy for early-stage extranodal natural killer/T-cell lymphoma with unfavorable prognostic factors: The GREEN study (NCT02276248). *First Author: Fei Qi, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: Currently concomitant or sequential chemotherapy with radiotherapy has been recognized as the standard treatment for extranodal natural killer/T-cell lymphoma, nasal type (ENKTL). However, the optimal schedule has not been fully defined. **Methods:** We designed a phase II prospective study to investigate the efficacy and toxicity profile of sequential radiation followed by systemic GDP (gemcitabine, dexamethasone and cisplatin) chemotherapy on previously untreated early-staged (stage IE/IIE) ENKTL patients with at least one unfavorable prognostic factor. The primary endpoint was 2-year progression-free survival (PFS). Secondary endpoints were 2-year overall survival (OS), overall response rate (ORR), and toxicity. **Results:** A total of40 patients were enrolled and completed the entire course of treatment between June 2010 and June 2014. The median age was 38 (range 25-63) years old. All the enrolled patients presented with at least one unfavorable prognostic feature: age $>$ 60 years (5.0%), B symptom (40%), elevated serum LDH (40.0%), regional lymph node involvement (32.5%) and primary tumor invasion (87.5%). At the completion of the whole treatment, ORR was 97.5% and the complete remission rate was 95.0%. Median follow-up time was 43.7 months (range 9.4-72.3 months). 2-, 3-, 5-year PFS rates were 84.7%, 82.1%, 77.5%, and OS rates were 89.9%, 87.1%, 79.7%, respectively. Recurrence within the RT field was observed in four patients and systemic failure in three individuals. Grade 1-2 skin reaction and mucositis were the main toxicity related to radiation. Grade 3-4 neutropenia (12/40), thrombocytopenia (7/40) and anemia (2/40) were observed during GDP chemotherapy. No clinically significant late toxicities were observed during follow-up visits. **Conclusions:** The current results indicates that first-line radiation followed by GDP chemotherapy can be one of the most effective and feasible treatment schedule for early-stage ENKTL patients, especially those with poor prognostic factors. Clinical trial information: NCT02276248.

7541 Poster Session (Board #303), Mon, 8:00 AM-11:30 AM

MYC+ relapsed and refractory (R/R) diffuse large b-cell lymphoma (DLBCL): Impact of additional hits and outcomes with subsequent therapy. *First Author: Narendranath Epperla, Medical College of Wisconsin, Milwaukee, WI*

Background: Translocations involving *MYC* are a hallmark of poor prognosis among patients with newly diagnosed DLBCL. The impact of *MYC* translocations with or without additional "hits" involving *BCL2* or *BCL6* in response to salvage therapy and survival in R/R DLCBL is not well defined. **Methods:** We performed a multicenter retrospective study of 176 patients with R/R DLBCL failing to achieve CR or relapsing within 6 months after completion of upfront chemoimmunotherapy and for whom FISH information on *MYC*, *BCL2* and *BCL6* was available. The objectives were to examine the response to salvage therapy, utilization of hematopoietic cell transplantation (HCT) and survival outcomes in *MYC*- (n = 120), *MYC*+ single hit (SH, n = 28), and *MYC*+ double hit (DH, n = 36) R/R DLBCL. **Results:** Overall response rate to first salvage therapy and utilization of HCT was comparable between the 3 cohorts (Table). 2-year OS was 0% in *MYC*+ SH, 8.8% in *MYC*+ DH and 29.9% in *MYC*- cases (p = 0.001) without difference in OS between SH and DH (P = 0.8). The higher risk of death for *MYC*+ SH (HR 1.79, 95% C.I. 1.03-3.11, P = 0.03) and *MYC*+ DH (HR 1.93, 95% C.I. 1.23-3.00, P = 0.004) persisted after adjustment for covariates. For patients who underwent auto-HCT, 2-year OS was 0% in *MYC*+ SH, 29.3% in *MYC*+ DH and 55.4% in *MYC*- cases (p $<$ 0.001) without significant difference between SH and DH (P = 0.8). All 4 *MYC*+patients who underwent allo-HCT relapsed in $<$ 4 months. **Conclusions:** *MYC*+ R/R DLBCL have similar response to salvage therapy than the *MYC*- counterparts but dismal survival irrespective of additional "hits" and even if HCT can be performed. *MYC*+ R/R DLBCL represents an unmet medical need and should be prioritized for clinical trials with novel agents and innovative cellular therapies.

Table	*MYC*+ SH N = 20 (%)	*MYC*+ DH N = 36 (%)	*MYC*- N = 120 (%)	P
Median age	57	61	58	0.3
Cell of origin -GCB	16 (80)	32 (89)	65 (52)	$<$ 0.001
Upfront therapy				$<$ 0.001
R-CHOP	14 (70)	23 (64)	108 (90)	
More intense	6 (30)	13 (36)	12 (10)	
Int. High/High NCCN-IPI at failure	13 (65)	13 (36)	55 (46)	0.1
Salvage therapy				0.8
ICE (+/- R)	13 (65)	23 (64)	69 (58)	
Response to first salvage therapy				0.2
CR+PR	9 (45)	18 (50)	57 (47)	
SD+PD	9 (45)	9 (25)	29 (24)

7542 Poster Session (Board #304), Mon, 8:00 AM-11:30 AM

Frequency of secondary malignancies (SM) in patients with large granular lymphocytic leukemia (LGLL): A single institutional experience. *First Author: Leidy Lismeri Isenalumhe, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Large granular lymphocyte (LGL) disorders represent a spectrum of aberrant T-cell or natural killer cell lymphocytic proliferations. LGLL is classically associated with autoimmune conditions and bone marrow (BM) failure disorders. SM has been reported in association with LGLL in about 10%. The aim of this study is to evaluate the impact of SM on the clinical course of LGLL. **Methods:** This is a retrospective study of LGLL patients (pts) evaluated at Moffitt Cancer Center between January 1995 and May 2016. The diagnostic clinico-pathological criteria consisted of LGL count $>$ 0.5 k/μL with T-cell receptor gene rearrangement. Lower absolute number of clonal circulating LGLs with characteristic immunophenotype associated with BM involvement, cytopenias, splenomegaly and/or associated symptoms were also diagnostic. Pts with myelodysplastic syndrome were excluded. Survival analysis was performed using the Kaplan-Meier method with log-rank test. Chi-square and T-test were used to analyze association among various variables. Significant P-value was considered $<$ 0.05. **Results:** Out of 668 screened pts with LGL expansions in peripheral blood, 261 met criteria for LGLL. SM were present in 44% (116/261) of LGLL pts, of which 38% were hematological and 80% arose prior to onset of LGLL. Most common solid SM included skin cancer (14%), prostate cancer (12%), and breast cancer (12%), while most common hematological SM consisted of non-Hodgkin lymphoma (17%) and chronic leukemia (14%). 5-year overall survival (OS) for all LGLL pts was 75% and 10-year OS 63%. There was a statistically significant difference in 5-year OS between LGLL pts with SM compared to without (p = 0.049), but no difference between both groups in median OS or 10-year OS. Pts diagnosed with SM prior to LGLL had worse 5-year OS (p = 0.031) and 10-year OS (p = 0.05) compared to all other LGLL pts. **Conclusions:** This study showed that the frequency of SM is higher than previously described, especially with onset prior to diagnosis of LGLL. Even though median age of LGLL is around 60 years, it appears that age itself cannot explain this phenomenon. Our results suggest that having a SM is a poor prognostic factor in LGLL patients.

7543 Poster Session (Board #305), Mon, 8:00 AM-11:30 AM

Central line-associated complications during treatment with DA-R-EPOCH therapy for NHL. *First Author: Rachel Julie David, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Certain non-Hodgkin lymphomas (NHL) such as primary mediastinal B-cell, Burkitt's, and high-grade B-cell lymphoma with MYC and BCL2 rearrangements are often treated with infusional dose-adjusted rituximab, etoposide, prednisone, vincristine, cyclophosphamide and doxorubicin (DA-R-EPOCH), which requires a central line. We have observed meaningful line-associated complications (LAC) in patients (pts) treated with DA-R-EPOCH. With the ongoing use of this regimen, we sought to identify the rates and correlates of LAC in this population. **Methods:** We retrospectively identified all pts treated with DA-R-EPOCH at the Wilmot Cancer Institute between 3/2011 and 10/2015. Our primary endpoint was the rate of LAC, including venous thromboembolism (VTE), extravasation, and line-associated infection (LAI) diagnosed during DA-R-EPOCH therapy. Our secondary endpoint was the rate of VTE during therapy. Rates and 95% confidence intervals (95% CI) were calculated for all endpoints. Univariate logistic regression was used to calculate odds ratios to evaluate potential predictors. **Results:** 43 pts received DA-R-EPOCH during the study period. 70% of pts were male; median age was 52 years. 17 pts (39.5%, 95% CI 0.25 - 0.56) experienced at least 1 LAC: 15 pts (35%, 95% CI 0.21 - 0.51) had VTE; 3 pts had LAI; and 2 pts experienced extravasations. Grade 3 toxicity was seen in 41% (7/17): 4 pts with VTE, and 3 pts with LAI. Both extravasation events were grade 2, and both occurred with mediports. In univariate analysis, BMI $\geq$ 35 kg/m^2 and receiving therapy via peripherally inserted central catheter (PICC) line were significantly associated with an increased risk of VTE (p=0.04 and p=0.02, respectively). **Conclusions:** 40% of pts receiving DA-R-EPOCH therapy for treatment of NHL developed LAC, almost half of whom experienced grade 3 toxicities. Clinicians need to balance these risks when selecting therapy, particularly with the lack of randomized data to support the DA-R-EPOCH approach in many circumstances. Given observed extravasations, we avoid mediports in favor of PICC lines, however this approach carries a significant risk of VTE. Future studies are needed to evaluate the role of prophylactic anticoagulation in this population.

7544 Poster Session (Board #306), Mon, 8:00 AM-11:30 AM

Phase I dose escalation of ibrutinib and buparlisib in relapsed/refractory diffuse large B-cell lymphoma (DLBCL), mantle cell lymphoma (MCL), and follicular lymphoma (FL). *First Author: Connie Lee Batlevi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In vitro studies of BTK and PI3K inhibitors demonstrate synergy in non-Hodgkin lymphoma (NHL). We embarked on a phase I/Ib investigator-initiated clinical trial evaluating the combination of ibrutinib (BTK inhibitor) and buparlisib (pan-PI3K inhibitor) in relapsed/refractory (R/R) NHL. The completed dose escalation is reported. **Methods:** Patients (pts) were eligible if they had R/R DLBCL, MCL, or FL with ECOG≤2 and adequate organ function. Ibrutinib and buparlisib were given daily by mouth on a 28-day cycle. Dose reductions were permitted after cycle 1. Tumor response was based on Lugano Classification however CR required both PET resolution and ≥ PR by CT. **Results:** As of Dec 16, 2016, 13 pts were enrolled and evaluated for toxicity (DLBCL 5, FL 2, MCL 6). Dose levels and DLT per table. Six pts discontinued treatment for disease progression (DLBCL 4, FL 2). Hematologic AE ≥ grade 3 are anemia (2), leukocytosis (2), and leukopenia (4). Relevant non-hematologic AEs of any grade ≥ 20% across all pts were fatigue (77%), diarrhea (62%), anorexia (54%), rash (46%), hyperbilirubinemia (46%), gastric reflux (46%), CMV reactivation (31%), mood change (31%), and hypertension (23%). Most common related grade 3/4 toxicity is rash (N = 3). No grade 5 toxicities noted. Serious adverse events (SAE) include: grade 2 pleural effusion and grade 2 nausea (N = 1), grade 1 fever with hospitalization (N = 1), grade 2 confusion and grade 4 hyponatremia (N = 1) were unrelated to therapy. Responses noted in 13 pts: MCL (N = 6: CR 4, PR 2), FL (N = 2: SD 2), DLBCL (N = 5: SD 1). One CR was a MCL pt with CR after 2 cycles on combination therapy and continues in remission on ibrutinib alone because of buparlisib toxicity. **Conclusions:** Combination of ibrutinib and buparlisib while generally well tolerated has predicted toxicities of both BTK and PI3K inhibitors. The recommended phase 2 dose is ibrutinib 560 mg and buparlisib 100 mg though dose reductions for tolerability may be needed for long term oral therapies. Promising efficacy is observed in MCL. Clinical trial information: NCT02756247.

Dose Level	N	Ibrutinib (mg)	Buparlisib (mg)	DLT	Best Responses
1	6	420	80	1/6 Grade 2 anorexia	3 CR 1 SD
2	4	560	80	0/4	1 CR 2 SD
3	3	560	100	0/3	2 PR

7545 Poster Session (Board #307), Mon, 8:00 AM-11:30 AM

Clinical activity, safety and tolerability of ASN002, a dual SYK/JAK inhibitor, in patients non-Hodgkin lymphoma (NHL) and solid tumors. *First Author: Drew W. Rasco, START, San Antonio, TX*

Background: ASN002 is a novel, potent inhibitor of Spleen Tyrosine Kinase (SYK) and Janus Kinases (JAK). Pre-clinical studies indicate that ASN002 has low nM IC50s against SYK and JAK, decreases proliferation in ibrutinib-resistant cell lines, and suppresses tumor growth in rodent xenograft models of NHL and other hematologic malignancies. **Methods:** This Phase 1/2 clinical trial in patients with solid tumors and hematologic malignancies evaluates escalating ASN002 oral doses of 10, 20, 30, 40, 50 and' 75 mg BID and 80 and 120 mg QD mg (NCT02440685). Phase 1 allows patients with solid tumors or hematologic malignancies; Phase 2 allows only patients with diffuse large B-Cell lymphoma (DLBCL), follicular lymphoma (FL) or mantle cell lymphoma (MCL). Endpoints include safety, tolerability, pharmacokinetics, serum markers of inflammation, and response using RECIST or Lugano Classification System. **Results:** Twenty-eight patients have enrolled in the DLT phase at doses of 10 mg – 75 mg BID and at 80 mg QD. All patients had multiple prior lines of treatment (range: 2 – 8). ASN002 was well tolerated. No dose limiting adverse events have been reported at these dose levels. Most drug-related adverse events were Gr 1/2 (e.g. headache, fatigue). Steady-state systemic exposure was high (C_{max}, AUC (0-12h) and $T_{1/2}$ at 40 mg BID were 0.7 μM, 6.3 μM.h and 18 h, respectively). High systemic exposure was also observed at 80 mg QD. Robust reduction of CRP, IL-18, MIP1β, VCAM-1, TNFR2 was observed at all doses. Stable disease (RECIST, 9+ months) in a patient with primary peritoneal cancer, about 50% reduction in target lesions at 3 months in a FL patient (Lugano, 6 prior lines) and stable disease and reduction of pruritus in a peripheral T-Cell lymphoma patient after 2 months (Lugano, 2 prior lines) of treatment were observed. ASN002 treatment continues in both lymphoma patients. Accrual of patients continues. **Conclusions:** ASN002 was safe and well tolerated. Encouraging preliminary evidence of efficacy in NHL patients was observed. MTD has not been reached and dose escalation continues. Updated and detailed results will be presented. Clinical trial information: NCT02440685.

7546 Poster Session (Board #308), Mon, 8:00 AM-11:30 AM

Early disease progression in patients (pts) with newly diagnosed localized nasal extranodal NK/T-cell lymphoma, nasal type (ENKL) treated with radiotherapy with dexamethasone, etoposide, ifosfamide, and carboplatin (RT-DeVIC). *First Author: Motoko Yamaguchi, Mie University Graduate School of Medicine, Tsu, Japan*

Background: Approximately 25% of all pts with localized nasal ENKL experience disease progression during the first two years (yrs) after diagnosis under new treatments including concurrent chemoradiotherapy. The clinical features of those pts are largely unknown. **Methods:** The database of our study (NKEA project; UMIN000015491) was used for the present analysis. Data from pts with newly diagnosed localized (stage IE and contiguous IIE) nasal ENKL diagnosed between 2000 and 2013 at 31 institutes in Japan and treated with RT-DeVIC were retrospectively analyzed. Progression of disease within 2 yrs (POD24) (Casulo, JCO 2015) was applied as the definition of early progression. **Results:** Of 162 pts, 38 were in the POD24 group (23%) and 124 were in the reference group. Treatment yrs and doses of RT and DeVIC were not associated with the incidence of POD24. With a median follow-up of 5.8 yrs, the overall survival (OS) of the POD24 group was inferior to that of the reference group ($P < 0.00001$; 2-yr OS, 26% vs. 100%; 5-yr OS, 23% vs. 89%). The POD24 group showed the following features more frequently than the reference group: serum soluble interleukin-2 receptor (sIL-2R) level > upper limit of normal (ULN) (25/33, 76%; $P = 0.000012$), C-reactive protein (CRP) > ULN (28/37, 76%; $P = 0.013$), and detectable Epstein-Barr virus (EBV)-DNA in peripheral blood (15/17, 88%; $P = 0.033$). The positive predictive value and negative predictive value of elevated sIL-2R for POD24 were 42% and 90%, respectively; those of elevated CRP were 31% and 87%, respectively; and those of detectable EBV-DNA were 39% and 90%, respectively. Of the 9 pts who were negative for all three factors, none experienced POD24. A multivariate analysis in the POD24 group identified elevated sIL-2R as an independent predictive factor for worse OS (HR 3.16; 95% CI, 1.07 - 9.32). **Conclusions:** Pretreatment sIL-2R, CRP, and EBV-DNA were associated with POD24 among pts with localized nasal ENKL treated with RT-DeVIC. The strong association of elevated sIL-2R with early progression and short OS in the POD24 group provides a rationale for targeting strategies.

7547 Poster Session (Board #309), Mon, 8:00 AM-11:30 AM

Rapid, real-time central pathology review for E1412: A novel and successful paradigm for future National Clinical Trials Network diffuse large B cell lymphoma studies. *First Author: Rebecca L. King, Mayo Clinic, Rochester, MN*

Background: E1412 statistical design is based on results of lenalidomide/RCHOP (R2CHOP) vs RCHOP in ABC-DLBCL as determined by NanoString gene expression profiling (GEP). Central pathology review (CPR) was conducted to confirm diagnosis and to ensure adequate tissue for GEP. Initially, CPR occurred after randomization and treatment initiation. Due to high ineligibility rate (IR), the protocol was amended to include real-time CPR to determine patient eligibility prior to study enrollment. We describe the revision and how it affected the IR. **Methods:** Pre-amendment, CPR was done retrospectively. Post-amendment, CPR was done prior to enrollment, in real time, on a submitted tissue block, H&E, and CD20 slides. Based on CPR, if a diagnosis of DLBCL was confirmed, and sufficient tissue remained for GEP, a patient was deemed eligible and the submitter was notified by fax. Protocol goal was notification within 2 working days (WD) of receipt of materials at the CPR site. **Results:** Pre-amendment, 219 patients were enrolled. Material was typically received at the CPR site 6-9 months after patient registration. The IR with CPR was 36% for all those enrolled, and 26% for patients with adequate tissue for GEP. Post-amendment, 218 patients were submitted for CPR: 145 (67%) were eligible; 73 (33%) were ineligible. Reasons for ineligibility included insufficient tissue (n=27) or a diagnosis other than de novo DLBCL (n=46). Notification of eligibility occurred in a median of 2 WD (Mean 2 WD; Range 1-5 WD). 90% were notified within the protocol goal of 2 WD. GEP for all enrolled was completed within 6 weeks of CPR. **Conclusions:** The success of this novel, real-time CPR serves as a model for the future of NCTN DLBCL trials. When CPR is performed rapidly prior to enrollment, study slots may more accurately reflect the target population and eliminate excess costs. In the precision medicine era, rapid collection of relevant pathology and biomarker data is essential to trial success. Study Coordinated by ECOG-ACRIN Cancer Research Group (Robert L. Comis, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs), supported by NCI grant # CA180820, CA180794, CA180790, CA180799, CA180833.

7548 Poster Session (Board #310), Mon, 8:00 AM-11:30 AM

Significance of MYC rearrangement and chemotherapy type on survival outcomes of patients with central nervous system lymphoma. *First Author: Natalie Sophia Grover, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Central nervous system lymphoma (CNSL) has a poor prognosis and an optimal treatment regimen has not been established. Due to the rarity of this disease and frequently poor performance status at diagnosis, there have been few prospective therapeutic clinical trials in this patient population. We therefore performed a retrospective analysis of prognostic factors and treatment outcomes of patients with CNSL treated at a single institution. **Methods:** Pathology records were used to identify patients diagnosed with CNSL from 1/1/2005 to 9/1/2016 at the University of North Carolina Cancer Hospital. Information about demographics, disease characteristics, treatment, and outcomes was gathered from the electronic medical record. Overall (OS) and progression free survival (PFS) were estimated using the Kaplan-Meier method. **Results:** We identified 100 patients with CNSL. 49% had primary CNSL (PCNSL). 78% of cases were diffuse large B cell lymphoma. Out of 51 patients evaluated for MYC translocation by FISH, 13 were positive (3 PCNSL and 10 secondary CNSL). Out of 74 patients treated with chemotherapy, 51% received methotrexate (MTX), procarbazine, and vincristine (MPV), with or without rituximab, 28% were treated with other high dose MTX based regimens, with or without rituximab, and 20% received a non-MTX based regimen. There was no significant difference in OS between PCNSL and secondary CNSL (13.7 vs 7.9 months, p = 0.97). Patients with MYC translocation had a worse OS compared to those without MYC translocation (5.1 vs 29.5 months, p = 0.004). Patients treated with MPV had a longer PFS compared to those treated with other high dose MTX based regimens or those who were treated with a non-MTX based regimen (19.1 vs 10.9 vs 3.9 months, p = 0.05), but difference in OS did not reach statistical significance (29.5 vs 22.4 vs 10.6 months, p = 0.12). **Conclusions:** In this single institution analysis of CNSL, MYC translocation was associated with worse survival. MPV was associated with improved PFS compared to other chemotherapy regimens. Further prospective studies are needed comparing MPV to other MTX-based regimens in CNSL.

7549 Poster Session (Board #311), Mon, 8:00 AM-11:30 AM

Oncogenic activation of STAT3 pathway drives PD-L1 expression in natural killer/T cell lymphoma. *First Author: Soon Thye Lim, National Cancer Centre Singapore, Sinagpore, Singapore*

Background: Natural killer/T-cell lymphoma (NKTL) is a rare type of non-Hodgkin lymphoma that occurs more frequently in East Asia and Latin America and is associated with Epstein–Barr virus infection. Recent whole-exome sequencing studies in NKTL have reported recurrent somatic mutations in genes associated with JAK-STAT pathway, however the role of aberrant JAK-STAT signaling in tumor immune escape through PD-L1 regulation is unclear. **Methods:** To determine the prevalence of JAK-STAT pathway alteration in NKTL, we performed targeted sequencing of 188 genes associated with JAK-STAT pathway in 109 NKTL (22 Singapore cases, 79 China cases and 8 cell lines). Single nucleotide variants and micro-indels were called using Freebayes and candidate variants annotated using ANNOVAR. Ba/F3 model system was used to test the transformation capacity of identified variants. Cell lines were evaluated for PD-L1 expression by immunoblotting and flow cytometry. Tissue microarrays were examined for p-STAT3 and PD-L1 expression by immunohistochemistry. **Results:** We identified a total of 284 non-synonymous somatic mutations candidates in 114 genes, including 243 missense, 10 nonsense, 4 splice-site and 27 indel mutations. Recurrent mutations were most frequently located in STAT3 (25/109 cases, 23%) followed by TP53 (16/109 cases, 16%) and JAK3 (8/109 cases, 7%). A total of 18 STAT3 variants were identified including known hotspot mutations and novel mutations in the SH2, coiled coil and DNA-binding domains. Characterization of novel E616K mutant residing in the SH2 domain showed that E616K conferred IL3 independent growth to Ba/F3 cells, increased STAT3 phosphorylation and PD-L1 expression. Consistent with these findings, PD-L1 was over expressed in cell lines harboring STAT3 mutations. A positive correlation between PD-L1 and p-STAT3 expression was also observed in tumor tissue (R = 0.51, P = 0.02). **Conclusions:** We characterized a novel activating STAT3 mutant and demonstrated its ability to drive PD-L1 expression, which may promote tumor evasion from the antitumor immune response. The combination of PD-1/PD-L1 antibodies and STAT3 inhibitors might be a promising and novel therapeutic approach for NKTL in the future.

7550 Poster Session (Board #312), Mon, 8:00 AM-11:30 AM

Comparative double-blind randomized trial of 2 rituximab products in patients with CD20+ diffuse large B-cell lymphoma (DLBCL). *First Author: Sandip Shah, Gujarat Cancer and Research Institute, Ahmedabad, India*

Background: DRL-Rituximab (T) is a proposed biosimilar of the innovator reference rituximab (USA: Rituxan; EU: MabThera). Physicochemical analyses and nonclinical studies have shown T to be comparable with innovator Rituximab. This study evaluated the pharmacokinetics (PK), pharmacodynamics (PD), efficacy, safety and immunogenicity of T with EU sourced MabThera (R) in DLBCL patients. **Methods:** Multicentre randomized double-blind 2-arm parallel study conducted in patients aged 18-60 yrs, with a centrally confirmed newly diagnosed CD20+ DLBCL, as first line of treatment. Patients received 6 cycles (C), every 21 days, of either T or R at 375 mg/m^2 + CHOP. Primary objective was to compare C1 PK ($AUC_{0\text{-}21d}$ & C_{max}). Overall Response Rate (ORR) was the key secondary objective, with C6 PK parameters, PD parameters (B-cells measured as CD19+ positive cells in peripheral blood- depletion & repletion), treatment-emergent adverse events (TEAEs), and anti-drug antibodies (ADA) as other secondary objectives. PK similarity criterion was 90% CI of geometric mean ratios (GMRs) of $AUC_{0\text{-}21d}$ and C_{max} in C1, within 80-125%. **Results:** 151 patients were randomized (T, 76; R, 75). PK similarity criterion was met. The GMR T/R ratios with 90% CIs for $AUC_{0\text{-}21d}$ & C_{max} were 100.0% (87.7, 114.0) & 96.2% (88.7, 104.4), respectively. Per protocol, ORR with 95% CI was 82.1% (69.6, 91.1) with T and 87.1% (76.1, 94.3) with R. Trough concentration (C5/C6) GMR (90% CI) of 91.3% (86.3, 96.7) for T & 94.0% (88.9, 99.5) for R indicated steady state. C6 $AUC_{0\text{-}21d}$ & C_{max} GMR (T/R [90% CI]) were 88.9% (80.3, 98.5) and 94.6% (88.1, 101.7), respectively. T and R led to comparable B-cell depletion and repletion. Incidence of all grades of TEAEs were comparable. TEAEs ≥Grade 3 were 80.3% in T (n = 61) and 88.0% R (n = 66). Neutropenia was the most common TEAE (overall: T, 75.0%; R, 73.3% & ≥ grade 3: T, 64.5%; R, 64.0%). No neutralizing antibodies were observed in either of the arms. **Conclusions:** These data demonstrate that DRL-Rituximab has comparable PK, PD, efficacy, safety and immunogenicity to MabThera. MabThera already has an established efficacy in longer term follow-up. Clinical trial information: CTRI/2012/11/003129.

7551 Poster Session (Board #313), Mon, 8:00 AM-11:30 AM

Survival outcomes for various treatment modalities in early-stage grade 3 follicular lymphoma (FL3): a National Cancer Database (NCDB) study. *First Author: Upama Giri, University of Tennessee Health Sciences Center, Memphis, TN*

Background: The prognosis, response to therapy and curability of FL3 is controversial. 5-year Overall Survival (OS) in the literature ranges from 35-72% (Ganti 2006). The aim of this study was to compare the OS for patients with early-stage FL3 managed with single- and multi-agent chemotherapy (CT) with and without radiotherapy (RT). **Methods:** We identified patients (pts) diagnosed with stage I & II FL3 between 2004 – 2012 from the NCDB and categorized into 3 groups based on therapy – pts given single agent CT with or without RT were combined due to small sample sizes (SA±RT), multi-agent CT without RT (MA-RT), and multi-agent CT with RT (MA+RT). We calculated OS for each group using Kaplan-Meier method and compared the results using Log Rank test. Cox regression model was used to identify factors which had significant impact on OS. **Results:** 1,563 pts were identified – 827 (53%) with stage I and 736 (47%) with stage II FL3. Median age was 61 yrs (range 18-90yrs); 750 (48%) males, 813 (52%) females; 1423 (91%) whites, 76 (5%) blacks. 112 (7%) received SA±RT, 886 (57%) MA-RT and 565 (37%) MA+RT. 5-year OS for MA+RT (95%) was significantly more than MA-RT (87%; HR 0.33, P<0.001) or SA±RT (88%; HR 0.38, P=0.007). Cox regression indicated that age (HR 1.05, P<0.001), sex (HR 0.66 for females, P=0.02), comorbidities (HR 1.60 for Charlson Deyo Score 1, P=0.04; HR 3.07 for Score 2, P=0.001), stage (HR 1.79, P=0.001), insurance status (HR 0.22 for insured, P<0.001) and increasing year of diagnosis (HR 0.92, P=0.03) also had significant impact on OS. Median radiation dose for the MA+RT was 36Gy (interquartile range 30.6 – 36Gy), and the proportion of patients who received greater than 36Gy decreased from 55% in 2004 to 38% in 2012 and at the same time, the proportion of patients who received intensity modulated RT increased from 5% in 2004 to 15% in 2012. Use of MA CT declined (2004 95% v 2012 89%, P=0.02) but there was no significant trend in use of RT (2004 39% v 2012 34%) during the periods studied. **Conclusions:** For pts with early-stage FL3, there was an association of improved survival with the use of MA+RT over other treatment strategies and appear to have outcomes superior to what has been previously reported.

7552 Poster Session (Board #314), Mon, 8:00 AM-11:30 AM

Circulating tumor DNA assessment in patients with diffuse large B-cell lymphoma following CAR-T therapy. *First Author: Saurabh Dahiya, Stanford University School of Medicine, Stanford, CA*

Background: Circulating tumor DNA(CTD) have been used for disease monitoring in Diffuse Large B Cell Lymphoma(DLBCL) (Kurtz ASCO 2016). Role of CTD assessment in DLBCL patients treated with CAR-T therapy has not been studied. We prospectively analyzed CTD of dynamics measured by next generation sequencing(NGS) of BCR using ClonoSeq MRD(Adaptive Biotechnologies), before and after CAR-T therapy to determine feasibility and clinical utility. **Methods:** At Stanford, 7 patients were enrolled on ZUMA-1 clinical trial NCT02348216, treating chemo-refractory DLBCL patients with anti-CD19, CAR-T. Complete radiologic data and CTD analysis was collected for six subjects. Tumor-DNA was extracted from archival paraffin-embeded tissue & analyzed using the NGS-based assay. PCR amplification of IGH-VDJ, IGH-DJ & IGK regions using universal consensus primers was performed followed by NGS to determine the tumor clonotype(s). Blood collected at day 0,7,14,28,60 & 90 days in relation to CAR-T infusion was used to detect CTD by ClonoSeq quantification of clonotypes. **Results:** Clonotypes were successfully determined for all 6 subjects, and 30 blood samples for 6 patients were prospectively analyzed. All patients had measurable disease burden pre-CAR-T infusion. CTD dynamics correlated with PET-CT outcomes in 100% of the patients. Increasing CTD temporally preceded progressive disease(PD) before PETCT recognition in 4 of 5 patients and was always increasing when PETCT showed PD. Preceding CTD quantification correlated with disease volume increase. One patient achieved durable KTE-19 complete response(CR) and detectable CTD became undetectable on day 14(and on subsequent samples) following CAR-T infusion, corresponding to 1 & 3 month PETCT CR. Additionally, the burden of disease measured by lymphoma molecules per ml allowed volumetric response assessment in all the patients who experienced massive reduction in tumor volume, but by traditional response definition had partial response. **Conclusions:** ClonoSeq CTD provides precise total tumor quantification of DLBCL in the CAR-T cell setting. This technology may overcome fundamental limitations of DLBCL imaging(cost, radiation exposure & limited repetition).

7553 Poster Session (Board #315), Mon, 8:00 AM-11:30 AM

Clinicopathologic characteristics and outcomes of transformed diffuse large B-cell lymphoma in hepatitis C virus-infected patients: A case-control study of 84 patients. *First Author: Jeff Hosry, Department of Infectious Diseases, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Chronic hepatitis C virus (HCV) infection is associated with development of marginal zone lymphoma (MZL) and diffuse large B-cell lymphoma (DLBCL). Preliminary data showed particular characteristics of HCV-associated DLBCL; such as frequent transformation from indolent lymphomas and aggressive oncologic courses. We studied herein the clinicopathologic characteristics and outcomes of HCV-infected patients (pts) with transformed DLBCL. **Methods:** In this case control study, the medical records and pathology reports of HCV-infected (cases) and HCV-uninfected (controls) pts with transformed DLBCL seen at our institution (6/2004 - 5/2015) were reviewed. Included pts had a concomitant or a history of a low grade lymphoma. To determine their clinicopathologic characteristics, cases were compared to controls at a ratio of 1:3. To determine predictors of oncologic relapse, we compared pts with DLBCL relapse after first line chemotherapy to those who did not relapse in univariate and logistic regression analyses. **Results:** Twenty-one cases were compared to 63 controls. Compared to controls, cases were younger (median year age [interquartile range], 54 [49-62] *v* 62 [53-66], $P = .01$), had advanced Ann Arbor stages, 3-4 (95% *v* 76%, $P = .05$), and upper gastro-intestinal involvement (48% *v* 25%, $P = .05$). Immunophenotypically, cases had more CD10-negative B-cells (76% *v* 43%, $P = .008$) and CD5-positive B-cells (39% *v* 7%, $P = .004$) compared to controls, consistent with an activated B-cell phenotype. A comparison between pts who relapsed after first line chemotherapy (n = 42) and those who did not (n = 40) revealed that having CD5-positive B-cells was the only factor associated with DLBCL relapse in univariate (24% *v* 6%, $P = .03$) and multivariate analyses (OR = 10.7, $P = .02$). **Conclusions:** HCV-infected pts with transformed DLBCL are younger, present with advanced stages, are more commonly CD5-positive, and have an activated B-cell phenotype, suggesting more frequent transformation from MZL compared to HCV-uninfected pts. The higher frequency of CD5-positive B-cells might explain the higher DLBCL relapses previously described in HCV-infected pts.

7554 Poster Session (Board #316), Mon, 8:00 AM-11:30 AM

Survival outcomes for various treatment modalities in advanced-stage grade 3 follicular lymphoma (FL3): A National Cancer Database (NCDB) study. *First Author: Upama Giri, University of Tennessee Health Sciences Center, Memphis, TN*

Background: The prognosis, response to therapy and curability of FL3 is controversial. 5-year Overall Survival (OS) in the literature ranges from 35-72% (Ganti 2006). The aim of this study was to compare the OS for patients with advanced-stage FL3 managed with various treatment modalities. **Methods:** We identified patients (pts) diagnosed with stage III & IV FL3 between 2004 – 2012 from the NCDB and categorized them into 3 groups based on therapy – pts given single agent chemotherapy with or without radiotherapy were combined due to small sample sizes (SA±RT), multi agent chemotherapy without radiotherapy (MA-RT), and multi agent chemotherapy with radiotherapy (MA+RT). We calculated OS using Kaplan-Meier method and compared the results using Log Rank test. Cox regression model was used to identify other factors which had significant impact on OS. **Results:** 2,808 pts were identified – 1,508 (54%) with stage III and 1,300 (46%) with stage IV disease. Median age was 60 yrs (range 21-90yrs); 1,331 (47%) males, 1,477 (53%) females; 2,559 (91%) whites, 142 (5%) blacks. 170 cases (6%) were treated with SA±RT, 2,508 (89%) with MA-RT and 130 (5%) with MA+RT. There was no significant difference in 5-year OS between MA-RT (83%) and MA+RT (82%; HR 1.07, P=0.76). There was no difference between SA±RT (73%) and MA+RT (82%; HR 0.62, P=0.069) likely due to small sample sizes, but survival for MA-RT (83%) was significantly higher than SA±RT (73%; HR 1.78, p<0.001). Cox regression indicated that age (HR 1.04, P<0.001), sex (HR 0.77 for females, P=0.008), comorbidities (HR 1.48 for Charlson Deyo Score 1, P=0.001; HR 2.59 for Score 2, P<0.001), stage (HR 1.29, P=0.007), insurance status (HR 0.65 for insured, P=0.048) and increasing year of diagnosis (HR 0.91, P<0.001) also had significant impact on OS. Use of MA chemotherapy declined (2004 96% v 2012 91%, P=0.008) but there was no significant trend in use of radiotherapy (2004 5% v 2012 3%) during the periods studied. **Conclusions:** MA chemotherapy in pts with advanced-stage FL3 was associated with improved survival compared to SA therapy, and radiation does not appear to influence outcomes. Outcomes were superior to what has been previously reported.

7555 Poster Session (Board #317), Mon, 8:00 AM-11:30 AM

A single institutional experience of 261 patients with large granular lymphocytic leukemia (LGLL). *First Author: Magali Van den Bergh, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: LGLL is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy. **Methods:** This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between 1995 and 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher's Exact Test. Kaplan-Meier curves were used for overall survival (OS). P-values were two-sided with significance set at < 0.05. **Results:** We identified 261 patients with LGLL (91.6% T, 8.4% NK). Median age was 66 years [21-90] and M:F ratio 1.2:1. Median follow up was 3.07 years [0-21.88]. 42.9% presented with anemia, 37.1% neutropenia, 30.7% thrombocytopenia, 29.1% bicytopenia and 6.9% pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.2% and bone marrow (BM) involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% autoimmune cytopenias. 45.6% were observed while the remainder required at least 1 line of therapy. 5-yr and 10-yr OS were 75.0% and 63.1% respectively. There was no statistically significant difference in OS, complete response or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any therapy was noted. There was no statistically significant difference in OS based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in those with LGL count <0.5 k/μL (p=0.0078), BM involvement (p<0.0001), and splenomegaly (p<0.0001). **Conclusions:** In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. We confirmed that there is no difference in OS among first line therapies.

7556 Poster Session (Board #318), Mon, 8:00 AM-11:30 AM

Results of GROC-rev salvage regimen: Gemcitabine, rituximab, and oxaliplatin chemotherapy with revlimid for relapsed/refractory aggressive non-Hodgkin lymphoma (NHL). *First Author: Fernando Cabanillas, Auxilio Mutuo Cancer Center, San Juan, PR*

Background: Currently there is no optimal salvage regimen for relapsed/refractory NHL (R/R NHL). Prognosis of pts who fail to achieve CR to salvage therapy is dismal. We sought to improve the CR rate by adding Lenalidomide (L) to GROC (ASCO #8530, 2008). **Methods:** Primary endpoint was rate of conversion to CR after switch to L for pts whose best response to GROC was <CR. Secondary endpoint was progression free survival (PFS) of all pts as well as those who achieve <CR on chemotherapy and were crossed over to L.Pts who failed to achieve at least PR after GROC x2 and those who didn't achieve CR after GROC x6, were crossed over to L 25 mg x 3 weeks q 28 days. CRs were maintained on L x 2 yrs. **Results:** 34 pts were enrolled of which 32 are evaluable. Median age: 61 and 56% males. Histologies included DLBCL (81%), PTCL (9%), follicular grade 3-B (9%). Stage was III-IV in 75% and median IPI=2. Best overall response rate (ORR) at any point during treatment= 19/32 (59%) and CR 13/32 (41%). ORR before crossover to L=13/32 (41%) and CR= 8/32 (25%). There were 24 who failed to achieve CR on GROC (19 who didn't respond at all and 5 whose maximum response was PR). Of these, 21 crossed over to L and 7 (33%) responded (CR in 5, PR in 2). The fact that 5 pts attained a CR to L thus improving the CR rate from 25% to 41% after exhibiting refractoriness to GROC is noteworthy. Of the 7 responders to L, all are alive and only 1 relapsed. At 2 yrs., overall survival (OS) was 48% and PFS 35%. This compares favorably with our previous GROC study without L in which 2 yr. OS= 33% and PFS 29%. In total, 11 pts were eligible for ASCT after chemo plus L and 8 were transplanted (3 refused). Of these eight, 6 remain in CR at 11, 18, 21, 22, 52, 74 mos. At 2 yrs, PFS for transplanted pts is 73% and for those whose response to GROC before crossover to L was <CR, it is 27 mos. Toxic events included 2 neutropenic fevers, 1 MDS (34 mos. after ASCT) and 1 AML (11 mos. after ASCT). Both of these remain continuously in CR after allo SCT. **Conclusions:** 2 yrOS=48% and PFS=35% with GROC-Rev are the best observed with any salvage regimen we have tested. L is active as a single agent in 29% of cases whose best response to GROC was <CR. A larger study is desirable to confirm these data. Clinical trial information: NCT01307592.

7557 Poster Session (Board #319), Mon, 8:00 AM-11:30 AM

Interim metabolic tumor volume to predict response in diffuse large B-cell lymphoma. *First Author: Prioty Islam, Emory University School of Medicine, Atlanta, GA*

Background: DLBCL is a heterogeneous disease with varied clinical outcomes following treatment with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP). [^{18}F] fluorodeoxyglucose (FDG) – positron emission tomography (PET)/computed tomography (CT) imaging is ubiquitously used in monitoring of DLBCL. PET-derived metrics for analysis of tumor FDG uptake include: tumor maximum standardized uptake value (SUV); metabolically active tumor volume (MTV); and total lesion glycolysis (TLG), calculated from the intensity of FDG uptake in tumor volume. We evaluated the predictive value of interim SUV, MTV and TLG for patients (pts) with DLBCL treated with R-CHOP. **Methods:** Pts with DLBCL treated at Emory University 2005-2016 were eligible. Cases were included if there was a diagnosis of DLBCL confirmed by record review, available information on date of diagnosis, date of last contact or date of death. Analyses were restricted to patients who received R-CHOP and had PET/CT scans available at baseline, Cycle 2 or 4 and end of treatment. Maximum SUV, MTV, and TLG were calculated using MIM software for tumor with an SUV threshold of > 4. Logistic regression analysis was used to calculate the predictive value of interim PET/CT metrics on end of treatment response. **Results:** Pre-treatment PET/CT scans for 42 patients were identified, along with 28 interim and 31 post-treatment scans. The mean pre-treatment MTV was 303ml (range 4 – 1,327) and mean TLG was 3188 (range 28 – 16,176). MTV and TLG were undetectable in 79% of interim scans and 74% of the post-treatment scans. A Deauville score of 3 or less was observed in 71% of the interim PET/CT scans and 56% of the post-treatment scans. A positive interim MTV was correlated with a positive post-treatment MTV and post-treatment Deauville score at 0.58 and 0.66, respectively, and a positive interim MTV result was a significant predictor of a positive post-treatment MTV result ($p = 0.02$). **Conclusions:** PET-derived metrics of assessing interim tumor response to therapy offer significant predictive value for end of treatment response, and can guide a response-adapted treatment approach for DLBCL pts that builds on the R-CHOP backbone.

7558 Poster Session (Board #320), Mon, 8:00 AM-11:30 AM

Allogeneic hematopoietic stem cell transplantation for mantle cell lymphoma in a heavily pretreated patient population. *First Author: Daniel Allen Kobrinski, Loyola University Medical Center, Maywood, IL*
