POSTMASTER: Send address changes to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. ASCO members should send changes of address to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Nonmembers should send changes of address to *Journal of Clinical Oncology* Customer Service, 2318 Mill Road, Suite 800, Alexandria, VA 22314.

2017 annual subscription rates, effective September 1, 2016: United States and possessions: individual, $625 one year, $1,188 two years; single issue, $40. International: individual, $867 one year, $1,647 two years; single issue, $50. Institutions: bundled (print + online): Tier 1: $1,047 US, $1,452 Int'l; Tier2: $1,207 US, $1,602 Int'l; Tier 3: $1,743 US, $2,122 Int'l; Tier 4: contact *JCO* for quote. Institutions: online only, worldwide: Tier 1: $882; Tier 2: $1,010; Tier 3: $1,457; Tier 4: contact *JCO* for quote. See ascopubs.org/pb-assets/pdfs/2017-ASCO-Institutional-Products-Catalog.pdf for descriptions of each tier. Student and resident: United States and possessions: $303; all other countries, $421. To receive student/resident rate, orders must be accompanied by name of affiliated institution, date of term, and the signature of program/residency coordinator on institution letterhead. Orders will be billed at individual rate until proof of status is received. Current prices are in effect for back volumes and back issues. Back issues sold in conjunction with a subscription rate are on a prorated basis. Subscriptions are accepted on a 12-month basis. Prices are subject to change without notice. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. *JCO* Legacy Archive (electronic back issues from January 1983 through December 1998) is also available; please inquire.

Gastrointestinal (Noncolorectal) Cancer
Scheduled presentations (Abstracts 4000 - TPS4154) 199s

Genitourinary (Nonprostate) Cancer
Scheduled presentations (Abstracts 4500 - TPS4601) 237s

Genitourinary (Prostate) Cancer
Scheduled presentations (Abstracts 5000 - TPS5097) 263s

Gynecologic Cancer
Scheduled presentations (Abstracts 5500 - TPS5615) 287s

Head and Neck Cancer
Scheduled presentations (Abstracts 6000 - TPS6099) 316s

Health Services Research, Clinical Informatics, and Quality of Care
Scheduled presentations (Abstracts 6500 - TPS6626) 341s

Hematologic Malignancies—Leukemia, Myelodysplastic Syndromes, and Allotransplant
Scheduled presentations (Abstracts 7000 - TPS7075) 373s

Hematologic Malignancies—Lymphoma and Chronic Lymphocytic Leukemia
Scheduled presentations (Abstracts 7500 - TPS7579) 392s

Hematologic Malignancies—Plasma Cell Dyscrasia
Scheduled presentations (Abstracts 8000 - TPS8058) 412s

Lung Cancer—Non-Small Cell Local-Regional/Small Cell/Other Thoracic Cancers
Scheduled presentations (Abstracts 8500 - TPS8586) 427s

Lung Cancer—Non-Small Cell Metastatic
Scheduled presentations (Abstracts 8509 - TPS9107) 448s

Melanoma/Skin Cancers
Scheduled presentations (Abstracts 9500 - TPS9600) 476s

Patient and Survivor Care
Scheduled presentations (Abstracts LBA10000 - TPS10129) 501s

Pediatric Oncology
Scheduled presentations (Abstracts LBA10500 - TPS10579) 534s

Sarcoma
Scheduled presentations (Abstracts 11000 - TPS11082) 554s

Tumor Biology
Scheduled presentations (Abstracts 11500 - TPS11628) 575s

53rd Annual Meeting

2017 Abstracts

Descriptions of Scientific Sessions

Plenary Session
The Plenary Session includes abstracts selected by the Scientific Program Committee as having practice-changing findings of the highest scientific merit.

Highlights of the Day Sessions
Highlights of the Day Sessions invite expert discussants to provide an overview of the previous day's Oral Abstract presentations, focusing on key findings and putting abstracts into clinical context.

Oral Abstract Sessions
Oral Abstract Sessions include didactic presentations of abstracts of the highest scientific merit, as determined by the Scientific Program Committee. Experts in the field serve as discussants and provide comprehensive themed discussions of the findings from the abstracts.

Clinical Science Symposia
Clinical Science Symposia provide a forum for science in oncology, combining didactic lectures on a specific topic with abstract presentations. Experts in the field serve as discussants, placing studies in the appropriate context and critically discussing the applicability of the conclusions in clinical practice. Three special Clinical Science Symposia will be designated around specific topics that cut across cancer types.

Poster Discussion Sessions
Select posters from the Poster Sessions will be discussed by expert discussants, with the abstract authors participating in a question and answer period as panel members. These sessions will be followed by networking with the discussants and authors.

Poster Sessions
Poster Sessions include selected abstracts of clinical research in poster format. Trials in Progress (TPS) abstracts are presented within a track's Poster Session.

Publication-Only Abstracts
Publication-only abstracts were selected to be published online in conjunction with the Annual Meeting, but will not be presented at the Meeting.

All presented and publication-only abstracts are citable to this Journal of Clinical Oncology *supplement. For citation examples, please see the Letter from the Editor.*

This publication contains abstracts selected by the ASCO Scientific Program Committee for presentation at the 2017 Annual Meeting. Abstracts selected for electronic publication only are available in full-text versions online through ASCO.org and JCO.org. The type of session, the day, and the session start/end times are located to the right of the abstract number for scheduled presentations. To determine the location of the abstract session, refer to the Annual Meeting Program or the iPlanner, the online version of the Annual Meeting Program, available at am.asco.org.

Dates and times are subject to change.
All modifications will be posted on am.asco.org.

Letter From the Editor

The *2017 ASCO Annual Meeting Proceedings* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,400 abstracts selected by the ASCO Scientific Program Committee for presentation at the 53rd ASCO Annual Meeting. Accepted abstracts not presented at the meeting are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org.

The majority of abstracts selected for presentation are included here in full and are categorized by scientific track. Abstracts can be also accessed online through ASCO abstracts website (abstracts.asco.org) or Meeting Library (meetinglibrary.asco.org). Online abstracts include the full list of abstract authors and their disclosure information.

Late-Breaking Abstracts are represented here by abstract title and first author only. The full-text versions of these abstracts will be publicly released during the Annual Meeting. Print versions of these abstracts will be available onsite at the Annual Meeting in the *ASCO Daily News*.

All abstracts carry *Journal of Clinical Oncology* citations. The following are citation examples for print and electronic abstracts:

J Clin Oncol 35:5s, 2017 (suppl; abstr LBA1)

J Clin Oncol 35, 2017 (suppl; abstr e12000)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Important Tiers and Pricing Notes
Additional rates along with tier descriptions are available online at ascopubs.org/pb-assets/pdfs/2017-ASCO-Institutional-Products-Catalog.pdf

1. Prices are in effect from September 1, 2016, through August 31, 2017. Prices are subject to change.
2. Print-only subscriptions or additional print subscriptions are available for $886 in the US and $1,281 outside the US.
3. For multisite licenses, please contact the appropriate agent for a quote.
4. Subscribers outside the US, add $150 per print subscription for expedited delivery.
5. Single-issue price: $40 US, $50 international.
6. Prices quoted are in US dollars, and payments must be made in US dollars.
7. Except on consortia orders, the publisher allows for a 5% discount on Tiers 1-3 to recognized subscription agents.

Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. Back issues sold in conjunction with a subscription are on a prorated basis.

ASCO Abstracts Policy

Public Release of Abstracts

The abstracts published in the *2017 ASCO Annual Meeting Proceedings,* including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 17, 2017. These abstracts are publicly available online through ASCO.org, the official website of the Society. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Friday, June 2, will be publicly released Friday, June 2, through ASCO.org at 2:00 PM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Saturday, June 3, will be publicly released Saturday, June 3, through ASCO.org at 7:30 AM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Sunday, June 4, will be publicly released Sunday, June 4, through ASCO.org at 7:30 AM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Monday, June 5, or Tuesday, June 6, will be publicly released Monday, June 5, through ASCO.org at 7:30 AM (EDT).

Late-Breaking Abstracts will be available in Section D of *ASCO Daily News* on the day of their scientific presentation, with the exception of abstracts presented on Friday (these will appear in the Saturday issue) and those presented on Tuesday (these will appear in the Monday issue).

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on ASCO.org.

Conflict of Interest Disclosure

As the CE provider for the Meeting, ASCO is committed to balance, objectivity, and scientific rigor in the management of financial interactions with for-profit health care companies that could create real or perceived conflicts of interest. Participants in the Meeting have disclosed their financial relationships in accordance with ASCO's Policy for Relationships with Companies; review the policy at asco.org/rwc.

ASCO offers a comprehensive disclosure management system, using one disclosure for all ASCO activities. Members and participants in activities use coi.asco.org to disclose all interactions with companies. Their disclosure is kept on file and can be confirmed or updated with each new activity.

Please email coi@asco.org with specific questions or concerns.

Driving new CARs for cancer: PACE CARS, NASCARs, and SWEET CARs.

Carl H. June, MD; University of Pennsylvania, Philadelphia, PA

The emergence of immune-oncology as the first broadly successful strategy for metastatic cancer will require clinicians to integrate this new pillar of medicine with the pillars of chemotherapy, radiation, and targeted small molecule compounds. Chimeric antigen receptor (CAR) T cells have proven that engineered immune cells can serve as a powerful new class of cancer therapeutics. Adoptive immunotherapy retargeting T cells to CD19 via a chimeric antigen receptor (CAR) is an investigational treatment capable of inducing complete tumor regression of B-cell malignancies when there is sustained survival of infused cells. Clinical experience has helped to define the major challenges that must be met to make engineered T cells a reliable, safe, and effective platform that can be deployed against a broad range of tumors. The emergence of synthetic biology approaches for cellular engineering is providing us with a broadly expanded set of tools for programming immune cells. I will discuss how these tools could be used to design the next generation of smart T-cell precision therapeutics.

Science of Oncology Award and Lecture
Sunday, June 4, 1:00 PM

Lessons learned from the development of imatinib.

Brian J. Druker, MD; Oregon Health & Science University, Portland, OR

Imatinib (Gleevec) exemplifies the successful development of a rationally designed, molecularly targeted therapy for the treatment of a specific cancer. Imatinib is an inhibitor of the ABL, platelet-derived growth factor receptor, and KIT tyrosine kinases. Given the pathogenetic role of the BCR-ABL tyrosine kinase in chronic myeloid leukemia (CML), this was the first disease selected for clinical trials with imatinib, and the development of imatinib for CML from preclincal to clinical results will be summarized. In patients with CML who acquire resistance to imatinib, mutations in the kinase domain of ABL are the most common mechanism of resistance, and the development of second generation drugs targeting these mutations will also be reviewed. Imatinib has now been successfully used in other malignancies driven by each of the targets of imatinib, and the extension of imatinib to other diseases will be described. Unfortunately, targeted therapies for most advanced cancers have not yielded results as dramatic as those observed with imatinib for CML. There are numerous reasons for these less remarkable results, including accumulation of molecular defects with clonal evolution and disease heterogeneity in more advanced disease. Potential paths forward to extend the success of imatinib to other cancers, including combination therapy and treatment earlier in the course of disease, will be discussed.

ASCO–American Cancer Society Award and Lecture
Monday, June 5, 11:30 AM

Cancer prevention as continuum of oncologic diagnostic and therapeutic disciplines: Targeting the eicosanoid system as an example.

Dean E. Brenner, MD, FASCO; University of Michigan Medical Center, Ann Arbor, MI

Our deepening understanding of the carcinogenesis process enables identification of targets for interventions that span the entire cancer process. Because of its pivotal role in normal and pathologic physiology including carcinogenesis biology, we have used the eicosanoid system as both therapeutic anticarcinogenesis target and as biomarkers of individual carcinogenesis risk. We chose to study the lower GI tract because it has an endoscopically accessible dysplastic lesion (adenoma) and a well described molecular carcinogenesis process, with high incidence and mortality. Our initial trials of aspirin in the colon documented potent inhibition of colonic mucosal prostaglandins at low doses (80 mg every 48 hrs), reduction of crypt proliferation, and shifting of the crypt lectin

binding profile. Subsequent work from other investigators has demonstrated aspirin-induced reduction in colonic adenoma formation, molecular biomarkers for aspirin's preventive activity, and activity as an inhibitor of metastatic progression in patients with stage III colorectal cancer. Because of nonsteroidal therapeutic index concerns for long-term, chronic treatment in otherwise healthy populations, we identified polyphenolic dietary components with strong anticarcinogenesis activity (curcumin, resveratrol, gingerols) and found that their strong in vitro eicosanoid and stem cell self-renewal inhibitory activity could not be replicated in humans, primarily due to bioavailability limitations. Most recently, we have translated new data showing that fatty acid binding to the cyclooxygenase-2 catalytic dimer is limited to the ω6 arachidonic acid or the ω3 eicosapentaneoic acid. Other common saturated and unsaturated fatty acids that bind to the allosteric cyclooxygenase-2 dimer can alter catalytic dimer activity, regulating prostaglandin synthesis. Translation to humans permits optimal individualization of ω3 fatty acid dosing using prostaglandin E_2 and other eicosanoid products as biomarker endpoints in normal weight but not in obese populations. These insights are driving new investigations into the biological linkage between obesity, carcinogenesis, and cancer prevention.

B. J. Kennedy Award and Lecture for Scientific Excellence in Geriatric Oncology
Monday, June 5, 3:00 PM

Has the time come to develop the concept of global geriatric oncology?

Jean Pierre Droz, MD, PhD; Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana

Global oncology is focused on cancer care, research, and care delivery issues unique to countries and settings with limited healthcare resources. Projections of the world population through 2050 indicate that the population of persons over 60 increases. The elderly people population will rise from 0.2 billion in 2008 to 0.4 billion in 2050 in the more developed countries, whereas it will rise, during the same period, from 0.4 billion to 1.6 billion in the less developed countries. Between 2016 and 2035, the estimated number of new cancers in patients older than 65 in less developed countries should increase from 3.2 million to 7.5 million. During the same period, the estimated number of cancer patients younger than 65 should increase from 4.8 million to 7.2 million. This demonstrates that geriatric oncology is a real challenge in less developed countries, where cancers have some specific characteristics: late diagnosis, more advanced stages and consequently increased mortality; particular biological features like frequency of triple-negative breast cancers and *BRCA1-2* mutations; frequent microorganisms implicated in the carcinogenesis. Conversely, knowledge on the aging characteristics in these populations is still scarce. Principles of contemporary geriatric oncology are not always enforceable to patients from these areas: This is often due to cultural differences, different comorbidities, different socioeconomic environment, and a lack of geriatricians and health professional education. It is therefore important to make efforts to develop geriatric oncology in this part of the world mostly through the development of adapted screening tools of frailty and the establishment of a decision-making process to suit resources and cultures and based on simple standardized screening tools and clinical exams, health professional training, and production of scientific knowledge. In conclusion, the development of the concept of global geriatric oncology is important and should be advisable.

Pediatric Oncology Award and Lecture
Monday, June 5, 1:15 PM

Recognizing when less is more: Progress in management of childhood Hodgkin lymphoma.

Michael P. Link, MD, FASCO; Stanford University School of Medicine, Palo Alto, CA

The improvement in outcome of children with Hodgkin lymphoma has been a spectacular achievement of the past four decades. Although the biology and clinical behavior of Hodgkin lymphoma in children closely resembles the adult counterpart, successful therapies designed for children are based on the unique concerns of the growing child as host. Early studies designed to reduce the dose and volume of radiation to minimize the impact on bone and soft tissue growth relied on the administration of chemotherapy to "substitute" for the omitted radiation. An unexpected result was improvement in overall disease control—particularly in children with advanced stage disease—over what would be expected from management with high-dose extended-field irradiation, which had been routine. Treatment strategies centered on chemotherapy and reduced radiation doses and volumes have emerged as the standard of care. More recent studies have provided further refinements of this approach, with long-term event-free survivals now exceeding 90%. Advances in imaging technologies have facilitated expeditious and accurate staging, while eliminating the need for meticulous surgical staging. With increasing numbers of children cured of Hodgkin lymphoma, late complications related to therapy that compromise quality of life and survival emerged as key concerns, particularly because children cured of cancer have a lifetime ahead of them to manifest the long-term toxicities of therapy. Secondary radiation-related cancers in survivors stimulated more recent studies of approaches designed to eliminate irradiation as a component of therapy for most children. The focus of modern studies is minimizing therapy for children with the most favorable prognosis, while reserving more

intensive therapy for children with advanced stage disease at higher risk of relapse. New agents under study promise to contribute to improved therapy for such children with high-risk disease. As has been true in the management of all childhood cancers, improvements in therapy have resulted from multi-institutional and interdisciplinary collaborations focused on achieving high cure rates while reducing the acute and long term toxicities of therapy.

Gianni Bonadonna Breast Cancer Award and Lecture
Saturday, June 3, at 4:45 PM

Advances in HER2+ breast cancer: Can we score the ultimate goal.

Eric P. Winer, MD, FASCO; Dana-Farber Cancer Institute, Boston, MA

Over the last two decades, we have seen dramatic advances in the treatment of HER2+ breast cancer. There are now four approved anti-HER2 agents—trastuzumab, lapatinib, pertuzumab, and T-DM1—and others likely to be approved in the near future. For women with stage II/III HER2+ disease, the clinical outcome is excellent with distant recurrences arising in no more than 10-20% of patients who are treated with contemporary anti-HER2 regimens. The outcome is even more promising for women with stage I disease, many of whom can be successfully treated with regimens that have limited toxicity. In the metastatic setting, patients with HER2+ disease are living far longer than in the past and with much better quality of life. In spite of all the good news, we face multiple challenges. There are still thousands of women who lose their lives to HER2+ breast cancer each year. Some of these women are unable to access medical care, and for these individuals social and behavioral changes are essential. Many others, however, lose their lives because of drug resistance. Many HER2+ cancers simply outsmart the drugs that we have available. In addition, central nervous system disease remains a vexing problem for many patients. Approximately half of all women with HER2+ metastatic disease develops CNS metastases, and for many of these women CNS disease is the cause of death. There are challenges related to drug delivery in the CNS and there may well be important differences in the tumor microenvironment. Translational and clinical research need to focus on approaches to overcome both drug resistance and CNS relapse. On the other end of the spectrum, there are also many patients in 2017 who are receiving far more treatment than they need, and this overtreatment leads to unnecessary toxicities. If we are going to de-escalate therapy, we will need to design thoughtful and creative clinical trials that seek to minimize excessive treatment while ensuring that we do not compromise the excellent results that have been achieved. Finally, the challenge we face, beyond science and research funding, is that some believe that we have solved the problem of HER2+ breast cancer and it is time to move on to other areas. Although other areas are important, we need to maintain a focus on the ultimate goals—the elimination of mortality and minimization of unnecessary toxicity.

Allen S. Lichter Visionary Leader Award and Lecture
Monday, June 5, 1:15 PM

Heroes, mentors, role models, and friends.

Patrick J. Loehrer, MD, FASCO; Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN

The development of leaders is as varied as the human genome. This is in part because of the uniqueness of individuals in the various roles of leadership and the uniqueness of the times. For over a half century, the American Society of Clinical Oncology has been a conclave for the best and the brightest individuals in the field of oncology. The seven original founders sought a home for clinical investigators to share accomplishments in cancer research and to educate an emerging workforce for what was becoming a new discipline. ASCO has now evolved to become the preeminent, international leader in cancer research, education and advocacy. Today, its membership, over four thousand fold greater than at its inception, looks to its future through a cautionary lens. A legacy of the Lichter era was that of professional development. ASCO's Leadership Development Program, just one of Dr. Lichter's brainchilds, links senior and younger physicians from various disciplines and geographic locations for an intense year of collective learning on leadership skills important for our society and beyond. One of its lessons is that leadership begins with conversations, delineates the cause (or the project), asks for commitment, and in the end, affects change. Ultimately, our society is only as strong as its members and the causes they choose to champion. Our vision, *"A world where cancer is prevented or cured, and every survivor is healthy"* lays the gauntlet down. This lecture will highlight the professional and personal journey of one of its members through three decades of the society, built upon the shoulders of mentors, role models, and friends.

ABSTRACTS
American Society of Clinical Oncology
53rd Annual Meeting
June 2-6, 2017
McCormick Place
Chicago, Illinois

LBA1 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Prospective pooled analysis of six phase III trials investigating duration of adjuvant (adjuv) oxaliplatin-based therapy (3 vs 6 months) for patients (pts) with stage III colon cancer (CC): The IDEA (International Duration Evaluation of Adjuvant chemotherapy) collaboration. *First Author: Qian Shi, Mayo Clinic Cancer Center, Rochester, MN*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, June 4, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News.*

LBA2 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Overall survival results of a randomized trial assessing patient-reported outcomes for symptom monitoring during routine cancer treatment. *First Author: Ethan M. Basch, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, June 4, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA3 **Plenary Session, Sun, 1:00 PM-4:00 PM**

LATITUDE: A phase III, double-blind, randomized trial of androgen deprivation therapy with abiraterone acetate plus prednisone or placebos in newly diagnosed high-risk metastatic hormone-naive prostate cancer. *First Author: Karim Fizazi, Gustave Roussy Cancer Campus and University Paris-Sud, Villejuif, France*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, June 3, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA4 **Plenary Session, Sun, 1:00 PM-4:00 PM**

OlympiAD: Phase III trial of olaparib monotherapy versus chemotherapy for patients (pts) with HER2-negative metastatic breast cancer (mBC) and a germline *BRCA* mutation (gBRCAm). *First Author: Mark E. Robson, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, June 4, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA100 **Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

Routine molecular screening of advanced refractory cancer patients: An analysis of the first 2490 patients of the ProfilER Study. *First Author: Olivier Tredan, Département d'Oncologie Médicale, Centre Léon Bérard, Lyon, France*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, June 3, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

101 **Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

Clinical application of comprehensive next generation sequencing in the management of metastatic cancer in adults. *First Author: Erin Frances Cobain, University of Michigain Health System, Ann Arbor, MI*

Background: Next generation sequencing (NGS) platforms are frequently utilized in the care of patients (pts) with metastatic cancer to identify tumor genomic alterations that may serve as therapeutic targets. Biomarker driven clinical trials, such as NCI-Molecular Analysis for Therapy Choice (MATCH) and Targeted Agent and Profiling Utilization Registry (TAPUR) have augmented clinicians' ability use this strategy in clinical practice. **Methods:** From 2011-2015 over 500 adult pts with metastatic solid tumors of diverse lineage underwent biopsy for whole exome and transcriptome sequencing of tumor and matched normal sample through the Michigan Oncology Sequencing Center (Mi-Oncoseq). Genomic alterations identified were reviewed at Precision Medicine Tumor Board and tiered according to their clinical relevance. Alterations were also classified as being identifiable or not identifiable by a commercially available NGS assay such as Oncomine Focus or FoundationOne. **Results:** Genomic alterations identified by Mi-Oncoseq provided rationale for enrollment in a clinical trial in 72% (n = 360) of cases. The percentage of pts who did receive therapy informed by NGS results increased over time (5% in 2012 versus 11% in 2015). 11% of pts (n = 55) had a pathogenic germline variant (PGV) conferring increased cancer risk identified, none of which were known prior to study entry. Numerous pts had clinically relevant molecular alterations identified by Mi-Oncoseq that would not have been identifiable utilizing targeted NGS assays, including PGVs and activating/deleterious gene fusions. **Conclusions:** Comprehensive NGS, including DNA and RNA sequencing, readily identifies potentially actionable alterations in the vast majority of pts beyond what is observed with use of targeted NGS platforms. Observed modest increase in utilization of NGS results to direct subsequent therapy over time is due to clinician employment of this strategy earlier in the therapeutic algorithm, increased availability of biomarker driven clinical trials and changes in physician referral patterns. Comprehensive NGS identified many unanticipated PGVs of clinical importance for pts and their families. Clinical trial information: HUM00067928.

102 **Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

Next generation sequencing in community oncology practice: Beneficial or economical burden? *First Author: Natraj Reddy Ammakkanavar, Community Cancer Center, Indianapolis, IN*

Background: Precision genomics medicine is a fast growing in cancer care. Targeted therapy has yielded substantial benefit when appropriately used. With next generation sequencing (NSG) use increasing in non-academic setting outside clinical trial, we need to consider benefits and economical burden of this. **Methods:** Retrospective chart analysis of cancer patients (pts) treated at a large community practice was undertaken. With IRB approval, demographic, clinical and NSG data were collected for 209 pts who had NSG in 2015 and 2016. Pts were placed in 1 of 4 categories based on NSG results with available drug for specific mutation and change in management (CIM): a) CIM for current, b) Potential to CIM with subsequent therapy, c) No CIM due to poor performance status, d) No CIM due to lack of new target and/or drug. Alternate economical standard test for the mutation noted. Statistical analysis was done using chi-square and fisher's exact test. **Results:** Median age was 64yr. Most common tumor types tested where as listed in table 96% had stage 4 disease. 82% had ≥1 prior systemic therapy. Pts were assigned to categories as per table below. When RAS mutation status where accounted by standard testing, none of the colon cancer pts benefited from NSG test. 6 of 54 pts who had CIM had alternate test option. Financial responsibility for these tests is approximately $1.21 million. 18 pts in 2015 and 17 pts in 2016 where billed for test after exhausting insurance and support option. More financial data may be available at time of presentation. **Conclusions:** NGS tumor test might benefit small group of selective pts at time of testing. It is likely not prime time to use for colon cancer. Benefits with later therapy are difficult to predict. NSG should be used more judiciously due to financial implications.

	Total Pt. N=209 (%)	Lung Cancer N = 63(%)	Colonrectal Cancer N= 31(%)	Ovarian /Endometrial cancer N= 23(%)	Breast cancer N=15(%)	Pancreatic N=9(%)	Other cancer N=68(%)

103 **Clinical Science Symposium, Sun, 9:45 AM-11:15 AM**

The effect of pembrolizumab in combination with CD19-targeted chimeric antigen receptor (CAR) T cells in relapsed acute lymphoblastic leukemia (ALL). *First Author: Shannon L. Maude, Cancer Immunotherapy Program, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: CD19-targeted CAR T cells show CR rates of 70-95% in B-ALL. Yet a subset of patients do not respond or relapse due to poor CAR T cell expansion and persistence. We hypothesized that PD-1 checkpoint pathway inhibition may improve CAR T cell expansion, function and persistence. **Methods:** Four children with relapsed B-ALL treated with murine (CTL019) or humanized (CTL119) anti-CD19 CAR T cells received 1-3 doses of the PD-1 inhibitor pembrolizumab (PEM) for partial/no response or prior history of poor CAR T cell persistence starting 14d-2mo post CAR T cell infusion. **Results:** PEM increased and/or prolonged detection of circulating CAR T cells in all 4 children, with objective responses in 2/4. It was well tolerated, with fever in 2 pts and no autoimmune toxicity. Pts 1-3 received CTL119 for CD19+ relapse after prior murine CD19 CAR T cells. Pt 1 had 1.2% CD19+ residual disease despite expansion with detectable CTL119 by D28 and received PEM at 2mo for progressive disease with decreasing circulating CTL119. CTL119 became detectable at 0.2% of CD3+ cells by flow cytometry, but disease progressed. Pt 2 had no response after initial CTL119 expansion with a rapid disappearance by D28. After CTL119 reinfusion with PEM added 14d later, circulating CAR T cells remained detectable at 4.4% by D28, but disease progressed with decreased CD19 expression. In Pt 3, prior treatment with both CTL019 and CTL119 produced CR with poor CAR T cell persistence followed by CD19+ relapse. CTL119 reinfusion combined with PEM at D14 resulted in CR with prolonged CTL119 persistence (detectable at D50 compared to loss by D36 after 1st CTL119 infusion). Pt 4 received PEM for widespread extramedullary (EM) involvement at D28 post CTL019 infusion despite marrow remission. Initial CTL019 expansion peaked at 63% at D10 and fell to 20% at D28. Resurgence of CTL019 expansion, with a 2nd peak of 70% 11d after PEM, was associated with dramatic reduction in PET-avid disease by 3mo post CTL019. **Conclusions:** PEM was safely combined with CAR T cells and increased or prolonged CAR T cell detection, with objective responses seen. Immune checkpoint pathways may impact response to CAR T cell treatments and warrant further investigation. Clinical trial information: NCT02374333, NCT02906371.

104 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Preliminary results of a phase I/IIa study of BMS-986156 (glucocorticoid-induced tumor necrosis factor receptor–related gene [GITR] agonist), alone and in combination with nivolumab in pts with advanced solid tumors. *First Author: Lillian L. Siu, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: BMS-986156 is a fully human IgG1 agonist mAb that binds GITR and promotes T effector cell activation and possible reduction/inactivation of T regulatory cells. Preclinical data show enhanced antitumor T-cell activity with anti-GITR + anti–programmed death-1 (PD-1). Here we describe preliminary dose escalation data from a phase I/IIa study of BMS-986156 ± nivolumab (anti–PD-1 mAb) in pts with advanced solid tumors (NCT02598960). **Methods:** During dose escalation, pts received BMS-986156 (10–800 mg) or BMS-986156 (30–800 mg) + nivolumab (240 mg) every 2 weeks. Objectives included safety (primary), immunogenicity, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy. **Results:** As of Dec 12, 2016, 66 pts were treated with BMS-986156 (n = 29) or BMS-986156 + nivolumab (n = 37).No dose-limiting toxicities (DLTs) were reported during dose escalation. The most common treatment-related adverse events reported with BMS-986156/BMS-986156 + nivolumab included pyrexia (21%/30%), chills (10%/16%), and fatigue (14%/14%); events were G1/2 in all pts except for 4 pts (6%) treated with the combination (G3 lipase [n = 1], G3 lung infection [n = 1], G3 fatigue [n = 1], and G3 aspartate aminotransferase with G4 creatine phosphokinase [n = 1; leading to discontinuation of treatment]). Preliminary data indicate that the incidence of immunogenicity to BMS-986156 was low when BMS-986156 ± nivolumab was administered. Preliminary data also indicate that BMS-986156 ± nivolumab exhibits linear PK with dose proportionality after a single dose, and BMS-986156 ± nivolumab is biologically active in PD analyses in peripheral blood. Initial antitumor activity has been observed in several pts treated with the combination; these data will be reported. **Conclusions:** This is the first report of clinical data with an anti-GITR mAb ± a PD-1 inhibitor.BMS-986156 ± nivolumab was well tolerated, with no DLTs and low immunogenicity. Antitumor activity was observed with BMS-986156 + nivolumab at doses predicted to be biologically active. Further evaluation of this combination in pts with advanced solid tumors is ongoing. Clinical trial information: NCT02598960.

105 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

A phase Ib dose escalation study of combined inhibition of IDO1 (GDC-0919) and PD-L1 (atezolizumab) in patients (pts) with locally advanced or metastatic solid tumors. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Nashville, TN*

Background: GDC-0919, a small molecule inhibitor of indoleamine-2,3-dioxygenase 1 (IDO1), reduces tryptophan catabolism and kynurenine production within the tumor microenvironment that may promote normal effector T cell activity and an immunogenic state. IDO1 inhibition may complement targeting of PD-L1 with atezolizumab. **Methods:** A Phase Ib, open-label, study assessed safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity (RECIST v1.1) of GDC-0919 and atezolizumab in pts with locally advanced or metastatic solid tumors. Pts were given escalating doses of GDC-0919 (50-1000 mg orally twice daily, for 21 days) and atezolizumab (1200 mg IV, every 3 weeks) using a standard 3 +3 design. **Results:** As of 14Dec2016, 52 pts were treated in 6 cohorts of GDC-0919 plus atezolizumab. The median number of prior systemic therapies was 3 (range 1-9); 2 pts received prior immunotherapy. Pts received a median of 4 cycles of GDC-0919 and atezolizumab (range 1-17). No MTD was identified. Across all dose levels, 1 DLT was observed (Grade [G] 3 sepsis syndrome at GDC-0919 200 mg); no G4/5 AEs were attributed to study treatment. G3+ AEs, regardless of causality were reported in 34 (65%) pts. Related G3 AEs were reported in 7 (13%) pts, included nausea, rash, sepsis syndrome, fatigue, and pneumonitis. Two pts (4%) had AEs leading to treatment discontinuation, related in 1/2 (G3 pneumonitis). Combination PK was consistent with single agent observations and supports BID dosing of GDC-0919. Peripheral PD showed dose-dependent decreases in plasma kynurenine, consistent with systemic modulation of IDO1. Preliminary efficacy data from 45 pts with ≥ 1 on-treatment tumor assessments included 4 patients (9%) with partial response and 11 (24%) pts with stable disease. **Conclusions:** The combination of GDC-0919 and atezolizumab was generally well-tolerated and demonstrated peripheral IDO1 modulation and preliminary efficacy in a heterogeneous patient population during dose escalation. The study is currently enrolling pts with select tumor types in expansion cohorts to assess tumor PD and combination efficacy. Clinical trial information: NCT02471846.

106 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

A phase I study of enfortumab vedotin (ASG-22CE; ASG-22ME): Updated analysis of patients with metastatic urothelial cancer. *First Author: Daniel Peter Petrylak, Yale School of Medicine, New Haven, CT*

Background: Enfortumab vedotin, an antibody–drug conjugate, delivers monomethyl auristatin E to tumors expressing Nectin-4, which is overexpressed in metastatic urothelial cancer (mUC). **Methods:** This Phase I study (NCT02091999) enrolled patients (pts) with solid tumors, including pts with mUC, treated with ≥1 prior chemotherapy regimen. All pts received different dose levels of IV enfortumab vedotin (0.5, 0.75, 1, 1.25 mg/kg) once weekly for 3 out of 4 wks. Nectin-4 expression was determined by IHC on archival tumor specimens and quantified by histochemical scoring (H-score). Primary endpoint was tolerability; secondary endpoint was antitumor activity assessed every 8 wks per RECIST v1.1. **Results:** As of 3 Jan 2017, 68 pts with mUC (46 M/22 F; median age, 67 yr [range: 41–84]) had been treated. Of these, 62% received ≥2 prior therapies in the metastatic setting and 40% had prior immune checkpoint inhibitor (CPI) therapy. In these pts, Nectin-4 expression was high and prevalent (median H-score, 280 [range: 32–300]). Treatment-related adverse events (TRAEs) were reported in 58 pts (85%); diarrhea, fatigue, nausea, and pruritus were TRAEs reported in ≥25% of pts. Most TRAEs were grade ≤2 in severity; 19 pts (28%) experienced a TRAE of grade ≥3. The most common grade ≥3 AEs (occurring in ≥5 pts), regardless of attribution to treatment, were urinary tract infection (10%) and hypophosphatemia (9%). No treatment-related deaths have occurred. Sixty pts had ≥1 post-baseline assessment. Antitumor activity was observed across the dose range; overall response rate (ORR) was 40% (95% CI: 27.6–53.5) for all evaluable pts (n = 60), 46% (95% CI: 25.6–67.2) in pts with prior CPI exposure (n = 24), and 44% (95% CI: 19.8–70.1) in pts with metastasis to the liver (n = 16). Complete responses were noted in 3 pts at doses ≥1 mg/kg. Median treatment duration was 26 wks (range: 5.1–64.6), median duration of response was 18 wks (95% CI: 8.4–40.1), and median progression-free survival was 17 wks (95% CI: 15.1–23.3). Study enrollment is ongoing. **Conclusions:** Enfortumab vedotin demonstrated a favorable tolerability profile with encouraging antitumor activity in heavily pretreated mUC, including pts for whom CPIs have failed. Clinical trial information: NCT02091999.

108 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Single agent activity of DS-8201a, a HER2-targeting antibody-drug conjugate, in heavily pretreated HER2 expressing solid tumors. *First Author: Toshihiko Doi, Department of Experimental Therapeutics, National Cancer Center Hospital, Chiba, Japan*

Background: Human epidermal growth factor 2 (HER2) is a potential strong tumor driver for breast (BC) and gastric cancer (GC) as well as other HER2 expressing tumors. Antibody-drug conjugates (ADC) provide wider therapeutic window by more efficient and specific drug delivery. DS-8201a is a HER2 targeting ADC of high drug to antibody ratio (7 to 8) with a novel topoisomerase I inhibitor. In preclinical studies, DS-8201a showed a broader antitumor spectrum than T-DM1, including efficacy against low HER2 expressing tumors. Current trial includes dose escalation (Part 1) and expansion (Part 2) focusing on HER2 expressing solid tumors (NCT02564900). **Methods:** Part 1 used a modified continuous reassessment method to identify the expansion dose in patients (pts) with BC or GC. Part 2 was designed to evaluate the safety and efficacy in 4 expansion cohorts: T-DM1 treated HER2+ BC, trastuzumab treated HER2+ GC, BC with low HER2 expressing and other HER2 expressing solid tumors. Adverse events (AEs), objective response rate (ORR) and durability of responses were assessed. **Results:** 89 pts were administered in total: 24 pts in Part 1 and 65 pts (BC, GC, colorectal, salivary and non-small cell lung cancer) in Part 2 with median prior therapies of 4. DS-8201a was administered up to 8.0 mg/kg in Part 1, and dose levels of 6.4 and 5.4 mg/kg IV every 3 weeks were chosen for Part 2. There was no dose limiting toxicity, and maximum tolerated dose was not reached in Part 1. The most common AEs in Part 1 and Part 2 were nausea (62%), anorexia (56%) and platelet count decreased (28%). 29% pts experienced ≥ Gr3 AEs (Gr3: 25% Gr4: 4%). The ORR and disease control rate (DCR: CR + PR + SD) are shown in the table. ORR and DCR were 40% and 90%, respectively in evaluable 73 pts including 14 low HER2 expression. One T-DM1 treated BC pt achieved CR. 4 PRs were achieved in pts with low HER2 expression. 63 pts in total are currently being treated. Median duration of treatment was ≥27 weeks in Part 1 and not reached in Part 2. **Conclusions:** DS-8201a was well tolerated and is remarkably active in heavily pretreated HER2 expressing cancers. Clinical trial information: NCT02564900.

	ORR	DCR
Total	40% (29/73)	90% (66/73)
Part 1	43% (10/23)	91% (21/23)
Part 2	38% (19/50)	90% (45/50)
Low HER2	29% (4/14)	93% (13/14)

109 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

A phase II study of glembatumumab vedotin (GV), an antibody-drug conjugate (ADC) targeting gpNMB, in advanced melanoma. *First Author: Patrick Alexander Ott, Dana-Farber Cancer Institute, Boston, MA*

Background: gpNMB is an internalizable transmembrane glycoprotein expressed in melanoma and multiple other tumor types. The ADC GV (CDX-011) delivers the potent cytotoxin MMAE to gpNMB+ cells. GV has shown promising activity in advanced melanoma and breast cancer. **Methods:** This Phase II study (CDX011-05) assessed the efficacy and safety of GV monotherapy (1.9 mg/kg q3w) for patients (pts) with advanced melanoma progressive after ≤1 chemotherapy, ≥1 checkpoint inhibitor (CPI) and if $BRAF^{V600}$mutated, ≥1 BRAF/MEK inhibitor. Central IHC determined gpNMB expression in archival and/or pre-treatment tumor. Primary endpoint was objective response rate (ORR) (RECIST 1.1) with ≥6 responders out of 52 evaluable pts as threshold for antitumor activity. Additional endpoints: progression free survival (PFS), overall survival (OS), duration of response (DOR), safety, PK/PD and correlation of tumor gpNMB expression with efficacy. **Results:** 62 pts enrolled (all evaluable) had median age of 67 years; 55% male; 21% $BRAF^{V600}$mutated; 63% with ≥3 lines prior therapy; 100% had prior CPI; 100% Stage IV; 89% M1c. One confirmed complete response (CR) and 6 confirmed partial responses (PR, including 1 unconfirmed CR) were seen (confirmed ORR = 11%, p = 0.035 comparing to reference ORR 5%); 33 pts had stable disease including 3 unconfirmed PR. Median DOR = 6.0 (range: 4.1, 14+) months (mos), median PFS = 4.3 mos and median OS = 9.8 mos; 26 pts continue to be followed for survival. All pts with available tissue (60/60) had gpNMB+ tumors; 47/60 had 100% gpNMB+ epithelial cells; no clear correlation with outcome was seen in this population with consistent high expression. Toxicities included alopecia, neuropathy, rash, fatigue and neutropenia. Treatment-related rash in cycle 1 was associated with improved ORR (rash = 22%; no rash = 7%), PFS (p = 0.007) and OS (p = 0.035). **Conclusions:** GV has promising activity (primary endpoint of ORR was met) with a manageable safety profile in heavily pre-treated melanoma pts. Additional cohorts evaluating GV with either varlilumab, an activating anti-CD27 monoclonal antibody, or PD-1 inhibitors are open to accrual to provide further insights into the synergy of ADC and immunotherapy. Clinical trial information: NCT02302339.

LBA500 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

APHINITY trial (BIG 4-11): A randomized comparison of chemotherapy (C) plus trastuzumab (T) plus placebo (Pla) versus chemotherapy plus trastuzumab (T) plus pertuzumab (P) as adjuvant therapy in patients (pts) with HER2-positive early breast cancer (EBC). *First Author: Gunter Von Minckwitz, German Breast Group (GBG), Neu-Isenburg, Germany*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Monday, June 5, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

501 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

9 weeks vs 1 year adjuvant trastuzumab in combination with chemotherapy: Results of the phase III multicentric Italian study Short-HER. *First Author: Pier Franco Conte, Department of Surgery, Oncology and Gastroenterology, University of Padua, Medical Oncology 2, Instituto Oncologico Veneto IRCCS, Padova, Italy*

Background: 1-year trastuzumab with chemotherapy is the standard adjuvant treatment for HER2+ breast cancer patients (pts). The efficacy of less extended trastuzumab exposure is still under investigation. The Short-HER study is an independent, non-profit study aimed to test the non-inferiority of 9 weeks vs 1 year of adjuvant trastuzumab. **Methods:** This is a phase III, multicenter, Italian trial where pts with HER2+ breast cancer were randomly assigned to: Arm A (Long) AC or ECx4 followed by 4 courses of 3-weekly docetaxel in combination with trastuzumab, followed by 14 additional courses of 3-weekly trastuzumab; or Arm B (Short) 3 courses of 3-weekly docetaxel plus weekly trastuzumab for 9 doses followed by FEC x3. When indicated, radiation therapy was administered after the completion of chemotherapy. Hormonal therapy started at the completion of chemotherapy for pts with hormone receptor positive tumors. This is a non-inferiority trial with disease-free survival (DFS) as primary end-point.Overall survival (OS) is evaluated as second primary analysis outcome. The sample size of 1250 pts has been estimated based on a hazard ratio <1.29 for the short arm to be non-inferior. The definitive analysis will take place after 198 DFS events. Secondary aims include 2-yrs failure rate, cardiac toxicity, correlative biomarkers analyses. Hazard ratio for DFS and OS (90% CI) will be estimated according to the Cox model. Data will also be analyzed by the Bayesian approach. **Results:** from Dec-2007 to Oct-2013, 1254 pts from 82 centers have been randomized. Pts characteristics are the following: median age 55 yrs (25-78), stage I 37.3%, IIA 40%, IIB 20.6%, III 2.1%. 30% of the pts had 1-3 positive nodes, 16% $>=4$. Sixty-eight% of the pts had ER+ tumors. Characteristics were balanced between the two arms. At the time of this writing, 95% of the planned DFS events have been reported. 105 Grade ≥ 2 cardiac events have been reported, 78 in arm A (long) and 27 in arm B (short). Grade 3-4 cardiac events were 20 in arm A and 11 in arm B. **Conclusions:** Shorter trastuzumab administration almost halves the rate of severe cardiac toxicity**.** Final DFS data will be available at the time of the meeting. Clinical trial information: NCT00629278.

502 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

Updated results from the phase III ALTTO trial (BIG 2-06; NCCTG (Alliance) N063D) comparing one year of anti-HER2 therapy with lapatinib alone (L), trastuzumab alone (T), their sequence (T→L) or their combination (L+T) in the adjuvant treatment of HER2-positive early breast cancer. *First Author: Alvaro Moreno-Aspitia, Mayo Clinic, Jacksonville, FL*

Background: Pre-specified 5-year analyses of the phase III Adjuvant Lapatinib and/or Trastuzumab Treatment Optimisation (ALTTO) Trial defined in Amendments 11&12. **Methods:** From June 2007 to July 2011, 8381 patients (pts) were randomised from 946 sites in 44 countries to receive either L+T, T→L, L, or T. In 2011, due to futility the L arm was closed and is not included in this analysis. The primary end point is disease-free survival (DFS). Secondary objectives include treatment comparisons with respect to overall survival (OS), time to recurrence (TTR), time to distant recurrence (TDR), cardiac and overall safety and tolerability. Primary analysis results of the study were published in JCO 2015 34:1034-1042. This updated analysis occurs at a 6.9 yrs median follow up (MFU). **Results:** All patients have reached 5-years of follow-up. 705 DFS events for L+T vs T have been observed. HR for DFS was 0.86 (95% CI, 0.74-1.00; 6-yr DFS%=85% vs 82%) for L+T vs T and 0.93 (95% CI, 0.81-1.08; 6-yr DFS%=84% vs 82%) for T→L vs. T. The 6-year OS was 93%, 92%, and 91% for L+T, T→L, and T, respectively. HR for OS was 0.86 (95% CI, 0.70-1.06) for L+T vs. T and 0.88 (95% CI, 0.71-1.08) for T→L vs. T. DFS differences for L+T vs. T were slightly higher for the hormone-receptor(ER)-negative [HR 0.80 (95% CI, 0.64-1.00; 6-yr DFS%=84% vs. 80%)] and the sequential chemotherapy [HR 0.83 (95% CI, 0.69-1.00; 6-yr DFS%=83% vs.79%)] subgroups. There were no differences in sites of first DFS events according to treatment arm for CNS, locoregional, or distant recurrences. There were more AEs related to study treatment (L+T 93% vs T 64%). The incidence of primary cardiac end points was low: 1% for L+T, 0.5% for T→L and 0.9% for T. **Conclusions:** The HRs for this updated analysis are similar to those from the Primary Analysis and the event rate remains lower than anticipated (705 vs 850 planned). Cardiac toxicity remains low. This analysis suggests that HER2+/ER- tumors may have a different biology than HER2+/ER+ and may benefit more from dual HER2 blockade. Long-term follow up continues. Clinical trial information: NCT00490139.

503 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

SOLE (Study of Letrozole Extension): A phase III randomized clinical trial of continuous vs intermittent letrozole in postmenopausal women who have received 4-6 years of adjuvant endocrine therapy for lymph node-positive, early breast cancer (BC). *First Author: Marco Colleoni, IBCSG and SOLE Investigators, Bern, Switzerland*

Background: In animal models of hormone receptor positive (HR+) breast cancer, acquired resistance to continued letrozole was shown to be reversed by estrogen-induced apoptosis. Sensitization to reintroduction of estrogen withdrawal by letrozole was hypothesized to improve treatment outcome. SOLE tested the hypothesis that 3 mos treatment-free intervals during extended adjuvant therapy will improve disease-free survival (DFS). **Methods:** SOLE enrolled 4884 postmenopausal women with HR+ lymph node-positive BC who had completed 4-6 yrs of adjuvant endocrine therapy (19% SERM, 43% AI, 38% both; stratification factor). Pts were randomly assigned to an additional 5 yrs continuous letrozole (2.5 mg daily; n = 2441) vs 5 yrs intermittent letrozole (taken for the first 9 mos of yrs 1-4, and 12 mos in yr 5; n = 2443). The primary endpoint was DFS (randomization until invasive local, regional, distant recurrence or contralateral BC; 2nd malignancy; death). Final analysis was at 665 DFS events, after 2 interim analyses. SOLE required 4800 pts for 80% power to detect a 20% DFS hazard reduction with 2-sided $\alpha = 0.05$ using a stratified log rank test. Analysis is by intention-to-treat. **Results:** At 60 mos median follow-up, 5 yr DFS from randomization was 85.8% vs 87.5% for patients assigned intermittent vs continuous letrozole (HR = 1.08; 95% CI 0.93-1.26; P = 0.31). Similar outcome was observed for breast cancer-free interval (HR = 0.98; 95% CI 0.81-1.19), distant recurrence-free interval (HR = 0.88; 95% CI 0.71-1.09), and overall survival (HR = 0.85; 95% CI 0.68-1.07). AEs of grade $>$ 3 were reported for 43.5% vs 41.6% of pts assigned intermittent vs continuous letrozole. Overall 24% pts discontinued letrozole early in both groups. **Conclusions:** Among postmenopausal women with HR+ BC, extended intermittent letrozole did not improve DFS vs continuous letrozole. The similar observed outcomes and incidence of AEs provides clinically relevant information on the intermittent administration of extended letrozole for patients who could benefit from temporary treatment breaks. Clinical trial information: NCT00553410.

504 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

Prospective WSG phase III PlanB trial: Final analysis of adjuvant 4xEC→4x doc vs. 6x docetaxel/cyclophosphamide in patients with high clinical risk and intermediate-to-high genomic risk HER2-negative, early breast cancer. *First Author: Nadia Harbeck, Brustzentrum der Universität München (LMU), Munich, Germany*

Background: Optimal chemotherapy in HER2-negative, particularly HR-positive, early breast cancer (EBC), especially the survival impact of anthracyclines, is still a matter of debate. Retrospective analyses saw most benefit of 6xCEF vs. 6xCMF in HER2+ EBC. Prospective trials have shown conflicting results; no predictive molecular factors have been validated so far, particularly for HR+ EBC. The WSG PlanB trial is the first trial that randomized only patients with high clinical risk or with Recurrence Score >11 in the HR+/HER2- subgroup (pN0-1). Patients with RS<11 (pN0-1) had an excellent prognosis (five-year DFS of 94%) with endocrine therapy alone (Gluz et al. ASCO 2016). **Methods:** The WSG PlanB trial was originally planned as a non-inferiority study for comparison of 6 cycles of anthracycline-free TC (Arm A) vs. standard anthracycline-taxane based chemotherapy (4xEC→4xDoc) (Arm B) in patients with high-risk pN0 (T2-4, G2-3, <35 years, or high uPA/PAI-1) or pN+ HER2- EBC. Following an early amendment, Oncotype DX was performed in all HR+ tumors, and omission of chemotherapy (CT) was recommended in RS≤11 HR+ pN0-1 disease. Primary endpoint was DFS, defined as time to any recurrence, secondary cancer or death. Final analysis for the CT randomization was planned after completed 5-year follow-up in all patients. **Results:** From 2009 to 2011, PlanB enrolled 3198 patients (n=3073 with central pathology review). In 348 patients (15.3%), CT was omitted based on RS≤11. 2449 patients were randomized to 6xTC (n=1222) and 4xEC→4xDoc (n=1227). Within this cohort, 41% were pN+, 42% had G3 tumors and 18% HR-negative tumors by central pathology. After median follow-up of 61 months, very similar five-year DFS of 89.9% [88.1%-91.7%] vs. 90.2% [88.4%-92.0%] and five-year OS of 94.7% [93.4%-96.1%] vs. 94.6% [93.2%-96.0%] were observed in Arms A vs. B. Five treatment-related deaths were observed in Arm A (TC) vs. one in Arm B (EC-Doc) (0.4% vs. 0.1%), despite a trend to more SAE's in Arm B vs. Arm A (n=397 vs. 358). Although recurrence score is a strong prognostic factor, it was not predictive for anthracycline efficacy; no efficacy differences between the study arms were observed in (locally) triple-negative patients or in those with >4 involved lymph nodes, despite the prognostic impact of these factors. **Conclusion:** In the WSG PlanB trial, patients with early HER2-negative BC seem to be sufficiently treated by six cycles of docetaxel/cyclophosphamide compared to four cycles of EC followed by four cycles of docetaxel – no efficacy differences are evident in high-risk subgroups defined by triple-negative status, nodal status, or high Recurrence Score. Further prospective studies are urgently needed before final conclusions for impact of anthracyclines in HER2-negative BC can be drawn. Clinical trial information: NCT01049425.

505 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

Targeted sequencing in a phase III trial of luminal breast cancer: Identification of novel targets. *First Author: John Bartlett, Ontario Institute for Cancer Research, Toronto, ON, Canada*

Background: The International Cancer Genome Consortium and The Cancer Genome Atlas have had a global transformative impact on our understanding of cancer. These programs have mapped the genomic landscape of common and rare tumors setting the scene for a comprehensive change in the approach to cancer diagnosis and treatment. However, the task remains incomplete until these mutational events are linked to clinical outcomes in the context of current therapeutic intervention to drive future stratified medicine approaches. **Methods:** We performed targeted sequencing in patients from the Tamoxifen Exemestane Adjuvant Multicentre trial. DNA was extracted and a 101 gene panel analysed using a novel mutation calling pipeline. Both a priori and machine learning analyses were performed using distant recurrence free survival as the primary endpoint. **Results:** In 1,491 successfully analyzed samples 1,070 (71.76%) samples exhibited at least one single nucleotide mutation (range 0-94, 1.828+/-0.133, mean+/-s.e.). 98/101 genes were mutated in at least one patient. Only variants in *PIK3CA*, *TP53*, *MLL3*, *CDH1* were detected in 5% or more of samples. Twenty genes were associated with increased risk of recurrence in multivariate analyses corrected for clinic-pathological variables, 50% of these genes were involved in transcriptional regulation or RNA/protein processing. In a multivariate analysis, two combined signalling modules were independently prognostic for residual risk following hormone therapy (HRvalidation 3.10 95%CI 1.78-5.40 and HRvalidation 2.70 95%CI 1.57-4.64). **Conclusions:** We successfully performed a signalling pathway-based targeted sequencing analysis within predefined signalling modules. In supervised and unsupervised analyses we identified multiple signalling cassettes linked to poor outcome in patients with ER+ve breast cancers treated with modern endocrine therapy in the context of a phase III clinical trial. These results identify novel candidates as targets to treat endocrine refractory breast cancers.

506 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

Pembrolizumab plus standard neoadjuvant therapy for high-risk breast cancer (BC): Results from I-SPY 2. *First Author: Rita Nanda, The University of Chicago, Chicago, IL*

Background: Pembro is an anti-PD-1 antibody with single agent activity in HER2– metastatic BC. I-SPY 2 is a multicenter, phase 2 platform trial which evaluates novel neoadjuvant therapies; the primary endpoint is pathological complete response (pCR, ypT0/Tis ypN0). We report current efficacy results, with final results at ASCO. **Methods:** Patients (pts) with invasive BC ≥2.5 cm by exam or ≥2 cm by imaging are assigned weekly paclitaxel x 12 (control) +/- an experimental agent, followed by doxorubicin/cyclophosphamide x 4. Combinations of hormone-receptor (HR), HER2, & MammaPrint (MP) status define the 8 signatures studied. MP low HR+ BC is excluded. Adaptive randomization is based on each arm's Bayesian probability of superiority over control. Graduation by signature is based on an arm's Bayesian predictive probability of a successful 1:1 randomized phase 3 trial with a pCR endpoint. We provide raw & Bayesian estimated pCR rates adjusted for covariates, time effects over the course of the trial, & serial MRI modeling for pts not yet assessed for pCR surgically. **Results:** 69 pts were randomized to pembro (HER2- subsets only) from Dec 2015 until it graduated in Nov 2016. 46 pts have undergone surgery (table); the other 23 have on-therapy MRI assessments. In 29 HR–/HER2– (TNBC) pts, pembro increased raw & estimated pCR rates by >50% & 40%, respectively; in 40 HR+/HER– pts, it did so by 13% and 21%. 5 pts had immune-related grade 3 adverse events (AEs); 1 hypophysitis & 4 adrenal insufficiency. 4 pts presented after completion of AC (149-179 d after starting pembro); 1 presented prior to AC (37 d after starting pembro). 7 pts had grade 1-2 thyroid abnormalities. **Conclusion:** Pembro added to standard therapy improved pCR rates in all HER2- BCs that meet I-SPY 2 eligibility, especially in TNBC. Immune-mediated AEs were observed; pt follow up is ongoing. Clinical trial information: NCT01042379.

	Current raw data: pCR/n [total assigned]		Estimated pCR rate (95% prob interval) [equivalent n]		Prob pembro superior	Pred prob of success in phase III
Signature	Pembro	Control	Pembro	Control		
HR+/HER2–	7/25 (28.0%) [40]	13/88 (14.8%) [99]	34.2% (17-51%) [29.4]	13.6% (6-21%) [72.4]	99.0%	86.8%
TNBC	15/21 (71.4%) [29]	16/83 (19.3%) [89]	62.4% (45-80%) [28.6]	22.3% (12-33%) [58.4]	>99.9%	99.3%

507 **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

A phase III trial of neoadjuvant chemotherapy with or without anthracyclines in the presence of dual HER2-blockade for HER2+ breast cancer: The TRAIN-2 study (BOOG 2012-03). *First Author: Mette S. Van Ramshorst, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant chemotherapy with dual HER2 blockade boosts pathologic complete response (pCR) rates in HER2+ breast cancer. The optimal chemotherapy backbone in this setting is unknown. We conducted a multicenter phase III trial to study whether anthracyclines would improve outcome compared to a carboplatin-taxane regimen (NCT01996267). **Methods:** We randomly assigned (1:1) patients with stage II-III HER2+ breast cancer to receive 9 cycles paclitaxel (80mg/m^2 day 1 and 8) and carboplatin (AUC = 6mg/ml·min) (arm A) or 3 cycles 5-fluoruoracil (500mg/m^2), epirubicin (90mg/m^2), and cyclophosphamide (500mg/m^2) followed by 6 cycles paclitaxel and carboplatin (arm B). Both arms received trastuzumab (6mg/kg, loading dose 8mg/kg) and pertuzumab (420mg, loading dose 840mg) concurrent with all chemotherapy cycles, and cycles were repeated every 3 weeks. The primary endpoint was pCR in breast and axilla (ypT0/is,ypN0). **Results:** 438 patients were included and 418 (arm A 206 vs arm B 212) were evaluable for the primary endpoint. The pCR rate did not differ between arms (arm A 68% [95% CI 61-74] vs arm B 67% [95% CI 60-73], p = 0.75). Hormone receptor (HR) negative tumors had significantly higher pCR rates (87% vs 54%, p < 0.0001), but we found no evidence for treatment-by-HR interaction (p = 0.23). Common adverse events grade ≥3 were neutropenia (arm A 53% vs arm B 57%, p = 0.34), febrile neutropenia (arm A 2% vs arm B 11%, p = 0.0001), and diarrhea (arm A 17% vs arm B 12%, p = 0.14). Neuropathy grade ≥2 was common in both arms (arm A 31% vs arm B 29%, p = 0.83), while left ventricular ejection fraction (LVEF) decline grade ≥2 (defined as ≥10% decline from baseline or LVEF < 50%) was more common in arm B (arm A 18% vs arm B 29%, p = 0.007). Symptomatic left ventricular systolic dysfunction was rare (< 1%) in both arms. **Conclusions:** Anthracyclines increase the incidence of febrile neutropenia and grade ≥2 LVEF decline, but do not improve pCR rate in the contemporary neoadjuvant treatment of HER2+ breast cancer with dual HER2 blockade. Therefore, we currently favor a carboplatin-taxane based regimen. Follow-up is required to confirm these results with regard to long-term outcome. Clinical trial information: NCT01996267.

508 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Mastectomy rates in relation to adoption of a margin guideline. *First Author: Monica Morrow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Surgery after initial lumpectomy to obtain a bigger negative margin is common and may lead to mastectomy. The impact of a 2014 consensus statement endorsing a minimal negative margin for invasive breast cancer on surgeon attitudes, re-excision rates, and final surgical procedure is uncertain. **Methods:** Women with stage I and II breast cancer diagnosed between 7/13–8/15 and reported to the Los Angeles and Detroit SEER registries were surveyed about 2 months post diagnosis, and 70% responded; 3729 comprise the analytic sample. All attending surgeons identified by the patients (n=489) were sent a questionnaire at the end of the patient survey period, and 376 (77%) responded. Pathology reports were reviewed for margin status. Multinomial regression models were used to assess trends. **Results:** The 67% initial lumpectomy rate was unchanged during the study. The final lumpectomy rate increased by 13% (to 65% from 52%) from 2013–2015, accompanied by a decrease in unilateral (to 18% from 27%) and bilateral (to 16% from 21%) mastectomy (p=0.002). Surgery after lumpectomy, both re-excision and mastectomy, declined by 16% ($p<0.001$). Pathology review showed no association between date of treatment and positive margins. Patient report of surgeon-recommended mastectomy after initial lumpectomy declined to 8% from 20% ($p<0.001$). 69% of surgeons endorsed a margin of no ink on tumor to avoid re-excision in ER+PR+ cancer and 63% for ER-PR- cancer. Surgeons treating >50 breast cancers annually were more likely to accept this margin than those treating <20 cases ($p<0.001$). **Conclusions:** Additional surgery after initial lumpectomy markedly decreased between 2013–2015 after publication of a margin guideline endorsinga minimal negative margin. This resulted in a substantial increase in lumpectomy as the definitive surgical procedure, which illustrates that guidelines can be an effective, low-cost approach to addressing clinical controversies.

509 Poster Discussion Session; Displayed in Poster Session (Board #109), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

A randomized, double-blind, phase III study comparing SB3 (trastuzumab biosimilar) with originator trastuzumab in patients treated by neoadjuvant therapy for HER2-positive early breast cancer. *First Author: Xavier B. Pivot, University Hospital Jean Minjoz, Besançon, France*

Background: SB3, a proposed biosimilar to the originator trastuzumab (TRZ), demonstrated similarity to its originator in terms of biological activities and pharmacokinetic (PK) equivalence. This study compared SB3 to TRZ in terms of efficacy, safety, PK, and immunogenicity in patients treated by neoadjuvant therapy for HER2 positive early breast cancer (NCT02149524). **Methods:** Phase III, randomized, double blind, multicenter study compared neoadjuvant SB3 or TRZ for 8 cycles concurrently given with chemotherapy (docetaxel followed by 5-fluorouracil/epirubicin/cyclophosphamide). Then patients underwent surgery followed by 10 cycles of SB3 or TRZ. The primary endpoint was breast pathologic complete response (bpCR) rate. Equivalence was declared if the 90% confidence interval (CI) of the ratio or the 95% CI of the difference of the bpCR rates in the per-protocol set (PPS) were contained within the pre-defined equivalence margins (0.785, 1.546) and (-13%, 13%), respectively. Secondary endpoints were total pathologic complete response (tpCR), overall response rate (ORR), event-free survival, PK, immunogenicity, and safety. **Results:** 800 patients were included in PPS. The bpCR rates were 51.7% for SB3 and 42.0% for TRZ. The ratio of bpCR rate was 1.259 and its 90% CI was 1.112-1.426, within the pre-defined equivalence margin. The difference of bpCR rate was 10.70% and its 95% CI was 4.13-17.26; the lower margin was contained within, the upper margin was outside the pre-defined equivalence margin. Secondary endpoints were comparable between SB3 vs TRZ: tpCR rate (45.8% vs 35.8%); ORR (96.3% vs 91.2%). Safety was comparable between SB3 vs TRZ during neoadjuvant period: incidence of treatment-emergent adverse events (96.6% vs 95.2%), most commonly neutropenia, alopecia, and nausea; incidence of serious adverse events (10.5% vs 10.7%). PK equivalence was demonstrated and immunogenicity between SB3 vs TRZ was comparable (0.7% vs 0.0%). **Conclusions:** Equivalence was demonstrated between SB3 and TRZ based on the ratio of bpCR rates. Safety, PK, and immunogenicity were similar. Complete safety and survival data will follow. Clinical trial information: NCT02149524.

510 Poster Discussion Session; Displayed in Poster Session (Board #110), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Double-blind, randomized phase III study to compare the efficacy and safety of CT-P6, trastuzumab biosimilar candidate versus trastuzumab as neoadjuvant treatment in HER2 positive early breast cancer (EBC). *First Author: Justin Stebbing, Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: CT-P6 (C) is a proposed biosimilar to trastuzumab. This trial (NCT02162667) evaluated the similarity of C and trastuzumab in efficacy and safety for HER2+ EBC. **Methods:** 549 patients with HER2+ EBC were randomized to receive C (n=271) or trastuzumab (n=278) in combination with docetaxel (Cycles 1-4) and 5-fluorouracil, epirubicin, and cyclophosphamide (Cycles 5-8). C or trastuzumab was administered at 8 mg/kg (Cycle 1 only) followed by 6 mg/kg every 3 weeks. The primary endpoint was pathological complete response (pCR) rate at surgery. Secondary endpoints were overall response rate (ORR), PK, PD and safety. After surgery, patients received adjuvant C or trastuzumab to complete a total of 1-year treatment. **Results:** The pCR rate was 46.8% for C and 50.4% for trastuzumab. The 95% CIs for the risk ratio estimate were within the equivalence margin (0.74, 1.35) in PPS and ITT analyses. Other efficacy endpoints were similar between C and trastuzumab. The proportion of patients with at least 1 treatment-emergent SAE was 6.6% for C and 7.6% for trastuzumab. Only 1 patient in each group withdrew treatment due to significant LVEF decrease. Infusion-related reaction was reported for 8.5% of patients in C and 9.0% of patients in trastuzumab. **Conclusions:** This study demonstrated the similarity of efficacy in terms of pCR between CT-P6 and trastuzumab in EBC patients. Secondary efficacy endpoints also supported the similarity between CT-P6 and trastuzumab. CT-P6 was well tolerated with a similar safety profile to that of trastuzumab during the neoadjuvant period. Clinical trial information: NCT02162667.

Summary of efficacy endpoints.

Seven-year (yr) follow-up of adjuvant paclitaxel (T) and trastuzumab (H) (APT trial) for node-negative, HER2-positive breast cancer (BC). *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Retrospective data suggest that patients (pts) with small HER2+ cancers have more than just minimal risk of disease recurrence. The APT trial was designed to address treatment for such pts. We have previously reported 3-yr disease-free survival (DFS) and here we provide an updated analysis with 7-yr DFS. **Methods:** APT is a single arm multicenter, phase II study of TH. Pts with HER2+ BC (IHC 3+ and/or FISH ratio > 2.0) with negative nodes (a single axillary lymph node micrometastasis was allowed) and tumor size < 3 cm were eligible. Pts received T (80 mg/m^2) with H x 12 weekly (w), followed by H (weekly or q3w) x 39w. The primary endpoint was DFS. Recurrence Free Interval (RFI), Breast Cancer Specific Survival (BCSS), and overall survival (OS) were also analyzed. Intrinsic subtyping by PAM50 was performed on the nCounter Analysis system on archival tissue. **Results:** 410 pts were enrolled from September 2007 to September 2010 and 406 began protocol therapy. 67% had hormone-receptor (HR)+ tumors. Distribution by tumor size: 2% T1mi; 17% T1a; 30% T1b; 42% T1c, and 9% T2 ≤ 3 cm. 6 pts had a nodal micrometastasis. With a median follow-up of 6.5 yrs, there were 23 DFS events observed: 4 (1.0%) distant recurrences, 5 local/regional recurrences (1.2%), 6 new contralateral BC (1.5%), and 8 deaths without documented recurrence (2.0%). The 7-yr DFS was 93.3% (95% CI 90.4-96.2); 7-yr DFS for HR+ pts was 94.6% (95% CI 91.8-97.5) and for HR- pts was 90.7% (95% CI 84.6-97.2). 7-yr RFI was 97.5% (95% CI 95.9-99.1); 7-year BCSS is 98.6% (95% CI 97.0-100); and 7-yr OS was 95.0% (95% CI 92.4-97.7). Ongoing PAM50 testing (n = 227 pts) identified 142 (63%) HER2-enriched; 22 (10%) luminal A, 26 (11%) luminal B, and 20 (9%) basal-like; 17 samples had a poor quality assay. Additional testing and associations with clinical outcomes will be presented at the meeting. **Conclusions:** These data suggest that TH as adjuvant therapy for node-negative HER2+ BC is associated with few recurrences and only 4 distant recurrences with longer follow-up. Based on these data, if chemotherapy/trastuzumab is given to a pt with stage I HER2+ breast cancer, the TH regimen should be considered a standard treatment. Clinical trial information: NCT00542451.

Survival outcomes of the NeoALTTO study: Updated results of a randomized multicenter phase III neoadjuvant trial. *First Author: Jens Bodo Huober, University of Ulm, Ulm, Germany*

Background: In the neoadjuvant NeoALTTO trial dual HER2 blockade with lapatinib (L) plus trastuzumab (T) combined with weekly paclitaxel significantly increased the pathologic complete response rate (pCR) compared with either anti-HER2 agent alone plus paclitaxel. At first analysis pts with pCR had a better event free survival (EFS) and overall survival (OS) after median follow-up of 3.84 yrs. **Methods:** 455 pts with operable HER2-positive breast cancer were randomized to receive either L (n=154) 1500mg/day, T 4mg/kg loading dose followed by 2mg/kg/wk (n=149) or L 1000mg/day plus T (n=152) for 6 weeks followed by the assigned anti-HER2 treatment combined with paclitaxel weekly x 12. Following surgery pts received 3 cycles fluorouracil, epirubicin and cyclophosphamide q 3 weeks. The assigned anti-HER2 treatment was continued for 34 weeks thereafter. Primary endpoint was pCR (ypT0/is), secondary endpoints were EFS and OS and the association between pCR and OS analyzed by landmark analysis 30 weeks after randomization. Median follow-up was 6.7 years. **Results:** 6-yrs EFS rate was 67%/ 67%/74% with L/T/TL, respectively (L vs T HR 0.98 [95% CI 0.64–1.51] p=0.93; TL vs T HR 0.81 [95% CI 0.52–1.26] p=0.35). In the hormone receptor negative group 6- yrs EFS rate was 61%/ 63%/74% for the 3 groups, respectively (L vs T HR 1.09 [95% CI 0.61–1.95] p=0.76; TL vs T HR 0.81 [95% CI 0.44–1.51] p=0.52). OS at 6 yrs was 82%/79%/ 85% for L, T and TL, respectively (L vs T: HR 0.85 [95% CI 0.49-1.46] p=0.56; TL vs T HR 0.72 [95% CI 0.41-1.27] p=0.26). In landmark analyses, pts with a pCR had significantly higher 6-yrs EFS (77% /65%) and OS (89% /77%) compared to those without pCR, both overall and for the hormone receptor negative cohort. **Conclusions:** The updated results of the NeoALTTO study confirm the sustained survival benefits for pts who achieve a pCR. EFS and OS after 6 yrs did not differ significantly between the 3 treatment groups. The combination of T and L showed numerically higher EFS compared to T, especially in the hormone-receptor negative group. Clinical trial information: NCT00553358.

Chemotherapy (CT) for isolated locoregional recurrence (ILRR) of breast cancer in ER-positive (ER+) and ER-negative (ER-) cohorts: Final analysis of the CALOR trial. *First Author: Irene Wapnir, International Breast Cancer Study Group, NSABP/NRG Oncology, Breast International Group, Bern, Switzerland*

Background: ILRR is associated with a high risk of developing breast cancer distant metastases and death. The CALOR trial (NCT00074152) investigated the effectiveness of CT following local therapy for ILRR. Previously reported results at 5-yrs median follow-up (MFU) showed significant benefit of CT for ER- ILRR, but further follow-up was required in ER+ ILRR. This report presents results at 8.8 yrs MFU within ER status cohorts. **Methods:** CALOR is an open-label, randomized trial for patients with completely excised ILRR after unilateral breast cancer. Eligible patients were randomized to CT (selected by the investigator; multidrug for at least 3 months recommended) or No-CT, and stratified by prior CT, hormone-receptor (ER, PR) status, and location of ILRR. Patients with ER and/or PR positive ILRR received adjuvant endocrine therapy. Radiation therapy was mandated for patients with microscopically involved margins, and anti-HER2 therapy was optional. Endpoints are disease-free survival (DFS), overall survival (OS) and breast cancer-free interval (BCFI). **Results:** From August 2003 to January 2010, 162 patients were enrolled: 104 ER+ and 58 ER-. The results at 8.8 years MFU in ER status cohorts are summarized in the Table (40 and 27 DFS events, respectively). The reduction in the hazard of an event associated with CT for the ER- ILRR cohort was sustained, but no benefit was observed for the ER+ cohort; interactions were significant for DFS and BCFI. The reduction in the hazard of an event seen in the ER- cohort was not apparent in ER+, with significant interactions for DFS and BCFI. Results for the 3 endpoints were consistent in multi-variable analyses adjusting for location of ILRR, prior chemotherapy, and interval from primary surgery. **Conclusions:** The final analysis of CALOR confirms that CT benefits patients with resected ER- ILRR. Long-term CALOR trial results do not support the use of CT for ER+ ILRR. Clinical trial information: NCT00074152.

		CT 10-yr %	No-CT 10-yr %	HR	95% CI	P-int

Breast conservation after neoadjuvant chemotherapy for triple-negative breast cancer: Surgical results from an international randomized trial (BrighTNess). *First Author: Mehra Golshan, Brigham and Women's Hospital and Dana-Farber Cancer Institute, Boston, MA*

Background: Neoadjuvant systemic therapy (NST) increases the frequency of breast-conserving therapy (BCT) in stage II-III breast cancer, but there is little data on how often it converts patients (pts) from BCT-ineligible (BCT-I) to BCT-eligible (BCT-E) and on the impact of other factors on surgical choices. We collected surgical assessment and management data from an international randomized trial of NST in triple-negative breast cancer (TNBC). **Methods:** Women with operable TNBC were randomized to veliparib (V) with carboplatin (C) and paclitaxel (P), placebo with C and P or placebo with P followed by doxorubicin and cyclophosphamide. The surgeons assessed BCT candidacy by clinico-radiographic criteria before and after NST; surgical management was at surgeon and patient discretion. We assessed interactions between BCT eligibility pre- and post-NST, germline BRCA mutation (*gBRCA)* status, continent of treatment and achievement of pathologic complete response(pCR) and percentage of pts who underwent BCT versus mastectomy. **Results:** Pre- and post-NST surgical assessments were available for 604 pts who underwent surgery. BCT rates are listed in the Table. The BCT rate was 68% among pts deemed BCT-E after NST. pCR rates were identical between BCT-E pts who chose BCT (55%) vs. mastectomy (53%). Of 141 pts deemed BCT-I at baseline, 75 (53%) converted to BCT-E but only 42 (56%) of these opted for BCT. pCR rates were 49% in BCT-E converts vs. 36% in those remained BCT-I. *gBRCA* pts (n = 84) were less likely to choose BCT even if they were BCT-E. Pts treated in North America (NA) were less likely to choose BCT (55% vs. 80% for Europe and Asia P<0.0001) even among non-*gBRCA* considered BCT-E post-NST (61% vs. 85% P<0.0001). **Conclusions:** This largest prospective analysis of the impact of NST in TNBC demonstrates a conversion rate from BCT-I to BCT-E of 53%. BCT rates were lower in pts with *gBRCA*; the much higher mastectomy rate among BCT-E pts in NA merits investigation. Clinical trial information: NCT02032277.

	All pts		Post-NST BCT-E	
Category	**N**	**BCT**	**N**	**BCT**

515 Poster Discussion Session; Displayed in Poster Session (Board #115), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Phase 3 randomized study of adjuvant anastrozole (A), exemestane (E), or letrozole (L) with or without tamoxifen (T) in postmenopausal women with hormone-responsive (HR) breast cancer: The FATA-GIM3 trial. *First Author: Francesco Perrone, Istituto Nazionale per lo Studio e la Cura dei Tumori "Fondazione G. Pascale"- IRCCS, Naples, Italy*

Background: Uncertainty still exists regarding the optimal schedule of adjuvant treatment of breast cancer with aromatase inhibitors (AI) and no trial has ever compared all the three AI. **Methods:** FATA-GIM3 is a multicenter, open label, 2x3 factorial phase 3 randomized study of adjuvant A, E and L upfront (UP - for 5 years) or sequentially (SEQ - for 3 years after 2 years of T) in postmenopausal HR breast cancer pts. Two comparisons were planned: UP vs SEQ and A vs E vs L. DFS (including local or distant relapse, second breast or non-breast cancer, DCIS and death, whichever came first) was the primary end-point; 2% at 5 yrs (corresponding to a HR of 0.79) was defined as the minimum difference required to declare superiority of UP vs SEQ. With two-tailed alfa 0.05, power 80%, 669 events and the enrolment of 3600 patients were planned. Following Data Monitoring Committee advice, final analysis was performed after 5yrs median follow-up. For each comparison a Cox regression model was applied adjusted by stratification factors and stratified by the other treatment factor. Analyses were based on intention-to-treat. **Results:** from 3/2007 to 7/2012, 3697 patients were enrolled at 76 centres. Median age 64, pT1 69.7% , pN0 64.3%, ER and PgR positive 88.9%, HER2 positive 8.9%, previous chemotherapy 38.3%. At 60 months median follow-up, 401 events were reported. 5yrs DFS was 89.8 with UP and 88.5 with SEQ (delta 1.32%, 95% CI -0.90-3.54; HR 0.89, 95% CI 0.73-1.08; P=0.23). 5yrs DFS was 90.0 with A, 88.0 with E and 89.4 with L (P=0.19). **Conclusions:** in the FATA-GIM3 trial there is a small non statistically significant DFS advantage for UP vs SEQ. No significant difference is evident among the three AI. Supported by the FARM5K3MEE AIFA grant from the Italian Drug Agency. Clinical trial information: NCT00541086.

Standard anthracycline-based vs. docetaxel-capecitabine in early breast cancer: Results from the chemotherapy randomization (R-C) of EORTC 10041/ BIG 3-04 MINDACT phase III trial. *First Author: Fatima Cardoso, Breast Unit, Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, Portugal*

Background: The MINDACT trial demonstrated that 46% of breast cancer patients (pts) at high clinical (C) but low genomic (G) risk based on MammaPrint (70-gene signature), might safely forego adjuvant CT *(Cardoso NEJM 2016).* A second 1:1 randomization (R-C) was optional in all pts for whom CT was decided, between standard anthracycline-based regimens (AT) and experimental docetaxel 75 mg/m² IV + oral capecitabine 825 mg/m² bid x 14 days (DC), q3wks for 6 cycles after surgery. **Methods:** MINDACT included 6693 pts, of whom 2895 received CT. C-low/G-low pts were allocated to no CT, C-high/G-high to CT and those with discordant G/C results were randomized to use either G or C risk to decide use of CT. Primary endpoint for R-C was disease-free survival (DFS). Secondary endpoints included OS and safety. Statistical hypothesis: HR-0.76 in favour of DC. **Results:** A total of 1301 pts (45%), of whom 787 (61%) were C-high/G-high, 351 (27%) C-high/G-low, 137 (11%) C-low/G-high, and 26 (2%) C-low/G-low, were randomized to AT or DC. Main reason for not inclusion in R-C was CT given outside the trial. Compliance rates for R-C were 97% overall. At 5-years median follow-up, DFS was not significantly different between AT (649 pts) and DC (652 pts) [HR = 0.83 (0.60- 1.15, p = 0.263], and OS was similar in both arms (HR 0.91, 95% CI, 0.54- 1.53). For the relevant C-high/G-high group, DFS was also not different (5-years DFS 86.1 vs 88.1%; HR 0.83, 95% CI, 0.58-1.21). Of note, number of events is still small (AT: 30; DC: 27). Commonest adverse events in DC were grade 2 hand/foot syndrome (28.5% vs 3.3%), grade 2 diarrhea (13.7% vs 5.8%) and grade 1 peripheral neuropathy (27.1% vs 11.2%). Grade 2 anemia (14.2% vs 5.1%) and grade 4 neutropenia (24.6% vs 20.5%) were higher in AT. Cardiac events occurred in 9 pts overall, including 1 cardiac failure (AT), while 53 pts developed secondary cancers (AT: 32; DC: 21; leukemia: 2 in AT vs. 1 in DC). Four deaths occurred (AT:1 and DC:3) while on therapy. **Conclusions:** Docetaxel-capecitabine did not improve DFS or OS, compared with standard anthracycline-based CT, including for the C-high/G-high group. Safety profile of both regimens was as expected. Clinical trial information: NCT00433589.

517 Poster Discussion Session; Displayed in Poster Session (Board #117), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

A phase III, open label, prospective, randomized, multicenter, neoadjuvant study of chemotherapy versus endocrine therapy in premenopausal patient with hormone responsive, HER2 negative, breast cancer (KBCSG 012). *First Author: hee Jeong Kim, Department of Surgery, University of Ulsan, College of Medicine, Asan Medical Center, Seoul, South Korea*

Background: Neoadjuvant endocrine therapy has shown efficacy in hormone-responsive postmenopausal breast cancer patients. We aimed to assess the efficacy and safety of cytotoxic chemotherapy versus endocrine therapy for hormone-responsive lymph node-positive premenopausal breast cancer patients in a neoadjuvant setting. (NCT01622361). **Methods:** In this phase 3, randomized, double blind, parallel group, multicenter study, we enrolled premenopausal women with estrogen receptor (ER)-positive, HER2-negative, and lymph node-positive premenopausal breast cancer patients. Patients were randomized to either 24 weeks of neoadjuvant chemotherapy with adriamycin plus cyclophosphamide (AC) followed by taxane (T) or neoadjuvant endocrine therapy with zoladex and tamoxifen. **Results:** 187 patients were randomly assigned to chemotherapy (n=95) or endocrine therapy (n=92), and 174 patients completed the 24 week neoadjuvant treatment period (n=87, both). More patients in the chemotherapy group had a complete or partial response than did those in endocrine therapy arm on both caliper (chemotherapy 83.9% vs endocrine therapy 71.3%, OR 0.476 95% CI 0.228 to 0.994) and MRI (chemotherapy 83.7% vs endocrine therapy 52.9%, OR 0.219, 95% CI 0.107 to 0.447). Three patient on chemotherapy group (3.4%) and 1 patients (1.15%) on endocrine treatment group showed complete pathologic response. In the patients who had breast cancer with low Ki 67 expression (<20%) on initial biopsy, clinical response on caliper were shown similar on both treatment group (HR 0.958, 95%CI 0.296 to 3.101). Five patients who had no tumor on the breast or lymph node after 24 week neoadjuvant endocrine therapy had higher ER score (all allred score >6), all low grade (1or 2) low Ki 67(≤20%) expression (4/5 patients) on initial biopsy specimen. **Conclusions:** In premenopausal breast cancer patients, 24 weeks neoadjuvant chemotherapy showed better clinical response than endocrine therapy. Low Ki 67 expression could be a parameter of the endocrine treatment. Clinical trial information: NCT01622361.

518 Poster Discussion Session; Displayed in Poster Session (Board #118), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

A randomised phase III trial comparing two dose-dense, dose-intensified approaches (EPC and PM(Cb)) for neoadjuvant treatment of patients with high-risk early breast cancer (GeparOcto). *First Author: Andreas Schneeweiss, University of Heidelberg, Heidelberg, Germany*

Background: The sequential use of intense does-dense (idd) epirubicin, paclitaxel, cyclophosphamide (EPC) and weekly paclitaxel/liposomal doxorubicin (+/- carboplatin (Cb) in triple negative breast cancer (TNBC) (PM(Cb)) are considered highly efficient regimens for high-risk early stage breast cancer (BC). **Methods:** GeparOcto (NCT02125344) patients (pts) received 18 weeks (wks) either EPC (3x E 150mg/m² q2w followed by 3x P225 mg/m² q2w followed by 3x C 2000mg/m² q2) or PM(Cb) (12x P 80mg/m² plus M 20 mg/m² q1w, plus Cb AUC 1.5 q1w in TNBC). For HER2+ BC trastuzumab 6 (8) mg/kg q3w and pertuzumab 420 (840) mg q3w cycles were given concomitantly with P and C. Pts with histologically confirmed, cT1c - cT4a-d BC and central receptor assessment were included. Pts with HER2+ or TNBC were eligible irrespective of nodal status, luminal B-like tumours only if pN+. Primary objective compared pathologic complete response (pCR) rates (ypT0/is ypN0). Sample size calculations assumed a pCR rate of 50% for EPC and 60% for PM(Cb), requiring 950 pts to show superiority of PM(Cb). Secondary objectives compared pCR rates within the stratified subgroups (BC subtype, HER2+ vs HER2- HR+ vs HER2- HR-), amongst others. **Results:** 961 pts were recruited between 12/2014 and 05/2016, 945 started treatment. Median age was 48 years, 4% T3, 2% T4d, 46% N+, 82% ductal invasive, 66% G3 tumors; 40% were HER2+, 43% TNBC. 347 pts reported SAEs (176 EPC/171 PM(Cb)) and 2 pts died. 35 pneumonias (2 EPC vs 33 PM(Cb)) and 18 pneumonitis (3 EPC vs 15 PM(Cb)) were reported. 16.4% pts with EPC and 33.8% with PM(Cb) discontinued treatment (p<0.001), mainly due to AEs (47 EPC vs 113 PM (Cb)). Mean treatment duration was 17 wks with EPC and 16 wks with PM (Cb). pCR rate was 48.3% with EPC and 47.6% with PM(Cb)(OR 0.97 (95%CI 0.75-1.25), p=0.876). pCR rate in TNBC was 48.5% with EPC and 51.7% with PM(Cb); in HER2+ 62.0% vs 57.4% and in Luminal B 14.1% vs 14.6%. **Conclusions:** In high-risk early stage breast cancer pts pCR rates of idd EPC compared to weekly PM(Cb) were not significantly different. PM(Cb) appeared to be less feasible. Clinical trial information: NCT02125344.

519 Poster Discussion Session; Displayed in Poster Session (Board #119), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Effects of neoadjuvant chemotherapy (NAC) on tumor infiltrating lymphocytes (TIL) and PD-L1 expression in the SWOG S0800 clinical trial. *First Author: Vasiliki Pelekanou, Yale School of Medicine, New Haven, CT*

Background: Higher baseline TILs and PD-L1 expression are associated with greater pathologic complete response (pCR) rates, but how chemotherapy affects these immune parameters is unknown. The goal of this study was to examine TIL and PD-L1 expression in pre- and post-NAC tumor specimens from the S0800 clinical trial that compared weekly nab-paclitaxel/bevacizumab + dose-dense doxorubicin and cyclophosphamide (AC) with nab-paclitaxel + AC as NAC for HER2-negative cases. Association between immune parameters, pCR and NAC-induced changes were tested using ER and NAC-arm adjusted logistic regression. **Methods:** TILs were assessed on H&E stained full sections of 120 pre- and 62 post-NAC tissues (tumor bed of pCR) including 59 matched samples. PD-L1 immunohistochemistry was performed using the FDA cleared 22C3 assay and results were available for 121 baseline and 43 matched post-NAC samples. **Results:** At baseline, the mean TIL count was 18%; 16% had no TILs and 9% had > 50% TILs. Higher baseline TILs were associated with higher pCR rate (p = 0.043, trend test p = 0.014) but there was no interaction with NAC arm. Post-NAC, the mean TIL counts was 11%; 5% had no TILs and 1.6% had > 50% TILs. In the matching post-NAC samples, the mean change was 15% decrease in TILs, but in 32% of cases TILs increased. Cases with residual disease (n=44) had lesser average decrease (p=0.029) than cases with pCR (n=15). The post-NAC decrease in TILs was also observed after excluding cases with pCR. At baseline, PD-L1 expression either in the stroma or on epithelial cells or in both was detected in 52 (43%) of 121 cases (5 tumor only, 29 stroma only, 18 tumor + stroma). Those with baseline PD-L1 expression had higher pCR (63% vs. 37%; p=0.008). Post-NAC, PD-L1 expression was seen in 14 of 43 (33%) cases (7 stroma only, 7 tumor + stroma). In the 39 matching pre- and post-NAC samples, PD-L1 expression was negative in both in 20, positive in both in 10 cases and 6 patients had PD-L1 expression at baseline but not in the post-NAC sample. **Conclusions:** TIL counts and PD-L1 expression generallydecreased, but in a minority of cases increased after NAC. The decrease in TIL was significantly greater in cases achieving pCR. Clinical trial information: NCT00856492.

520 Poster Discussion Session; Displayed in Poster Session (Board #120), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Phase 3 study evaluating efficacy and safety of veliparib (V) plus carboplatin (Cb) or Cb in combination with standard neoadjuvant chemotherapy (NAC) in patients (pts) with early stage triple-negative breast cancer (TNBC). *First Author: Charles E. Geyer, Virginia Commonwealth University Massey Cancer Center, Richmond, VA*

Background: Clinical studies suggest that TNBC is sensitive to DNA-damaging agents, including Cb. V is a potent PARP inhibitor that may enhance the antitumor activity of such agents. We present primary response data from a phase 3 randomized, placebo-controlled study (NCT02032277) evaluating the addition of V + Cb or Cb to neoadjuvant paclitaxel (P) followed by doxorubicin + cyclophosphamide (AC). **Methods:** Pts with histologically confirmed, invasive TNBC (T2–T4 N0–2 or T1 N1–2) amenable to surgical resection were randomized 2:1:1 to (Arm A) P 80 mg/m^2 weekly + Cb AUC 6 mg/mL/min q3 weeks + V 50 mg PO BID; (Arm B) P + Cb + PO placebo; or (Arm C) P + IV placebo + PO placebo, for 12 weeks followed by AC (60 mg/m^2 or 600 mg/m^2 q2 or 3 weeks) $\times$ 4. Primary endpoint was pathologic complete response (pCR) in breast and nodes with $>$ 80% power at 2-sided α of 0.05 using pair-wise comparisons for A vs B and A vs C to detect significant treatment effects using X^2 test; secondary endpoint was rate of conversion to eligibility for breast conservation surgery (BCS). Adverse events (AEs) were assessed with NCI CTCAE V4.0. **Results:** Six hundred thirty-four pts (median age 50 years; range 22–79) were randomized to Arms A (n = 316), B (n = 160), or C (n = 158). Baseline characteristics were well balanced. No pCR difference was observed between Arms A and B (53.2% vs 57.5% p = 0.36), but pCR in Arm A was higher than Arm C (53.2% vs 31.0% p $<$ 0.001). In non-prespecified analysis, pCR in Arm B was also higher than Arm C (57.5% vs 31.0% p $<$ 0.001). Among pts ineligible for BCS at screening (n = 141), 62% were eligible after NAC in Arm A vs 44% each in Arms B (p = 0.13) and C (p = 0.14). Grade 3–4 AEs (Arms A/B/C, 86%/85%/45%) and serious AEs (30%/27%/14%) neutropenia, thrombocytopenia, anemia, nausea, and vomiting were increased with the addition of Cb; V did not impact toxicity. Median cycles of NAC were not reduced with V + Cb + P or Cb + P vs P. **Conclusions:** Addition of V to neoadjuvant Cb + P followed by AC did not increase pCR rate in breast and nodes in stage II–III TNBC, while addition of V + Cb or Cb alone to P followed by AC did. Cb (+/– V) increased toxicity but did not impact delivery of NAC. Clinical trial information: NCT02032277.

SWOG S0221 updated: Randomized comparison of chemotherapy schedules in breast cancer adjuvant therapy. *First Author: G. Thomas Budd, Cleveland Clinic, Cleveland, OH*

Background: S0221 investigated weekly vs q 2 week dosing of doxorubicin/cyclophosphamide (AC) and paclitaxel (P) in patients (pts) with high risk early breast cancer as previously reported (JCO 33:58-64, 2015). After enrollment of 2716 pts randomization to the two AC arms was stopped for futility and an additional 578 pts received 4 cycles of q 2 week AC and were randomized to P weekly (Pw) or P q 2 weeks (P2). We report updated results of the original trial design and the first report of the 578 pts treated with AC x 4 and Pw x 12 or P2 x 6. **Methods:** Between December 2003 and November 2010, 2716 pts were randomized in a 2x2 factorial design to 1) 15 weeks of weekly AC (A 24 mg/m2/week and C 60 mg/m2/day po) vs 6 cycles of q 2 week AC (A 60 mg/m2 and C 600 mg/m2) and 2) Pw (paclitaxel 80 mg/m2/week x 12) vs P2 (paclitaxel 175 mg/m2 q 2 weeks x 6), with growth factor support as previously described. After study amendment 578 patients received 4 cycles of q 2 week AC followed by Pw or P2. Updated survival was assessed using log-rank tests and Cox regression models. **Results:** At a median follow-up of 8.5 years, among the pts treated in the original protocol, there were no significant differences among the four treatments for DFS (p=0.21) or OS (p=0.08). The triple-negative subset had worse DFS (P$<$0.001) than the HER2-positive or ER/PR+/HER2- subsets, with 5 year DFS of 75% vs 83% and 84%, respectively. While we previously found in the triple negative subset that the arm using q 2 weeks for both AC and paclitaxel was marginally superior, the differences among the arms are no longer significant for DFS (p=0.12) or OS (p=0.11). Among the 578 pts assigned ACx4 and randomized to Pw v P2 there were no overall differences in DFS (p=0.70) or OS (p=0.63) after 4.4 years median follow-up. **Conclusions:** There were no significant differences in DFS or OS between any of the schedules with extended follow-up in the original cohort and no difference in outcome by paclitaxel schedule for the 578 additional patients in the revised protocol. Either paclitaxel schedule may be recommended, with selection based on toxicity, cost, or patient preference rather than efficacy. Support: NCI grants CA32102, CA38926, CA21115, CA21076, CA77597, CA25224, CA77202, CCSRI15469, and Amgen, Inc. Clinical trial information: NCT00070564.

522 Poster Session (Board #122), Sun, 8:00 AM-11:30 AM

Multi-institutional comparison of breast cancer risk stratification by 70-gene signature and 21-gene assay. *First Author: David J. Dabbs, Department of Pathology Magee Women's Hospital, Pittsburgh, PA*

Background: Breast cancer risk stratification with the 70-gene signature (70-GS) provides a binary low risk (LR) or high risk (HR) result; by contrast the 21-gene assay (21-GA) provides LR, intermediate (IR), and HR results. Results from these two assays were compared for 769 patients from 5 institutions. **Methods:** The study included patients from McGill University (n = 86), UPMC (n = 437), USF (n = 135), Morton Plant North Bay Hospital (n = 79), and Cleveland Clinic (n = 32, all 21-GA IR). **Results:** With the 70-GS, 487 (63%) patients had a LR and 282 (37%) patients had a HR result. Excluding 32 cases selected for 21-GA IR results (n = 737), the 21-GA gave 369 (50%), 250 (34%), and 118 (16%) patients with LR, IR, and HR scores, respectively. Using the TAILORx cutoff, there were 134 (18%), 432 (59%), and 171 (23%) patients with LR, IR, and HR scores, respectively. There were 329 (45%) and 486 (66%) patients who were not classified in the same risk category by both assays using the clinical and TAILORx cutoffs for IR, respectively. **Conclusions:** In a large multi-institutional study the 70-GS and 21-GA results were discordant in 45-66% of patients, and the proportion of patients with a 21-GA score in the IR range varied from 34-59%. The 70-GS provided clinically actionable results for all patients.

523 Poster Session (Board #123), Sun, 8:00 AM-11:30 AM

Anastrozole after tamoxifen in early breast cancer patients with chemotherapy-induced ovarian function failure. *First Author: Vivianne C. Tjan-Heijnen, Maastricht University Medical Centre, Maastricht, Netherlands*

Background: The DATA study compared 6 and 3 years of anastrozole therapy in postmenopausal women with hormone-receptor positive early breast cancer previously treated with 2-3 years tamoxifen (oral presentation SABCS 2016 #S01-03). The study included postmenopausal women, allowing those with chemotherapy-induced ovarian function failure (CIOFF). However, these may be at risk of ovarian function recovery (OFR). The current analysis compared the survival of women with CIOFF with definite postmenopausal women and examined the influence of OFR on survival. **Methods:** We selected patients from the DATA study aged 45-57 years at randomization who had received (neo-)adjuvant chemotherapy. They were classified by menopausal status at randomization (definite postmenopausal before chemotherapy or by ovariectomy, versus CIOFF). The latter were monitored by estradiol measurements for OFR during anastrozole. Endpoints: Disease-free Survival (DFS), Distant Recurrence-free Survival (DRFS), and Overall Survival (OS), corrected for tumor size, nodal status, grade, and hormone-receptor status. We used the landmark method to calculate residual 5-year survival rates. **Results:** In total, 261 patients were definite postmenopausal and 395 had CIOFF, of whom 39 experienced OFR while 290 did not (66 were excluded from the landmark analysis because follow-up estradiol levels were lacking). When comparing the CIOFF with the definite postmenopausal women, the 5-year survival rates were not significantly different. Within the group with CIOFF, experiencing OFR was associated with a trend for worse outcome (DFS-event HR 1.33 (95% CI 0.61-2.90), P=0.48; DRFS-event HR 2.11 (95% CI 0.89-5.02), P=0.09; and OS-event HR 2.24 (95% CI 0.92-5.45), P=0.07). Patients who experienced OFR in the first year had a residual 5-year rate for DFS of 73.1% compared with 87.4% in those who did not. For DRFS these rates were 76.9% vs. 92.1%, and for OS 80.8% vs. 94.4% respectively. **Conclusions:** These results suggest that women with CIOFF undergoing anastrozole treatment may be at increased risk of disease recurrence if experiencing OFR despite close monitoring of estradiol levels and adjusting endocrine treatment. Clinical trial information: NCT00301457.

524 Poster Session (Board #124), Sun, 8:00 AM-11:30 AM

Copy-number and targeted sequencing analyses to identify distinct prognostic groups: Implications for patient selection to targeted therapies amongst anti-endocrine therapy resistant early breast cancers. *First Author: Jane Bayani, Ontario Institute for Cancer Research, Toronto, ON, Canada*

Background: Hormone receptor positive breast cancer is a therapeutic challenge. Despite optimal anti-endocrine therapies, most breast cancer deaths follow a diagnosis of early luminal cancer. To understand the impact of multiple aberrations in the context of current therapy, we assessed the prognostic ability of genomic signatures as a putative stratification tool to targeted therapies. **Methods:** This *a priori* study is based on molecular pathways which might predict response to targeted therapies. DNA from 420 patients from the phase III TEAM pathology cohort were used. Patients with a distant recurrence within 5 years were matched by clinical variables to those disease-free at follow up. Copy number analysis was performed using the Affymetrix Oncoscan Assay. Targeted sequencing was performed in a subset of samples for genes based on signaling cassettes mined from the ICGC. Pathways were identified as aberrant if there were copy number variations (CNVs) and/or mutations in any of the pre-determined pathway genes: 1) CCND1/CCND2/CCND3/CDK4/CDK6; 2) FGFR1/FGFR2/FGFR2/FGFR4; and 3) AKT1/AKT2/PIK3CA/PTEN. Kaplan-Meier and log-rank analyses were used for DFS between groups. Hazard ratios were calculated using the Cox proportional hazard models adjusted for age, tumour size, grade, lymph node and HER2 status. **Results:** 390/420 samples passed informatics QC filters. For the CCND/CDK pathway, patients with no CNV changes experienced a better DFS (HR = 1.7, 95% CI 1.3-2.3, $p < 0.001$). For the FGFR/FGF pathway, a similar outcome is seen among patients without CNVs (HR = 1.5, 95% CI 1.1-2.0; p = 0.005). For AKT/PIK3CA, a decrease in DFS was seen in those with aberrations (HR = 1.4, 95% CI 1.0-1.8, p = 0.03). **Conclusions:** We demonstrated that CNVs of genes within CDK4/CCND, PIK3CA/AKT and FGFR pathways are independently linked to high risk of relapse following endocrine treatment, with implications for identifying those patients who are at high-risk for recurrence despite optimal anti-endocrine therapy and linking molecular features driving these cancers to targeted therapies.

525 Poster Session (Board #125), Sun, 8:00 AM-11:30 AM

COOLHAIR: A prospective randomized trial to investigate the efficacy and tolerability of scalp cooling in patients undergoing neoadjuvant chemotherapy for early breast cancer. *First Author: Katharina Smetanay, National Center for Tumor Diseases (NCT) and Women's University Hospital Heidelberg, Heidelberg, Germany*

Background: Chemotherapy induced alopecia (CIA) is a distressing side effect for women with breast cancer (BC) undergoing chemotherapy (CT). Scalp cooling is a method aiming to prevent CIA, but its efficacy is not well defined. Observational studies show a positive effect of scalp cooling to reduce hair loss, but randomized trials until recently have been lacking. **Methods:** In our monocentric prospective randomized trial patients with early BC undergoing (neo)adjuvant CT were 1:1 randomized to either scalp cooling (CAP) or not (noCAP). All patients received 18 to 24 weeks of anthracycline (A) and/or taxane (T)-based CT. The DigniCap System was used for scalp cooling. The primary endpoint was patient reported rate of alopecia according to the Dean Scale (Grade 0: no hair loss, grade 1: > 0 - 25%; grade 2: > 25 - 50%; grade 3: > 50 - 75%; grade 4: > 75%). Hair preservation was defined as hair loss £ grade 2. Secondary endpoints were rate of alopecia determined by nursing staff and an independent and blinded evaluator, rate of wig/scarf use as well as quality of life. **Results:** From August 2014 until January 2016 seventy-nine patients were included (41 CAP and 38 noCAP). The drop-out rate was 32% in the CAP arm and 34% in the noCAP arm. Main reasons for drop out were hair loss, adverse events (CAP) and randomization into control arm. At the time of this analysis all patients had completed CT. Hair preservation was observed in 39% of patients in the CAP arm versus 0% in the No CAP arm ($p < 0.001$). There was a strong concordance between patients and staff evaluation (weighted Cohen's Kappa = 0.92). Wig/scarf use was significantly less frequent in the CAP group (36% vs 92% at home, $p < 0.001$; 64% vs 91% outside, $p < 0.001$). We did not observe any differences in hair preservation between A-based and non A-based regimens. **Conclusions:** Our prospective randomized trial shows that scalp cooling is effective in preventing CIA in a relevant number of patients. This option should be made available for patients undergoing T+/-A-based (neo)adjuvant chemotherapy for EBC.

526 Poster Session (Board #126), Sun, 8:00 AM-11:30 AM

Non-adherence behaviors among young women on adjuvant endocrine therapy for breast cancer. *First Author: Johanna Wassermann, Dana-Farber Cancer Institute, Boston, MA*

Background: Young age at diagnosis (dx) is a predictor of worse prognosis in patients (pts) with luminal breast cancer (BC). Poorer adherence to endocrine therapy (ET) among younger women may contribute to this disparity. Aim: To assess non-adherent behaviors and associated factors among young women with stage 1-3 hormone receptor (HR)+ BC taking ET. **Methods:** This study is a part of a multicenter, prospective cohort of pts with dx of BC at or under age 40. On a survey 30 months after dx, among pts reporting taking ET, adherence was measured using a 3-item Likert-type scale (Do you ever forget to take your ET? If you feel worse when you take your ET, do you stop taking it? Did you take your ET exactly as directed by your doctor?). Pts reporting any non-adherent behavior during the last 3 months were classified as non-adherers. Variables with a *p*-value <0.20 were included in a multivariate logistic model. **Results:** Among361 pts eligible for this analysis, 174 (48%) reported some non-adherent behaviors in the last 3 months; 56 (16%) moderate or greater non-adherent behaviors. None of the studied variables was associated with non-adherent behaviors (table). **Conclusions:** Non-adherent behaviors to ET are present in almost half of the young women with HR+ BC. Further analyses of explanatory factors and impact of non-adherence are required to understand and potentially improve this problem.

Yoga in women undergoing treatment for breast cancer: Impact on quality of life in a randomized controlled trial. *First Author: Nita S. Nair, Department of Surgical Oncology, Breast Disease Management Group, Tata Memorial Centre (TMC), Mumbai, India*

Background: Yoga has been tested in multiple small-randomized studies for its impact on quality of life (QOL) on breast cancer (BC). We propose to study the effect of yoga on disease free survival as the primary endpoint in women with operable breast cancer. (Study methodology details refer to NCT02161900). **Methods:** Women with non-metastatic BC were randomized to yoga and conventional exercise (YCE) versus conventional exercise only (CE) in addition to standard therapy. Over and above documentation of recurrence and death, QOL was assessed in these women using the EORTC QLQC30, BR23, Brief fatigue inventory (BFI), Visual pain scores (VPS) and a spirituality questionnaire (SQ). EORTC QLQ was assessed at baseline (BL), 6-9 months (mo), 18-21 mo. BFI and VPS at BL, 6-8 mo and 12-15 mo and SQ at BL and 12-15 mo. We report the first interim analysis of QOL in 605 patients randomized to the study with atleast 1 year of follow up. The groups were balanced in both arms with respect to clinico-pathological factors. **Results:** At 6-9 mo (completion of adjuvant therapy), there was no significant difference in global QOL scores (p = 0.08), however 52% women on YCE showed an improvement from baseline compared to 42% in CE. At 18-21 mo emotional function scores were better in YCE (p = 0.002); with lesser systemic side effects in YCE arm (44% vs 56% p = NS). The median score of fatigue after adjuvant therapy measured by QLQ C30 was lower in YCE (17.37vs22.22, p = 0.003) which was similar to that observed by BFI at 12-15 mo (1.6vs 2, p = 0.04). Also in YCE there was lower reporting of detriment in general activity (41%vs 59%) and mood (34%vs66%) (p = NS). In VPS at 12-15mo, the median scores for pain intensity (p = 0.042), pain on movement (p = 0.038), pain on mobilization (p = 0.008) were lower in YCE. Lastly SQ assessed spirituality and showed no difference, but less deterioration compared to baseline scores in YCE. **Conclusions:** Yoga did not show a significant difference in global QOL but had a major benefit reaching statistical significance in fatigue, emotional score and pain. Yoga is a low-risk, low-cost complementary therapy that may improve compliance to therapy by improving parameters that can affect day-to-day activity in women with breast cancer. Clinical trial information: NCT02161900.

528 Poster Session (Board #128), Sun, 8:00 AM-11:30 AM

Refined estimates of local recurrence risks and the impact of the DCIS score adjusting for clinico-pathological features: Meta-analysis of E5194 and Ontario DCIS cohort studies. *First Author: Eileen Rakovitch, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Better tools are needed to estimate the risk of local recurrence (LR; DCIS or invasive) after breast-conserving surgery (BCS) for DCIS to inform treatment decisions. The DCIS Score (DS) was validated as a predictor of LR in E5194 and Ontario DCIS Cohort (ODC) after BCS without radiation (Solin,2013; Rakovitch,2015). We performed a meta-analysis (MA) combining data from E5194 and ODC with additional follow-up from E5194 adjusting for pertinent clinico-pathologic factors to provide refined prediction estimates of LR risk after BCS alone. **Methods:** The MA used data from E5194 and ODC. Patients with positive margins and multifocality were excluded. Identical Cox regression models were fit including age at diagnosis (<50, ≥ 50 yr), tumor size (1cm, >1cm), DCIS Score and year of surgery (before vs after 2000). Grade was not significant. MA was used to calculate precision-weighted estimates of 10 year LR risk by DS. **Results:** Combined cohort includes 773 pts (tamoxifen used in 20% E5194, 17% of ODC $>$ 65 yr). The DS and the clinico-pathologic variables age, tumor size and year provided independent prognostic information on 10 yr LR risk ($p \leq .009$). Hazard ratios from E5194 and ODC cohorts were similar for tumor size ≤ 1 vs. >1cm (1.45, 1.47), age ≥ 50 vs. <50 yr (0.61, 0.84) and surgery year after 2000 (0.67, 0.49). 10 yr LR risks by combinations of age, tumor size, and DS are detailed in Table. For patients ≥ 50 yr with tumors ≤ 1cm and low risk DS, the 10 yr LR risks range from 5.3-10.0%. A high risk DS is associated with a higher 10 yr predicted risk of LR in all subsets. 10 yr risk of contralateral BC was 5.4%. **Conclusions:** This MA provides refined estimates of 10 yr LR risk after BCS alone for DCIS. Adding clinico-pathologic factors to the DCIS Score provides enhanced prognostic LR risk estimates to guide individualized treatment decision-making.

		10 yr LR risk (Range) (%)		
Tumor Size (cm)	Age (yr)	Low Risk DS	Intermediate Risk DS	High Risk DS
≤1	≥50	7.2 (5.3-10.0)	11.3 (10.2-12.7)	14.6 (12.9-23.1)
	< 50	10.2 (7.4-13.9)	15.8 (14.1-17.4)	19.6 (17.7-30.7)
1.1-2.5	≥50	10.1 (7.3-12.6)	13.9 (12.8-15.6)	19.5 (15.8-28.7)
	< 50	14.5 (10.1-17.2)	18.9 (17.4-21.1)	23.2 (21.4-37.2)

529 Poster Session (Board #129), Sun, 8:00 AM-11:30 AM

Impact of DNA repair deficiency signature on outcomes in triple negative breast cancer (TNBC) patients treated with AC chemotherapy (SWOG S9313). *First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

Background: Biomarkers of response and resistance to adjuvant chemotherapy for TNBC are needed. Deficiency in DNA damage response (DDR) and repair pathways have been reported in TNBC and may impact response to chemotherapy. Aims: To investigate DNA damage response deficiency (DDRD) molecular signature, *BRCA1*mRNA expression and Tumor Infiltrating Lymphocytes (TILs) as prognostic markers in TNBC patients treated with adjuvant AC on S9313. **Methods:** S9313 accrued 3125 early stage BC patients to two alternative schedules of AC with no difference in outcomes between the two arms. We identified 425 (14%) patients with centrally determined TNBC with tissue availability. DDRD signature (44 gene signature, Almac Inc.) and *BRCA1*expression (NanoString nCounter) were performed on RNA isolated from pre-treatment FFPE tumor tissue. DDRD score was classified in quartiles. TILs evaluation was performed using previously described criteria. Markers were tested for prognostic effect on DFS and OS using Cox regression model with adjustment for randomized treatment assignment. **Results:** For 425 TNBC patients median age: 45 yrs, and 5 year DFS and OS = 74% and 82%, respectively. DDRD signature was successfully evaluated in 89.6% (381/425) but only 267 (62.8%) met 60% tumor content criterion for inclusion. DDRD score quartiles were associated with DFS (5 year DFS 59% & 82% in the lowest & highest quartiles respectively, $p = 0.0005$) and OS (5 year OS 74% and 86% in lowest and highest quartiles respectively, $p = 0.008$). *BRCA1* expression and TILs were successfully determined in 78% and 99% samples, respectively. *BRCA1*expression was not associated with DFS. TILs were associated with DFS (10% increase HR = 0.88; 95% CI 0.79-0.97; $p = 0.016$) and OS (HR = 0.84; 95% CI 0.74-0.94; $p = 0.0005$). DDRD score and TILs were highly correlated (Pearson = 0.62). In multivariate model of DFS including TILs and DDRD quartiles, only DDRD remains significant ($p = 0.018$). **Conclusions:** DDRD signature was prognostic in TNBC patients treated with AC chemotherapy and has the potential to be used as a selection criterion to identify TNBC patients whose prognosis is sufficiently poor to justify evaluation of alternative treatment.

530 Poster Session (Board #130), Sun, 8:00 AM-11:30 AM

Effects of age, immune landscape, and response to trastuzumab (H) in HER-2 positive (HER2+) breast cancer in NCCTG (Alliance)-N9831. *First Author: Aixa Elena Soyano, Mayo Clinic Florida, Jacksonville, FL*

Background: Therapeutic efficacy of H involves activation of the immune system.Age-dependent progressive deterioration of the immune response is referred as immunosenescence. In HER2+ breast cancer, the effects of aging and the ability of H to activate endogenous anti-tumor immunity is unknown. A previous report from HERA trial showed no significant increase in risk of early recurrence with age ($\leq$ or $>$ 40). We evaluated the long-term outcome of HER2+ patients (pt) related to age and immune landscape. **Methods:** 1,392 pt from N9831 trial were evaluated. Stromal tumor infiltrating lymphocytes (sTIL) were evaluated in H&E slides. Lymphocyte predominant breast cancer (LPBC) was defined as sTIL $\geq$ 50%. Molecular TIL (mTIL) and immune subset signatures were evaluated using NanoString research CodeSets. Cox proportional hazard ratio (HR) was used for analysis. **Results:** There were 1,111 (79.8%) pt $>$ 40 years old (yo) and 281 (20.2%) pt $\leq$ 40 yo. Younger age was significantly associated with hormone receptor positivity (p 0.00011) and luminal B subtype (p 0.011). With a median follow up of 10.6 years, there was no significant difference in long-term outcome among pt $\leq$ 40 vs. $>$ 40 yo who received H (HR = 0.88 (0.62-1.24), p = 0.45). Similar findings were observed when age was dichotomized at 50 and 60 yo. While there was no association between sTIL and age, a small but significant increase in mTIL CD45 expression with age (p 0.003) was observed. Similar small increases in cytotoxic cell (p 0.007) and T cell (p 0.015) immune scores were also observed with increasing age. Among pt who received chemotherapy alone, pt $>$ 40 yo with LPBC (n 55) had excellent outcome with 92.4% recurrence free survival (RFS) at 10 years. However, there was no significant difference in RFS among pt $\leq$ 40 yo with or without LPBC. **Conclusions:** Among pt treated with H, there was no significant difference in outcome related to age. In contrast to a decline expected from immunosenescence, we observed small but significant increases in mTIL signatures for total lymphocytes, cytotoxic, and T cell subsets. Among patients who received chemotherapy alone, our data suggested that pt $>$ 40 yo with LPBC had excellent prognosis, compared to pt $>$ 40 yo without LPBC.

531 Poster Session (Board #131), Sun, 8:00 AM-11:30 AM

Endocrine therapy non-persistence in young women with early-stage breast cancer. *First Author: Shoshana M. Rosenberg, Dana-Farber Cancer Institute, Boston, MA*

Background: The greatest age disparity in early stage breast cancer (BC) outcomes is in young women with hormone receptor positive (HR+) BC. While differences in biology may play a role, understanding the role of non-persistence (early discontinuation) with endocrine therapy (ET) is critical given the demonstrated efficacy of ET in this population. **Methods:** As part of a prospective cohort that enrolled women with BC diagnosed (dx) at age $\leq$40 between 2006-2016, we identified women with HR+, Stage I-III BC. Socio-demographic and treatment information, fertility concerns and confidence with the ET treatment decision were assessed by survey within 1 yr of dx. Medical record review was used to ascertain stage and HR status. Women who initiated ET but did not report taking tamoxifen or an aromatase inhibitor at 3 yrs post-diagnosis (or last follow-up if $<$3 yrs) were classified as non-persistent. Chi-square tests were used to compare categorical variables between persisters and non-persisters and stepwise multivariable regression to evaluate predictors of non-persistence. **Results:** In 538 women who initiated ET, median age at dx was 36; 10% were non-persistent. Discontinuation of ET was more likely in those who were less confident with their ET decision compared to those who were more confident (25/179, 14% vs 18/263, 7%, p=0.01). A greater proportion of women concerned about fertility discontinued vs. women not concerned (29/213,14% vs 25/319, 8%, p=0.03), and fertility concerns were associated with non-persistence in multivariable analyses (OR: 1.85, 95% CI 1.05-3.26, p=0.03). Age at dx, race, education, employment, financial comfort, marital status, parity, stage, chemotherapy and local therapy were not associated with non-persistence. **Conclusions:** A significant minority of women with HR+ BC discontinued ET within 3 yrs. The association between fertility concerns expressed soon after dx and non-persistence underscores a need to address psychosocial issues that can impact treatment decisions in young women. Strategies to reduce decisional conflict and increasing confidence with the choice to take ET, may influence persistence. Future work will evaluate the contribution of other factors (eg symptom burden) to non-persistence.

532 Poster Session (Board #132), Sun, 8:00 AM-11:30 AM

A population-based analysis of treatment and outcomes in 2,500 metaplastic breast cancer patients. *First Author: Cecilia Tuongquang Ong, Department of Surgery, Duke University Medical Center, Durham, NC*

Background: Metaplastic breast cancer (MBC) is a rare, aggressive variant that is often triple negative (TN). Current guidelines recommend use of standard receptor-based treatment for MBC despite evidence of chemoresistance. We sought to compare treatment patterns and outcomes of MBC and non-MBC. **Methods:** Women age > 18 with stage I-III MBC and non-MBC histology diagnosed from 2010-2013 were identified in the National Cancer Database. Kaplan Meier and multivariate Cox proportional hazards models were used to estimate MBC association with overall survival (OS). Subgroup analyses were conducted for (1) MBC patients only and (2) TN MBC and TN non-MBC patients. **Results:** 2451 MBC and 568,057 non-MBC patients were included. 70.3% of MBC were TN vs 11.3% of non-MBC ($p < 0.001$). 19.2% of MBC were luminal (i.e., ER+ and/or PR+, and HER2-). MBC presented with higher clinical T stage (cT4: 5.4% vs 1.8%) and grade (grade 3: 72.1% vs 29.7%) but was less frequently node-positive (19.1% vs 29.7%, all $p < 0.001$). A higher proportion of MBC patients were treated with mastectomy (59.0% vs 44.9%), axillary dissection (ALND, 35.2% vs 32.2%), and chemotherapy (74.1% vs 43.1%, all $p \leq 0.001$). 5-year OS was reduced among MBC vs non-MBC patients for both the entire cohort (72.7% vs 87.5%) and the TN-only analysis (71.1% vs 77.8%, both log-rank $p < 0.001$). Among MBC cases, TN subtype was not associated with worse OS than the luminal subtype (HR 1.16, $p = 0.28$). Chemotherapy (HR 0.69, $p = 0.004$) and/or radiotherapy (HR 0.52, $p < 0.001$) improved OS in MBC, and the proportional benefit of chemotherapy did not vary with pathological T or N stage (interaction $p > 0.05$ for both). Among TN patients, a higher proportion of TN MBC patients underwent mastectomy (58.4% vs 49.5%, $p < 0.001$), but in contrast to the full cohort, a lower proportion of TN MBC patients received chemotherapy (76.6% vs. 78.7%, $p = 0.008$) and ALND (35.2% vs. 38.2%, $p = 0.01$) vs TN non-MBC patients. **Conclusions:** MBC had worse OS vs non-MBC, and unlike other histologies, outcome was not driven by receptor status. Multimodal therapy improved outcomes. Further investigation into MBC tumor biology and the development of MBC-specific guidelines could potentially improve treatment standardization and outcomes.

533 Poster Session (Board #133), Sun, 8:00 AM-11:30 AM

Prognostic value of histopathology, stromal tumor infiltrating lymphocytes (sTILs) and adjuvant chemotherapy (AdjCT) in early stage triple negative breast cancer (TNBC). *First Author: Roberto Antonio Leon-Ferre, Mayo Clinic, Rochester, MN*

Background: Current guidelines define TNBC as complete absence of estrogen (ER) and progesterone receptor (PR), without HER2 amplification. However, the prognostic impact of clinical and histopathological factors, sTILs, and AdjCT in TNBC meeting these strict criteria is unknown. **Methods:** From a cohort of 9985 women who underwent upfront surgery for M0 breast cancer (BC) at Mayo Clinic Rochester from 1985-2012, 1159 pts with ER negative or low (≤10%) BC were identified for central ER/PR/HER2 staining and HER2 FISH (IHC2+ only) to select those with TNBC by modern definitions. Cox proportional hazards models were used to assess the impact of clinicopathological variables on invasive disease-free (IDFS) and overall survival (OS). **Results:** Tumors from 605 pts (median age 56.3 yrs) met criteria for TNBC (ER < 1%, PR < 1% and HER2 0, 1 or 2+ and FISH negative). 51% were T1, 65% N0, 88% grade 3, and 75% had Ki67 > 15%. Histologically, 39% were anaplastic, 26% invasive ductal, 16% medullary, 8% metaplastic, 6% apocrine and 5% others. Median sTILs was 20% (0-90%). 55% pts received AdjCT [21% anthracycline (A), 19% A + taxane, and 15% other]. Median follow-up for IDFS and OS were 7.4 and 10.6 yrs, respectively. Multivariate analyses demonstrated that higher N stage ($p < 0.01$), lower sTILs ($p = 0.01$) and no AdjCT ($p < 0.01$) were independently associated with worse IDFS and OS. Histology (medullary subtype) was associated with better IDFS in univariate (HR 0.56, 95% CI, 0.35-0.89) but not in multivariate analyses, once sTILs were accounted for. Among systemically untreated pts ($n = 182$), higher N ($p < 0.01$) and lower sTILs ($p = 0.04$) were associated with worse IDFS. For systemically untreated T1N0 pts ($n = 111$), the 5-yr IDFS was 70% (95% CI, 61-81) [T1a: 83% (95% CI, 63-100), T1b: 68% (95% CI, 52-88) and T1c: 67% (95% CI, 55-83)], compared to 78% (95% CI, 68-84) for T1N0 pts treated with AdjCT. **Conclusions:** In TNBC pts, N stage, sTILs and receipt of AdjCT were independently prognostic for IDFS and OS. sTILs remained prognostic for IDFS in systemically untreated TNBC. In N0 TNBC, the risk of recurrence or death was substantial in the absence of chemotherapy, even for those with T1 tumors.

534 Poster Session (Board #134), Sun, 8:00 AM-11:30 AM

Prospective study of magnetic resonance imaging (MRI) and multiparameter gene expression assay in ductal carcinoma in situ (DCIS): A trial of the ECOG-ACRIN Cancer Research Group (E4112). *First Author: Seema Ahsan Khan, Northwestern Memorial Hospital, Chicago, IL*

Background: Prior retrospective studies have evaluated breast MRI in DCIS, and prospective-retrospective biomarker studies have shown that the DCIS Score is prognostic for recurrence after BCS alone. E4112 is a prospective cohort study designed to assess the combined impact of breast MRI and DCIS Score on surgical and RT management. **Methods:** Women diagnosed with screen-detected DCIS on core biopsy, if BCS eligible, underwent breast MRI. Those remaining so following MRI and related biopsies, with no invasive disease, underwent BCS. If final surgical margins were ≥2 mm, the DCIS lesion was submitted for DCIS Score assay. Women with low DCIS Score (≤39, LS) were advised that RT could be avoided; RT was recommended to those with high/intermediate (H/I) scores. The primary objective was to estimate the fraction converting to mastectomy (Mx) following MRI. Secondary objectives included estimation of re-operation rates after first BCS, and DCIS Score distribution.A sample size of 333 evaluable women would allow estimation of Mx rate of 12% with 95% confidence interval 9-16%. **Results:** 334 enrolled women had completed surgery; the first surgical procedure was Mx in 54 (16.2%) and BCS in 280 (83.8%), of whom 62 (22.1%) required at least one re-excision, and 11 (3.9%) converted to Mx. DCIS Scores were obtained on 171 patients who completed BCS, of whom 82 were LS and 89 were H/I. Demographics were similar between the two groups, other features will be reported. Only 7/82 (8.5%) of the LS group received RT, whereas 82/89 (92.1%) of the H/I group received RT. Of the 98 BCS patients who did not qualify for DCIS Score-based therapy, 23 had invasive disease, 34 had final surgical margins < 2 mm, and 13 had both. There was insufficient tissue for DCIS Score in 11, and 17 did not complete follow-up. **Conclusions:** In this study, among DCIS patients who were BCS-eligible following MRI, total mastectomy rate was 19.5%; re-excision rate was 22.1% for women who had BCS. Approximately half had low DCIS Scores, and RT recommendations based on the DCIS Score were acceptable to most women. Clinical trial information: E4112.

535 Poster Session (Board #135), Sun, 8:00 AM-11:30 AM

Long-term outcome of breast cancer patients diagnosed ≤40 years according to breast cancer subtype in the absence of adjuvant systemic therapy: The PARADIGM initiative. *First Author: Gwen Dackus, Division of Molecular Pathology, Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Young age at breast cancer diagnosis is considered a poor prognostic factor. As a result, many treatment guidelines advice adjuvant systemic treatment for young patients. Answering prognostic questions on young patients has therefore become a challenge. The PARADIGM (PAtients with bReast cAncer DIaGnosed preMenopausally) project aims to assess the long-term outcome of women diagnosed with breast cancer ≤40 years in the absence of adjuvant systemic therapy, using real world data from the nationwide Netherlands Cancer Registry (NCR) coupled with tissue biobanking. **Methods:** All women ≤40 years, diagnosed in the Netherlands between 1989-2000 with a primary invasive, histologically proven, $T_{any}N_0M_0$ breast cancer, without adjuvant systemic treatment were identified through the NCR. Back then N_0 patients were considered low risk and did not receive adjuvant systemic treatment. Tissue specimens were revised by a team of dedicated breast pathologists. Cox regression was performed to estimate hazard ratios for recurrence-free (RFS) and overall survival (OS) according to immunohistochemical (IHC) subtype. Analyses were adjusted for grade, pathological T-stage, histological subtype and radiotherapy. **Results:** We included 2310 patients with a mean follow-up of 15.4 years (range 0-25 years). OS for the whole cohort was 68% and RFS 58.4% at 25 years. In total 740 deaths and 1043 recurrences were observed. Hormone receptor (HR)+/HER2+ patients had a significantly worse OS when compared to HR-HER2+ patients (adjusted Hazard Ratio 1.58; 95% confidence interval 1.05-2.38; p=0.029). No difference was observed between HR-HER2+ and the triple negative and HR+/HER2- subgroups at 25-years. RFS was similar for all IHC subtypes. **Conclusions:** In this large cohort of non-adjuvant systemically treated young breast cancer patients with long-term follow-up HR+/HER2+ patients have a significantly worse survival when compared to triple negative, HR-/HER2+ and HR+/HER2- patients. The latter three subtypes have similar OS at 25 years. Future molecular studies have been planned to distinguish the favorable from the unfavorable prognostic patients.

536 Poster Session (Board #136), Sun, 8:00 AM-11:30 AM

Independent validation of stromal uPA in archived tumor samples from the prospectively randomized ABCSG8 trial to provide level 1b evidence for a prognostic value of uPA immunohistochemistry in endocrine-treated postmenopausal breast cancer patients. *First Author: Christian F. Singer, Medical University of Vienna, Department of Obstetrics and Gynecology, Comprehensive Cancer Center, Vienna, Austria*

Background: We have recently demonstrated that urokinase Plasminogen Activator (uPA), together with its inhibitor PAI-1, have prognostic value in hormone-receptor positive early breast cancer, and can be measured in FFPE archived tumor samples. We have now aimed to validate the prognostic role of uPA protein expression in FFPE archived tumor samples in an independent cohort of endocrine-treated breast cancer patients. **Methods:** 303 post-menopausal women with hormone receptor–positive, early breast cancer who had received 5 years of endocrine therapy in the prospectively designed ABCSG-08 trial, and in whom FFPE tumor tissue was available, were included in this analysis. Stromal uPA and PAI-1 protein expression was evaluated by immunohistochemistry and correlated with distant recurrence-free survival (DRFS) and overall survival (OS). **Results:** Stromal uPA was detected in 132 of 297 tumors (44.4%), and 74 out of 269 samples (27.5%) exhibited stromal PAI-1, while co-expression of both proteins was found in 48 of 294 (16.3%) samples. Neither uPA nor PAI-1 expression were associated with tumor size, age, nodal status, grading, or receptor status. Patients whose tumor stroma expressed uPA protein were more likely to have a shorter DRFS (adjusted HR for relapse: 2.78; 95% CI 1.31-5.93; p=0.008 Cox regression analysis) and OS (adjusted HR for death: 1.29; 95% CI 0.86-12.50; p=0.161) than women without uPA expression. No such association was observed for PAI-1 and for the uPA/PAI1 ratio. After a median follow-up of 5.6 years women with uPA-positive tumors experienced a significantly shorter DRFS (93.3% vs 84.8%; p<0.013 log rank test) and tended to have a worse OS (83.0.4% vs 77.3%; p=0.106) compared to women with uPA negative tumors. **Conclusions:** By confirming the clinical utility of stromal uPA IHC in archived breast cancer samples from an independent prospective randomized trial, we now provide level 1b evidence for a prognostic role of stromal uPA in women with endocrine-responsive early breast cancer.

537 Poster Session (Board #137), Sun, 8:00 AM-11:30 AM

The performance of the 21-gene assay standard cutpoints of 18 and 31 in HR+, HER2- invasive breast cancer (BC), while waiting for TAILORx mid-range recurrence score results. *First Author: Dave P. Miller, Genomic Health, Redwood City, CA*

Background: The Recurrence Score (RS) was shown in NSABP B-20 to predict chemotherapy (CT) benefit for RS ≥31 and no CT benefit for RS <18. The TAILORx results for RS <11 (NEJM 2015) reported excellent outcomes with no opportunity for CT to add additional benefit. As we await TAILORx results for RS 11-25, we characterized BC specific mortality (BCSM) for RS groups (cutoffs of 11, 18, 25, and 31) in the population-based SEER study of pts treated based on RS. **Methods:** RS results were provided to SEER registries per their methods (npj Breast Cancer 2016). Pts diagnosed (Jan 2004 - Dec 2012) with NO HR+ HER2- negative BC, and no prior malignancy were eligible. BCSM estimates by CT use were computed using standard cutpoints of 18 and 31 and TAILORx cutpoints of 11 and 25. **Results:** Among 49,681 with a RS, 9,486 (19%) had RS <11, 17,988 (36%) had RS 11-17, 14,541 (29%) had RS 18-25, 3,805 (8%) had RS 26-30, and 3,861 (8%) had RS ≥31. Reported CT use and 5-y BCSM increased with increasing RS. For pts with both RS <11 and RS 11-17, CT use was uncommon and 5-y BCSM was low regardless of CT use. For pts with RS 18-25, CT use was more common and the 5-y BCSM was about 1% regardless of CT use. For pts with RS of 26-30 or ≥31, CT was common, and lower 5-y BCSM was observed with CT reported yes than with CT reported no or unknown. **Conclusions:** Pts in real-world clinical practice with RS <11, consistent with TAILORx, and pts with RS 11-17 have low 5-y BCSM with limited CT use, supporting hormonal therapy alone for pts with RS <18. The high end of the TAILORx mid-range (18-25) also showed good 5-y BCSM both with and without CT, highlighting the importance of the randomized results of TAILORx.

	CT Reported No or Unknown		CT Reported Yes	
RS	**N (%)**	**5-y BCSM (95% CI)**	**N (%)**	**5-y BCSM (95% CI)**

538 Poster Session (Board #138), Sun, 8:00 AM-11:30 AM

Which patient characteristics drive treatment decisions in elderly patients with early stage hormone receptor–positive breast cancer? *First Author: Sacha Satram-Hoang, Q.D. Research, Inc., Granite Bay, CA*

Background: Hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) is the most common biologic subtype of breast cancer (BC). We examined treatment patterns and outcomes associated with adjuvant or neoadjuvant therapy among elderly patients (pts) in the US. **Methods:** The analysis included 18,470 first primary HR+HER2- BC pts from the linked SEER-Medicare database. Pts were diagnosed with Stage I-III disease between 1/1/2007-12/31/2011, ≥66 years, continuously enrolled in Medicare Parts A/B in the year prior to diagnosis, enrolled in Part D in the year after diagnosis, and underwent BC surgery ≤6 months after diagnosis. Time-varying Cox proportional hazards regression assessed overall survival adjusting for pt characteristics. Date of last follow-up was 12/31/2013. **Results:** There were 13,670 (74%) pts treated with hormonal therapy +/- chemotherapy and 4,800 (26%) untreated. Compared to treated pts, untreated pts were older, had earlier stage, lower grade, smaller tumors, poorer performance, higher comorbidity, and less genomic testing for risk of recurrence (p<0.0001). In a multivariate analysis, increasing age, stage, tumor size, tumor grade, comorbidity score and poor performance were significantly associated with higher mortality risks, while use of genomic testing was associated with a lower risk of death. The Cox model showed a 48% higher risk of death in untreated compared to treated pts (HR=1.48; 95% CI=1.35-1.61). Even in a subset of 8,967 pts with stage I disease, tumor size <2.0cm and grade 1/2; untreated pts had a 22% higher risk of death compared to treated pts (HR=1.22; 95% CI=1.05-1.41). **Conclusions:** Patients who are older with favorable disease characteristics (earlier stage, smaller tumor, lower grade) are less likely to be treated and have a higher risk of death compared to pts who received adjuvant or neoadjuvant therapy. The unmet need among elderly BC pts remains, suggesting that age should not deter guideline-based therapy.

	Treated N=13670	Untreated N=4800

539 Poster Session (Board #139), Sun, 8:00 AM-11:30 AM

A propensity score analysis exploring the impact of adjuvant chemotherapy (aCT) in a multi-center series of resected early stage pure invasive lobular breast carcinoma (ILC). *First Author: Luisa Carbognin, University of Verona, Verona, Italy*

Background: Patients (pts) resected for early breast cancer are assigned to receive aCT according to international guidelines based upon immunophenotype and clinical/pathological features, regardless of the histotype, given the lack of prospective data for ILC. Thus, the magnitude of the benefit of aCT for ILC is still not sizable. The aim of this analysis was to investigate the effect of aCT in a multi-center series of early stage pure ILC. **Methods:** Clinical-pathological data of consecutive pts affected by pure ILC, undergone surgery at 3 Italian institutes, were correlated with disease-free and overall survival (DFS/OS) using a Cox model. A propensity score analysis was performed to evaluate the prognostic impact of aCT. Kaplan-Meier curves were compared with Log-Rank analysis. **Results:** Data from 739 pts were gathered (median age 57 years (yrs); Luminal/Triple-Negative/HER2 pos.: 98%/1.6%/0.4%). At median follow-up of 78 months, 5-/10-yrs DFS and OS were 79.4%/66.0% and 91.4%/76.5%, respectively. Tumor-size according to TNM (T, HR 1.34, 95% CI 1.04-1.72, *p=0.025*) and lymph-node (N) status (HR 2.39, 95% CI 1.47-3.89, *p<0.0001*) were independent predictors for DFS at multivariate analysis. T (HR 1.87, 95% CI 0.99-3.54, *p=0.05*), N status (HR 3.24, 95% CI 1.69-6.22, *p<0.0001*), Ki67 (HR 2.48, 95% CI 0.95-6.42, *p=0.06*), and age (HR 2.23, 95% CI 1.16-4.30, *p=0.016*) were predictors for OS. A significant prognostic effect of aCT upon OS was found after adjusting for independent factors with the propensity score method, as shown in the table below. Particularly, aCT significantly prolongs OS and DFS in pts with T >1, with an absolute difference of 17%/35% and 15%/13% at 5 and 10 yrs, respectively (*p=0.003* and *p=0.04*). OS was longer for pts with positive N (*p=0.02*), Ki67 >4% (*p=0.01*) and grading >1 (*p=0.01*). **Conclusions:** Despite the retrospective nature of this analysis, the propensity score analysis indicates that pts with ILC may significantly benefit from aCT in terms of long-term survival, particularly for larger and more aggressive tumors.

Outcome	**Category**	**5-yrs (%)**	**10-yrs (%)**	***Log-Rank***
DFS	aCT	84.3	75.6	*p=0.33*
	No aCT	84.7	64.0	
OS	aCT	94.3	87.4	*p=0.002*
	No aCT	88.7	64.5	

540 Poster Session (Board #140), Sun, 8:00 AM-11:30 AM

Longer follow-up on cardiac safety and distant disease free survival of dose-dense doxorubicin and cyclophosphamide followed by paclitaxel and trastuzumab in patients with early-stage HER2-positive breast cancer. *First Author: Rui Wang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We previously reported the cardiac safety results and distant disease-free survival (DDFS) on a phase 2 trial of dose-dense (dd) doxorubicin and cyclophosphamide (AC) followed by paclitaxel (T) and trastuzumab (H) in patients with early stage, human epidermal growth factor receptor 2 (HER2)-positive breast cancer. The incidence of congestive heart failure (CHF) was 1.4% both at a median follow-up of 2 and 7 years. Here, we report updated CHF and DDFS rates with longer follow-up. **Methods:** Patients were enrolled with HER2 overexpressed (immunohistochemistry 3+) or amplified (fluorescent in situ hybridization ratio $>$ 2.0) disease, regardless of size or nodal status, and baseline left ventricular ejection fraction (LVEF) of $>$ 55%. Patients (pts) received dd AC (60/600 mg/m2) q 2 weeks (w) x 4 $\rightarrow$T (175 mg/m2) q 2 w x 4 with H (loading dose 4 mg/kg $\rightarrow$ 2 mg/kg q w during T $\rightarrow$ 6 mg/kg q 3 w for rest of 1 year); pegfilgrastim was administered after each chemotherapy cycle. LVEF monitoring with multigated acquisition scan occurred at baseline, months 2 (after AC), 6, 9, and 18 (after therapy completion). **Results:** From January 2005 to November 2005, 70 pts were enrolled; 2 (3%) and 68 (97%) were treated in neoadjuvant and adjuvant settings, respectively. In 68 pts treated in adjuvant setting, 40 (60%) and 27 (40%) had node-positive and node-negative disease, respectively. The median age was 49 years old (range 27-72); 55 (79%) had hormone-receptor positive disease, 11 (16%) had hypertension, and 21 (30%) had left sided radiation. The median baseline LVEF was 68% [range, 55%-81%]). With a median follow-up of 10.9 yrs, there was no additional CHF event. Therefore, the cumulative incidence of CHF remains to be 1.4% (95% confidence interval [95% CI], 1.36%- 7.7%). The 9 and 10 year DDFS rates were 89% (95% CI, 78%-94%) and 87% (95% CI 75%-93%), respectively. **Conclusions:** Longer follow-up of this study has demonstrated that ddAC $\rightarrow$TH is associated with a low risk of CHF and promising DDFS in patients with early-stage HER2-positive breast cancer.

541 Poster Session (Board #141), Sun, 8:00 AM-11:30 AM

Recent time trends in chemotherapy use and oncologists' chemotherapy recommendations for early-stage, hormone receptor-positive breast cancer. *First Author: Allison W. Kurian, Stanford School of Medicine, Stanford, CA*

Background: Advances in tumor genomic profiling enable increasingly precise estimates of the benefit of adjuvant chemotherapy in early-stage breast cancer. However, little is known about how chemotherapy use, medical oncologists' (MO) perspectives and recommendations have changed in recent years, particularly in key clinical subgroups such as node-negative and node-positive. **Methods:** We surveyed 5,080 women (70% response rate), newly diagnosed with breast cancer in 2013-2015 and accrued through two population-based SEER registries (Georgia and Los Angeles), about their MOs' chemotherapy recommendations and whether they received chemotherapy. Using patient report, we identified 470 attending MOs and surveyed them (n=310, 66% response) about approaches to chemotherapy recommendation, using node-negative and node-positive case scenarios. We evaluated factors associated with chemotherapy receipt over time using multi-level logistic regression. **Results:** The analytic sample was 2,926 patients with stages I-II, estrogen receptor-positive, HER2-negative breast cancer. Chemotherapy use declined to 21% from 34% during the study period (2013-2015, p$<$.001). For node-positive patients, chemotherapy use declined to 64% from 81% and for node-negative/micrometastasis patients to 14% from 27%. Based on patient report, MOs' recommendations for chemotherapy declined during the study period to 32% from 45% (p$<$.001). Recommendations reported by MOs were generally guideline-concordant. MOs were much more likely to order tumor genomic profiling when patient preferences were discordant with recommendations [67%, standard error (SE) 3% versus 18% (SE 2%) without discordance], and they adjusted chemotherapy recommendations based on patient preferences and genomic profiling results. **Conclusions:** For both node-negative/micrometastasis and node-positive patients, chemotherapy receipt and oncologists' recommendations for chemotherapy declined markedly in recent years. The results of ongoing clinical trials of genomic profiling will be essential to confirm the quality of this approach to breast cancer care. Funded by NCI P01CA163233.

543 Poster Session (Board #143), Sun, 8:00 AM-11:30 AM

Clinical outcomes in ER+ HER2-negative breast cancer (BC) where treatment decisions incorporated the 21-gene recurrence score (RS): Elderly (≥70 yrs) vs younger patients (Pts). *First Author: Salomon M. Stemmer, Davidoff Cancer Center, Tel Aviv, Israel*

Background: Elderly BC pts are generally undertreated, despite evidence suggesting that they may benefit from adjuvant chemotherapy (CT). We compared treatments/clinical outcomes in elderly vs younger Clalit Health Services (CHS) pts undergoing RS testing. **Methods:** This exploratory analysis of the CHS registry included BC pts with N0/N1mi/N1 disease who were RS-tested from 1/2006 (CHS approval of the test) through 12/2010 (N0) or 12/2011 (N1mi/N1). Medical records were reviewed to verify treatments/recurrences/survival. **Results:** The analysis included 458 elderly and 2052 younger pts, with a median (range) follow-up of 5.7 (0.9-9.6) and 6.1 (0.1-10.3) yrs, respectively. In the elderly/younger pts, median age was 73/58 yrs, 48%/52% had grade 2 tumors, median tumor size was 1.6/1.5 cm, 70%/72% were N0 and 30%/28% were N1mi/N1. RS distribution ($<$18, 18-30, ≥31) among elderly pts was 56%, 33%, and 11%, respectively, compared to 49%, 41%, and 10%, respectively, in younger pts. In pts with RS 18-30 and RS≥31, CT use was significantly lower in the elderly (*P*$<$.001). Kaplan-Meier estimates for 5-yr distant recurrence and BC death risk are presented (Table). **Conclusions:** In elderly pts, the proportion of those with RS≥31 was very similar to younger pts; however, overall CT use was significantly lower. Within each RS group, there was no statistically significant difference in clinical outcomes between the age groups; though, numerically, in RS 18-30 pts, outcomes were worse in the elderly. In pts with RS$<$18, outcomes were excellent regardless of age and despite very low rates of CT use.

* Distant recurrence risk/BC death across RS groups were compared using log-rank test.

544 Poster Session (Board #144), Sun, 8:00 AM-11:30 AM

An NCDB analysis of trends in male breast cancer from 2004-2009 and 2010-2014. *First Author: Esther Dubrovsky, NYU Langone Medical Center, New York, NY*

Background: To examine the trends in clinicopathologic features, treatment, and survival of male breast cancer (MBC), utilizing the National Cancer Data Base (NCDB). **Methods:** MBC patients entered in the NCDB from 2004-2009 were compared with those from 2010-2014 for demographics, stage at diagnosis, tumor characteristics, treatment type, and overall survival (OS). Male patients were also compared to female patients from the same time periods. Statistical analysis included Pearson's chi-square test. **Results:** Of 2,047,868 breast cancer cases, a total of 19,409 (0.95%) men were available for analysis. The group of MBC patients from 2004 to 2009 included 9,790 men with a median age of 65. The group from 2010 to 2014 included 9,619 men with a median age of 66. In the later group there was a decreased rate of DCIS, increased rate of invasive ductal carcinoma, and increased rate of hormone positive tumors. Among the earlier and later MBC groups, 24% vs. 27% of patients underwent lumpectomy. Of these, 61% vs 68% received post-lumpectomy radiation, respectively. Patients in the later group (2010-2014) were more likely to receive adjuvant hormonal therapy (61% vs. 84%, p $<$ 0.0001). MBC patients were older than female patients (65 vs. 61 years, p $<$ 0.0001), had larger tumors (20mm vs. 16mm, p $<$ 0.0001), slightly later stage at diagnosis, and more likely to undergo mastectomy (74 vs. 42%, p $<$ 0.0001). MBC patients also had higher rates of hormone positive tumors, but lower rates of adjuvant hormonal therapy (55% vs. 58%, p $<$ 0.0001). The OS for male vs. female patients in the 2004-2009 groups was 66% vs. 77% (median follow-up 73.9m vs 80.4m) respectively. Similarly, in the 2010-2014 groups, survival was 84% vs. 90% (median follow-up 33.85m vs 35.91m), respectively. **Conclusions:** Although men have higher rates of hormone positive tumors, they are less likely to receive adjuvant hormonal therapy. There was a significant trend over time towards more standard therapies in men, such as post-lumpectomy radiation and hormonal therapy use. There has been an improvement of OS in men which mirrors that in women. The disparities in outcomes between male and female patients, however, still require further investigation.

546 Poster Session (Board #146), Sun, 8:00 AM-11:30 AM

Breast Cancer Index (BCI) prognostic and predictive classification in older versus younger patients with early-stage HR+ breast cancer (BC) and correlation with clinical risk factors. *First Author: Yuan Yuan, City of Hope, Duarte, CA*

Background: Older patients with HR+ BC may present distinct challenges for treatment decision-making. BCI is a validated gene expression assay for pts with early stage HR+ BC that provides 2 results: BCI Predictive, based on HoxB13/IL17BR (H/I ratio), reports a prediction of likelihood of benefit from extended endocrine therapy (EET); BCI Prognostic, based on the combination of H/I and proliferation-based genes, reports individualized risk of late distant recurrence (DR). Here, the predictive and prognostic value of BCI results across the aging spectrum (< 64y, 65-74y, ≥75y) and correlation with clinical risk factors were examined. **Methods:** The BCI Clinical Database for Correlative Studies is an IRB-approved de-identified database that contains > 50 clinicopathologic and molecular variables from cases submitted for BCI in clinical practice (N = 14,463). Clinicopathologic variables were abstracted from pathology reports, and were available for a subset of cases. Chi-squared tests were used to compare BCI results between age groups and clinical subsets. **Results:** Analyses included LN- pts (N = 3,395): median age 59.1y; 5.5% ≥75y (N = 188), 24.0% 65-74y (N = 814), 70.5% ≤64y (N = 2,393). BCI Prognostic had a wide distribution of individual risk assessments in all age groups. The proportion of pts classified as high risk was similar between age groups (48.4%, 48.4% and 49.8% in ≥75y, 65-74y and ≤64y; p = 0.76). The proportion of pts with high risk results increased with increasing tumor size and grade in all age groups (P < 0.05 for all). Notably, in pts ≥75y, BCI identified 31.9% of T1a/b and 21.1% of Grade 1 tumors as high risk of late DR. BCI Predictive (H/I) also identified similar proportions as High H/I across age groups (42.0%, 41.8%, and 40.6% in ≥75y, 65-74y, and ≤64y; p = 0.81). Similar proportions of pts ≥75y were identified as high H/I across size and grade subsets (P = 0.702, P = 0.193, respectively). **Conclusions:** BCI identifies pts with high risk disease and who may benefit from EET across the aging spectrum. Individualized decisions for EET also must include life expectancy, competing comorbidities and potential toxicities from therapy.

547 Poster Session (Board #147), Sun, 8:00 AM-11:30 AM

Adjustments in relative dose intensity (RDI) for FECD chemotherapy in breast cancer: A population analysis. *First Author: Zachary William Neil Veitch, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: Reductions in RDI of adjuvant chemotherapy for breast cancer (BC) has been associated with inferior survival. However, earlier studies may be confounded by uncharacterized BC subtype(s) (TNBC, HER2+) and non-taxane chemotherapy regimens (CMF, AC). This retrospective study evaluates survival (DFS/OS) outcomes for patients receiving RDI reductions for FECD adjuvant chemotherapy in Alberta, Canada. **Methods:** Patients with stage I-III, ER +/-, HER2- BC receiving adjuvant FECD chemotherapy from 2007-2014 were identified using the Alberta Cancer Registry. RDI of individual chemotherapeutics (cycle 1-6) were recorded. Average RDI was stratified by <85% vs ≥85% of total dose. Subgroup analysis for early (cycle 1-3) versus late (cycle 4-6) RDI reductions were evaluated. Events (recurrence/death) from any cause were identified. **Results:** FECD patients (n=1304) receiving an average RDI <85% (range 25-84%) compared to ≥85% demonstrated a significant decline in DFS (79% vs 85%; p<0.01) and OS (82% vs 89%; p<0.01). Early reductions (any) compared to no reduction in RDI were correlated with inferior DFS (77% vs 86%; p<0.01) and OS (79% vs 90%; p<0.01). Late reductions in RDI did not affect DFS/OS. Proportions of TNBC were non-significant for comparative cohorts. Significantly more N0 and N1-3 patients were seen in the any and no early reduction cohort respectively. **Conclusions:** In high risk BC patients, average RDI <85% is correlated with reduced DFS/OS for FECD. Early (FEC) compared with late (docetaxel) reductions in RDI are correlated with inferior survival. This data suggests that where possible, total (<85%) and early (FEC) dose reductions should be avoided in patients receiving adjuvant FEC-D chemotherapy.

An estimation model for Oncotype Dx score using routine clinical and pathological parameters. *First Author: Rossana Esther Ruiz Mendoza, Scientific & Academic Direction, Oncosalud - AUNA, Lima, Peru*

Background: Oncotype Dx(ODX) prognosticates the risk of recurrence and predicts the benefit of adjuvant chemotherapy in estrogen-receptor-positive breast cancer (BC). However, its cost makes it prohibitive for many health care systems. Our objective is to develop a model using routine clinical and pathological parameters to estimate ODX high risk category to guide adjuvant chemotherapy decisions. **Methods:** We retrospectively reviewed ODX and pathology reports from 190 early BC patients (2014 to 2016) in a specialized cancer center. Variables were selected through a multiple linear regression model. Coefficients of statistically significant variables were used to build an equation. Its results were divided into 2 estimated risk categories. ODX RS was also divided into 2 categories; above or below 25 (cut-off in TAILORx and RxPONDER). The final locked model was independently validated in 57 patients. **Results:** Among the tested variables, tumor size (pT), progesterone receptor (PR), Ki67 and Elston-Ellis grade were significantly associated with ODX RS (Table 1). The linear predictor is: (0.2544 x pT) – (0.0739 x PR) + (0.0861 x Ki67) + (5.4232 x Elston grade). The threshold score for this equation was set on 13 (median value) to discriminate low and high estimated risks. The correct classification rate (CCR) for the training and validation sets was 60% and 56%, respectively. CCR for high risk was 72% and 87% in the training and validation sets, respectively. **Conclusions:** An equation based on readily available variables correctly classified more than half of cases. Although the overall CCR is modest, our equation is remarkably useful for high risk cases requiring chemotherapy. With further validation, our model could provide a clinically useful estimation of high risk at lower cost.

Variable	Coefficient	S.E.	t-value	p-value

Toxicity of extended adjuvant aromatase inhibitors therapy in postmenopausal breast cancer patients: A systematic review and meta-analysis. *First Author: Hadar Goldvaser, Rabin Medical Center, Beilinson Hospital, Davidoff Center, Toronto, ON, Canada*

Background: Aromatase inhibitors (AI) are a gold standard adjuvant endocrine therapy for postmenopausal women with breast cancer. A number of randomized trials (RCTs) have reported modest improvements in breast cancer outcomes from extending treatment with AI beyond the initial 5 years after diagnosis. However, less in known about the toxicity of extended AI compared with no therapy. **Methods:** We conducted a systematic review of MEDLINE to identify RCTs that compared extended AI to placebo or no treatment. The search was supplemented by a review of abstracts from the American Society of Clinical Oncology and San Antonio Breast Cancer Symposium meetings between 2013 and 2016. Odds ratios (ORs), 95% confidence intervals (CI), absolute risks, and the number needed to harm (NNH) associated with one adverse event were computed for prespecified safety and tolerability outcomes including cardiovascular disease, bone fractures, second cancers (excluding new breast cancer), treatment discontinuation due to adverse events and death without recurrence. **Results:** Seven trials comprising 16349 patients met the inclusion criteria. Longer treatment with AI was associated with increased odds of cardiovascular disease (OR = 1.18, 95% CI 1.00-1.40, P=0.05; NNH = 122) and bone fractures (OR = 1.34, 95% CI 1.16 - 1.55, P < 0.001; NNH = 72). Compared to control, longer AI therapy was associated with a higher odds of treatment discontinuation due to adverse events (OR = 1.45, 95% CI 1.25 - 1.68, P < 0.001; NNH = 20). Longer AI therapy did not influence the odds of second cancers (OR = 0.93, 95% CI 0.73-1.18, P = 0.56). There was a numerical excess of death without recurrence with longer AI therapy, but this was not statistically significant (OR = 1.11, 95% CI 0.9 - 1.36, P = 0.34). **Conclusions:** Longer durations of AI use are associated with increased cardiovascular events and bone fracture. There is a numerical, but non-statistically significant excess of deaths without breast cancer recurrence among patients receiving longer AI therapy. These data should be taken into account when considering extended adjuvant AI therapy for breast cancer patients.

550 Poster Session (Board #150), Sun, 8:00 AM-11:30 AM

Disparities in multigene signature testing and its impact on adjuvant therapy in early stage breast cancer. *First Author: Maris S. Jones, John Wayne Cancer Institute, Santa Monica, CA*

Background: Commercially available prognostic multigene signature tests (PMT) have been available for over a decade to guide adjuvant therapy in early stage breast cancer. This study explores persistent disparities in the availability of PMT and how results influence the use of adjuvant therapy. **Methods:** Females > 18 years of age with newly diagnosed, primary, Stage I-III, ER positive, HER2-neu negative breast cancer that did not receive neoadjuvant therapy between 2006-2014 were captured from the National Cancer Database (NCDB) participant user file. Univariate and multivariate analyses identified factors associated with utilization of PMT as well as receipt of adjuvant chemotherapy for patients with PMT risk stratification. **Results:** Of 574,921 eligible females, 130,297 (22.66%) received PMT. Almost all patients that had PMT had pathologically negative (pN0 = 83%) or 1-3 positive LNs (pN1 = 16%). Controlling for tumor features, patients least likely to have PMT were of lower socioeconomic status, uninsured, not White non-Hispanic, < 40 or > 70 years of age, and treated at community hospitals or in the Western region (all $p < 0.001$). Very few patients with PMT results actually received adjuvant chemotherapy (0.64% of 92,235). Of this small group, younger patients (ages 18-49) those with less education (OR = 1.37, 95%CI:1.07-1.76), positive lymph nodes, and larger tumors (OR = 1.62, 95%CI:1.37-1.91) were more likely to receive adjuvant chemotherapy whereas patients with PR positive tumors (OR = 0.33, 95%CI:0.18-0.60) and those treated at academic facilities (OR = 0.81, 95%CI:0.68-0.96) were less likely to receive adjuvant chemotherapy after controlling for competing factors. Intermediate (OR = 5.34, 95%CI: 4.42-6.45) or high risk (OR = 32.65, 95%CI: 25.74-41.43) PMT scores had the greatest impact on receipt of adjuvant chemotherapy regardless of nodal status. **Conclusions:** Common socioeconomic and racial/ethnic disparities exist for PMT testing, though inappropriate use (high T or N stage) was minimal. Since PMT results strongly influenced recommendation of adjuvant therapy, decreasing disparities and making PMT available to all patients that are deciding on adjuvant therapy should be a priority.

551 Poster Session (Board #151), Sun, 8:00 AM-11:30 AM

Clinical utilization of Breast Cancer Index (BCI) for late recurrence risk assessment and prediction of extended endocrine therapy (EET) benefit in early stage HR+ breast cancer. *First Author: Reshma L. Mahtani, Sylvester Comprehensive Cancer Center University of Miami Health System, Deerfield Beach, FL*

Background: Randomized trials demonstrated a modest (3-5%) absolute benefit from EET in patients (pts) with early stage HR+ breast cancer (BC), but also a risk of toxicities. BCI is a validated gene expression-based assay that provides 2 results: BCI Prognostic, based on the algorithmic combination of HoxB13/IL17BR (H/I ratio) and a set of proliferation-based genes, reports individualized risk of late distant recurrence (DR); BCI Predictive, based on H/I alone, reports a prediction of high vs low likelihood of benefit from EET. The objective of this study was to assess clinical and pathologic patient characteristics, prognostic and predictive assay results, and physician testing patterns in >14,000 clinical cases. **Methods:** The BCI Clinical Database for Correlative Studies is a de-identified database developed under an IRB approved protocol that contains >50 clinicopathologic and molecular variables from cases submitted for BCI in clinical practice. Clinicopathologic variables were abstracted from pathology reports, and were available for a subset of cases. **Results:** Across all pts (N=14,463), median age was 58.2y (range: 23-92y; 73.9% ≥50y). The majority were Stage I (47.3% IA, 3.5% IB, 29.1% IIA, 14.1% IIB, 6% III). Cases were 29%, 51%, and 20% Grade 1, 2, and 3, respectively. Most pts were ER+/PR+ (87.7%) or ER+/PR- (11.3%); 11.3% were HER2+. The majority of cases (55.7%) were ordered 4-6y postdiagnosis, with 23.1% >6y, 14.4% between 1-4y, and 6.8% <1y postdiagnosis. In LN- pts (n=3395), BCI Prognostic identified 50.6% as low risk for late DR vs 49.4% as high risk, while BCI Predictive (H/I) classified 41.0% as high vs 59.0% as low likelihood of benefit. In LN+ pts tested with the BCIN+ Prognostic algorithm (BCI + size/grade, n=818), 77.3% were classified as high risk vs 22.7% as low risk, while BCI Predictive (H/I) classified 44.6% and 55.4% as high vs low likelihood of benefit. **Conclusions:** Findings from this large cohort characterize utilization of BCI in clinical practice for pts with early-stage, HR+ BC. BCI stratification of pts with high risk and high likelihood of benefit from EET may facilitate selection of pts for prolonged regimens.

552 Poster Session (Board #152), Sun, 8:00 AM-11:30 AM

Effect of denosumab on bone mineral density (T-score classification of −1.0 to −2.5) in postmenopausal Japanese women receiving adjuvant aromatase inhibitors for nonmetastatic breast cancer. *First Author: Katsuhiko Nakatsukasa, Department of Endocrine and Breast Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan*

Background: Adjuvant aromatase inhibitor (AI) therapy is well established in postmenopausal women with hormone receptor-positive breast cancer, but such therapy is associated with bone loss and increased fracture risk. Denosumab, a fully human monoclonal antibody against receptor of nuclear-κB ligand, was previously proven to protect against AI-induced bone loss. In Japan, however, the efficacy of denosumab in the treatment of AI-associated bone loss has not been proven in a prospective study. **Methods:** This non-randomized prospective study was conducted at four institutions in Japan. we prospectively evaluated the bone mineral density (BMD) of the lumbar spine and bilateral femoral neck in hormone-receptor positive clinical stageI–IIIA, postoperative postmenopausal breast cancer patients who were scheduled for treatment with AI as adjuvant endocrine therapy or during AI adjuvant therapy. They received supplemental calcium, vitamin D and subcutaneous denosumab 60mg (n=103) every six months. At enrollment, all patients were required to have evidence of low bone mass, excluding osteoporosis. The primary endpoint was percentage change in lumbar spine BMD from baseline to month 12. The secondary endpoint was percentage change in bilateral femoral neck BMD from baseline to month 12. This is the first trial where the right and left femoral neck BMD are measured separately. **Results:** We enrolled 103 patients between November, 2014 to October, 2016. At 12 months, lumber spine BMD increased by 4.7 %. The patients who were administered prior AI therapy (n=60) had a 4.8 % increase, and the patients without prior AI therapy (n=40) had a 4.6 % increase. At 12 months, the right and left femoral neck BMD increased by 2.9 % and 2.0 %, respectively. Hypocalcemia ≥ grade2, osteonecrosis of the jaw (ONJ) and non-traumatic clinical fracture were absent in this study. **Conclusions:** Twice-yearly treatment with denosumab was associated with consistently greater gains in BMD among Japanese women receiving adjuvant AI therapy, regardless of whether prior AI therapy was administered. Clinical trial information: UMIN000013863.

553 Poster Session (Board #153), Sun, 8:00 AM-11:30 AM

Long term cardiac outcomes and anthracycline exposure in breast cancer survivors: A retrospective cohort data linkage and competing risks analysis. *First Author: Kelly Rust, NHS Lothian, Edinburgh, United Kingdom*

Background: Anthracycline chemotherapy is used frequently in adjuvant breast cancer treatment but there is clinical trial evidence of cardiac toxicity. Attempts to quantify this risk in routine care have been limited by follow up time & confounding factors. The aim of this project was to exploit rich Scottish NHS datasets for this purpose. **Methods:** Patients treated surgically for stage I-III invasive breast cancer between 2000 & 2010 were identified from a local cancer database (Edinburgh Cancer Centre). Outcomes were captured by linkage to the Scottish Morbidity & death Records. Follow-up was until March 2016. The primary outcome was a cardiac event or cardiac death, identified from coding. Analysis used the Latouche approach (estimating cause-specific hazards & sub-distribution hazards) for the primary outcome & the competing risks of death from breast cancer & death from other causes. Results were adjusted for age, deprivation (SIMD), co-morbidity (Charlson), year of diagnosis, side of radiotherapy, cancer stage, grade, ER & HER 2 status. **Results:** 4080 patients were identified, 1658 received an anthracycline containing regime, 297 received non-anthracycline chemotherapy & 2125 received no chemotherapy. A total of 33946 women years were analysed. During median follow up of 8.2 years there were 448 cardiac events & 559 breast cancer deaths. After adjustments there was no association between anthracycline use & cardiac outcomes (HR 0.9, 95% CI 0.67-1.21). There was an increased risk of breast cancer death (HR 1.66, 95% CI 1.28-2.16).Age & Charlson score were associated with an increased cardiac risk. Stage & grade were statistically associated with breast cancer death. **Conclusions:** No increased risk of cardiac events was seen in women treated with anthracyclines, they can be safely used in carefully selected patients. This data suggests selection may be over-cautious, a lower threshold for treatment may lead to improved breast cancer outcomes. Rich routine health datasets & appropriate analysis methods make outcomes monitoring feasible in Scotland. Oncologists are skilled at assessing both cardiac risk factors & breast cancer risk.

554 Poster Session (Board #154), Sun, 8:00 AM-11:30 AM

Role of axillary node dissection after mastectomy with positive sentinel nodes. *First Author: Tristen Sinae Park, Duke University, Durham, NC*

Background: The ACOSOG Z11 trial demonstrated that sentinel lymph node biopsy (SLNB) alone was safe for women with early stage node positive cancer undergoing breast conservation therapy with radiation. Little data exists regarding management of this population undergoing mastectomy. The purpose of our study is to determine the benefit of axillary lymph node dissection (ALND) or SLNB with adjuvant radiation in patients with 1-3 positive SLN after mastectomy. **Methods:** Using data from the National Cancer Database (2004-2014), we performed a retrospective review of patients who underwent mastectomy and were clinically node negative at presentation, but were found to have 1-3 positive nodes on pathology. Patients were categorized as undergoing SLNB alone (1-5 nodes examined) or ALND (≥8 nodes examined). Patients who received SLNB without ALND were further categorized by receipt of radiation treatment (RT). Patients with either neoadjuvant chemotherapy or stage IV disease were excluded. **Results:** Of 42,371 patients, 10.0% had SLNB+RT, 22.4% had SLNB alone, and 67.5% had ALND. Median age of the cohort was 58 years and median tumor size 2.3 cm. Median follow up was 4.1 years. After adjustment for covariates including age at diagnosis, tumor size, chemotherapy, endocrine therapy and receptor status, SLNB+RT had comparable overall survival to ALND (HR = 1.06, p = 0.52), but SLNB alone was found to be associated with a 25% increase in hazard of death compared to ALND (HR = 1.25, 95% CI 1.11-1.41, $p < 0.001$). **Conclusions:** In clinically node negative patients with 1-3 positive sentinel nodes treated with mastectomy, SLNB alone was associated with a significantly increased risk of all-cause mortality compared to ALND or SLNB+RT. These results suggests that ALND may be avoided in these patients in the setting of adjuvant radiation, possibly avoiding the morbidity associated with axillary lymphadenectomy.

555 Poster Session (Board #155), Sun, 8:00 AM-11:30 AM

Randomized surgical multicenter trial to evaluate the usefulness of lymphoscintigraphy (LSG) prior to sentinel node biopsy (SLNB) in early breast cancer: SenSzi (GBG80) trial. *First Author: Sherko Kummel, Breast Unit, Kliniken Essen-Mitte, Essen, Germany*

Background: It is not clear whether SLNB performed with LSG is necessary to reliably detect sentinel lymph nodes (SLN) in breast cancer. The omission of LSG might offer an accelerated preoperative workflow, cost reduction, and the opportunity for developing innovative, safe detection strategies. **Methods:** Patients with cN0 early breast cancer or extensive/high grade DCIS received standard radiolabeled colloid LSG and SLNB. Patients were randomized 1:1 to either conducting SLNB with the performing surgeon knowing the preoperative LSG pictures and results or without knowledge of the LSG results. Since the false negative rate (FNR) of SLNB correlates with the number of harvested SLN, our primary endpoint was the average number of histologically detected SLN per patient in both treatment arms in a non-inferiority design. An average number of 2.7 SLN with a standard deviation of 1.8 was assumed. LSG of all patients were collected postoperatively for central review. **Results:** Between May 2014 and October 2015 n = 1198 patients were randomized in 23 participating breast centers. Baseline characteristics were well-balanced between the treatment arms. Modified intention-to-treat analysis (n = 1163) confirmed the omission of LSG. The average number of histologically detected SLN was 2.207 with LSG and 2.258 without. The range for the one-sided 95% CI for the difference between the arms was (-0.18, +infinity), i.e. above the pre-specified non-inferiority margin of -0.27. Secondary endpoints were analyzed to rule out differences in reliable detection of nodal metastases. Rates of nodal positive disease as identified by SLNB (Odds ratio (OR) 1.005, 95%CI (0.759, 1.33), p = 0.972) and rates of completion axillary dissection (OR 0.984, 95% CI (0.567, 1.71), p = 0.954) in the two treatment arms and in specific subgroups showed no statistically significant differences. **Conclusions:** Our results support the hypothesis that SLNB is equally effective irrespective of the knowledge of preoperative LSG results. We therefore suggest performing SLNB without LSG to accelerate the preoperative workflow, reduce costs, and improve the comfort for the patients. Clinical trial information: NCT02481128.

556 Poster Session (Board #156), Sun, 8:00 AM-11:30 AM

Pembrolizumab (pembro) + chemotherapy (chemo) as neoadjuvant treatment for triple negative breast cancer (TNBC): Preliminary results from KEYNOTE-173. *First Author: Peter Schmid, Barts Cancer Institute, London, United Kingdom*

Background: Pembro has shown efficacy and acceptable safety in pts with previously treated metastatic TNBC. The phase Ib KEYNOTE-173 study (NCT02622074) evaluated pembro + chemo as neoadjuvant therapy for locally advanced TNBC. We present cohorts A and B. **Methods:** Women aged ≥18 y with locally advanced, nonmetastatic TNBC; ECOG PS 0/1; and no prior chemo, targeted therapy, or immunotherapy within 12 mo were eligible. Dosing in A was single-dose pembro followed by 4 cycles of pembro Q3W + nab-paclitaxel (Np) weekly followed by 4 cycles of pembro + doxorubicin + cyclophosphamide Q3W. Dosing in B was the same as in A but with carboplatin Q3W added to pembro + Np. Concentrations were pembro 200 mg; doxorubicin 60 mg/m^2; cyclophosphamide 600 mg/m^2; Np 125 mg/m^2 in A, 100 mg/m^2 in B; and carboplatin AUC 6 (1 cycle = 21 d). DLTs were assessed at cycles 1-3 and 6-7. Dose levels were deemed toxic if ≥3 of the first 6 pts or ≥4 of 10 pts had DLTs. Surgery was 3-6 wk after treatment completion/discontinuation. Primary end points were safety and recommended phase 2 dose of pembro combined with chemo. Key efficacy end points were pathological CR (pCR) rate, defined as ypT0/Tis, ypN0, and ypT0 ypN0, and ORR (RECIST v1.1, investigator). pCR analyses included all pts. **Results:** By Jan 6, 2017, 10 pts were in each cohort. Median age was 53 y (range 32-71); most pts had invasive ductal histology (90%), primary tumor stage ≥T2 (90%), and nodal involvement (75%). DLTs (myelosuppression) occurred in 7 pts (3 in A, 4 in B) and were unrelated to pembro. Gr 3-4 treatment-related AEs (TRAEs) occurred in 8 pts in A and 10 pts in B; none were fatal. One pt in A and 2 pts in B discontinued for a TRAE (2 ALT elevations with pembro; 1 DVT with chemo). Overall ORR (CR+PR) before surgery was 80% (90% CI, 49-96) in A and 100% (90% CI, 74-100) in B. ypT0/Tis pCR rate was 70% (90% CI, 39-91) in A and 100% (90% CI, 74-100) in B; ypT0 ypN0 pCR rate was 50% (90% CI, 22-78) in A and 90% (90% CI, 61-100) in B; and yT0/Tis ypN0 pCR rate was 60% (90% CI, 30-85) in A and 90% (90% CI, 61-100) in B. **Conclusions:** Preliminary data suggest that pembro + chemo as neoadjuvant therapy for TNBC results in manageable toxicity and promising antitumor activity. Clinical trial information: NCT02622074.

557 Poster Session (Board #157), Sun, 8:00 AM-11:30 AM

Primary operation in synchroneous metastasized invasive breast cancer patients: First oncologic outcomes of the prospective randomized phase III ABCSG 28 POSYTIVE trial. *First Author: Florian Fitzal, Medical University Vienna, Vienna, Austria*

Background: The ABCSG 28 Posytive trial compared primary surgery versus primary systemic therapy without surgery in stage IV breast cancer patients. The primary aim was to investigate whether immediate resection of the primary tumor followed by standard systemic therapy improves median survival compared with no surgical resection (NCT01015625). The trial had to be stopped early due insufficient recruitment. **Methods:** Untreated stage IV breast cancer patients with the primary in situ were randomly assigned to either surgery of the primary versus no surgery followed by systemic therapy between 2011 and 2015 in 15 breast health centers in Austria. Systemic therapy included endocrine therapy or chemotherapy. Patients were routinely followed every 3-6 months. Primary endpoint was median survival. **Results:** 90 patients (45 with surgery, 45 with primary systemic therapy without surgery) were randomized. Stratification criteria were age, endocrine responsiveness, her2 expression, planned first line therapy and bone only versus other metastases. Patients in the surgery arm had more cT3 breast cancer (22% versus 7%) and more cN2 staging (16% versus 4%) as well as more her2 positive breast cancer cases (27% versus 18%). The median follow up was 37.5 months and immunohistochemical subtype analysis showed 9% basal like, 22% her2 positive, 51% luminal A and 13% luminal B cancers. Both groups were well balanced regarding first line treatment (endocrine versus chemotherapy) however, there were more taxane treated patients in the no surgery group (24.4 versus 15.6%). The median survival in the surgery arm was 34.6 months versus 54.8 months in the no surgery arm without statistical significance (HR 0.691 CI 0.358 – 1.333; p=0.267). Time to distant progression was insignificantly longer in the no surgery arm (surgery arm 13.9 versus no surgery arm 29.0 months). **Conclusions:** This first analysis of the prospective randomized phase III trial POSYTIVE-ABCSG-28 demonstrated no benefit in overall survival for immediate surgery of the primary in de novo stage IV breast cancer patients. Clinical trial information: NCT01015625.

Contemporary breast conservation patient outcomes for ductal carcinoma in situ and margins < 2 mm. *First Author: Audree Tadros, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Recent national consensus guidelines regarding optimal margin width for the management of DCIS have been published; however, controversy remains for managing margins <2mm. The relationship between margin width and locoregional recurrence (LRR) was determined in a contemporary cohort of patients. **Methods:** 1504 patients with DCIS undergoing definitive breast conserving surgery from 1996 to 2010 were analyzed for clinical and pathologic characteristics from a prospectively managed comprehensive academic cancer center database. Cox proportional hazard models were used to examine the relationship between margin width (<2mm or ≥2mm) and LRR by adjuvant radiation therapy (RT). Patients with positive margins (n=11) were excluded. **Results:** Overall, 3.4% of patients had a LRR at a median follow-up of 8.7 years. Univariate analysis of age, family history, grade, tumor size, comedonecrosis, RT, adjuvant hormonal therapy, ER status, and margin width found younger age (< 40 yr, p=0.02), no RT (n=299, p=0.005), and margin width <2mm (n=138, p=0.005) to be associated with LRR. The association between margin width and LRR differed by adjuvant radiation therapy status (p=0.02 for the interaction). There was no statistical significant difference in LRR for patients with margins <2mm vs ≥2 mm who received RT, (10-year LRR 6.0% vs 3.2%, respectively; HR 1.5, 95% CI 0.5-4.2, p=0.48). For patients who did not receive RT (n=299), those with margins < 2 mm were significantly more likely to develop a LRR than those with margins ≥2mm (10-year LRR 35.7% vs. 4.6%, respectively; HR 7.2, 95%CI 2.6-19.4, p=0.0001). **Conclusions:** In patients with <2mm margins receiving adjuvant radiation therapy, there is no difference in locoregional recurrence when compared to patients with ≥2mm margins. Additional surgery for wider margins of resection are not routinely justified in this group of patients but should be obtained for patients with <2mm margins who forego radiotherapy.

560 Poster Session (Board #160), Sun, 8:00 AM-11:30 AM

Systematic analysis of parameters predicting pathological axillary status (ypN0 vs. ypN+) in patients converting from cN+ to ycN0 through primary systemic therapy (PST). *First Author: Cornelia Liedtke, University of Schleswig-Holstein Campus Luebeck, Lübeck, Germany*

Background: Optimization of axillary staging in patients converting from cN+ to ycN0 through PST is needed. The aim of this analysis was to develop a nomogram predicting the probability of ypN+ after PST based on clinical/pathological parameters. **Methods:** Patients converting from cN+ to ycN0 through PST from a prospective study (SENTINA arm C) were included. Univariate/multivariate analyses were carried out for 14 clinical/pathological parameters to predict ypN+ using logistic regression models. Odds ratios and 95% confidence intervals were reported. Model performance was assessed by leave-one-out cross-validation (LOOCV at .5 cut-offs) and ROC analyses. Calculations were performed using the SAS Software (Version 9.4). **Results:** 553 patients were assessed. Stepwise backward variable selection based on a multivariate analysis of all significant parameters resulted in a model (5M, Table, N = 369 evaluable) including ER (3.81; 2.25-6.44), multifocality (2.22; 1.26-3.92), LVI (9.16; 4.68-17.90), detection of SLN after PST (.50; .26-.95) and ycT (1.03; 1.01-1.06). In LOOCV, this model had an area under the curve of .81. Multivariate analysis of parameters available preoperatively showed an association between ypN0/ypN+, ER and ycT. Full subset selection resulted in a model (2M, N = 414) containing only ER (4.36; 2.80, 6.81) and ycT (1.04; 1.02, 1.07). **Conclusions:** A prediction model including parameters evaluable before/after definitive surgery resulted in a nomogram with acceptable accuracy. Limitation to parameters evaluable before surgery (i.e. ER, ycT) showed reduced accuracy that was comparable/superior to accuracy of using individual parameters. Since tumor biology was the strongest parameter in our models, we hypothesize that modern tumor biologic parameters such as gene expression profiling might optimize prediction of axillary status after PST improving patient counseling.

	Accuracy (%)	Sensitivity (%)	Specificity (%)	Positive Predictive Value (%)	Negative Predictive Value (%)
5M (N = 369)	72.6	73.4	71.8	75.0	70.0
2M (N = 414)	67.9	81.4	52.6	66.1	71.3
ER (N = 414)	67.9	80.5	53.6	66.3	70.7
ycT (N = 414)	58.2	64.5	51.0	60.0	55.9

561 Poster Session (Board #161), Sun, 8:00 AM-11:30 AM

Axillary management in early breast cancer: Surgeon attitudes in a population-based study. *First Author: Monica Morrow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The ACOSOG Z0011 trial established the safety of omitting axillary dissection (ALND) for patients with 1–2 sentinel node (SN) metastases having breast-conserving therapy (BCT) to reduce treatment-related morbidity. Little is known about surgeon uptake of this practice. **Methods:** Women with stage I and II breast cancer diagnosed between 7/13–8/15 (n=3729) reported to the Los Angeles and Georgia SEER registries were surveyed about 2 months after diagnosis. All attending surgeons identified by the patients (n=489) were sent a questionnaire and 77% (n=377) responded. Pathology reports for SN positive patients are under review. **Results:** Mean surgeon age was 54 years, 25% were female, and median years in practice was 21. 49% and 63% endorsed ALND for Z0011 eligible patients with 1 or 2 SN macrometastases, respectively. Surgeons were classified as low (n=92), selective (n=178), or high (n=91) users of ALND based on responses to case scenarios with SN involvement ranging from isolated tumor cells in 1 SN (12% would do ALND) to macrometastasis in 3 SNs (92% would do ALND). 93% of high-use surgeons would perform ALND for any SN macrometastasis vs 40% of selective surgeons and 1% of low-use surgeons (p<.001). High-use surgeons were older, male, saw fewer breast cancer patients, and were less likely to discuss cases in tumor board (Table). High-ALND users were substantially less likely to endorse BCT margins of no ink on tumor (40%) than selective (63%) or low users (83%; p<.001). **Conclusions:** Wide variation exists in acceptance of Z011 results with one-quarter of surgeons endorsing routine ALND. Surgeons favoring ALND also endorse wider margins for BCT, suggesting an overall more aggressive surgical approach. Lower breast volume and lack of tumor board participation identify surgeons who should be targeted for educational interventions.

Surgeon characteristics.

	Low ALND	Selective ALND	High ALND	p-value
Number	92	178	91

562 Poster Session (Board #162), Sun, 8:00 AM-11:30 AM

What drives overtreatment? Surgeon and radiation oncologist views on omission of adjuvant radiotherapy for elderly women with early stage breast cancer. *First Author: Dean Alden Shumway, University of Michigan, Ann Arbor, MI*

Background: Although trials have shown no survival advantage and only a modest improvement in local control from adjuvant radiotherapy after lumpectomy in older women with stage I, ER+ breast cancer, radiotherapy is commonly administered, raising concerns about overtreatment. Therefore, we sought to evaluate physician attitudes, knowledge, communication, and recommendations in this scenario. **Methods:** We mailed a survey to a national sample of 713 radiation oncologists and 879 surgeons between June to October 2015. Of these, 913 responded (57%). We assessed physicians' attitudes, knowledge of pertinent risk information, and responses to clinical scenarios. **Results:** In patients age > = 70 with stage I, ER+ breast cancer treated with lumpectomy and endocrine therapy, omission of radiotherapy was felt to be unreasonable by 40% of surgeons and 20% of radiation oncologists (p < 0.001). Many surgeons (29%) and radiation oncologists (10%) erroneously associated radiotherapy in older women with improvement in survival. Similarly, 32% of surgeons and 19% of radiation oncologists tended to substantially overestimate the risk of locoregional recurrence in older women with omission of RT. In a scenario with an 81-year-old with multiple comorbidities, 31% of surgeons and 35% of radiation oncologists would still recommend radiotherapy. On multivariable analysis, erroneous attribution of a survival benefit to radiotherapy (OR 6.2; 95% CI 3.9-9.8) and overestimation of remaining life expectancy (OR 6.5; CI 4.2-9.9) were strongly associated with the opinion that radiotherapy omission is unreasonable. **Conclusions:** Many radiation oncologists and surgeons continue to consider omission of radiotherapy as substandard therapy. A sizeable proportion of surgeons overestimate radiotherapy's benefits and consider omission of radiotherapy to be an unreasonable departure from the standard of care, suggesting that surgeon involvement in decisions about radiotherapy omission may be a key factor in reducing overuse of aggressive care in this setting.

563 Poster Session (Board #163), Sun, 8:00 AM-11:30 AM

Evaluation of simplified lymphatic microsurgical preventing healing approach (SLYMPHA) for the prevention of breast cancer-related clinical lymphedema after axillary lymph node dissection. *First Author: Tolga Ozmen, University of Miami, Department of Surgical Oncology, Miami, FL*

Background: Lymphedema (LE) is a serious complication of axillary lymph node dissection (ALND) with an incidence rate of 16%. Lymphatic Microsurgical Preventing Healing Approach (LYMPHA) has been proposed as an effective adjunct to ALND for the prevention of LE. This procedure however requires microsurgical techniques. The aim of this study was to assess the efficiency of Simplified-LYMPHA (SLYMPHA) in preventing LE in a prospective cohort of patients. **Methods:** All patients, undergoing ALND with or without SLYMPHA between January 2014 and December 2016 were included in the study. SLYMPHA is a slightly modified and simplified version of LYMPHA. It is performed by the operating surgeon performing the ALND. One or more lymphatic channels identified by reverse arm mapping are inserted using a sleeve technique into the cut end of a neighboring vein. During follow-up visits, tape-measuring limb circumference method was used to detect clinical LE. Demographic, clinical, surgical and pathologic factors were recorded. The incidence of clinical LE was compared between ALND with and without SLYMPHA. Univariate and multivariate analysis were used to assess the role of other factors in the appearance of clinical LE. **Results:** 406 patients were included in the study. SLYMPHA procedure was attempted in 81 patients and was completed successfully in 90% of patients. Early complication rates were similar between patients who underwent SLYMPHA and who did not (4% vs. 4.13%; p = 0.948). Median follow-up time was 15±13.73 [1-32] months. Patients, who underwent SLYMPHA, had a significantly lower rate of clinical LE both in univariate and multivariate analysis (3% vs 19%; p = 0.001; OR 0.12 [0.03-0.5]). Excising > 22 lymph nodes and a co-diagnosis of diabetes were also correlated with higher clinical LE rates on univariate analysis, but only excising > 22 lymph nodes remained to be significant on multivariate analysis. **Conclusions:** SLYMPHA is a safe and relatively simple method, which decreases incidence of clinical LE dramatically. It should be considered as an adjunct procedure to ALND for all patients during initial surgery.

565 Poster Session (Board #165), Sun, 8:00 AM-11:30 AM

Prediction of radiation therapy response in breast cancer patients. *First Author: Divya Arora, Baylor Scott and White Hospital, Temple, TX*

Background: While radiation portals are tailored to a patient's unique anatomy and the selection of systemic agents routinely employs biomarker data, the selection of radiotherapy based on a patient's tumor biology is not routinely utilized in breast cancer. The purpose of this study was to identify which genetic markers are possible predictors for local recurrence as a surrogate for radiation response. **Methods:** We identified 200 patients who received radiotherapy for breast cancer. Selected tumor markers included: Androgen receptor (AR), Hypoxia Inducible Factor 1-α (HIF-1), Phosphotidylinosotol-4,5-bisphosphate 3-kinase (PI3K), and Interleukin 13 (IL-13). Biomarkers were analyzed in terms of "extent" and "intensity" on a scale of 0-3 and scored by 2 separate pathologists. The primary endpoint of local recurrence (LR) & secondary endpoint of overall survival were analyzed using Kaplan-Meier survival curves, log-rank test for differences, and Cox regression models. **Results:** Median follow up was 7.98 years. At 5 years, the rate of LR was 92.6% and overall survival was 89.4%. On multivariate Cox regression analysis, a one unit increase in IL-13 extent increased the hazard of LR by 73%. A one unit decrease in AR extent increased the hazard of LR by 134%. The hazard of death increased 3.2 times for each unit increase in HIF1 extent. The hazard of death increased 1.5 times for each unit increase in PI3K extent. PI3K extent and intensity was increased, and AR extent and intensity was decreased in triple negative breast cancer (TNBC) (n = 68) vs non-TNBC ($p < 0.0001$). African Americans had a 4.2 times hazard of LR vs Caucasians. **Conclusions:** Expression of IL-13 was associated with a higher risk of LR; expression of AR was associated with decreased LR. These two markers may be instrumental in predicting radiation response. If this study is validated, cancers that express more IL-13 may require higher doses or targeted therapy. In contrast, those cancers expressing AR may not require as aggressive therapy. Lastly, PI3K and HIF1 α expression were significant predictors of worse overall survival. The clinical implications of these biologic markers are significant as they may help to guide biologically-driven, personalized breast cancer radiotherapy.

566 Poster Session (Board #166), Sun, 8:00 AM-11:30 AM

Locoregional surgery of the primary tumor in stage IV breast cancer patients. *First Author: Ying Wang, Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Existing guidelines lack clear recommendations for the role of locoregional treatment for the primary tumor in women with stage IV breast cancer. We aimed to compare the effectiveness of locoregional surgery with no surgery of the primary tumour in stage IV breast cancer patients. **Methods:** Eligible studies were randomized clinical trials (RCTs) that investigated the effect of locoregional surgery versus no surgery of the primary tumour in stage IV breast cancer patients. The primary outcome was overall survival (OS), measured as hazard ratios (HRs). Secondly outcomes included 2-year and 3-year OS, expressed as odds ratios (ORs). Meta-analyses and trial sequential analysis (TSA) were conducted. Quality was evaluated using the GRADE. **Results:** Data were included from four RCTs involving 767 participants, including 377 who underwent locoregional surgery and 390 who with no surgery. The median follow-up was 28.6 months (95% confidence interval (CI) 24.1 to 33.9). In a meta-analysis of these trials, the low-quality evidence indicated that locoregional surgery versus no surgery did not significantly affect OS (HR = 0.87, 95% CI 0.59 to 1.29, $P = 0.490$), 2-year OS (OR = 1.23, 0.66 to 2.30, $P = 0.510$), or 3-year OS (OR = 1.08, 0.94 to 1.25, $P = 0.263$). TSA showed that more trials were needed before reliable conclusions could be drawn regarding in both 2-year and 3-year OS. Across the subgroup analysis of OS, we found the moderate-quality evidence that locoregional surgery followed by chemotherapy versus chemotherapy alone resulted into a significantly improved survival (HR = 0.65, 95% CI 0.49–0.87, $P = 0.004$); but no statistically significant difference was identified in term of response to chemotherapy with or without locoregional surgery (HR = 1.06, 95% CI 0.83–1.36, $P = 0.632$). **Conclusions:** The current evidence suggests that locoregional surgery followed by chemotherapy, compared with chemotherapy alone, was beneficial for prolonging OS in patients with stage IV breast cancer, but surgery did not impact OS among patients who have responded to chemotherapy.

567 Poster Session (Board #167), Sun, 8:00 AM-11:30 AM

The combination of preoperative computed tomography lymphography and intraoperative fluorescence imaging navigation for sentinel lymph node biopsy of early breast cancer patients. *First Author: Hajime Abe, Breast Center, Bell Land General Hospital, Sakai, Japan*

Background: This study investigated a usefulness of the combination of fluorescence imaging and computed tomography lymphography (CTLG) for sentinel lymph node biopsy (SLN) biopsy of early breast cancer patients. **Methods:** Between January 2013 and August 2016, 350 breast cancer patients without clinical evidence of lymph node metastasis were treated. Preoperaitve CTLG was performed using 64-row multidetector CT injected contrast agent. The contrasted lymph route and SLN were identified in reconstructed three-dimensional imaging. The SLN spot was indicated by CT laser light navigator system. We established typical pattern of the lymphography: stain defect of SLN, stagnation of lymphatic route for preoperative diagnosis of metastatic SLN. Intraoperative fluorescence images were obtained using the fluorescence imaging system (pde-neo). After dye mixed indocyanine green and indigocarmin was injected, lymphatic route was observed with fluorescence images. SLN biopsy was performed referring to the point by axillary compression technique by plastic device. **Results:** The median age of the 350 patients was 59 (range 28 – 90) years old. CTLG could visualize lymphatic route and accurately identify SLN in 336 (96.0 %) and 343 (98.0 %) cases, respectively, whereas fluorescence imaging identified successfully lymphatic route and SLN in all patients. Lymphatic routes of CTLG were completely consistent with those of fluorescence imaging. The number of SLN identified by CTLG was significantly lower than that by fluorescence imaging (1.1 vs. 1.6, $p<0.01$). Fifty of 350 patients had metastatic SLN pathologically, and 11 of them had micrometastases of SLNs. The accuracy for metastatic diagnosis of SLN using CTLG without micrometastasis was 84.1 %, sensitivity was 82.1 % and specificity was 84.3 %. The positive predictive value was 40.5 % and negative predictive value was 97.3 %. **Conclusions:** This combined navigation method of fluorescence imaging and CTLG revealed more easy and effective to detect SLN than fluorescence imaging alone. In addition, the information from CTLG would be helpful for the preoperative diagnosis of SLN metastasis.

568 Poster Session (Board #168), Sun, 8:00 AM-11:30 AM

Hypofractionated, normofractionated and intraoperative breast irradiation: Long term cosmetic outcome based on photographic evaluation. *First Author: Tarek Ellethy, Department of Radiotherapy and Nuclear Medicine, South Egypt Cancer Institute, Assiut University, Assiut, Egypt*

Background: Photographic documentation of breast changes after breast radiotherapy (RT) is a helpful tool to both subjectively and objectively evaluate cosmesis. The aim of this study was to evaluate cosmesis in breast cancer patients after receiving hypofractionated whole breast RT (HF-WBRT), normofractionated (NF-WBRT), intraoperative RT (IORT) or combined WBRT/IORT. **Methods:** After excluding cases with missing or inadequate photos from three prospective clinical trials, KOSIMA, TARGIT-A & TARGIT-E, 155 and 205 cases were included in a subjective analysis while 132 and 185 cases were included in an objective analysis postoperatively and after 2 years respectively. Subjective evaluation was done by 9 observers using the Harvard scale. Objective evaluation was done by assessing percentage breast retraction (pBRA). Based on the treatment received, patients were divided into 5 groups: 1. HF-WBRT 40/2,67 Gy ± Boost, 2. NF-WBRT 50/2 Gy ± Boost, 3. NF-WBRT 56/2 Gy, 4. IORT 20 Gy, 5. IORT 20 Gy+WBRT 46/2 Gy. **Results:** Subjectively, the rate of excellent-good cosmesis was 92% postoperatively and 84% after 2 years while objectively it was around 56% at both time points. At 2 years, no significant difference was observed between the 5 treatment groups with the subjective excellent-good cosmesis being 82%, 80%, 92%, 83%, 85% ($p = 0.546$) and objective being 56%, 61%, 52%, 53%, 50% ($p = 0.883$) in groups 1-5 respectively. Factors possibly affecting cosmesis at 2 years were examined. No significant difference was observed with age, smoking, BMI, chemotherapy, hormone therapy or type of axillary surgery. Significantly better cosmesis was observed with upper outer tumor location compared to other quadrants ($p < 0.0001$) also with a ratio of excised/total breast volume under 20% ($p < 0.0294$). **Conclusions:** Cosmetic outcome after hypofractionated and IORT was similar to normofractionated breast RT. After 2 years of treatment, cosmetic deterioration remained acceptable, overall < 10%. Tumor location and excised breast volume were the only factors significantly affecting cosmetic outcome.

569 Poster Session (Board #169), Sun, 8:00 AM-11:30 AM

Trends in rates of modified radical mastectomies and bilateral mastectomies in unilateral breast cancer. *First Author: Ajaz Bulbul, Kymera Independent Physicians, Carlsbad, NM*

Background: Women with unilateral breast cancer (BC) without genetic predisposition have a low risk for local and contralateral recurrence with breast conservation surgery (BCS) and adjuvant treatment. We aimed to study the pattern of surgical care across centers in rural New Mexico and its correlation to clinical outcomes. **Methods:** We retrospectively evaluated 533 patients with Stage 1-3 BC diagnosed between January 1989 to October 2015. Clinical Outcomes with BCS, sentinel lymph node dissection (SLND), simple mastectomy (SM), modified radical mastectomy (MRM) and Bilateral Mastectomy (BM) were studied. Descriptive statistics were performed to describe the proportion of surgery types. Predictors of clinical outcomes were evaluated by multivariate logistic regression. **Results:** Out of 533 patients, 510 (82%) had early stage (0-3) resectable BC. Among these, 48% (246/510) had either MRM (209/510) or BM (37/510). MRM was performed in 3% of stage 0 (6/209), 23% (49/209) stage I, 46%(97/209) of stage II and 27% (57/209) of Stage III patients. Overall, the rate of SLND was 42% among Early stage Breast cancer. Of 41 patients treated with bilateral mastectomy, 10 were positive for BRCA mutation, 6 for family history and 3 for contralateral disease. Median age of BM was 53 +12 y. The local recurrence rate was 8.8% (45/510), and metastatic recurrence rate was 15.5% (79/510). Lymphedema rate was 9.2% (47/510). Using MRM as reference, the Odds Ratio (OR) for lymphedema after BM and BCT were 2.15 (95% CI, 0.84-5.50) and 0.58 (0.28-1.22), respectively. With 9.6 years of median follow up, the predictive probabilities of lymphedema after BCT, SM, MRM and BM were 1%, 4%, 9% and 18%. The OR for local recurrence in women with BCT were 1.46 (95^{th} C/I: 0.72-2.95), SM 0.27 (0.03-2.13), BM 2.06 (95^{th} C/I:0.70-6.06). **Conclusions:** Less BCT and more aggressive procedures are being performed, and the latter is associated with more lymphedema. No significant differences were noted in local recurrences. Presence of a genetic mutation was not the sole indicator of BM's in our patient population. There is a need for evidence-based shared decision-making and surgical management of breast cancer, especially in a rural community setting.

570 Poster Session (Board #170), Sun, 8:00 AM-11:30 AM

Effect of neoadjuvant chemotherapy regimen choice in patients with breast cancer with pathologic complete response. *First Author: Anna Weiss, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Breast cancer patients with a pathologic complete response (pCR) to neoadjuvant chemotherapy (NACT) have improved survival. We hypothesize there is no difference in post-surgical recurrence free survival (RFS) between regimens used if pCR has been achieved. **Methods:** Breast cancer patients treated with NACT (using various regimens) between 1996 and 2011 who achieved pCR were examined, using a prospectively maintained electronic database. RFS was estimated by Kaplan-Meier method, differences between groups assessed using log-rank test. Cox proportional hazards regression analysis adjusted for age, menopausal status, stage, grade, tumor subtype, and adjuvant treatments. **Results:** 721 patients were identified: 40.4% Stage IIA, 21.2% IIB, 10.8% IIIA, 9.2% IIIB, 18.3% IIIC. 21.8% were hormone receptor positive (HR), 43.3% HER2 amplified, 32.7% triple negative. 50.9% of patients were treated with adriamycin-based chemotherapy plus taxane (adriamycin+taxane), 7.8% without taxane (adriamycin-taxane), 31.5% HER2 targeted therapy, and 9.8% provider choice. Median follow up was 7.4 years. There was no significant difference in RFS by treatment group (table 1). Adjusted RFS hazard ratios comparing each treatment to adriamycin+taxane were 1.25 (95% confidence interval 0.47-3.35) adriamycin-taxane, 0.90 (CI 0.37-2.20) HER2 targeted, and 1.28 (CI 0.55-2.98) provider choice. **Conclusions:** These data suggest that post-surgical RFS among patients with pCR is not significantly influenced by the type of NACT. Meta-analysis of randomized trial data should be explored to evaluate these findings. If RFS of pCR patients is not affected by regimen, this could allow flexibility in treatment choice and length.

RFS for the total cohort, and by tumor subtype.

	Overall N=721, P=0.45		HR N=143, P=NA		HER2 Amplified N=312, P=0.42		Triple Negative N=216, P=0.59

571 Poster Session (Board #171), Sun, 8:00 AM-11:30 AM

Impact in delay of start of chemotherapy and surgery on pCR and survival in breast cancer: A pooled analysis of individual patient data from six prospectively randomized neoadjuvant trials. *First Author: Sibylle Loibl, German Breast Group, Neu-Isenburg, Germany*

Background: Time interval from diagnostic biopsy to neoadjuvant chemotherapy (NACT) start (TBC) and from last chemotherapy application to surgery (TCS) are influenced by many factors. It is unclear whether a delay of systemic therapy or surgery impacts patients (pts) outcome. **Methods:** 9127 pts with early BC from 6 German neoadjuvant trials receiving an anthracycline-taxane based NACT were included. pCR (ypT0/is ypN0), disease free survival (DFS) and overall survival (OS) were compared according to TBC and TCS length (cut-off of ≤4 vs >4weeks (w)), overall and in subgroups (BC subtypes [luminal, HER2+, triple-negative breast cancer (TNBC)] and pCR [yes vs no] for survival endpoints) adjusted by study. **Results:** Data on TBC were available for 8072 pts, on TCS for 6420, on follow-up (FU) for 7889. Median age was 49 yrs, 25.6% had cT3-4, 48.6% N+, 44.1% G3, 46.0% luminal, 26.4% TNBC, 27.6% HER2+ tumors. Median (m) FU-time was 65 months [0-201]. mTBC was 23 days [0-228] (67.5% ≤4w vs 32.5% >4w), mTCS was 28d [0-204] (53.7% ≤4w vs 46.3% >4w), with inter-study variability for mTBC ranging from 14 to 32d and for mTCS ranging from 24 to 29d from the oldest to the most recently conducted study. TBC did not influence the pCR rate, neither in all patients nor in subgroups. At multivariable logistic regression analysis TBC length did not independently predict pCR. TBC did not influence DFS or OS, neither in all patients nor in subgroups. TCS<4w was associated with a trend towards a better DFS in all patients (HR=1.11 95%CI (0.99-1.24), p=0.08) and in pts not achieving pCR (HR=1.12, 95%CI (0.99-1.26), p=0.08). No difference was observed within BC subtypes. OS was not impacted by TCS length. At multivariable Cox regression analysis TBC or TCS≤4 vs >4w did not independently influence DFS or OS. **Conclusions:** A delay in starting NACT does not impact the pCR rate, DFS or OS and results are independent of the subgroup. However, early surgery after NACT in pts without pCR seems to influence outcome. Our analysis is explorative, but indicates for the first time, that time interval of starting NACT and undergoing surgery might be uncritical. Further research is ongoing.

572 Poster Session (Board #172), Sun, 8:00 AM-11:30 AM

Safety of MEDI4736 (anti-PD-L1 antibody) administered concomitant with weekly nab-paclitaxel and dose dense doxorubicin/cyclophosphamide (ddAC) as neoadjuvant chemotherapy for stage I-III triple negative breast cancer (TNBC): A Phase I/II trial. *First Author: Lajos Pusztai, Yale Cancer Center, New Haven, CT*

Background: Pathologic complete response (pCR) rates to neoadjuvant chemotherapy in TNBC plateaued at 40% with existing regimens, the co-administration of an immune checkpoint inhibitor might increase pCR rate. The objective of the Phase I portion of this trial was to assess the safety of administering MEDI4736 concomitant with sequential taxane and anthracycline chemotherapy. **Methods:** The Phase I part followed the 3+3 design exploring two dose levels of MEDI4736 (3 and 10 mg/kg iv q2wk) in combination with weekly nab-paclitaxel (100 mg/m2) x 12 followed by ddAC x 4. Dose limiting toxicities (DLT) were evaluated during the entire 20 weeks of therapy and were defined as (1) gr 4 immune related adverse event (irAE), (2) gr 3 irAE that did not resolve to gr 2 within 3 days or to $\leq$ gr 1 within 14 days, (3) $>$ gr 3 colitis or pneumonitis, (4) $\geq$ gr 3 non-irAE causally related to MEDI4736. **Results:** 3 patients completed therapy at the 3 mg/kg dose without any DLT, 1 additional patient refused further study medication because of recurrent gr 2 fatigue after 7 weeks of therapy. At the 10 mg/kg dose level, all 3 patients completed the nab-paclitaxel+MEDI4736 treatment without any DLT and 2 patients also completed 3 of the 4 planned treatments with ddAC without DLT. Among all 7 patients who started therapy, 1 at the 3 mg/kg group experienced gr 3 dehydration and dyspnea without chest X ray abnormalities which resolved within 48 hours with hydration. There were no other gr 3 AEs. Among the 3 patients who have completed therapy as per protocol (not including the patient who withdraw consent), 1 achieved pCR, 1 had minimal, and 1 had extensive residual cancer. No surgical AE were seen. All patients at the 10 mg/kg dose level will complete surgery by March 2017 and final Phase I toxicity and efficacy results will be presented. **Conclusions:** Concomitant administration of MEDI4736 10 mg/kg with weekly nab-paclitaxel and subsequently with ddAC neoadjuvant chemotherapy appears safe. The Phase II portion of the trial is open and will accrue a maximum of 50 patients to assess the efficacy of the combination. Clinical trial information: NCT02489448.

573 Poster Session (Board #173), Sun, 8:00 AM-11:30 AM

Association of molecular subtype, proliferation, and immune genes with efficacy of carboplatin versus gemcitabine addition to taxane-based, anthracycline-free neoadjuvant chemotherapy in early triple-negative breast cancer (TNBC): Results of the randomized WSG ADAPT-TN trial. *First Author: Oleg Gluz, West German Study Group, Moenchengladbach, Germany*

Background: In the ADAPT-TN neoadjuvant trial, 12-week nab-paclitaxel (nab- pac)+carboplatin (carbo) was highly effective and superior to nab-pac +gemcitabine (gem). However, within TNBC, reliable predictive markers for carbo use have yet to be identified. **Methods:** Patients with early TNBC (centrally confirmed) were treated by nab-pac 125 mg/m2 with either carbo AUC2 or gem 1000 mg/m2 d 1,8 q21 given for 4 cycles. Genomic data (80 genes) and Prosigna (PAM-50) scores were available in 306 pre-therapeutic samples of 331 treated patients. Fisher's exact test was performed for pCR differences; associations of continuous measurements or scores with pCR were analyzed by the Mann-Whitney statistic. **Results:** pCR was 44.5% to 28.4% (p=.004) in favor of nab-pac - carbo. Specifically within the carbo-containing arm, immunological (CD8, PD1, PFDL1) genes and proliferation markers (proliferation score and ROR scores, MKI67, CDC20, NUF2, KIF2C, CENPF, EMP3, TYMS) were positively associated with pCR ($p<.05$ for all). Specifically within the gem-arm, angiogenesis genes were negatively associated with pCR (ANGPTL4: p=.05; FGFR4: p=.02; VEGFA: p=.03). In the whole collective, basal-like (83.3%) was favorable for pCR (38% vs. 20%, p=.015) compared to other subtypes (HER: 6.4%; luminal-A: 1.7%; normal: 8.7%), as was lower HER-2 score ($p<.001$). Proliferation was positively associated with pCR: i.e., Pam50 proliferation score, ROR scores (all $p<.004$), and higher Ki67 by central IHC ($p<.001$) – though not MKI67 RNA expression, despite their moderate correlation. **Conclusions:** In early TNBC, basal-like subtype, higher Ki67 (by IHC), and lower HER-2 score were associated with chemo-sensitivity for both neoadjuvant arms. Chemo-resistance pathways differed between the two taxane-based combinations (low proliferation and immune marker gene expression for carbo, high angiogenesis for gem). The positive predictive impact of immunological genes in the nab-pac - carbo arm could influence optimal patient selection for immune-modulative therapy. Clinical trial information: NCT01815242.

574 Poster Session (Board #174), Sun, 8:00 AM-11:30 AM

Antitumor activity of trabectedin and lurbinectedin in germline BRCA2 carriers with metastatic breast cancer (MBC) as compared to BRCA1 carriers: Analysis of two phase II trials. *First Author: Judith Balmana Gelpi, Hospital Vall d'Hebron, Barcelona, Spain*

Background: BRCA 1/2-associated breast cancer share homologous recombination deficiency, but also have independent and potentially actionable roles. Novel drugs with innovative mechanism of action, lacking cross-resistance with other used agents are needed for BRCA 1/2 MBC. Trabectedin (TR) and its analog, lurbinectedin (L), have shown to be active in BRCA 1/2 MBC. This study was sought to determine if there was a difference in activity of these agents between BRCA1 and 2 carriers. **Methods:** Safety and efficacy in MBC BRCA 1/2 were analyzed in 2 separate phase II trials of single agent TR and L. **Results:** 88 patients were evaluated: 34 with TR, 54 with L. Median age: 46 and 43, respectively. Median (range) prior chemotherapy lines: TR, 4 (1-10); L, 2 (0-5). Clinical responses were seen in the 2 trials (see table) and were higher in BRCA2 than in BRCA1 (33% vs 9% with TR and 61% vs 26% with L). Main adverse event was myelosuppression (grade 3-4 neutropenia / thrombocytopenia / febrile neutropenia: TR, 62.1%/24.3%/10.8% L, 66.7%/20.4%/20.4%). Non-hematological toxicity was mostly grade 1-2: fatigue, nausea/vomiting and high transaminases (grade 3/4 TR, 40.5%, L 18.5%). **Conclusions:** Remarkable activity of trabectedin and lurbinectedin as single agents was observed in BRCA 2 associated MBC. This finding warrants further investigation. One potential mechanistic rationale is the role of both lurbinectedin and BRCA 2 in transcription. Safety was acceptable and manageable in both studies. Clinical trial information: NCT01525589.

575 Poster Session (Board #175), Sun, 8:00 AM-11:30 AM

A gene signature of chemo-immunization to predict outcome in patients with triple negative breast cancer treated with neoadjuvant chemotherapy. *First Author: Mohamed-Amine Bayar, Service de Biostatistique et d'Epidémiologie, Gustave Roussy, Villejuif, France*

Background: In patients with triple-negative breast cancer (TNBC), the extent of tumor-infiltrating lymphocytes (TILs) in the residual disease after anthracycline-based neo-adjuvant chemotherapy (NACT) is associated with a better prognosis. We aimed to develop a genomic signature from pre-treatment samples to predict the extent of TILs after NACT, and then to test its prognostic value on survival. **Methods:** Using 99 pre-treatment samples (training set), we generated a four-gene signature that predicts post-NACT TILs using the LASSO technique. Prognostic value of the signature on survival was assessed on the training set (n=99) and then evaluated on an independent validation set including 185 patients with TNBC treated with NACT. **Results:** A four-gene signature, assessed on pre-treatment samples and combining the expression levels of HLF, CXCL13, SULT1E1, and GBP1 predicted the extent of lymphocytic infiltration after NACT. In a multivariate analysis performed on the training set, a one-unit increase in the signature value was associated with distant-relapse free survival (DRFS) (HR: 0.28, 95% CI: 0.13-0.63, p=0.002). For the validation set, the four-gene signature was significantly associated with DRFS in the entire set (HR: 0.26, 95%CI: 0.11-0.59, p=0.001) and in the subset of patients with residual disease (HR: 0.23, 95%CI: 0.10-0.55, $p<0{\cdot}001$). **Conclusions:** We developed a four-gene signature of chemotherapy-induced immune-activation, which predicts outcome in patients with TNBC treated with NACT.

Prognostic value of the four-gene signature on distant relapse-free survival.

576 Poster Session (Board #176), Sun, 8:00 AM-11:30 AM

Adjuvant or neoadjuvant chemotherapy in early stage triple negative breast cancer (TNBC) comparison of outcomes in both BRCA positive and BRCA negative patients. *First Author: Katherine Clifton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NSABP Protocol B-18 was a randomized trial which found no statistically significant difference in overall survival (OS) in patients (pts) receiving neoadjuvant (NAC) or adjuvant chemotherapy (AC), however outcome was not analyzed by breast cancer subtypes. Subsequent retrospective studies in TNBC reported conflicting results with an initial study showing a significant OS benefit with AC and later studies showing a trend toward improved survival with NAC. Furthermore, studies have not included a significant number of pts with BRCA mutations. This study aims to analyze outcomes of AC versus NAC in pts with early stage TNBC with and without BRCA germline mutations. **Methods:** Pts with stage I or II TNBC who had BRCA testing were identified from a prospective cohort study of 4027 pts at MD Anderson Cancer Center. Clinical, demographic, genetic test results, chemotherapy, recurrence, survival data were collected. OS and disease free survival (DFS) were estimated using the Kaplan-Meier method, and log-rank tests were used to compare groups. **Results:** 305 pts with stage I and II TNBC who met eligibility criteria were included in the analysis. Pts who received both NAC and AC or no chemotherapy were excluded. 181 received AC (59.3%) and 124 received NAC (40.7%). The majority of the pts were less than 50 years old (236, 77.4%) and white (194, 63.8%). 134 were BRCA positive (44.1%) and 170 were BRCA negative (55.9%). The majority of the pts received an anthracycline and taxane regimen (223, 73.1%). There was no significant association between OS or DFS and treatment with NAC versus AC in the overall cohort. Furthermore, there were no significant differences between pt subgroups (NAC BRCA positive, NAC BRCA negative, AC BRCA positive, and AC BRCA negative) with respect to either OS or DFS. **Conclusions:** NAC versus AC with standard anthracycline and taxane containing regimens results in similar DFS and OS survival amongst pts with stage I and II TNBC regardless of BRCA status. Further studies are needed to evaluate whether similar results are observed with newer agents, such as platinums, PARP inhibitors and other targeted agents.

577 Poster Session (Board #177), Sun, 8:00 AM-11:30 AM

Pathologic complete response (pCR) rates after neoadjuvant pertuzumab (P) and trastuzumab (H) administered concomitantly with weekly paclitaxel (T) and 5-fluorouracil/epirubicin/cyclophosphamide (FEC) chemotherapy for clinical stage I-III HER2-positive breast cancer. *First Author: Julia Foldi, Yale Cancer Center, New Haven, CT*

Background: Inclusion of H with chemotherapy has increased pathologic complete response (pCR) rates in HER2 positive breast cancer, and dual HER2 blockade involving H + P further increased efficacy. With dual HER2 blockade and taxane-based (+/-carboplatin followed by anthracycline) chemotherapies, pCR rates reach, 75% in estrogen receptor (ER) negative and 45% in ER+ patients. HER2 targeted therapies also increase the efficacy of anthracyclines but are not routinely combined due to potential cardiotoxicity. The goal of this phase II study was to assess pCR rate when H+P is administered during the entire treatment duration, including the anthracycline phase, of weekly T (80 mg/m^2) x 12 followed by FE(75 mg/m^2)C x 4 neoadjuvant chemotherapy. **Methods:** pCR (ypT0/is and ypN0) rate was assessed separately in ER+ and ER- cancers following Simon's two-stage design to detect improvement in pCR rates to 90% and 70% in the ER- and ER+ cohorts, respectively. Eligibility included age <65, stage I-III, HER2+ disease, and normal cardiac function. **Results:** The ER- cohort completed full accrual of 25 patients: 23 completed therapy and surgery, 2 patients are still receiving treatment. The pCR rate is 78% (n=18, 95% CI:58-90%). The ER+ cohort was closed after 23 patients were accrued to the first stage due to lower than expected pCR of 26% (n=6, 95% CI:13-46%) at interim analysis. The incidence of grade 3/4 adverse events was 48% (n=24/50), the most common being neutropenia (n=12) and diarrhea (n=7). No patient experienced symptomatic congestive heart failure, one patient had a drop in LVEF to < 50% following completion of chemotherapy. Thirteen patients (27%) had a >10% asymptomatic drop in their LVEF but remained above 50%, LVEF returned to baseline by the next assessment in half of these cases. **Conclusions:** Neoadjuvant P and H administered concomitantly with weekly T followed by FEC resulted in 78% pCR rate in ER-/HER2+ cancers. This pCR rate is among the highest reported in the literature. The pCR rate was substantially lower in ER+ cancers. Clinical trial information: NCT01855828.

578 Poster Session (Board #178), Sun, 8:00 AM-11:30 AM

Utilization, trend and impact of neoadjuvant endocrine therapy compared to neoadjuvant chemotherapy in postmenopausal breast cancer patients: Analysis of the National Cancer Data Base. *First Author: Alina Basnet, SUNY Upstate Medical University, Syracuse, NY*

Background: Three small prospective trials that compared the efficacy of neoadjuvant endocrine therapy (NET) to neoadjuvant chemotherapy (NCT) showed no statistically significant difference. We report the differences in utilization of NET and NCT using National Cancer Data Base (NCDB) and their trend, response rates (RR) and breast conservation rates (BCR). **Methods:** A retrospective review of hormone receptor positive breast cancer patients ≥ 50 yrs without metastasis using NCDB was performed (2004-2014). Patients underwent NET or NCT prior to definitive surgery. Utilization pattern, practice trend, RR and BCR between NET and NCT was assessed using univariate and multivariate logistic analysis. **Results:** Out of 2,246,279 breast cancer patients reported in NCDB, 38,632 met our inclusion criteria. 9178 received NET and 29,454 received NCT. On multivariate analysis NET use was higher in academic vs community centers [Odds ratio (OR) 1.355, 95% CI 1.270-1.445], age >70 vs < 70 (OR 6.603, 95% CI 6.110-7.137) and high vs low Charlson Deyo comorbidity index (OR 1.817, 95% CI 1.548-2.133). NET use was lower in black vs white (OR 0.790, 95% CI 0.712- 0.875), tumors with higher vs lower grade (OR 0.153, 95% CI 0.138-0.169), higher vs lower T stage (OR 0.372, 95% CI 0.340-0.407), higher vs lower N stage (OR 0.274, 95% CI 0.243-0.310) and private vs no insurance (OR 0.600, 95% CI 0.509- 0.707), (all p<0.0001). A significant upward trend in utilization of NET was observed from year 2011 (25.9%) compared to before (22.2%), p<0.0001. RR was significantly higher for patients receiving NCT (90.5%) compared to NET (77.2%), with an [adjusted OR (aOR) 2.413; 95% CI 2.116-2.752], however the BCR was superior in the NET group (50.0%) compared to NCT group (31.1%) with (aOR 1.676; 95% CI 1.567-1.794). **Conclusions:** Our study is the first to compare NET and NCT utilization and their efficacy using NCDB database. Our results have shown striking differences in outcome among these two strategies as compared to other prospective trials. Despite high RR, more patients underwent mastectomy in the NCT group. We also see a steady upward trend in usage of NET from year 2011.

579 Poster Session (Board #179), Sun, 8:00 AM-11:30 AM

EarlyR genomic signature to predict pathological complete response following neoadjuvant anthracycline-taxane chemotherapy in estrogen-receptor positive (ER+) breast cancer. *First Author: Steven Allen Buechler, University of Notre Dame, Notre Dame, IN*

Background: EarlyR is a prognostic signature computed from expression values of *ESPL1, SPAG5, MKI67, PLK1* and *PGR* that stratifies ER+ breast cancer (BC) into EarlyR^{Low}, EarlyR^{Int}, and EarlyR^{High} risk strata. Here, we show that EarlyR is also predictive of pathological complete response (pCR) following neoadjuvant anthracycline-taxane (AT) based chemotherapy. **Methods:** The ability of EarlyR gene signature to predict pCR was assessed in Affymetrix microarrays datasets (GSE25065, GSE25066, GSE20194, GSE20271; n = 541, pCR = 42 (7.8%) collectively labeled as Cohort A) derived from patients with ER+ breast cancer treated with neoadjuvant TFAC or FEC. For 2 of these datasets (GSE25065, GSE25066 (n = 291)) distant metastasis-free survival (DMFS) results were also available. The DMFS data in cohort A were compared to that of BC patients not treated with chemotherapy (denoted Cohort B, n = 1269) derived from ER+ samples from 7 GEO datasets (GSE3494, GSE7390, GSE12093, GSE6532, GSE2034, GSE11121, GSE17705). **Results:** In cohort A, EarlyR is a significant predictor of pCR ($p = 1.0 \times 10^{-6}$) (EarlyR^{Low}, n = 273, pCR = 5, 1.8%; EarlyR^{Int}, n = 11, pCR = 1, 9.1% and EarlyR^{High}, n = 256, pCR = 36, 14.1%). Notably, 86% of the 42 cases with pCR have EarlyR^{High}. Of the 291 patients with 8-year DMFS data from Cohort A, who had received chemotherapy, the survival of EarlyR^{High} [0.79 (95%CI 0.70-0.89)] was nearly the same as that of EarlyR^{Low} [0.82 (95%CI 0.74-0.90)]. In contrast, in cohort B, who were not treated with chemotherapy, 8-year DMFS is significantly ($p = 5 \times 10^{-15}$) lower in EarlyR^{High} [0.57 (95%CI 0.51-0.64)] than in EarlyR^{Low}[0.81 (95%CI 0.78-0.84)]. **Conclusions:** EarlyR is a strong predictor of pathological complete response in patients treated with TFAC or FEC. In addition, EarlyR also predicts poor DMFS outcomes for patients in EarlyR^{High} not receiving chemotherapy. More importantly, neoadjuvant chemotherapy dramatically improved survival of patients in EarlyR^{High}. These results document that EarlyR identifies a set of patients, EarlyR^{High}, with a high risk of distant metastasis, who are also likely to respond favorably to chemotherapy.

580 Poster Session (Board #180), Sun, 8:00 AM-11:30 AM

Effect of neoadjuvant pertuzumab-containing regimens on pathologic complete response rates in stage II-III HER2-neu positive breast cancer: A retrospective, single institutional experience. *First Author: Rashmi Krishna Murthy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pertuzumab (P) in combination with trastuzumab (H) based chemotherapy is currently FDA- approved as a standard neoadjuvant treatment for patients with clinical stage II-III HER2-positive (HER2+) breast cancer (BC). The chemotherapy backbone of HER2-targeted therapy varies and may include taxane (T) and/or anthracycline (A), or carboplatin (C). The goal of this study was to retrospectively evaluate the pathologic complete response (pCR) rate for HP-containing regimens compared to H containing regimens for stage II-III HER2+ BC. **Methods:** We identified all patients (n = 1150) with stage II-III HER2+ BC who received neoadjuvant HER2-targeted therapy from 2005 to 2016 through an institutional database. All patients underwent primary breast and lymph node surgery. pCR was defined as ypT0/is, ypN0. Univariate/multivariate logistic regression and chi-squared test for comparing proportions was used for the statistical analysis. **Results:** pCR was significantly higher for the HP group (n = 200) compared to the H group (n = 950): 44% vs. 41%, odds ratio = 1.8 (95% CI = 1.3, 2.5; P = 0.0002). Even with adjustment for all clinically significant factors (age, stage, tumor grade, hormone receptor (HR) status, A or C exposure), the improvement was statistically significant (adjusted OR = 2.1 (95% CI = 1.5, 2.9; P < 0.0001). The pCR rate by stage and HR status for the HP group is 62% vs. 55% (stage II vs. III) and 71% vs. 51% (HR- vs. HR+). The effect of P was not modified by HR status (HR-, OR = 2.3; HR+, OR = 1.7, P = 0.39) or by A (A-yes, OR = 1.8; A-no, OR = 2.6) (P = 0.28 for interaction) or C (C-yes, OR 2.6; C-no, OR = 1.8) (P = 0.30 for interaction). P was significantly more likely to be given to patients without A (36% vs. 10%, P < 0.0001) and more likely to be given to patients with C (30% vs. 14%, P < 0.001). In both groups, significant predictors of pCR were found to be stage, HR status, and C exposure. **Conclusions:** Pertuzumab containing regimens yield higher pCR rates compared to non-Pertuzumab containing regimens in stage II- III HER-2 positive breast cancer. The effect of Pertuzumab is not modified by anthracycline or carboplatin use.

581 Poster Session (Board #181), Sun, 8:00 AM-11:30 AM

Comparing outcomes of neoadjuvant endocrine therapy versus chemotherapy in ER-positive breast cancer: Results from a prospective institutional database. *First Author: Nathalie LeVasseur, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: While neoadjuvant chemotherapy (NACT) has been established as the standard of care for medically fit patients, there has been renewed interest in utilizing neoadjuvant endocrine therapy (NET) for the treatment of women with estrogen-receptor (ER) positive, HER-2 negative breast cancer. Rates of pCR are known to be low in this population, but there is inconsistent data regarding downstaging and long-term outcomes in a non-trial setting with NET vs NACT. **Methods:** A prospective institutional databaseof breast cancer patients treated with neoadjuvant therapy at the British Columbia Cancer Agency from 2012-2016 was analyzed to identify all medically fit patients with ER positive, HER2 negative breast cancer. Patients were then divided into two groups: those who received NET or NACT. Baseline characteristics were compared between groups. A matched analysis (age, stage and grade) was then performed to compare rates of downstaging, pCR and scores from a validated neoadjuvant therapy outcomes calculator (CPS+EG). **Results:** A total of 154 patients met eligibility criteria for this study. One hundred and six patients (69%) received NACT and 48 (31%) received NET. Women offered NACT were significantly younger (51 vs 64y, p < 0.001) than those offered endocrine therapy and presented with a higher clinical stage (LR 27.93, p = 0.002). According to multiple linear regression for downstaging, clinical stage followed by NACT were the most important predictors of downstaging. When matched for age, stage and grade, downstaging was significantly higher with NACT (31/48, 65%) as compared to NET (12/48, 25%), p < 0.001. Of these, 12.5% achieved pCR with NACT as compared to 2.1% with NET, LR 4.243, p = 0.039. No significant differences in CPS+EG scores were identified when comparing NACT to NET. **Conclusions:** Significantly higher rates of downstaging were achieved with NACT as compared to NET when patients were matched for age, stage and grade. Rates of pCR remain low for ER-positive breast cancer patients. Although not validated with the use of NET, CPS+EG scores predicting long-term outcomes were not significantly different with NET compared to NACT.

582 Poster Session (Board #182), Sun, 8:00 AM-11:30 AM

Results of multicenter phase II WSG Neo-Predict trial: Predictive markers for evaluation of response to neoadjuvant paclitaxel+trastuzumab+lapatinib in HER2-positive early breast cancer. *First Author: Christian Eichler, Krankenhaus Köln-Holweide, Cologne, Germany*

Background: Trastuzumab (T) and Lapatinib (L) containing neoadjuvant chemotherapy (NACT) increases pathological complete response (pCR) (vs. T or nihil) in HER2+ early breast cancer (EBC). Early clinical response markers (e.g. Ki67) in a 3-week biopsy or in residual tumor correlate with therapy efficacy and risk of relapse. This WSG Neo-Predict trial aimed to define early predictive markers for therapy response in a dual blockade (T+L) NACT setting. **Methods:** Patients with cT1c-cT4c HER2+ EBC were treated by paclitaxel (P) (80 mg/m^{2}weekly) with L (750 mg p.o. daily) + T (2 mg/kg) weekly for 12 weeks. Adjuvant treatment with 4 cycles of Epirubicin/Cyclophosphamide (omission allowed in patients with pCR) and T for an additional 40 weeks was recommended. Primary objectives were pCR (ypT0/is/ypN0) and identification of a dynamic predictive test for pCR using a re-biopsy after three weeks of NACT (early response defined as central Ki67 decrease >30% (vs. baseline) and/or low cellularity (<500 invasive tumor cells)). **Results:** From 2013-2015, 64 patients (n=80 planned) were recruited. Overall pCR was 41% (41% for HER2+/HR+ (n=34) and 45.5% for HER2+//HR- (n=22)). A 0% pCR in the "non-responder" (n=7) group (vs. 50% in the "responder" (n=34) and 42% in the "missing response" (n=20) groups) is intriguing despite methodological limitations. Missing data for early response assessment in a substantial number of patients and negative DFS data from the ALTTO trial did not justify trial continuation. 27% of patients experienced severe adverse events (AE). 11.5% had > grade 3 AEs (including diarrhea, septic shock, leukopenia, and pneumonia). **Conclusions:** We observed a clinically meaningful pCR with moderate toxicity with only 12 weeks of paclitaxel weekly with dual HER2 blockade (T+L). Effect of additional chemotherapy in patients with pCR after 12 weeks of monochemotherapy remains questionable due to a strong prognostic effect of pCR in HER2+ EBC. In view of 0% pCR (by hypothesis-generating explorative analysis), a different treatment approach should be investigated in patients without "early response" by further prospective trials. Clinical trial information: 2012-003679-21.

583 Poster Session (Board #183), Sun, 8:00 AM-11:30 AM

Effect of TCHL-based therapy on immune cell content in on-treatment, neoadjuvant-treated HER2-positive breast cancer patients. *First Author: Niamh M. Keegan, St. James's Hospital, Dublin, Ireland*

Background: In the TCHL trial (NCT01485926) 78 women with HER2-positive breast cancer (BC) underwent neo-adjuvant treatment with either TCH (Docetaxel, Carboplatin, Trastuzumab) or TCHL (TCH + Lapatinib) therapy. Of the 78 patients, 24 consented to an optional on-treatment biopsy 20 days after 1 cycle of therapy. We analysed the impact of tumour infiltrating lymphocytes (TILs) on pathological complete response (pCR) and also determined the impact of TCH/TCHL therapy on immune cell modulation after 20 days of treatment. **Methods:** We assessed TIL and stromal lymphocytes (SL) counts using immunohistochemical staining with Haemotoxalyin+Eosin, AE1/AE3 and CD45 in formalin fixed paraffin embedded (FFPE) baseline biopsy samples and in fresh frozen (FF) biopsies taken 20-days post cycle 1 (Day-20) of TCH/TCHL. RNA libraries were generated, using the Truseq mRNA library prep kit on the Neoprep platform and sequenced on the NextSeq 500. We measured the transcriptomic profile of 8 pre and on-treatment sample pairs and then used the Microenvironment Cell Populations (MCP)-counter method to measure the abundance of 10 immune cell populations (T cells, CD8 T cells, cytotoxic lymphocytes, NK cells, B lineage, myeloid dendritic cells, neutrophils, endothelial cells and fibroblasts). **Results:** We found that higher baseline levels of TILs (p = 0.045) but not SL were associated with an increased likelihood of a patient achieving a pCR to TCH/L based therapy. We found in day 20 on-treatment biopsies of women that subsequently went onto have a pCR that levels of SLs but not TILs were significantly higher (p = 0.049) than in those women who did not have a pCR. Finally we found significant increases in the level of monocytes (p = 0.05) and fibroblasts (p = 0.01), but not other immune cell populations, in the day 20 on-treatment biopsies in comparison with the mutated pre-treatment biopsies. **Conclusions:** In our study baseline TILs but not SLs have a predictive role in the likelihood of a patient achieving a pCR. We also found that TCHL based therapy significantly altered both monocytes and fibroblasts, indicating a possible role for these immune subtypes in response to TCHL therapy.

584 Poster Session (Board #184), Sun, 8:00 AM-11:30 AM

The impact of quality and quantity of visceral fat on survival outcome of early-stage breast cancer patients with prior chemotherapy. *First Author: Toshiaki Iwase, Breast Medical Oncology, MD Anderson Cancer Center, Houston, TX*

Background: Obesity not only increases morbidity, but also chemo-resistance of breast cancer (BC). Several studies focusing on body mass index (BMI) of BC patients have been performed; however, a recent report suggested that the quality of visceral adipose tissue (VAT) plays a crucial role in fat cell function. We set out to clarify the effect of quality and quantity of VAT on survival outcome of BC patients who underwent chemotherapy. **Methods:** From 2,230 patients who underwent treatment for BC at our institution from January 2004 to December 2015, we included 271 patients who received chemotherapy in neo-adjuvant (NAC) or adjuvant setting. Quantification was performed using computed tomography (CT) 3-dimensional volumetric software and quality of VAT was assessed based on the CT Hounsfield Unit of VAT (VAT-HU) using electrically stocked CT images. The correlation between BMI, amount of VAT (aVAT), and VAT-HU were analyzed using Pearson's correlation test. The effect of these factors on pathologic complete response (pCR) was evaluated using Logistic regression model with the following covariates: menopausal status, size, nodal status, and subtype. Furthermore, survival analysis for distant disease-free survival (DDFS) was performed using Kaplan Meier method and Cox proportional hazard model. **Results:** aVAT and VAT-HU were significantly correlated with patient BMI ($p<0.05$). Forty-six patients achieved pCR (24%). Logistic regression model for pCR showed that aVAT and VAT-HU did not affect pCR (p=0.60 and 0.36). After a median follow-up of 112 months, tertile stratification revealed that the third tertile of aVAT had significantly shorter DDFS in the NAC setting ($p<0.05$). When adjusted by covariates in the Cox proportional regression model, aVAT and VAT-HU demonstrated significant contribution to worse DDFS ([$p<0.05$, hazard ratio {HR} 1.39; 95% confidence interval {CI} 1.11 to 1.75] and [$p<0.05$, HR 1.20, 95% CI 1.01 to 1.43], respectively). **Conclusions:** The quantity and quality of VAT was significantly related to the survival outcome especially in the NAC setting. This new insight would enable prediction of recurrence risk in obese BC patients with prior chemotherapy.

585 Poster Session (Board #185), Sun, 8:00 AM-11:30 AM

Improving pathological response in locally advanced triple negative breast cancer: Comparison between CbD and AC-T regimens. *First Author: Daniel Enriquez, Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru*

Background: Pathological complete response (pCR) is a well-known surrogate for DFS and OS in triple negative breast cancer (TNBC). New approaches are being tested to increase pCR rate. We compared the standard of care (AC-T) vs Carboplatin/Docetaxel (CbD) for locally-advanced TNBC. Our objective is to determine whether CbD will increase the pCR rate, with PFS and OS as secondary objectives. **Methods:** A single arm phase II prospective trial with historical controls. 61 stage II-III TNBC patients were included between 2013-2014 at Instituto Nacional de Enfermedades Neoplasicas (Peru). 27 patients received Carboplatin 6AUC + Docetaxel 75mg/m^2 q21d for 6cy, and 34pts, Adriamycin 60mg/m^2 + Cyclophosphamide 600mg/m^2 q21d for 4cy followed by weekly paclitaxel 80mg/m^2 for 12 weeks. The Miller and Payne method was used to evaluate pathological response after definitive surgery. **Results:** Median age was 47 years, most patients were premenopausal (55.7%), median tumor size was 61 mm (T3=32.8%, T4=50.8%) and most patients had LN+ve (77%). There was a significantly greater tumor size in the CbD arm (mean 72.8 vs 52.2mm, p=0.007), no toxicity differences were noted. Only pCR was independently associated with OS/PFS on multivariate analysis. pCR was achieved in 37% (n=10) and 23.5% (n=8) in the CbD and AC-T groups, respectively (p=0.44). Partial pathological response was achieved in 37% (n=10) and 38.2% (n=13) patients in AC-T and CbD respectively. No characteristics were associated to pCR on logistic regression. At 2-year follow-up, all patients with pCR were alive and without recurrence, while patients with partial response achieved a 2-year PFS of 75% and, 2-year OS of 83.5%. The non-respondent group had the worse outcomes (2-year PFS: 32.7%, 2-year OS: 58.7%). The CbD group had a better 2-year PFS and OS (73.1% and 84%, respectively) than the AC-T group (59.3% and 71%, respectively), however no-statistical difference was found. **Conclusions:** CbD is an effective and promising neoadjuvant chemotherapy regimen for TNBC. Despite a larger mean tumor size in the CbD group, a non-significant trend towards higher pCR rate and longer PFS and OS was observed and warrants further exploration.

TPS586 Poster Session (Board #186a), Sun, 8:00 AM-11:30 AM

ABC trial (A011502): A randomized phase III double blinded placebo controlled trial of aspirin as adjuvant therapy for node positive breast cancer. *First Author: Wendy Y. Chen, Dana-Farber Cancer Institute, Boston, MA*

Background: In-vitro and in-vivo evidence suggest that aspirin, an inexpensive and widely available drug may have anti-tumor activity via effects on multiple pathways. Multiple epidemiologic studies have reported improved breast cancer survival among regular aspirin users compared to non-users. Furthermore, pooled data from randomized trials of aspirin for cardiovascular disease have also reported a decreased risk of metastatic cancer among aspirin users, especially metastatic adenocarcinoma (RR 0.52 (95% CI 0.35-0.75). In order for aspirin to be considered standard of care, the exact benefits and risks for breast cancer survivors need to be confirmed in a randomized trial. **Methods:** The primary objective is to compare the effect of aspirin versus placebo upon invasive disease-free survival (iDFS) in stage II-III node-positive HER2 negative breast cancer patients. Secondary objectives include effects on overall survival and cardiovascular disease and to collect toxicity and adherence. A biospecimen repository will be created for future correlative analyses including tumor collection at baseline and blood and urine samples at baseline and 2 years. Questionnaires assessing lifestyle factors associated with inflammation (pain, sleep, stress, and depression) will also be collected at baseline and 2 years. Study design: Subjects will be randomized (1:1) to aspirin 300 mg vs placebo daily for 5 years in a double-blinded fashion. Stratification factors include hormone receptor status (positive vs negative), body mass index ($<$ or $\geq$ 30 kg/m2), and stage (II vs III).Subjects will be followed every 6 six months while on study drug and then annually until 10 years from registration. 2936 patients will be enrolled with 80% power to detect HR 0.75. Eligibility: Eligible subjects include patients aged 18-70 diagnosed with a primary invasive stage II or III node positive HER2 negative breast cancer in the past year. Patients who currently use any oral or injectable anticoagulant or those with a prior history of GI bleeding, atrial fibrillation, myocardial infarction, or grade IV hypertension will be excluded. Patients who regular used aspirin over the past year will be excluded. Clinical trial information: NCT02927249.

TPS587 Poster Session (Board #186b), Sun, 8:00 AM-11:30 AM

PEARLY: A randomized, multicenter, open-label, phase III trial comparing anthracyclines followed by taxane versus anthracyclines followed by taxane plus carboplatin as (neo)adjuvant therapy in patients with early triple-negative breast cancer. *First Author: Gun Min Kim, Yonsei University College of Medicine, Seoul, Republic of Korea*

Background: Triple-negative breast cancer (TNBC) is an aggressive tumor with poor prognosis. There are no molecular targets for TNBC, and there is an unmet need to provide new drugs to patients with TNBC. Platinum agents are known to have an anti-tumor activity in TNBC, especially in BRCA-mutated tumor. Addition of carboplatin significantly increased pathologic complete response rates with neoadjuvant chemotherapy in recent randomized studies. There are no data about adjuvant role of carboplatin for TNBC in a randomized trial. **Methods:** PEARLY is a randomized, multicenter, open-label, phase III trial comparing anthracyclines followed by taxane versus anthracyclines followed by taxane plus carboplatin as (neo)adjuvant therapy in patients with triple-negative breast cancer (TNBC). Patients with stage II or III TNBC who need adjuvant or neoadjuvant chemotherapy were included. Any prior systemic therapy for breast cancer was not allowed. Bilateral, metastatic, and inflammatory breast cancer are excluded. A total of 840 patients will be enrolled for 3 years. Patients were randomized 1:1, stratified based on the node positivity (N0 vs N+), institution, treatment setting (neoadjuvant vs. adjuvant), and BRCA mutation status (positive vs. negative). Standard arm treatment consists of doxorubicin 60 mg/m2 IV + cyclophosphamide 600 mg/m2 IV every 3 weeks for 4 cycles followed by taxane treatment (paclitaxel 80 mg/m2 IV weekly for 12 doses or docetaxel 75mg/m2 IV every 3 weeks for 4 cycles). Experimental arm added carboplatin AUC5 IV every 3 weeks for 4 cycles during taxane treatment. The primary objective was to evaluate 5-year event free survival (EFS) rate. Secondary objectives included overall survival, distant recurrence free survival, pathologic complete response, and tolerability. The analysis is planned at 248 EFS events, which provides approximately 80% power to detect superiority of standard treatment plus carboplatin versus standard treatment using a log-rank test, assuming a hazard ratio of 0.7 at a two sided alpha of 0.05. Data is expected in 2023. Clinical trial information: NCT02441933.

TPS588 Poster Session (Board #187a), Sun, 8:00 AM-11:30 AM

A randomized controlled trial comparing primary tumor resection plus systemic therapy with systemic therapy alone in metastatic breast cancer (JCOG1017 PRIM-BC). *First Author: Tadahiko Shien, Okayama University Hospital, Okayama, Japan*

Background: The possibility of improving the survival of stage IV breast cancer patients by primary tumor resection (PTR) has been reported by several retrospective studies; however, these studies essentially suffer from biases such as arbitrary patient selection, diverse timing of surgery or various regimens of systemic therapy. Five prospective randomized trials including our trial have evaluated the efficacy of PTR for them. Two have reported final results, but those results were inconsistent. Therefore, this subject still remains a hotly debated topic at major breast conferences. **Methods:** Our trial is being conducted to confirm the superiority of PTR plus systemic therapy over systemic therapy alone in stage IV pts who are sensitive to primary systemic therapy (PST) in this study. The inclusion criteria are untreated pts with histologically confirmed invasive breast cancer with one or more measurable distant metastatic lesions diagnosed by radiological examination.All pts receive PST according to the ER and HER2 status of the primary breast cancer after the first registration. After three months, the pts who are sensitive to PST are randomized to the PTR plus systemic therapy arm or the systemic therapy alone arm. After randomization and surgery in the former arm, or after randomization in the latter arm, the same systemic therapies are continued until progression of diseases and next appropriate regimens are started after that. The primary endpoint is the overall survival, and the secondary endpoints are proportion of pts without tumor progression at the metastatic sites, yearly local recurrence-free survival, proportion of local ulcer/local bleeding, yearly primary tumor resection-free survival, adverse events (AEs) of chemotherapy, operative morbidity, and serious AEs. Sample size for randomized pts was determined to attain at least 80% of power to detect a 6 months difference with one-sided alpha of 0.05.The pts accrual was started in May 2011. Enrollment of 410 pts for randomization is planned over a 7-year accrual period. 307 pts have been randomized until Jan 2017. This trial was registered at UMIN-CTR[umin.ac.jp/ctr/] as UMIN000005586. Clinical trial information: UMIN000005586.

TPS589 Poster Session (Board #187b), Sun, 8:00 AM-11:30 AM

NRG Oncology/NSABP B-51/RTOG 1304: Phase III trial to determine if chest wall and regional nodal radiotherapy (CWRNRT) post mastectomy (Mx) or the addition of RNRT to breast RT post breast-conserving surgery (BCS) reduces invasive breast cancer recurrence free interval (IBCRFI) in patients (pts) with positive axillary (PAx) nodes who are ypN0 after neoadjuvant chemotherapy (NC). *First Author: Eleftherios P. Mamounas, NSABP/NRG Oncology, and UF Cancer Center at Orlando Health, Orlando, FL*

Background: This phase III post-NC trial evaluates if CWRNRT post-Mx or whole breast irradiation (WBI) with RNRT after BCS significantly reduces the IBCR-FI rate in pts with PAx nodes that are negative after NC. Secondary aims are OS, LRR-FI, DR-FI, DFS-DCIS, second primary cancer, and comparison of RT effect on cosmesis in reconstructed Mx pts. Correlative science examines RT effect by tumor subtype, molecular outcome predictors for residual disease pts, and predictors for the degree of reduction in locoregional recurrence. **Methods:** Clinical T1-3, N1 IBC PAx nodes (FNA or core needle biopsy) pts complete ≥12 weeks of NC (anthracycline and/or taxane). HER2+ pts receive anti-HER2 therapy. Following NC BCS or Mx, sentinel node biopsy (≥3 nodes) and/or Ax dissection with histologically negative nodes is performed. ER/PR and HER-2neu status before NC is required. Pts receive required systemic therapy. Radiation credentialing with a facility questionnaire/case benchmark is required. Random assignment for Mx pts is to no CWRNRT or CWRNRT and for BCS pts to WBI or WBI RNRT. Statistics: 1636 pts to be enrolled over 5 yrs (definitive analysis at 7.5 yrs). Study is powered at 80% to test that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction of 4.6% (5-yr cumulative rate). Intent-to-treat analysis with 3 interim analyses (43, 86, and 129 events) and a 4th/final analysis at 172 events. Pt-reported outcomes focusing on RT effect will be provided by 736 pts before random assignment and at 3, 6, 12, and 24 mos. Accrual as of 2-2-17 is 534 (32.64%). Contacts: Questions: NRG Oncology Pgh Clin Coord Dpt: 1-800-477-7227 or ccd@nsabp.org. Support: U10 CA-2166; -180868, -180822; 189867; Elekta Clinical trial information: NCT01872975.

TPS590 Poster Session (Board #188a), Sun, 8:00 AM-11:30 AM

A randomized, triple negative breast cancer enrolling trial to confirm molecular profiling improves survival (ARTEMIS). *First Author: Clinton Yam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Following neoadjuvant chemotherapy (NACT), patients (pts) with triple negative breast cancer (TNBC) achieving pathologic complete response/residual cancer burden-0 (pCR/RCB-0) or minimal residual disease (RCB-I) have an improved relapse free survival when compared to pts with more extensive residual disease (RCB-II/III) (Symmans et al, JCO 2017). Pts with chemo-resistant TNBC have a poor prognosis as there are currently no FDA-approved targeted agents available for TNBC. We previously reported the ability of a novel gene expression signature (GES) to predict sensitivity to NACT (Hatzis et al, JAMA 2011). Here we seek to prospectively validate the use of this GES in combination with imaging to predict response to NACT and establish the clinical impact of selecting pts predicted to have non-responsive disease (NRD) for enrollment in clinical trials of targeted therapy. **Methods:** All pts will undergo a biopsy of the primary tumor for molecular characterization (MC) and will be randomized 2:1 to know their MC results (intervention arm) or not (control arm). A maximum of 360 pts will be enrolled and randomized using a group sequential design with one-sided O'Brien-Fleming boundaries, with two equally spaced binding interim tests for futility and superiority and one final test, having an overall Type I error of 0.05 and power of 0.80 to detect an improvement in pCR/RCB-I from 50% to 64%. Secondary endpoints include rates of clinical trial enrollment, disease free survival and integrated biomarker analyses. All pts will receive 4 cycles of anthracycline-based NACT with imaging done every 2 cycles to assess response. After completion or progression on anthracycline-based NACT, pts predicted to have NRD based on MC/imaging (intervention arm) or imaging alone (control arm) will be offered enrollment on a clinical trial. Pts are eligible if they have stage I-III TNBC with a primary tumor that is ≥1.5cm. Pts with contraindications to anthracyclines and/or taxanes are excluded. Enrollment began in November 2015. 105 pts have been enrolled to date with 71 and 34 pts randomized to the intervention and control arms, respectively. Clinical trial information: NCT02276443.

TPS591 Poster Session (Board #188b), Sun, 8:00 AM-11:30 AM

PARTNER: Randomised, phase II/III trial to evaluate the safety and efficacy of the addition of olaparib to platinum-based neoadjuvant chemotherapy in triple negative and/or germline BRCA mutated breast cancer patients. *First Author: Helena Margaret Earl, Cambridge University Hospitals, Cambridge, United Kingdom*

Background: No specific targeted therapies are available for Triple Negative Breast Cancers (TNBC), an aggressive and diverse subgroup. The basal TNBC sub-group show some phenotypic and molecular similarities with germline BRCA (gBRCA). In gBRCA patients, and potentially other homologous recombination deficiencies, these already compromised pathways may allow drugs called PARP inhibitors (olaparib) to work more effectively. Aims: To establish if the addition of olaparib to neoadjuvant platinum based chemotherapy for basal TNBC and/or gBRCA breast cancer is safe and improves efficacy (pathological complete response (pCR)). Trial design: 3-stage open label randomised phase II/III trial of neoadjuvant paclitaxel and carboplatin +/- olaparib, followed by clinicians' choice of anthracycline regimen. Stage 1 and 2: Patients are randomised (1:1:1) to either control (3 weekly carboplatin AUC5/weekly paclitaxel 80mg/m2 for 4 cycles) or one of two research arms with the same chemotherapy regimen but with two different schedules of olaparib 150mg BD for 12 days. Stage 3: Patients are randomised (1:1) to either control arm or to the research arm selected in stage 2. **Methods:** Stage 1 - Safety: both research arms combined. Stage 2 - Schedule selection criteria: pCR rate and completion rate of olaparib protocol treatment. It is a "pick-the-winner" design with 53 patients in each research arm. This allows a 90% power, 5% one-sided significance level to test null hypothesis of pCR ≤35% versus an alternative hypothesis of pCR ≥55% in each of the research arms. Stage 3 - Efficacy: anticipated pCR ~55-60% for all trial patients and ~60-65% for gBRCA patients. The trial is powered to detect an absolute improvement of 15% (all patients) and 20% (gBRCA patients) by adding olaparib to chemotherapy (enriched design). TNBC patient recruitment will be capped, to ensure required gBRCA patients are enrolled. Enrichment design is applied with overall significance level 0.05(α) = 0.025(αall)+ 0.025(αgBRCA) and 80% power. Target accrual: 527 [gBRCA 220] Current accrual: 17 Sites activated: 12 [expected number of sites 30-50].

TPS592 Poster Session (Board #189a), Sun, 8:00 AM-11:30 AM

Phase II trial of neoadjuvant (neo) palbociclib (Palbo) plus anastrozole (ana) in endocrine resistant clinical stage 2/3 estrogen receptor positive and HER2 negative (ER+ HER2-) breast cancer (BC). *First Author: Nusayba Ali Bagegni, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Persistent cell proliferation (Ki67 > 10%) on tumor biopsies as early as 2-4 weeks (wks) on neo endocrine therapy (ET) identifies resistant tumors in ~20% patients (pts) with early stage ER+ HER2- BC who are at high risk of relapse. Palbo plus ET significantly improves progression free survival in pts with ET naïve or resistant advanced ER+ HER2- BC, and is being evaluated in the adjuvant setting. However, biomarkers predictive of palbo sensitivity are unknown. Ki67 analysis of serial tumor biopsies in the neo palbo and ana (NeoPalAna) trial demonstrated that 2 wks of palbo plus ana potently inhibited Ki67 and induced complete cell cycle arrest (CCCA, Ki67≤2.7%) in tumors with high Ki67 post 4 wks ana run-in. This study is therefore aimed to prospectively investigate the biological activity of palbo plus ana in ET resistant ER+ HER2- BC. **Methods:** The primary objective is to assess the rate of CCCA (central Ki67 ≤2.7%) after 2 wks of neo palbo and ana. Secondary objectives include analysis of tumor biopsies to explore response biomarkers. Key inclusions include women with clinical stage 2/3 ER+ HER2- BC, central Ki67 > 10% after ≥2 wks of any neo ET, adequate organ function. Key exclusions include prior CDK 4/6 inhibitor, treatment of BC except ET, concomitant use of strong CYP3A4 inhibitor. Pts receive palbo (125mg PO daily, days 1-21, 28-day cycle), ana (1 mg PO daily) and goserelin (if premenopausal). Pts with C1D15 Ki67 > 10% will discontinue study. If C1D15 Ki67 ≤10%, pt will receive 4 cycles of treatment, and additional 10-12 days of palbo if counts normalized within 3 wks post C4D28. Following surgery, pts are eligible for 2 years of adjuvant palbo. A sample size of 37 (stage 1, n = 12, stage 2 n = 25) by simon optimal two stage phase II design will be employed to assess whether the rate of CCCA is ≤5% vs ≥20% (90% power, alpha 0.1). Stage 2 will proceed if ≥1 had CCCA in stage 1. If ≤3 of 37 had CCCA, this regimen will be considered ineffective. The study is active and has enrolled 4 pts. Clinical trial information: NCT01723774.

TPS593 Poster Session (Board #189b), Sun, 8:00 AM-11:30 AM

Towards omitting breast cancer surgery in select patient groups: Assessment of pathologic complete response after neoadjuvant systemic therapy using biopsies—The MICRA trial. *First Author: Marieke Van Der Noordaa, Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Improvements in systemic treatments for breast cancer patients has led to increasing rates of pathologic complete response (pCR). In addition, the identification of a pCR has been greatly improved with magnetic resonance imaging (MRI). In patients with a pCR, surgical resection of (part of) the original tumor area is performed to confirm the absence or presence of pCR and is not likely to contribute to locoregional control. With the MICRA trial (Minimally Invasive Complete Response Assessment) we aim to omit breast surgery in breast cancer patients achieving pathologic complete response (pCR) after neoadjuvant systemic therapy (NST) using biopsies, thus preventing overtreatment and improving quality of life. **Methods:** The MICRA trial is a multi-center observational prospective cohort study. In all breast cancer patients receiving NST, a marker is placed in the center of the tumor area before NST. 440 patients with radiologic complete response or partial response (0.1-2.0 cm residual contrast enhancement, ≥30% decrease in tumor size according to RECIST criteria) on contrast enhanced MRI will be included in the MICRA trial. Patients with hormone receptor positive, triple negative and Human Epidermal growth factor Receptor 2 tumors are eligible. After NST, 8 ultrasound-guided biopsies are obtained in the region surrounding the marker, while the patient is under general anesthesia. Immediately hereafter, breast surgery is performed and pathology results of the biopsies and resected specimens are compared. The primary endpoint is specificity of post-NST biopsies. In addition, sensitivity and positive and negative predictive value will be calculated. We will perform a multivariable analysis using data on MRI and ultrasound findings, pre-NST pathology parameters and post-NST biopsy results to determine what the most reliable method is to assess pCR and how many biopsies are needed for this purpose. Conclusion: With the MICRA-trial we aim to select a group of breast cancer patients in whom surgery of the breast after NST can be omitted, by predicting the presence of a pCR on biopsies. Clinical trial information: NTR6120.

TPS594 Poster Session (Board #190a), Sun, 8:00 AM-11:30 AM

CORALLEEN: A phase 2 clinical trial of chemotherapy or letrozole plus ribociclib as neoadjuvant treatment for postmenopausal patients with luminal B/HER2-negative breast cancer. *First Author: Joaquín Gavilá, Fundación Instituto Valenciano de Oncología, Valencia, Spain*

Background: Dysregulation of cyclin D-CDK4/6-Rb pathway is associated with endocrine resistance in hormone receptor–positive (HR+) breast cancer. Recently, a CDK4/6 inhibitor has shown unprecedented efficacy in metastatic disease, leading to its regulatory approval. Several others are currently in clinical development for the management of HR+ breast cancer in the early and advanced settings. However, it is vital to gain insights into the molecular and biological effects of this class of agents and could identify patients who can benefit the most, delaying or avoiding the use of chemotherapy.The neoadjuvant setting provides an ideal scenario to carry out these investigations. Hence, we propose to conduct an exploratory study to evaluate the biological effects and the efficacy of ribociclib in patients with primary luminal B tumors.We hypothesize that the combination of ribociclib plus letrozole may offer clinical benefit in the preoperative setting. **Methods:** This is a parallel, multicenter, two-arm, randomized exploratory study in postmenopausal women with primary operable HR+/HER2-negative Luminal B breast cancer designed to evaluate the clinical benefit of ribociclib plus letrozole. Eligibility includes stage I-III operable breast cancer, Luminal B by PAM50, ECOG 0-1. They will be randomized 1:1 to receive either six 28-days cycles of ribociclib (600mg; 3-weeks-on/1-week-off) plus daily letrozole (2.5mg) or chemotherapy: four cycles of AC (doxorubicin 60 mg/m^2, cyclophosphamide 600 mg/m^2 every 21 days) followed by weekly paclitaxel during 12 weeks. Baseline, Day 15 on-treatment, and surgical specimens will be collected for molecular characterization and evaluation of response (decrease in Ki67, change to ROR low disease) The primary endpoint is the rate of Residual Cancer Burden (RCB) per MD Anderson Cancer Center procedures. A rate of RCB 0 and 1 score at surgery, with a rank between 20% to 25% with 47 evaluable patients by group of treatment will offer a precision between 11.5% and 12.4%, respectively (95%CI). Ninety-four patients will be enrolled in 20 sites across Spain.

TPS595 Poster Session (Board #190b), Sun, 8:00 AM-11:30 AM

A feasibility study of neoadjuvant talazoparib for early-stage breast cancer patients with a germline *BRCA* pathogenic variant: NCT02282345. *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Poly-(adenosine diphosphate [ADP]-ribose) polymerase (PARP) is a family of enzymes responsible for DNA repair via base excision repair as well as maintenance of genetic stability. BRCA mutation carriers appear to have significant sensitivity to PARP inhibitors, not only from synthetic lethality but also potentially PARP trapping in the metastatic setting. A 2-month window study of talazoparib was reported at ESMO in 2016. In 13 patients treated, the median % tumor shrinkage by ultrasound was 88% (range 30-98%) and the study was halted early to allow for this expansion of neoadjuvant talzoparib as the only treatment prior to surgery to evaluate pathologic response. Primary Objective: Evaluate the rate of pathologic complete response (pCR)/RCB-0 + residual cancer burden (RCB)-I responses in patients with early stage breast cancer and a known BRCA pathogenic variant. **Methods:** 20 patients with stage I-III breast cancer and a known BRCA mutation will be accrued on this IRB-approved study. Patients will receive 4-6 months of neoadjuvant talazoparib and then proceed to surgery. Radiation, chemotherapy and endocrine therapy will be given when appropriate in teh adjuvant setting. Brief Eligibility Criteria: Patients with an identified BRCA pathogenic variant and diagnosed with a stage I-III breast cancer at least 1 cm in size are eligible. Tumors can have any ER or PR status but HER2 over-expressed cancers were excluded. Prior systemic or radiation therapy for previous breast cancer is excluded, but prior surgical treatment for contralateral DCIS is allowed. Correlative Science: Blood and biopsies prior to initiation of therapy will be collected to evaluate biomarkers of therapy efficacy as well as to initiate patient derived xenograft (PDX) models. Other studies will include: immunohistochemistry, targeted or whole exome sequencing for BRCA pathway mutations and other somatic and germline alterations; RNA sequencing; immune response; transcriptional profiles to assess TNBC subtype, reverse phase protein array (RPPA); generation of PDX models and mammosphere cultures. Clinical trial information: NCT02282345.

1000 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

MONARCH 2: Abemaciclib in combination with fulvestrant in patients with HR+/HER2- advanced breast cancer who progressed on endocrine therapy *First Author: George W. Sledge, Stanford University School of Medicine, Stanford, CA*

Background: Abemaciclib, an oral, selective inhibitor of CDK4 & 6, dosed on a continuous schedule, demonstrated clinical activity as monotherapy in patients (pts) with treatment refractory hormone receptor positive (HR+) metastatic breast cancer (MBC). The tolerability and activity of abemaciclib + fulvestrant (F) supported Phase 3 evaluation. **Methods:** MONARCH 2 is a double-blind Phase 3 trial of abemaciclib + F vs placebo (P) + F in women with HR+/HER2- advanced breast cancer. Women who progressed on (neo) adjuvant endocrine therapy (ET), ≤12 months from end of adjuvant ET, or on first line ET for MBC and who had not received chemotherapy for metastatic disease were eligible. Pts were randomized 2:1 to receive abemaciclib at 150 mg Q12H (or 200 mg prior to amendment) or P plus F (500 mg, per label) and stratified by metastatic site (visceral, bone only, or other) and resistance to prior ET (primary vs secondary). Pre/perimenopausal pts received a gonadotropin-releasing hormone agonist. The primary objective was investigator-assessed progression-free survival (PFS). Secondary endpoints included objective response rate (ORR) and other efficacy and safety endpoints. Assuming a hazard ratio (HR) of 0.703 in favor of abemaciclib + F, 378 events were needed for 90% power at one sided α=.025. **Results:** 669 pts were randomized to abemaciclib + F (N=446) and to P + F (N=223). 56% of pts had visceral disease, 72% had measurable disease, 25% had primary ET resistance, and 82% were postmenopausal. In the ITT population 379 PFS events were observed with a median PFS of 16.4 m for abemaciclib + F and 9.3 m for P + F (HR: 0.553; 95% CI: 0.449, 0.681, P<.0000001 by log-rank test). In pts with measurable disease, the ORR was 48.1% (3.5% complete response [CR]) for abemaciclib + F and 21.3% (0% CR) for P + F. The most frequent treatment emergent adverse events for abemaciclib + F vs P + F were diarrhea (86.4% vs 24.7%), neutropenia (46.0% vs 4.0%), nausea (45.1% vs 22.9%), and fatigue (39.9% vs 26.9%). **Conclusions:** Abemaciclib + fulvestrant was an effective treatment in patients with HR+/HER2- advanced breast cancer who progressed on endocrine therapy with significantly improved PFS and ORR. Clinical trial information: NCT02107703.

1001 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Overall survival results from the randomized phase II study of palbociclib (P) in combination with letrozole (L) vs letrozole alone for frontline treatment of ER+/HER2– advanced breast cancer (PALOMA-1; TRIO-18). *First Author: Richard S. Finn, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Preclinical data identified a synergistic role for P and hormone blockade in blocking growth of ER+ breast cancer (BC) cell lines. PALOMA-1 was an open-label phase II trial comparing progression-free survival (PFS) in patients (pts) with advanced ER+/HER2– BC treated with P+L or L alone. Median PFS increased with addition of P to L to 20.2 mos (vs 10.2 mos with L alone; HR = 0.488), with an acceptable safety profile, leading to accelerated approval by the US FDA. These results were confirmed in the phase 3 PALOMA-2 trial. At the time of the final PFS analysis, overall survival (OS) data were immature with only 61 events in both arms and a median follow-up of < 30 mos with a trend in favor of P+L vs L (37.5 vs 33.3 mos; HR = 0.813; *P*= 0.211). Here we present final OS results. **Methods:** PALOMA-1 was a 2-part study evaluating P+L in ER+/HER2– advanced BC. Part 1 enrolled postmenopausal pts with this subtype using only ER+/HER2– while Part 2 enrolled pts of this subtype additionally screened for CCND1 amplification and/or loss of p16. The primary endpoint was investigator-assessed PFS. Secondary endpoints included objective response rate, OS, safety, and correlative biomarker studies. A total of 165 pts were randomized; 66 in Part 1 and 99 in Part 2. Baseline characteristics were balanced between treatment arms. In both parts, pts were randomized 1:1 to receive P+L or L alone. OS data were collected as well as post-study therapy. **Results:** As of Dec 2016, there were 116 OS events. Median OS was 37.5 mos (95% CI: 31.4, 47.8) with P+L vs 34.5 mos (95% CI: 27.4, 42.6) for L (HR = 0.897 [95% CI: 0.623, 1.294]; *P*= 0.281). Median OS was 37.5 vs 33.3 mos (HR = 0.837; *P*= 0.280) for Part 1 and 35.1 vs 35.7 mos (HR = 0.935; *P*= 0.388) for Part 2. 78.6% of pts in the P+L arm received post-study systemic therapy vs 86.4% in the L arm. More pts in the L arm received ≥3 lines of therapy (37% vs 18%). Further subgroup analyses and details on post-study therapies will be presented. **Conclusions:** In PALOMA-1, P+L provided a statistically non-significant trend towards an improvement in OS. Survival data from the phase III, PALOMA-2 study is awaited. Sponsor: Pfizer; Clinical trial information: NCT00721409.

1002 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

A phase II trial of the CDK4/6 inhibitor palbociclib (P) as single agent or in combination with the same endocrine therapy (ET) received prior to disease progression, in patients (pts) with hormone receptor positive (HR+) HER2 negative (HER2−) metastatic breast cancer (mBC) (TREnd trial). *First Author: Luca Malorni, Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Istituto Toscano Tumori, Prato, Italy*

Background: P is approved for treatment of HR+/HER2− mBC combined with ET. There is paucity of clinical data of single-agent P in ET resistant pts. Pre-clinical data suggest P may partially reverse endocrine resistance, though this is yet to be tested in pts. **Methods:** This Phase II, open-label, multicenter study enrolled post-menopausal pts with HR+ HER2− mBC who progressed on 1 or 2 prior ETs. Pts were randomized to P (125 mg/d 3 w on/1 w off) alone or to continue their current ET (aromatase inhibitor or fulvestrant) in combination with P (same schedule as P arm). The primary endpoint was clinical benefit rate (CBR) [complete response (CR), partial response (PR) and stable disease (SD) for > 6 months (mo)]. Secondary endpoints were adverse events (AE) and additional measures of efficacy. A two-stage optimal design assessed treatment activity in each arm assuming activity as CB≥40% (α and β = 10%). Exploratory comparisons were planned for safety and efficacy endpoints. **Results:** 115 pts were enrolled (ITT population) 58 in the P arm and 57 in the P+ET arm. In both arms, 67% of pts had the study treatment as second line ET, 33% as third line, and about 1/3 of pts also received 1 prior chemotherapy for mBC. CBR was similar in both arms: 54% (95% CI 42 - 67%) with P+ET, and 60% (95% CI 48 -73%) with P alone. Median duration of CB was longer with P+ET (11.5 mo; 95% CI 8.6 – 17.8) than with P (6 mo; 95% CI 3.9 - 9.9) (HR 0.31, 95% CI 0.1 - 0.7, p-value 0.001, exploratory). Objective response rate (ORR; CR, PR) was 11% (95% CI 3 - 19%) and 7% (95% CI 0.4 -13%) with P+ET and P, respectively. PFS was 10.8 mo (95% CI 5.6 - 12.7) with P+ET and 6.5 mo (95% CI 5.4 - 8.5) with P alone (HR 0.69, 95% CI 0.4 - 1.1, p-value 0.13, exploratory). AEs were in line with previous data. **Conclusions:** Single agent P has clinical activity in ET pre-treated HR+/HER2− mBC pts. The observed increase in PFS and duration of CB with P+ET may suggest that P could reverse resistance to the prior line of ET. Translational studies are ongoing to explore potential biomarkers in this setting. Clinical trial information: NCT02549430.

1003 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Phase III, randomized study of first-line trastuzumab emtansine (T-DM1) ± pertuzumab (P) vs. trastuzumab + taxane (HT) treatment of HER2-positive MBC: Final overall survival (OS) and safety from MARIANNE. *First Author: Edith A. Perez, Genentech, Inc., San Francisco, CA*

Background: In MARIANNE (NCT01120184), patients with HER2-positive advanced breast cancer were randomized to trastuzumab + docetaxel or paclitaxel (HT; n=365), T-DM1 + placebo (T-DM1; n=367), or T-DM1 + P (T-DM1 + P; n=363) as first-line therapy. In the primary analysis, T-DM1–based treatment exhibited noninferior, but not superior, progression-free survival relative to HT (Perez EA, et al. J Clin Oncol 2016). OS was similar between treatments in the first interim analysis. Here we report OS from the final descriptive analysis. **Methods:** Enrolled patients had centrally assessed HER2-positive (IHC3+ or ISH+) progressive/recurrent locally advanced breast cancer or previously untreated MBC with a ≥6-month interval since (neo)adjuvant treatment with taxanes or vinca alkaloids. **Results:** At the clinical cutoff date of May 15, 2016, median follow-up was 54 months and 512 patients had died. Median OS was 50.9, 53.7, and 51.8 months with HT, T-DM1, and T-DM1 + P, respectively (Table). A sensitivity analysis in which HT-treated patients who received T-DM1 and/or P after disease progression (n=85) were censored prior to treatment switch found similar results. There were numerically fewer grade ≥3 adverse events (AEs) with T-DM1. **Conclusions:** With this longer follow-up, the T-DM1 safety profile was consistent with the primary analysis and prior experience. While OS was similar across treatment arms, a median OS of 53.7 months and fewer grade ≥3 AEs (vs other arms) supports T-DM1 as an effective and tolerable alternative first-line treatment for HER2-positive MBC patients. Clinical trial information: NCT01120184.

	HT (n=365)	T-DM1 (n=367)	T-DM1 + P (n=363)

1004 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Phase III study of lapatinib (L) plus trastuzumab (T) and aromatase inhibitor (AI) vs T+AI vs L+AI in postmenopausal women (PMW) with HER2+, HR+ metastatic breast cancer (MBC): ALTERNATIVE. *First Author: William John Gradishar, Robert H. Lurie Cancer Center of Northwestern University, Chicago, IL*

Background: Combination ofHER2-targeted therapy+AI improved clinical benefit in patients (pts) with HER2+, HR+ MBC vs AI alone in two previous trials, median progression free survival (mPFS) 4.8 vs 2.4 mo (TAnDEM), and 8.2 vs 3.0 mo (EGF30008). Dual HER2 blockade enhances clinical benefit vs single HER2 blockade. This study evaluated the safety and efficacy of dual vs single HER2 blockade (L+T vs T/L)+AI in HER2+, HR+ MBC progressing on (neo)adjuvant/first-line T+chemotherapy (CT). HER2 and HR status were assessed for eligibility at local lab. **Methods:** PMW were randomized 1:1:1 to receive T (8mg/kg followed by 6mg/kg IV Q3W)+L (1000mg/d)+AI or T+AI or L (1500mg/d)+AI. AI was per investigator's choice. Pts were excluded if they were intended for CT. The primary endpoint was to assess superiority of PFS with L+T vs T. Secondary endpoints included PFS (L vs T), overall survival (OS), overall response rate (ORR), and safety. **Results:** 369 pts were enrolled; current analysis included 355 pts (data cutoff, March 11, 2016); L+T (n = 120), T (n = 117) or L (n = 118). Final PFS data were analyzed after 137 events. Baseline characteristics were balanced across all treatment (tx) arms. The primary endpoint was met; superior PFS was observed with L+T vs T (mPFS, 11 vs 5.7 mo; HR = 0.62, 95% CI [0.45, 0.88], *P*= 0.0064). This benefit of L+T was consistent in key subgroups. mPFS with L vs T was 8.3 vs 5.7 mo (HR = 0.71, 95% CI [0.51, 0.98], *P*= 0.0361). ORR with L+T, T, and L was 32%, 14%, and 19% respectively. OS data are immature. Most common adverse events (AEs) with L+T, T and L (≥15%, any arm) were diarrhea (69%, 9%, 51%), rash (36%, 2%, 28%), nausea (22%, 9%, 22%), and paronychia (30%, 0, 15%). Hepatic abnormalities of > 3 ULN ALT/AST levels were noted in 4%, 6%, and 16% respectively. Incidence of tx-related SAEs was 5%, 2%, and 4% and on-tx deaths was 3%, 4%, and 5%, respectively. **Conclusions:** Dual HER2 blockade with L+T+AI showed superior PFS benefit vs T+AI, in pts with HER2+, HR+ MBC. Incidence of AEs was increased with L+T. This combination can potentially offer an effective CT-sparing tx option in subgroup of HER2+, HR+ pts without aggressive disease and who are not candidates for CT. Clinical trial information: 2010-019577-16.

1005 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

TBCRC 022: Phase II trial of neratinib + capecitabine for patients (Pts) with human epidermal growth factor receptor 2 (HER2+) breast cancer brain metastases (BCBM). *First Author: Rachel A. Freedman, Dana-Farber Cancer Institute, Boston, MA*

Background: Evidence-based treatments (tx) for metastatic, HER2+ BCBM are limited. We previously found a central nervous system (CNS) objective response rate (ORR) of 8% (95% CI 2-22%) for the irreversible, EGFR/HER2-targeted kinase inhibitor, neratinib. To enhance CNS activity, we evaluated the combination of neratinib + capecitabine in a subsequent cohort, and report results here. **Methods:** Pts with measurable BCBM (≥ 1 cm in longest dimension) and no prior lapatinib or capecitabine were eligible. All but 3 had CNS progression after local CNS tx. During 21 day cycles, pts received capecitabine 750 mg/m2 twice daily x 14 days followed by 7 days off + neratinib 240 mg orally once daily. Loperamide prophylaxis (16 mg total daily) was recommended during cycle 1. Brain MRI and non-CNS imaging were repeated every 2 cycles until 18 wks, then every 3 cycles. The primary endpoint was composite CNS ORR, requiring all of the following: ≥50% reduction in volumetric sum of target CNS lesions (central review, VORR), no progression of non-target or non-CNS lesions, no new lesions, no escalating steroids, and no progressive neurologic signs/symptoms. We used a two-stage design with hypotheses ORR 15% and 35% (error rates 5% and 20%), responses in ≥5/19 pts to enter 2ndstage; responses in ≥9/35 [26%] pts to be promising. **Results:** 39 pts enrolled between 4/2014-11/2016 (2 withdrew before tx, 37 analyzed); median age 51, median prior metastatic lines 2 (range 0-6), 65% had prior WBRT. As of 11/15/16, 23 (62%) patients are alive and 7 remain on protocol tx; median number of cycles initiated = 5 (range 1-26). 18 women (49%) had a VORR (95% CI 32-66%, neurologic exams not yet available on all pts). Overall 12-month survival is 63% (95% CI 43%-77%); 4/7 pts still on protocol therapy have not yet reached 6 cycles. No pts had grade 4 toxicity; 18 (49%) had grade 3 toxicity, with diarrhea most common (32%), and 6 pts discontinued tx for toxicity. **Conclusions:** The combination of neratinib and capecitabine is active for BCBM with VORR in nearly half of pts, supporting further development of the regimen for BCBM. Updated results will be presented at the meeting. Clinical trial information: NCT01494662.

1006 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Association of a four-gene decision tree signature with response to platinum-based chemotherapy in patients with triple negative breast cancer. *First Author: Jelmar Quist, King's College London, London, United Kingdom*

Background: Approaches to capture the molecular complexity of triple negative breast cancers (TNBCs) are lacking. We sought to classify TNBCs into subgroups with common biological features based on transcriptomic and genomic data using a Bayesian algorithm. **Methods:** Matched gene expression and copy number microarray data was available for the Guy's (n = 88) and METABRIC (n = 112) TNBC cohorts. CONEXIC was used to derive a decision tree signature for classification. Performance of the signature was tested in 7 TNBC cohorts (total n: 1,368), including 2 clinical trials assessing the efficacy of gemcitabine and carboplatin with and without iniparib. In the early-stage PrECOG 0105 Phase II neoadjuvant trial (n = 43), subtypes were evaluated in relation to response by residual cancer burden (RCB). In the metastatic Sanofi Phase III trial (n = 224), subtypes were assessed by RECIST. Results were compared to the BL1 TNBCtype-4 subtype and assessed using a multivariate analysis. **Results:** The integrative analysis using CONEXIC identified a four-gene signature. Across 7 TNBC cohorts this classification identified 6 entities, including 5 smaller groups and 1 major. Characterisation of the latter subgroup, referred to as MC6, revealed enrichment of CD4+ and CD8+ immune signatures, increased genomic instability and reduction in negative regulation of the MAPK signalling pathway. In PrECOG, 25 out of 41 MC6-TNBCs (61%, OR = 1.19, 95% CI = 0.37 to 3.81, P = 0.79) had RCB 0/I. Similarly, 65% of the BL1-TNBCs had an RCB 0/I, however in a smaller population (11 out of 17, OR = 1.30, 95% CI = 0.35 to 5.31), P = 0.77). In Sanofi Phase III, the objective response rate (ORR) in MC6-TNBCs was 46% versus 30% in non-MC6-TNBCs (OR = 1.97, 95% CI = 1.03 to 3.77, P = 0.04), in comparison to BL1-TNBCs with an ORR of 41% versus 32% in non-BL1-TNBCs (OR = 1.47, 95% CI = 0.75 to 2.86), P = 0.26). **Conclusions:** These results demonstrate that a four-gene signature can identify a subgroup of TNBCs responsive to platinum-based chemotherapy in the metastatic setting. The distinct features of these TNBCs suggest investigation of alternative actionable interventions with immunotherapy or MEK inhibitors in relation to this signature.

Final results of a phase 2 study of talazoparib (TALA) following platinum or multiple cytotoxic regimens in advanced breast cancer patients (pts) with germline *BRCA1/2* mutations (ABRAZO). *First Author: Nicholas C. Turner, Royal Marsden Hospital, The Institute of Cancer Research, London, United Kingdom*

Background: TALA is a dual-mechanism PARP inhibitor that traps PARP on DNA. This study was designed to assess the activity of TALA in pts with g*BRCA1/2*mutation previously exposed to platinum or multiple prior cytotoxic regimens. **Methods:** ABRAZO (NCT02034916) is a 2-cohort, 2-stage phase 2 study of TALA (1 mg/d) following platinum-based therapy (Cohort 1 [C1]) or ≥ 3 platinum-free cytotoxic-based regimens (Cohort 2 [C2]) in pts with locally advanced or metastatic breast cancer (MBC) and g*BRCA1/2*mutation. Pts had ECOG PS ≤ 1 and measurable disease by RECIST v1.1. Five responses per cohort were required in ≤ 35 pts to progress to stage 2. The primary endpoint was confirmed ORR by independent radiology facility (IRF). Secondary endpoints: clinical benefit rate ≥ 24 weeks (CBR24), DOR, PFS, and OS. **Results:** From May 2014 to Feb 2016, 84 pts were enrolled (C1, n = 49; C2, n = 35). At data cutoff (1 Sep 2016), 9 pts continued on treatment. Both cohorts proceeded to stage 2 before enrollment closed. Median age was 50 (range, 31–75) years; 58% of pts had an ECOG PS of 0. TNBC/HR+ incidence in C1 and C2 was 59%/41% and 17%/83%, respectively. Median number of prior cytotoxic regimens administered for advanced disease was 2 in C1 and 4 in C2. ORR by IRF for *BRCA1/BRCA2* was 24%/34%, and ORR by IRF for TNBC/HR+ was 26%/29%. Common all grade AEs: anemia (52%), fatigue (45%), nausea (42%), diarrhea (33%), thrombocytopenia (33%), and neutropenia (27%). Grade ≥ 3 AEs: anemia (35%), thrombocytopenia (19%), and neutropenia (15%). Nonhematological AEs grade ≥ 3 did not occur. AEs related to TALA led to drug discontinuation in 3 pts (4%); 4 AEs resulted in death, none related to TALA. **Conclusions:** TALA was well tolerated in MBC pts with a g*BRCA1/2* mutation, exhibiting promising antitumor activity in C1 and C2. TALA vs physician's choice of treatment in g*BRCA1/2*-mutated MBC is being evaluated in the phase 3 EMBRACA trial (NCT01945775). Clinical trial information: NCT02034916.

1008 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Phase 2 study of pembrolizumab (pembro) monotherapy for previously treated metastatic triple-negative breast cancer (mTNBC): KEYNOTE-086 cohort A. *First Author: Sylvia Adams, Perlmutter Cancer Center, New York University School of Medicine, New York, NY*

Background: In KEYNOTE-012, pembro showed durable activity and manageable safety in patients (pts) with PD-L1+ mTNBC. Cohort A of KEYNOTE-086 (NCT02447003) examined the efficacy/safety of pembro in previously treated mTNBC, regardless of PD-L1 expression. **Methods:** Pts with centrally confirmed mTNBC, ≥1 prior chemotherapy for metastatic disease, and ECOG PS 0-1 had pembro 200 mg Q3W for up to 24 mo; imaging q 9 wk for the first 12 mo, then q 12 wk. Clinically stable pts with PD could remain on pembro until PD confirmed on next assessment. Primary endpoints: ORR (RECIST v1.1, central review) in all pts and pts with PD-L1+ tumors, and safety. Secondary endpoints: DOR, disease control rate (DCR; CR + PR + SD ≥24 wk), PFS, and OS. Planned enrollment was 160 pts; analysis based on data as of Nov 10, 2016. **Results:** 60% of screened PD-L1-evaluable pts had PD-L1+ tumors (combined positive score ≥1%). Of 170 pts enrolled (100% women; median age 54 y), 44% had ≥3 prior lines of therapy, 51% had elevated LDH, 74% had visceral mets and 62% had PD-L1+ tumors. After a median follow-up of 10.9 mo, 9 (5%) pts remained on pembro. Treatment-related AEs (TRAEs) of any grade and grade 3-4 occurred in 60% and 12% of pts, respectively; 4% discontinued due to TRAEs. There were no deaths due to AE. Overall ORR was 5% regardless of PD-L1 expression (Table). Best overall response was 0.6% CR, 4% PR, 21% SD; not evaluable (3%). DCR was 8% (95% CI 4-13). Median DOR was 6.3 mo (range 1.2+ to 10.3+); 5 (63%) responders w/o PD at data cutoff. Median PFS and OS were 2.0 mo (95% CI 1.9-2.0) and 8.9 mo (95% CI 7.2-11.2), with 6-mo rates of 12% and 69%, respectively. ORR was numerically lower in pts with poor prognostic factors (e.g., high LDH, liver/visceral mets; Table). **Conclusions:** In KEYNOTE-086 Cohort A, pembro monotherapy showed manageable safety and durable responses in a subset of pts with heavily pretreated mTNBC. Randomized studies of monotherapy and combination therapy are ongoing. Clinical trial information: NCT02447003.

LOTUS (NCT02162719): A double-blind placebo (PBO)-controlled randomized phase II trial of first-line ipatasertib (IPAT) + paclitaxel (P) for metastatic triple-negative breast cancer (TNBC). *First Author: Rebecca Alexandra Dent, Division of Medical Oncology, National Cancer Centre, Singapore, Singapore*

Background: The oral Akt inhibitor IPAT is being evaluated in cancers with a high prevalence of PI3K/Akt pathway activation, including TNBC. **Methods:** Eligible patients (pts) had measurable inoperable locally advanced/metastatic TNBC previously untreated with systemic therapy. Pts were stratified by prior (neo)adjuvant therapy, chemotherapy-free interval and tumor PTEN status, and randomized 1:1 to P 80 mg/m^2 (d1, 8 & 15) with either IPAT 400 mg or PBO (d1–21) q28d until progression or unacceptable toxicity. Co-primary endpoints were progression-free survival (PFS) in the ITT population and pts with PTEN-low tumors by IHC. Secondary endpoints included objective response rate (ORR), duration of response (DoR) and overall survival in the ITT and IHC PTEN-low populations, efficacy in pts with *PIK3CA/AKT1/PTEN*-altered tumors by next-generation sequencing (NGS), and safety. **Results:** Baseline characteristics were generally balanced between arms. Efficacy is shown below. The most common grade ≥3 AEs (grouped terms) were diarrhea (23% IPAT+P vs 0% PBO+P; no grade 4 or colitis in either arm), neutropenia (18% vs 8%), asthenia (5% vs 6%), peripheral neuropathy (5% vs 5%) and pneumonia (5% vs 0%). More pts receiving IPAT+P than PBO+P had an AE leading to dose reduction of IPAT/PBO (21% vs 6%) or P (38% vs 11%) but median cumulative dose intensity was similar (IPAT/PBO: 99% vs 100%; P: 100% vs 100%). AEs led to IPAT/PBO discontinuation in 13% vs 11% of pts, respectively; 2 pts (3%) discontinued IPAT for grade 3 diarrhea. **Conclusions:** Adding IPAT to P for TNBC modestly improved PFS in the ITT pts. The effect was more pronounced in the prespecified subgroup with *PIK3CA/AKT1/PTEN* alterations, warranting further evaluation of IPAT in these pts. AEs were manageable. Clinical trial information: NCT02162719.

Everolimus (EVE) plus endocrine therapy in patients with estrogen receptor–positive (ER+), human epidermal growth factor receptor 2–negative (HER2−) advanced breast cancer (BC): First- and second-line data from the BOLERO-4 study. *First Author: Fatima Cardoso, Breast Unit, Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, Portugal*

Background: Initial first-line (1L) data from the phase 2 BOLERO-4 (NCT01698918) study of EVE + letrozole (LET) in postmenopausal patients (pts) with ER+, HER2− metastatic BC (MBC) or locally advanced BC (LABC) have been previously reported. Here, we present updated 1L progression-free survival (PFS) data, plus new data describing second-line (2L) EVE + exemestane (EXE) in pts with disease progression after EVE + LET. **Methods:** Postmenopausal pts with ER+, HER2− MBC or LABC with no prior therapy for advanced disease received EVE 10 mg/day + LET 2.5 mg/day. After disease progression, pts could receive EVE + EXE 25 mg/day until further disease progression, unacceptable toxicity, or withdrawal of consent. Primary endpoint: 1L PFS. Secondary endpoints: overall response rate (ORR), clinical benefit rate (CBR), 2L PFS, overall survival (OS), and safety (1L and 2L). **Results:** Among 202 pts (median age, 64 years) with 1L MBC (96%) or LABC (4%), median PFS (95% CI) was 21.7 (18.123.9) months, ORR was 43.6%, and CBR was 74.3%. 42 pts (median age, 62 years) with MBC (88%) or LABC (12%) who progressed on 1L EVE + LET received optional 2L EVE + EXE. 2L median PFS (95% CI) was 3.7 (1.89.1) months, ORR was 4.8%, and CBR was 21.4%. Common 1L adverse events (all grades, regardless of drug relationship) were stomatitis (69%), weight loss (44%), diarrhea (40%), nausea (37%), and anemia (35%); 2L adverse events included stomatitis (19%) and weight loss (19%). Median duration of follow-up from start of 1L to the data cutoff for these new analyses (17 June 2016) was 23.5 months. OS will be analyzed at a later data cut. **Conclusions:** EVE + LET is an effective regimen in 1L ER+, HER2− advanced BC. Thesedata support previously reported BOLERO-2 data demonstrating a PFS improvement from addition of EVE to an aromatase inhibitor. 2L data, although limited by the small number of pts, show preliminary evidence of EVE activity when continued beyond disease progression. No new safety signals were seen. Lower rates of stomatitis in 2L were noted. Clinical trial information: NCT01698918.

LCCC 1025: Phase II study of everolimus, trastuzumab, and vinorelbine for HER2+ breast cancer brain metastases (BCBM). *First Author: Carey K. Anders, University of North Carolina, Chapel Hill, NC*

Background: HER2+ BC is an aggressive subset of BC with high rates of BM and poor survival. Two-thirds of BCBM demonstrate activation of the PI3K/mTOR pathway driving resistance to anti-HER2 therapy (Rx). This phase II study evaluated everolimus (E), a brain permeable mTOR inhibitor, added to trastuzumab (T) and vinorelbine (V) in patients (pts) with HER2+ BCBM. **Methods:** Eligible pts had progressing HER2+ BCBM. Pts received E (5mg PO QD), T (2mg/kg IV weekly) and V (25mg/m^2 IV d1, 8 of 21d cycle). The primary endpoint was intracranial response rate (RR [CR+PR], modified RECIST); secondary objectives (CNS clinical benefit rate [CBR, CR+PR+SD], extracranial RR, time to progression (TTP), overall survival (OS), and correlative studies). Targeted DNA sequencing of 20 tissues from 18 pts was performed. We used a two-stage design to distinguish ORR of 5% vs 20%. **Results:** 32 pts were evaluable for toxicity; 26 for efficacy. Median age was 53 (28–70 yrs). 31/32 pts had prior radiation: 13 (42%) WBRT, 8 (26%) radiosurgery, 9 (29%) both. Median prior lines of metastatic Rx was 2 (0–7). 30 (94%) received anti-HER2 Rx: 91% T, 69% lapatinib, 38% pertuzumab, 25% TDM1. Intracranial RR was 4% (1 PR, 6 SD > 6 mos, 10 SD > 3 mos, 9 PD). CNS CBR (6 mos) was 27%; CNS CBR (3 mos) was 65%. Extracranial RR was 46%. Median TTP was 4 mos (95% CI, 2.2 –5). OS was 12.2 mos (95% CI, 0.6 – 20.2). Grade 3-4 toxicities included neutropenia (41%), anemia (16%), and stomatitis (16%). DNA sequencing showed heterogeneous HER2 copy number amplification (CN amp): only 11/20 show HER2 CN amp (median 40X v 0.7X; 5/11 BC, 4/4 BCBM, 1/2 liver mets, 1/3 LN). BCBM exhibited high-level HER2 CN amp (median 49X) vs other sites (16X). While 11/20 show both HER2 CN amp and PI3K pathway mutation, this was not associated TTP; RAD21 CN amp was associated with TTP < 3 mos. Lack of HER2 CN amp plus a HER2 Tyr-kinase domain mutation was seen in a pt with nonresponse and short OS. **Conclusions:** While intracranial RR to ETV was low in pts with HER2+ BCBM, a substantial proportion had CNS CBR; OS was 1 year for this pt population. No new toxicity signals were observed. Further evaluation of DNA heterogeneity, including degree of HER2 CN amp in HER2+ BCBM, and association with outcome is warranted. Clinical trial information: NCT01305941.

1012 Poster Discussion Session; Displayed in Poster Session (Board #4), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

Evaluating the addition of bevacizumab (Bev) to endocrine therapy as first-line treatment for hormone-receptor positive (HR+)/HER2-negative advanced breast cancer (ABC): Pooled-analysis from the LEA (GEICAM/2006-11_GBG51) and CALGB 40503 (Alliance) trials. *First Author: Miguel Martin, Hospital Gregorio Maranon, Universidad Complutense., Madrid, Spain*

Background: Data from randomized trials comparing ET v ET-Bev in 1st line HR+/HER2- ABC pts showed controversial results. We performed a pooled-analysis of two randomized trials (LEA and CALGB 40503) to refine the Bev value in this patient population. **Methods:** We analysed 749 ABC pts with ET (letrozole-673, tamoxifen-39, fulvestrant 250mg-37) +/- Bev. Primary objective was to compare progression-free survival (PFS). Secondary endpoints were: safety; other efficacy (overall response rate [ORR], clinical benefit rate [CBR] and overall survival [OS]) in all pts; and efficacy in de novo pts and by previous endocrine-sensitivity (-/+ 24 months [mo] without recurrence under ET in adjuvant setting). Multivariable Cox models were fitted for PFS adjusted by study co-variables and controlled for study level differences. **Results:** Median age was 61 years (yr) (range: 25-87); 40% had de novo ABC and 60% recurrent disease (with disease free interval of $\leq$ 1 yr in 5%, 1-2 yr in 7% and $>$ 2 yr in 88%); 82% of recurrent pts had previous ET sensitivity. Median PFS was 14.3 mo in the ET arm v 19 mo in the ET+Bev arm (HR 0.77; 95% CI 0.66-0.91; $p<0.01$). ORR and CBR with ET v ET+Bev were 40 v 61% ($p<0.01$) and 64 v 77% ($p<0.01$). OS did not differ between arms (HR 0.96; 95% CI 0.77-1.18; p=0.68). PFS for de novo ABC pts was 14.6 and 19.3 mo in the ET and ET+Bev arms (HR 0.82; 95% CI 0.63-1.06; p=0.13). PFS differed between arms for previous sensitive pts (HR 0.68; 95% CI 0.53-0.89; p=0.004) but not for ET-resistant pts (HR 0.73; 95% CI 0.4-1.3; p=0.29). Grade 3-5 hypertension (2.2 v 20.1%), proteinuria (0 v 9.3%), cardiovascular events (0.5 v 4.2%) and liver events (0 v 2.9%) were significantly higher in the ET+Bev arm (all $p<0.01$). Multivariable analyses showed age ($p<0.01$), PgR status ($p<0.01$), type of prior ET ($p<0.01$) and treatment arm ($p<0.01$) to be associated with PFS. **Conclusions:** The addition of Bev to ET increased PFS but not OS. Analyses to define subgroups with prolonged benefit from ET alone or ET-Bev are ongoing. Support: U10CA180821, U10CA180882, Breast Cancer Research Foundation, Genentech, Roche. Clinical trial information: NCT00545077 / NCT00601900.

FGFR gene amplification and response to endocrine therapy in metastatic hormone receptor positive (HR+) breast cancer. *First Author: Joshua Z. Drago, Massachusetts General Hospital, Boston, MA*

Background: Amplification in Fibroblast Growth Factor Receptor (FGFR) genes occurs in 10% of breast cancers, is associated with poor prognosis, and appears to drive resistance to endocrine therapies in vitro. However, the role of FGFR in modulating the clinical response to endocrine therapies is unclear, and could have important implications given that FGFR is a potential therapeutic target. This study aims to evaluate the association between FGFR amplification and clinical response to endocrine therapy in HR+ metastatic breast cancer (MBC). **Methods:** Primary or metastatic tumor specimens from patients with HR+/HER2 negative MBC underwent dual-color fluorescence in situ hybridization (FISH) of the FGFR1 locus on chromosome 8p. FISH ratios of $\geq$2 were considered positive for gene amplification (FGFR+). Time to progression (TTP) on first line endocrine therapy was evaluated in FGFR+ versus wild type (WT) patients using actuarial analysis. **Results:** Between 2012 and 2016, we identified 95 patients with HR+ MBC who underwent FGFR FISH testing. Of these, 24 (25.3%) were FGFR+. FGFR+ and WT patients did not differ in being postmenopausal at initial breast cancer diagnosis (28.6% vs. 31.7%; p = 1.0), having de-novo MBC (16.7% vs. 21.1%; p = 0.773), having received adjuvant chemotherapy (75% vs. 76.8%; p = 1.0) or having received adjuvant endocrine therapy (90% vs. 91.1%; p = 1.0). However, FGFR+ patients tended to be younger than WT patients (54.3 vs. 59.3 years; p = 0.045), and more likely to have PR-negative MBC (50.0% vs. 19.1%; p = 0.011). While there was no difference in TTP on first-line chemotherapy in FGFR+ vs. WT patients (5.0 vs. 6.2 months; p = 0.8), FGFR+ patients had a shorter median TTP on first-line endocrine therapy than WT (8.5 vs. 10.8 months; p = 0.047). These results were similar when stratified by presence of de-novo metastatic disease. **Conclusions:** In patients with HR+ MBC, FGFR gene amplification is associated with shorter time to progression on first line endocrine therapy. Further studies are needed to confirm these findings, and to investigate potential strategies for endocrine therapy and FGFR-directed combinatorial therapy in FGFR+ breast cancer.

Evaluation of RAD1901, a novel investigational, selective estrogen receptor degrader (SERD), for the treatment of ER-positive (ER+) advanced breast cancer. *First Author: Aditya Bardia, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: The treatment of advanced ER+ breast cancer remains a clinical challenge with the majority of patients eventually progressing due to resistance to endocrine therapy. RAD1901 is a novel, nonsteroidal, oral SERD that has demonstrated dose dependent degradation of ER, and ER regulated genes in preclinical studies. In multiple in vivo patient derived xenograft models of breast cancer, including those harboring ESR1 mutations, RAD1901 demonstrated significant antitumor activity. **Methods:** In a phase-1 Study RAD1901-005 (ClinicalTrials.gov ID: NCT02338349), patients with advanced ER+ breast cancer were enrolled in dose escalation cohorts, followed by a safety expansion cohort. Key inclusion criteria include postmenopausal women aged 18 years or older, with advanced ER+, HER2- breast cancer, who have received $\leq$ 2 prior chemotherapy regimens in the metastatic setting and $>$ 6 months of prior endocrine therapy. ESR1 mutation status was determined from circulating tumor DNA (ctDNA) samples. Clinical outcomes were evaluated based on RECIST v1.1 criteria. **Results:** As of January 25, 2017, total of 39 patients were enrolled at the 400 mg qd dose. Patients were heavily pre-treated (median lines of prior therapy = 3), with 38% and 41% having previously received fulvestrant and palbociclib/CDK4/6 inhibitor, respectively. RAD1901 was generally well-tolerated, with the most common adverse events being low grade nausea (Grade 3/4 = 0%) and dyspepsia (Grade 3/4 = 0%). ESR1 mutations, including D538G, Y537S/N/C, L536H/P/R, S436P and E380Q, were detected at baseline in 44% of patients and dynamic changes in the allele frequency of ESR1 mutations were observed in response to treatment. Confirmed partial responses were observed in patients with ESR1 mutations, and those who had previously received fulvestrant and palbociclib. **Conclusions:** RAD1901 has demonstrated evidence of single agent activity, with confirmed partial responses in heavily pre-treated patients with advanced ER+ breast cancer, including those with ESR1 mutations, warranting additional clinical development. Clinical trial information: NCT02338349.

Tracking evolution of aromatase inhibitor resistance with circulating tumour DNA (ctDNA) in metastatic breast cancer. *First Author: Charlotte Victoria Fribbens, Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Selection of resistance mutations may play a major role in the development of endocrine resistance. *ESR1* mutations are rare in primary breast cancer but have a high prevalence in patients treated with aromatase inhibitors (AI) for advanced breast cancer. We investigated the evolution of genetic resistance to first line AI therapy using sequential ctDNA sampling in patients with advanced breast cancer. **Methods:** Seventy-one patients on first line AI therapy for metastatic breast cancer were enrolled in a prospective study to collect plasma samples for ctDNA analysis every three months on therapy, and at disease progression. All plasma samples were analysed with *ESR1* multiplex digital PCR assays, and samples at disease progression were analysed by InVision (enhanced tagged-amplicon sequencing). Mutations were tracked back through samples prior to disease progression to study the evolution of mutations on therapy. **Results:** Of the 34 patients who progressed on first line AI, 53% (18/34) had *ESR1* mutations detectable at progression. Sequencing of progression plasma ctDNA identified polyclonal *RAS* mutations in 10.7% (3/28) progressing patients (2 polyclonal *KRAS*, 1 monoclonal *HRAS*), all of whom also had *ESR1* mutations, and a patient with an activating p.R248C *FGFR3* mutation. *ESR1* mutations were subclonal in 78.6% (11/14) patients, with all *RAS* mutations being rare subclones. In serial tracking prior to progression, *ESR1* mutations were detectable in plasma with a median of 5.3 months (95% CI 2.9-NA) prior to clinical progression. **Conclusions:** *ESR1* mutations are found at high frequency in patients progressing on AI, but are frequently subclonal and may not be the sole driver of AI resistance in these patients. Polyclonal *KRAS* mutations are identified as a novel mechanism of resistance to AI, associated with detection of *ESR1* mutations.

Genomic profiling of circulating tumor DNA (ctDNA) from patients (pts) with metastatic breast cancer (mBC). *First Author: Lajos Pusztai, Yale Cancer Center, New Haven, CT*

Background: Clonal evolution during progression to and treatment of mBC highlights the importance of genomic profiling of recent samples to guide clinical decision making. We undertook this study to characterize genomic alterations (GA) in ctDNA from pts with mBC during the course of clinical care. **Methods:** Hybrid-capture based genomic profiling of 62 genes (FoundationACT) was performed on ctDNA from 255 BC pts. The fraction of ctDNA in the blood was estimated using the maximum somatic allele frequency (MSAF) for each sample. **Results:** 168 pts were ER+ [16 HER2+, 134 HER2(-), 18 HER2 unknown (unk)]; 51 were ER(-) [7 HER2+, 38 triple negative (TNBC), 6 HER2 unk]; 36 were ER unk; 95% were stage 4. For pts with treatment information, 90% had prior chemotherapy and 90% ER+ pts had prior aromatase inhibitor therapy (AI). ≥1 GA was reported in 78% of all cases and in 88% of cases with evidence of ctDNA in the blood (MSAF >0). For 226 cases with MSAF >0, an average of 2.7 GA/case were reported. The most common GA for ER+ pts were in *TP53* (44%), *PIK3CA* (39%), *ESR1* (36%), *CDH1* (11%), *KRAS* (10%) and *ERBB2* (*HER2,* 9%). 101 *ESR1* GA were identified in 61 pts [54 ER+, 7 ER unk], including 4 HER2+ pts. For ER+ pts with treatment information: 37% (22/60) with prior AI had *ESR1* GA; all pts with *ESR1* GA had prior AI. 24 pts had >1 *ESR1* GA, with instances of GA in *cis*. Frequent *ESR1* GA were Y537S/N (n=47), D538G (n=29) and E380Q (n=7); rearrangement (n=3) and amplification (n=1) were also detected. Concurrent GA with *ESR1* were found in *PIK3CA* (41%), *FGFR1* (13%), *BRCA1/2* (5%), *HER2* (5%) and *AKT1* (3%). In ER(-) pts, the most common GA were in *TP53* (74%), *PIK3CA* (17%), *NF1* (11%), *BRCA1* (9%) and *EGFR* (9%). *HER2* activating mutation occurred in 3% of cases that were HER2(-) by prior testing. Kinase fusions in *FGFR2/3* (3 ER+) and *EGFR* (1 TNBC) were observed. **Conclusions:** In this study, evidence of ctDNA in the blood was observed in 89% of cases. *PIK3CA* and *ESR1* GA frequencies were similar to those reported in previous studies of ctDNA from ER+ pts after AI. Diverse *ESR1* GA and co-occurring GA suggest therapeutic approaches for AI refractory ER+ mBC. Our results demonstrate that genomic profiling of ctDNA may be a complementary approach to tissue-based genomic testing for pts with mBC.

Genomic alterations driving breast cancer (BC) metastases and their relationship with the subtype switch in the GEICAM ConvertHER study. *First Author: Joan Albanell, Medical Oncology, Hospital del Mar, Barcelona, Spain*

Background: To understand the mechanisms underlying the evolution of tumors in the process of metastasis, we studied 61 paired primary-relapse BC from the GEICAM ConvertHER study. While some of the metastases maintained the clinical (ER/PR and HER2 status) and/or intrinsic subtype (defined by expression arrays) of the original tumor (concordant), others exhibited a subtype shift (discordant). We aimed to identify the genomic alterations driving the metastases and, particularly, their relationship with the subtype switch. **Methods:** We detected the somatic variants (mutations and copy number alterations (CNAs)) affecting 202 genes across the 61 sample pairs via targeted sequencing. We employed the Cancer Genome Interpreter (cancergenomeinterpreter.org), a bioinformatics approach to identify the alterations most likely driving tumorigenesis, and subsequently identified those whose cancer cell fraction markedly changed in the metastases. We explored the clonal remodeling in metastasis comparing the cell fractions of driver mutations in both concordant and discordant tumors. **Results:** We found that 156 genes had 747 somatic mutations and 171 genes suffered 1042 somatic CNAs in the 61 studied tumor pairs. We identified a median of 11 and 9 mutations in primaries and metastases, respectively. Several frequent BC mutational drivers, such as *TP53*, *PIK3CA*, *MLL3*, *MAP3K1*, and *NOTCH2* were amongst the more frequently changed their cancer cell fraction in metastases with respect to primaries. We found that driver mutations of discordant tumors exhibited a significantly higher increase of clonal cell fraction. Moreover, whether the clonal status of a driver mutation was conserved in the metastasis was significantly associated to whether the tumor maintains its clinical subtype but not its intrinsic subtype. **Conclusions:** Our results suggest that a shift in the clinical subtype of BC undergoing metastasis is accompanied by more significant changes at the genomic level than those suffered by tumors that maintain their clinical subtype. This remodeling of the landscape of drivers could open new therapeutic opportunities to specifically target discordant BC.

Predicting sensitivity to palbociclib with early circulating tumor DNA dynamics in the PALOMA-3 trial. *First Author: Ben O'Leary, Royal Marsden Hospital, The Institute of Cancer Research, London, United Kingdom*

Background: Palbociclib improves progression free survival (PFS) in patients with advanced, hormone receptor positive, HER2-negative breast cancer. There are currently no biomarkers to predict sensitivity to palbociclib. We investigated if early circulating tumour DNA (ctDNA) dynamics could predict clinical outcome on palbociclib (Palbo) and fulvestrant (F) in the PALOMA-3 trial. **Methods:** Plasma samples were prospectively collected in PALOMA-3 for ctDNA analysis at baseline, cycle 1 day 15 (D15) and end of treatment (EOT), and were screened for *PIK3CA* and *ESR1* mutations using digital PCR. The primary objective was to assess whether early dynamic changes in *PIK3CA* mutations would predict PFS in patients treated with Palbo + F. Suppression of *PIK3CA* ctDNA levels below an optimised cut-off at cycle 1 D15, relative to baseline levels, was termed a 'circulating DNA ratio (CDR) response. **Results:** *PIK3CA* mutations were identified in 22.0% (100/455) of screened baseline samples with 52 of these randomised to Palbo + F and having matched D15 samples. Patients on Palbo + F with a CDR response had a median PFS of 11.2 months (95%CI 11.1 – undefined) whereas patients on Palbo + F without a CDR response had a median PFS of 4.1 months (95%CI 3.6 – 5.5) (HR for no CDR response 4.92, 95% CI 1.98 – 12.26, p = 0.0002). Overall, Palbo + F suppressed D15 *PIK3CA* ctDNA levels to a greater extent than placebo + F (p<0.0001). *ESR1* mutations were identified in 25.6% (114/445) of screened baseline samples, 65 having matched D15 samples. *ESR1* mutations showed greater ctDNA suppression than *PIK3CA* mutations, and were more frequently undetectable at EOT (25.8% *ESR1* undetectable 8/31, v 2.6% for *PIK3CA*, 1/38, p=0.004). Clearance of *ESR1* mutation at EOT was associated with early loss of *ESR1*at D15 (p = 0.027). **Conclusions:** Early circulating tumor DNA assessment may predict sensitivity to palbociclib and fulvestrant, and if validated by further analysis may allow treatment to be adapted prior to progression. *ESR1* mutations are frequently lost after treatment with palbociclib and fulvestrant.

Abemaciclib for the treatment of brain metastases (BM) secondary to hormone receptor positive (HR+), HER2 negative breast cancer. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Abemaciclib is an oral selective CDK4 and CDK6 inhibitor administered on a continuous dosing schedule, which has demonstrated clinical activity and an acceptable safety profile in patients (pts) with heavily pre-treated HR+ metastatic breast cancer (MBC). Abemaciclib has been shown preclinically to cross the blood-brain barrier, providing rationale for testing this agent in pts with BM. Furthermore, as previously presented, levels of abemaciclib similar to plasma were detected in resected BM in a subset of pts with HR+, HER2- MBC in this study. **Methods:** Study I3Y-MC-JPBO is an open-label, Phase 2, Simon 2-Stage trial evaluating the safety and efficacy of abemaciclib 200 mg BID in pts with new or progressive BM secondary to HR+ MBC, NSCLC, or melanoma. Eligible pts in Part B (the focus of this presentation) include pts with HR+, HER2- MBC who have ≥1 measurable brain lesion. The primary objective was objective intracranial (IC) response rate as defined by Response Assessment in Neuro-Oncology BM response criteria. Secondary objectives (IC related) include best overall response, duration of response, disease control rate, and clinical benefit rate. Exploratory objectives include assessment of drug concentrations in resected tumors. Safety, tolerability, and PK of abemaciclib were also assessed. Stage 1 includes 23 pts; if < 2 of the 23 pts respond to abemaciclib, futility is met. However, if ≥2 respond, 33 additional pts are to be enrolled to Stage 2. **Results:** This Stage 1 efficacy analysis included 23 pts; 32 pts were included in the safety analysis. Although 5 pts were considered nonevaluable, 2 pts (8.7%) had confirmed partial response (PR) (meeting the predefined threshold for advancement to Stage 2); enrollment is ongoing. At the time of the analysis, the 2 pts with PR had completed 14 and 15 cycles each (21d cycles) of therapy. The majority of adverse events were gastrointestinal in nature, consistent with previous studies of abemaciclib. **Conclusions:** This study has provided preliminary evidence that abemaciclib penetrated BM in pts with HR+, HER2- MBC and had antitumor activity in this population. Final results will be presented following Stage 2 analyses. Clinical trial information: NCT02308020.

Health-related quality of life (HRQoL) of postmenopausal women with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC) treated with ribociclib + letrozole: Results from MONALEESA-2. *First Author: Sunil Verma, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: In the MONALEESA-2 trial, ribociclib + letrozole significantly improved progression-free survival (PFS) and showed higher overall response rates vs letrozole alone in HR+, HER2− ABC. To place these clinical results in the context of patient experience, here we present key patient-reported outcomes (PROs) including HRQoL. **Methods:** 668 patients were randomized (1:1); 334 each to the ribociclib + letrozole and placebo + letrozole arms. PROs were evaluated during treatment and at progression using the EORTC QLQ-C30, QLQ-BR23, and EQ-5D-5L questionnaires. Changes from baseline in all subscales were analyzed using a linear mixed-effect model and time to 10% deterioration was compared between treatment arms using the stratified log-rank test. **Results:** Questionnaire compliance rates were high (≥90%). During treatment, HRQoL (global health status/QoL score) was maintained and similar in both treatment arms. At progression/end of treatment, HRQoL worsened numerically in both arms. Time to definitive 10% deterioration of HRQoL was similar between treatment groups, slightly favoring the ribociclib + letrozole arm (hazard ratio: 0.89; 95% confidence interval: 0.67–1.18). No statistically or clinically relevant differences were observed for key symptoms using EORTC QLQ-C30 including fatigue, nausea, and vomiting. There was a clinically relevant ($>$ 5 points) improvement in pain from baseline to post-baseline (up to Cycle 15) in the ribociclib + letrozole arm while there was only mild improvement ($<$ 5 points) observed in the placebo + letrozole arm. **Conclusions:** In addition to significantly improving PFS, ribociclib + letrozole maintains HRQoL when compared with letrozole + placebo. A numerical trend was observed favoring ribociclib + letrozole for pain reduction. Clinical trial information: NCT01958021.

1021 Poster Session (Board #13), Sun, 8:00 AM-11:30 AM

Long-term survival of de novo stage IV human epidermal growth factor receptor 2 (HER2)-positive breast cancers treated with HER2 targeted therapy. *First Author: Yao Wong, Yale School of Medicine, New Haven, CT*

Background: An increasing number of metastatic HER2 positive cancers represent *de novo* stage IV disease as fewer early stage patients relapse. We hypothesize that a subset of these has long progression free survival (PFS) after initial combined modality HER2-targeted therapies. **Methods:** 483 patients with *de novo* stage IV HER2 positive breast cancer diagnosed between 1998-2015 were identified through the medical records at Yale and MD Anderson Cancer Centers, respectively. Treatment, clinical variables and survival were extracted and compared between those who achieved "no evidence of disease" (NED) status with initial therapy and those who did not. **Results:** All patients received trastuzumab and 94 (20%) also received pertuzumab as first line therapy.The median OS was 5.5 years (95% CI: 4.8-6.2); OS rates at 5 and 10 years were 54% (95% CI: 48%-60.4%) and 18% (95% CI: 11.4%-28.3%), respectively and PFS were 41% (95% CI: 35%-48%) and 41% (95% CI: 35%-48%). Sixty-three patients (13.0%; 95% CI: 10.2% -16.4%) achieved NED. The PFS and OS at 5 and 10 years were the same 100% and 98% (95% CI: 94.6%-100%), respectively. For patients with no-NED (n = 420), the median OS was 4.7 years (95% CI: 4.2-5.3), the PFS and OS rates at 5 and 10 years were 12% (95% CI: 4.5%-30.4%) and 0% and 45% (95% CI: 38.4%-52.0%) and 4% (95% CI: 1.3%-13.2%), respectively. NED patients had significantly longer progression free survival (log-rank test p≤0.001) and overall survival (log-rank test p≤0.001), more frequently had single organ site metastasis (76% vs 57%, p = 0.005), and more frequently had surgery for primary tumor (59% vs. 25%, p ≤0.001) than no-NED patients, but there was no significant difference in age, grade, race, year of diagnosis, ER status, treatment distribution, or radiation between the groups. **Conclusions:** About 13% of *de novo*, stage IV, HER-2 positive MBC patients achieved NED with HER-2 targeted therapies, all of these patients were progression free at 5 years and overall survival at 10-years was 98% compared to 4% among those with no-NED in our data sets. These results suggest that aggressive multimodality therapy of newly diagnosed stage IV HER2 positive cancers to render them NED may be warranted.

1023 Poster Session (Board #15), Sun, 8:00 AM-11:30 AM

Efficacy of trastuzumab emtansine (T-DM1) in patients (pts) with HER2+ metastatic breast cancer (MBC) previously treated with pertuzumab (P). *First Author: Ander Urruticoechea, Onkologikoa Foundation, San Sebastian, Spain*

Background: T-DM1 was approved for pts with HER2+ MBC previously treated with trastuzumab (H) and a taxane based on the phase III EMILIA study. P in combination with H + docetaxel (T) later became the first-line standard of care for HER2+ MBC, but there are limited data on T-DM1 efficacy in pts who previously received P. We present exploratory efficacy results from pts treated with T-DM1 any time after P from 2 phase III studies: CLEOPATRA and PHEREXA. **Methods:** CLEOPATRA (NCT00567190) and PHEREXA (NCT01026142) are randomized, 2-arm trials evaluating P-based regimens for HER2+ MBC. CLEOPATRA studies H + T + P vs HT + placebo in pts with no prior anti-HER2 treatment (tx) or chemotherapy for MBC, while PHEREXA studies H + capecitabine (C) +/− P in pts who progressed during/after previous H tx for MBC. We assessed overall survival (OS) in an exploratory analysis of pts who either received or did not receive T-DM1 at any time after discontinuing study-assigned tx in CLEOPATRA or PHEREXA. **Results:** Of 408 pts who received HTP in CLEOPATRA and 228 pts who received HCP in PHEREXA, 32 and 43 pts received subsequent T-DM1, respectively (Table). Median duration of T-DM1 tx was 7.1 mo (range 0−44) and 4.2 mo (range 0−22), respectively, and median time from discontinuation of P to start of T-DM1 was 3.5 mo (range 1−47) and 10.6 mo (range 1−28). **Conclusions:** Although data are limited in these exploratory analyses, our results provide additional evidence of T-DM1 clinical activity in pts with HER2+ MBC who progressed on prior P + H, a finding with real-world implications. Clinical trial information: NCT00567190, NCT01026142.

Circulating PD-L1 (programmed death-ligand 1) and outcomes in a HER2-positive metastatic breast cancer cohort treated with first-line trastuzumab. *First Author: Ayesha Ali, Penn State Milton S. Hershey Medical Center, Hershey, PA*

Background: Recently the immune checkpoint inhibitors (ICIs) have demonstrated efficacy across a wide variety of cancers, but have been less effective in breast cancer. PD-L1 (B7-H1, CD274) is a ligand produced by many tumor cells and some immune cells, and suppresses the T cell immune response. This allows tumor cells to escape immune detection. PD-L1 is used as a companion tumor tissue IHC biomarker for patient selection for some of the FDA-approved ICIs (pembrolizumab), but not for others (nivolumab, atezolizumab). Circulating PD-L1 has been detected in multiple myeloma, renal, lung, and gastric cancer, but not in breast cancer. Here we correlated serum PD-L1 levels with outcome in a HER2-positive metastatic breast cancer cohort treated with trastuzumab. **Methods:** Pretreatment serum was obtained from 63 metastatic breast cancer patients before starting first-line trastuzumab-containing therapy. A novel ELLA microfluidic channel immunoassay platform (ProteinSimple, San Jose, CA) was employed to quantitate serum PD-L1. Serum PD-L1 levels were analyzed using continuous, quartile, and dichotomous (25%, median, and 75%) cutpoints. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method. **Results:** On a continuous basis, patients with higher serum PD-L1 had a significantly reduced PFS (p = 0.045) and overall survival OS (p = 0.004) compared to patients with lower serum PD-L1 levels. Patients with the higher quartiles of serum PD-L1 also trended to have reduced PFS (0.11) and significantly reduced OS (p = 0.015) compared to the lower quartiles of serum PD-L1. Finally, using either the 25th or 75th percentile of serum PD-L1 as dichotomous cutpoint, patients with higher serum PD-L1 had significantly reduced OS (p = 0.04). **Conclusions:** Higher circulating PD-L1 levels were prognostic for reduced PFS and OS in HER2-positive metastatic breast cancer patients treated with first-line trastuzumab. Circulating PD-L1 deserves further study for prognostic and predictive biomarker utility in larger trials of immune checkpoint inhibitors and other immunotherapies in breast and other cancers. AA, LK contributed equally.

1025 Poster Session (Board #17), Sun, 8:00 AM-11:30 AM

Eribulin in combination with pertuzumab plus trastuzumab for HER2-positive advanced or recurrent breast cancer (JBCRG-M03). *First Author: Kazutaka Narui, Breast and Thyroid Surgery, Yokohama City University Medical Center, Yokohama, Japan*

Background: Pertuzumab (P) provided overall and progression-free survival (PFS) benefits in HER2-positive metastatic breast cancer (MBC) in the CLEOPATRA study as a first-line therapy. However, long-term administration of intravenous docetaxel at a dose of 75 mg/m^2 every 3 weeks in MBC patients is difficult. Eribulin (E) is a well-tolerated cytotoxic agent. We report the efficacy and safety of E in combination with trastuzumab (T) plus P as first- and second-line therapy for metastatic or advanced BC in a multicenter, open-label phase II study (UMIN000012232). **Methods:** HER2-positive advanced or recurrent BC patients with no or a single prior therapy as advanced or recurrent chemotherapy were enrolled. All patients were administered T and taxane as adjuvant or first-line chemotherapy. Treatment consisted of E 1.4 mg/m^2 on days 1 and 8 of a 21-day cycle and T (8 mg/kg loading dose $>$ 6 mg/kg) plus P (840 mg loading dose $>$ 420 mg) once every 3 weeks, all given intravenously. The primary end point was PFS. **Results:** From November 2013 to April 2016, 50 patients were enrolled. Forty-nine patients were eligible for safety analysis; full analysis set (FAS) includes 46 patients. The median patient age was 56 years (range 23–70), and 8 (16%) and 41 (84%) patients were treated in first- and second-line settings, respectively. Twenty-eight patients out of 49 patients (57%) continued the protocol therapy at the end of 8 cycles and median PFS was not yet reached. The response rate by RECIST ver.1.1 was 56.5% in FAS. The relative dose intensity of E, T, and P were 93.3% (range 77.0%–100%), 100% (range 96.0%–100%) and 100% (range 89.7%–100%), respectively in FAS. The grade 3/4 adverse effects (AE) were neutropenia in 5 patients (10.2%) including 2 patients (4.1%) with febrile neutropenia, hypertension in 3 patients (6.1%), and other AEs in only one patient. Average of the ejection fraction did not decrease significantly. Symptomatic left ventricular systolic dysfunction was not observed. **Conclusions:** E in combination with T plus P was well-tolerated and could be an alternative to docetaxel-based combination therapy for HER2-positive MBC. Clinical trial information: 000012232.

1026 Poster Session (Board #18), Sun, 8:00 AM-11:30 AM

Phase I study of alpelisib (BYL-719) and T-DM1 in HER2-positive metastatic breast cancer after trastuzumab and taxane therapy. *First Author: Sarika Jain, Northwestern University Division of Hematology/Oncology, Chicago, IL*

Background: Constitutive activation of the phosphatidylinositol-3-kinase (PI3K) signaling pathway is a mechanism of trastuzumab resistance in HER2-positive metastatic breast cancer (MBC). Alpelisib (BYL-719) is the first oral PI3K inhibitor that selectively inhibits the *PI3K*α isoform. We aimed to determine the maximum tolerated dose (MTD), safety, and activity of alpelisib with ado-trastuzumab emtansine (T-DM1) in HER2-positive MBC that failed standard therapy. **Methods:** In this phase I study, pts received alpelisib daily (cohort 1: 300 mg, (-1): 250 mg) and T-DM1 3.6 mg/m^2 on Day 1 every 21 days using a 3+3 design with dose expansion at MTD. Dose-limiting toxicity (DLT) was defined as CTCAE Grade 3/4 adverse events (AE) during cycle 1. Data cut-off is Jan. 1, 2017. **Results:** 17 pts were enrolled. Median age was 53 (40-66). Median prior lines of therapy in metastatic setting was 4.5 (0-13) including 9 pts who progressed on prior T-DM1 (after median 8 cycles). Median number of metastatic sites was 2 (1-5). Median number of cycles per pt who completed at least 1 cycle was 8 (1-19). Five pts were enrolled in cohort 1 with 2 DLTs (grade 3 rash), leading to cohort (-)1, in which there were no DLTs. The most common alpelisib-related AEs were hyperglycemia (n = 9, 53%), fatigue (n = 9, 53%), nausea (n = 7, 35%), and rash (n = 8, 47%). Grade 3 alpelisib-related AEs included rash (n = 7), hyperglycemia (n = 3), weight loss (n = 1), hypertension (n = 2), and pancreatitis (n = 1). Grade 3 rash occurred during cycle 1, which resolved with interruption and subsequent dose reduction of alpelisib and use of steroids. Grade 3 hyperglycemia was reversible with oral anti-diabetic treatment. One Grade 4 AE occurred (thrombocytopenia) likely due to T-DM1. MTD for alpelisib was established as 250 mg daily. Median follow-up was 11.6 months (0.3-19.5). Median PFS was 6 months (95% CI 2.9-10.6). In 11 pts without prior T-DM1 mPFS was 4.3 months (95% CI 2.0-8.8) and in 6 pts with prior T-DM1 it was 10.6 months (95% CI 1.6-12.6), p = 0.18. **Conclusions:** The combination of alpelisib 250 mg daily and T-DM1 appears to be safe in HER2-positive MBC pts with significant anti-tumor activity, even in pts previously treated with T-DM1. A phase II study is planned. Clinical trial information: NCT02038010.

1027 Poster Session (Board #19), Sun, 8:00 AM-11:30 AM

TBCRC 036: Window of opportunity clinical trial reveals adaptive kinome reprogramming in single and combination HER2-targeting in breast cancer (BrCa). *First Author: Steven P Angus, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: HER2 targeting is challenging due to heterogeneity in response and resistance. Adaptive kinome reprogramming (AKRP) is a resistance mechanism to kinase-targeted therapy (Rx) in TNBC (*Cancer Discovery*2017). We studied AKRP in HER2+ BrCa by comparing transcriptome and kinome profiles before and after Rx with FDA-approved anti-HER2 drugs and combinations: trastuzumab (T), pertuzumab (P), T+P, or T+ lapatinib (T+L). Profiling was by RNA sequencing (RNAseq) and multiplexed inhibitor beads coupled with mass spectrometry (MIB/MS). MIB affinity-purification selectively enriches the functional kinome ($>$ 250 kinases per sample) for identification/quantification by MS. **Methods:** Eligible patients (pts) had biopsy then randomization to: T (8 mg/kg iv), P (840 mg iv), T+P (same doses), or T+L (8mg/kg iv x1, 1000 mg po/d) 7 days before breast surgery. RNAseq and MIB/MS on paired pre- and post-Rx samples were analyzed using DESeq2 (comparison of mean difference in $\log_2$fold change (post/pre)) and MaxQuant (kinome response profiling) software. **Results:** Of 23 evaluable pts, we obtained informative paired RNAseq data in 13 (5 T, 3 P, 3 T+P, 2 T+L), and identified distinct expression responses ($p_{adj} \leq 0.05$) between Rx arms, such as FGFR4 increase in P vs T or T+P. All samples had HER2 enrichment by RNAseq. Kinome response profiling from 11 pts (3 T, 3 P, 4 T+P, 2 T+L) revealed consistent increases in MIB binding (abundance a/o activity) of several tyrosine kinases regardless of Rx, including immune-related kinases SYK, IRAK4, FGR, and FES. Other kinases, such as p90Rsk and GSK3B, exhibited increased binding in response to T and T+P, but not P alone. While not quantifiable in every sample due to detection limits, HER2 inhibition was observed by loss of MIB binding in select post-Rx versus pre-Rx comparisons. **Conclusions:** HER2 inhibition upregulates and activates specific receptor tyrosine kinases in tumor cells as well as alterations that may reflect changes in the immune compartment. HER2+ BrCa exhibit plasticity, characterized by distinct expression and kinome profile changes within 1 week of initiating Rx, and reprogramming in both immune responses and BrCa cells. Clinical trial information: NCT01875666.

1028 Poster Session (Board #20), Sun, 8:00 AM-11:30 AM

Impact of 2013 ASCO/CAP guidelines on HER2 determination of invasive breast cancer: A single institution experience using frontline dual-color FISH. *First Author: Elisa Gasparini, Breast Unit Arcispedale S. Maria Nuova-Irccs, Reggio Emilia, Italy*

Background: ASCO/CAP new guidelines published in 2013 (AC2013) significantly modified the scoring criteria for HER2-FISH. We retrospectively evaluated the impact of AC2013 in a five-year cohort of consecutive invasive breast cancers (IBCs) underwent frontline dual-color FISH. Furthermore, we applied three different reflex tests and investigated clinical outcomes of patients with HER2-equivocal IBC. **Methods:** 2788 consecutive IBCs that underwent frontline HER2/CEP17 determination in our institution from January 2009 to December 2013 were reclassified based on the AC2013 guidelines. FISH HER2-equivocal cases underwent reflex tests: HER2-IHC, *RARA*-FISH, and *SMS*-FISH. Clinico-pathological correlation was performed. **Results:** Two hundred HER2-negative cases (7.2%) were classified differently based on the AC2013: 0.3% (8/2788) became HER2-positive and 6.9% (192/2788) HER2-equivocal. AC2013 equivocal-IBCs represented a subgroup of grade 3, luminal-like subtype IBCs, in patients with a higher age. After reflex tests, among 190 equivocal cases 102 (53.7%) were reclassified as HER2-positive, 51 (26.8%) negative and 37 (19.5%) equivocal. IHC resulted negative in 44.7% (85), whereas *SMS*-FISH showed the highest percentage of positive results (45.8%). No statistically significant differences were identified in the disease-free and overall survival. **Conclusions:** AC2013 compared with AC2007 significantly increased initial HER2-equivocal cases (6.9%vs1.6%, $p < 0.001$). After reflex testing, 4.5% of patients not treated with anti-HER2 therapy (either HER2-positive or "ultimate equivocal") resulted eligible to trastuzumab, but showed clinical outcome comparable with AC2007 HER2-positive patients, treated with trastuzumab. Our findings belittle the clinical impact of AC2013 HER2-equivocal reclassification; accordingly further studies are necessary to justify this category and the reclassification efforts by additional reflex tests.

1029 Poster Session (Board #21), Sun, 8:00 AM-11:30 AM

Burden of out-of-pocket spending among high-deductible health plan members with metastatic breast cancer. *First Author: Christine Leopold, Harvard Medical School and Harvard Pilgrim Heatlh Care Institute, Department of Population Medicine, Boston, MA*

Background: 50% of workers have high-deductible health plans (HDHP) that require major outofpocket (OOP) spending for cancerrelated care. The OOP burden among patients with advanced cancer in HDHPs is unknown. Our objective was to estimate OOP spending for women with metastatic breast cancer (mbc) stratified by health plan type. **Methods:** Our data source was administrative health insurance claims and enrollment data of members insured though a large national health plan. We included 7142 women age 25-64 with mbc who had at least 6 months enrollment before the diagnosis and at least 12 months followup. We used a time series design and plotted OOP spending stratified by HDHP vs low-deductible plan. Primary outcome measures included: (1) 20042012 calendar trends in total annual OOP spending, (2) monthly total OOP spending in the 6 months before and 24 months after women were diagnosed with mbc, and (3) monthly total OOP spending in the last 6 months of life. Plots were adjusted for age, socioeconomic status, race/ethnicity, and US region of residence, and we then conducted linear regression to assess for statistical significance of trends. **Results:** In 2004, average annual OOP spending for women with mbc cancer in low-deductible health plans was $1196.2 and increased to $2570 in 2012, a yearly increase of $159.2 (113.2205.2). For women in HDHP average OOP spending in 2004 amounted to $2648 and increased to $3736.4 in 2012, representing an annual increase of $160.4 per year (105.4215.4) Average OOP spending per person month peaked in the month of diagnosis to $1633.8 for women in HDHPs and to $643 among low-deductible plan members. Average OOP spending in the last 6 months of life were $285.7 per person month among low-plan ($1714.2 per 6 months) and $607.3 among HDHP ($3644 per 6 months). **Conclusions:** To our knowledge, this is the first analysis to estimate OOP spending for women with mbc accounting for enrollment in HDHPs versus low-deductible plans. We found that OOP spending is increasing over time and is high in the last 6 months of life. HDHP members with mbc faced much higher OOP spending than women in traditional plans across all analyses. Findings raise concerns that HDHPs could worsen access to mbc treatments.

1030 Poster Session (Board #22), Sun, 8:00 AM-11:30 AM

A mouse-human phase I co-clinical trial of taselisib in combination with TDM1 in advanced HER2-positive breast cancer (MBC). *First Author: Otto Metzger Filho, Dana-Farber Cancer Institute, Boston, MA*

Background: PI3K blockade has the potential to revert resistance to anti-HER2 therapies. **Methods:** Pre-clinical experiments were conducted in parallel to a phase Ib study with the PI3-kinase inhibitor Taselisib + T-DM1 in HER2+ MBC. **Results:** Pre-clinically, HER2+ cell lines (HCC1954, MDA-MB-361, MDA-MB453) treated with T-DM1 until resistance had decreased HER2 expression. Tx with Taselisib restored HER2 levels in T-DM1 resistant cells. In vivo, the combination of T-DM1 + Taselisib was superior to either agent alone in transgenic mammary carcinomas driven by *HER2* with or without a *PIK3CA* H1047R transgene. The phase Ib study enrolled 26 pts with HER2+ MBC. Median age was 57 (38-95), ER+ (58%), ER- (42%). *PIK3CA* wild type (35%) mutant (23%) pending results (42%). Pts had a median of 2 lines of prior tx for MBC. Prior T-DM1 was given to 38.5% of pts. Median duration of tx among 18 pts was 4 cycles (2-19). 8 pts remain on tx. No DLTs were observed in the 2 dose levels explored: T-DM1 (3.6mg/Kg) q3 wk with either Taselisib 2mg QD or Taselisib 4mg QD. 20 patients were included in the expansion phase. Most common G3 G4 AEs were thrombocytopenia (19.2%), diarrhea (15.4%), vomiting (7.7%), lipase increase (7.7%) and hyperglycemia (7.7%). Pneumonitis was reported in 4 cases (3 G1, 1 G2); further evaluation revealed elevated beta-glucan in 3 of the 4 cases raising suspicion for pneumocystis pneumonia (PJP). 24/26 pts were evaluable for confirmed response: (4% CR, 29% PR, 50% SD). Confirmed PR/CR according to prior TMD1 (yes 30% no 36%) and PIK3CA mut status (40% mut, 22% wild type; 9/23 PIK3CA results pending). Median PFS was 7.6 mos (95% CI 2.9 to NR). **Conclusions:** The combination of Taselisib + T-DM1 is superior to either agent alone in mouse models of HER2+ BC. In the phase Ib study, T-DM1 + Taselisib had an acceptable safety profile although PJP prophylaxis should be considered for this regimen. Thrombocytopenia was reversible with no bleeding events. Preliminary evidence of efficacy was observed regardless of *PIK3CA* status or prior tx with T-DM1. This co-clinical trial allowed for the rapid translation of lab observations to the clinical setting and provided data to facilitate interpretation of the clinical results. Clinical trial information: NCT02390427.

1031 Poster Session (Board #23), Sun, 8:00 AM-11:30 AM

DS-8201a, a HER2-targeting antibody-drug conjugate, to elicit immune responses and benefits in combination with an anti-PD-1 antibody. *First Author: Tomomi Nakayama Iwata, Daiichi Sankyo Co., Ltd., Tokyo, Japan*

Background: DS-8201a, a HER2-targeting antibody–drug conjugate (ADC), with a topoisomerase I inhibitor, exatecan drivative (DX-8951 derivative, DXd) has been shown to have antitumor effects in preclinical xenograft models and clinical trials, but the involvement of the immune system in the antitumor efficacy of DS-8201a has not been elucidated yet. **Methods:** The antitumor efficacy of DS-8201a individually and in combination with an anti-PD-1 antibody was determined in a syngeneic mouse model with human HER2-expressing CT26.WT (CT26.WT-hHER2) cells. Mice whose tumors had been cured by DS-8201a treatment were rechallenged with CT26. WT-hHER2 cells; their splenocytes were co-cultured with CT26.WT-hHER2 or CT26.WT-mock cells, and IFN-g secretion by these cells was determined. To investigate effects of DXd and DS-8201a on dendritic cells (DCs), the expression of DC markers on bone marrow derived DCs (BMDCs) and intratumoral DCs was analyzed by flow cytometry. Furthermore, MHC class I and PD-L1 expression on tumor cells was analyzed. **Results:** At a weekly dosage of 10 mg/kg, DS-8201a showed significant antitumor effects in the mouse model. Mice whose tumors had been cured by DS-8201a treatment rejected the rechallenge with CT26.WT-hHER2 cells, and splenocytes from these mice were activated by both CT26.WT-hHER2 and CT26. WT-mock cells. In the mouse model, DS-8201a treatment raised a population of intratumoral DCs ($CD45^+CD11c^+$MHC class II^+) and increased DC expression of CD86, a DC activation marker; DXd also up-regulated CD86 expression on BMDCs in vitro. Furthermore, DS-8201a up-regulated PD-L1 and MHC class I expression on tumor cells. Notably, antitumor effects of the combination of DS-8201a with an anti-PD-1 antibody were better than those of monotherapy. **Conclusions:** DS-8201a elicits immune responses via mechanisms other than cytotoxic effects on tumor cells. This finding suggests additional benefits of combining DS-8201a with an immune checkpoint inhibitor (ICI). The combination of DS-8201a and an anti-PD-1 antibody was effective in tumor suppression, indicating that DS-8201a may be successfully combined with an ICI in human clinical applications.

1032 Poster Session (Board #24), Sun, 8:00 AM-11:30 AM

Survival by HER2 receptor status in stage IV breast cancer: SEER 2010-2012. *First Author: Alexandra Thomas, Wake Forest Baptist School of Medicine, Winston-Salem, NC*

Background: Therapeutic advances have altered the course of once highly lethal HER2+ breast cancer (BC). We report survival in a recent population-based cohort by HER2 status, overall, and within hormone receptor(HR)+ BC. **Methods:** Surveillance, Epidemiology, and End Results Program data were queried to identify women diagnosed 2010-2012 with Stage IV BC as first cancer. Patients were grouped by HER2 and HR status. Kaplan Meier estimates of 3-yr observed survival (OS) were compared with log-rank tests. A multivariate cox model was fitted for the HER2+ cohort. **Results:** 3-yr OS for HER2+(any HR), HR+/HER- and triple-negative (TN) BC was 52.3%, 48.4% and 16.0% respectively ($p<0.01$ HER2+(any HR) vs TNBC; p=0.20 HER2+(any HR) vs HR+/HER2-). Across registries, OS for HER2+(any HR) BC ranged from 29.2% to 61.7% (p=0.05). On Cox model, survival in HER2+(any HR) BC was associated with age 50+ (Hazard ratio (HR) 1.84, 95% CI 1.45-2.34), HR+ status (HR 0.70, 0.58-0.84), high histologic grade (HR 1.30, 0.58-0.84), surgery (HR 0.40, 0.33-0.49), separated marital status (HR 1.72, 1.4-2.13), year 2012 (HR 0.81, 0.64-1.04), and registry (varies by reference group). For HR+ BC, OS also differed by HER2 status: 55.3% for HR+/HER+ and 48.4% for HR+/HER2- ($p<0.01$). 3-yr OS by HER2 status for women presenting with HR+ BC is shown (Table). **Conclusions:** Survival in de novo Stage IV HER2+ BC in the United States exceeds that in HER2- BC, with median survival >3 yrs. Survival was significantly better for HR+/HER+ BC than HR+/HER- BC. Disparate OS in HER2+ BC suggest opportunities may remain to fully realize advances in HER2-directed therapy. Given recent therapeutic advances, the trend of HER2+ survival gains from 2010 to 2012 will likely continue.

1033 Poster Session (Board #25), Sun, 8:00 AM-11:30 AM

Safety of trastuzumab emtansine (T-DM1) in HER2-positive advanced breast cancer (BC) patients (pts): Primary results from KAMILLA study cohort 1. *First Author: Carlos H. Barrios, PUCRS School of Medicine, Porto Alegre, Brazil*

Background: KAMILLA is a single-arm, open-label, phase 3b safety study of T-DM1 in pts with HER2-positive advanced BC from 278 sites in 40 countries. We report the primary analysis of the first study cohort (N = 2003). **Methods:** Pts with HER2-positive, locally advanced or metastatic BC (locally confirmed) with progression after prior treatment with chemotherapy and a HER2-directed agent for metastatic BC or within 6 mo of completing adjuvant therapy were enrolled. Pts received T-DM1 3.6 mg/kg every 3 wks until unacceptable toxicity, withdrawal, or disease progression. The primary outcome was safety. **Results:** A total of 2002 pts were treated (median age 55 yrs, range, 26–88). Most pts had a baseline ECOG score of 0 (n = 1110, 55.4%) or 1 (n = 775, 38.7%), and 1232 (61.5%) had ER and/or PR positive tumors. Median time since initial BC diagnosis was 5 yrs (range, 0–53). Most pts had received ≥2 prior lines of therapy (0–1 prior lines: 29.7%; ≥2: 66.0%); 1855 (92.8%) received prior targeted therapy in the locally advanced/metastatic setting. Median T-DM1 exposure was 5.6 mo (range, 0–46). Adverse events (AEs) were reported in 93.0% (n = 1862). Serious AEs occurred in 21.3% (n = 427), most commonly vomiting (17, 0.8%), pneumonia (16, 0.8%), anemia (13, 0.6%), and pyrexia (13, 0.6%). Grade ≥3 AEs occurred in 40.8% (n = 816), most commonly anemia (60, 3.0%), thrombocytopenia (55, 2.7%), and fatigue (50, 2.5%). Additional AEs of grade ≥3 (multiple individual items grouped) were thrombocytopenia/platelet count decrease (74, 3.7%), hepatic disorders (139, 6.9%), and hemorrhage (46, 2.3%). Grade 5 AEs occurred in 2.2% (n = 45). Treatment discontinuation was most often due to disease progression (1495, 78.1%). Median progression-free survival was 8.3 (95% CI: 8.0–9.7), 6.5 (5.6–8.0), 5.9 (5.6–8.1), 5.6 (5.0–5.9), and 5.6 (5.4–6.6) mo in pts with 0–1, 2, 3, 4, and 5+ prior lines of therapy. Median overall survival was 27.2 mo (95% CI: 25.5–28.7). **Conclusions:** KAMILLA isthe largest (to date) cohort of T-DM1 treated pts and these data are consistent with safety and efficacy seen in prior randomized studies, thereby supporting T-DM1 as therapy for previously treated HER2-positive advanced BC pts. Clinical trial information: NCT01702571.

1034 Poster Session (Board #26), Sun, 8:00 AM-11:30 AM

A phase II study of eribulin mesylate in combination with trastuzumab and pertuzumab in patients (pts) with human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (MBC). *First Author: Ines Maria Vaz Duarte Luis, Dana-Farber Cancer Institute, Boston, MA*

Background: As a single agent, eribulin is an active agent among MBC pts. In the first-line setting, pertuzumab improves progression free and overall survival when added to trastuzumab and chemotherapy (CT); however there are limited data in the second line or beyond. The primary aim of this study was to evaluate the activity of eribulin in combination with trastuzumab and pertuzumab in pts with HER2+ MBC whose cancers are refractory to trastuzumab containing regimens. Safety and toxicity were examined and correlative studies are also planned. **Methods:** Single center, single-arm, phase II, 2 cohorts study planned to enroll up to 81 pts. The studied combination would be of clinical interest if the true overall response rate (ORR) was 40% among those without prior pertuzumab exposure (Cohort A) and 30% among those with prior pertuzumab exposure (Cohort B). The trial was stopped prematurely due to low accrual. Prior to the start of the phase II study, a run-in established dose of eribulin with standard dose of trastuzumab and pertuzumab (1.4mg/m2 days 1, 8 /21 days). **Results:** Of 32 pts enrolled, 6 were in the run-in, 19 in Cohort A and 7 in Cohort B. Most pts were heavily pre-treated (median [range] lines of CT for metastatic disease, run-in: 4[2-11], cohort A: 2.5 [0-7], cohort B: 3[1-8]). In cohort A, 5 pts had partial responses (ORR = 26% [95% CI 9-51%]), 1 (5%) experienced stable disease (SD) lasting ≥ 6 months and 11 (58%) had a SD lasting < 6 months. In cohort B, the ORR was 0% [95% CI 0-41%]), 1(14%) experienced SD lasting ≥ 6 months and 5 (75%) had a SD lasting < 6 months. The combination was well tolerated, most adverse events (AE) were mild to moderate. Hematologic toxicity was the most frequent grade 3-4 AE. Analyses looking at tissue genomic markers and cell free DNA will be presented. **Conclusions:** We observed modest activity of the treatment combination in those without prior pertuzumab exposure but limited activity in unselected pts with HER2+ MBC. The study was limited by small sample size. Correlative studies may help us to understand resistance and response to eribulin with anti-HER2 therapy and the interplay between CT and targeted therapy. Clinical trial information: NCT01912963.

1035 Poster Session (Board #27), Sun, 8:00 AM-11:30 AM

Phase 1 dose escalation of ZW25, a HER2-targeted bispecific antibody, in patients (pts) with HER2-expressing cancers. *First Author: Funda Meric-Bernstam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The HER2 receptor is expressed across a range of cancers (ca) although expression and heterogeneity vary greatly within and between tumors. FDA approved HER2-targeted therapies (tx) have shown clinical benefit only in HER2 high (IHC3+ or IHC2+/FISH+) breast and gastric ca. ZW25, built on the Azymetric™ platform which utilizes unique Fc mutations to create IgG1-like bispecific antibodies, binds to the same extracellular domains of HER2 as trastuzumab (T) and pertuzumab (P) with increased binding and internalization compared to T alone. In preclinical studies ZW25 was well tolerated and active in models of HER2 low to high ca. **Methods:** Eligible pts (HER2 IHC 1-3+, progression after standard of care (SOC) tx, normal LVEF) were enrolled in a 3+3 dose escalation study of ZW25 (5, 10 or 15 mg/kg) IV weekly in 4 week cycles. Assessments included adverse events (AEs), LVEF, tumor response and PK. **Results:** 9 pts have received ZW25 at 5 (n = 3) or 10 mg/kg (n = 6); 15 mg/kg is ongoing. All pts were HER2 high (breast = 4; gastric/GEJ = 4; adnexal = 1). Prior tx included T in all pts; P and T-DM1 in 4 and lapatinib (L) in 3 of 4 breast pts. The most common AEs (all Gr 1/2) were infusion reaction (IR) (5/9), diarrhea (4/9), and fatigue (3/9), with no DLTs and one related Gr 3 AE of hypophosphatemia. The IRs occurred only with 1st dose and did not recur with prophylactic tx (primarily acetaminophen and diphenhydramine; steroids included for 2 pts). At 5 mg/kg, peak drug levels after C1D1 = ~100 ug/ml, accumulating ~50% higher by dose 4. Best response in 8 pts (1 too early): 2 PR (both breast ca with prior T, P, T-DM1, and L; 10 mg/kg, 55% and 33% target lesion decrease, respectively, after 2 cycles), 1 SD (breast ca, 5 mg/kg, ongoing after 4 cycles), and 5 PD. 5 pts currently active; includes 1 gastric pt (10 mg/kg) with PD (new nodal lesions) and clinical benefit with decrease in target lesions and CEA (33 to 1.5 ng/ml). **Conclusions:** ZW25 has been well tolerated with promising anti-tumor activity in pts with HER2-expressing ca progressing after SOC therapy. These early signs of activity support the therapeutic potential for bispecific antibodies using the Azymetric platform. Development of ZW25 is ongoing, including in lower HER2-expressing ca. Clinical trial information: NCT02892123.

1036 Poster Session (Board #28), Sun, 8:00 AM-11:30 AM

Quantification of intratumoral heterogeneity of HER2 status in breast cancer. *First Author: Rie Horii, Department of Pathology, Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Intratumoral heterogeneity (ITH) occurs as a consequence of epigenetic aberrations in tumor cells with genetic diversity. HER2 ITH can be classified into genetic (a mixture of tumor cells with and without HER2 gene amplification) and epigenetic ITH (a mixture of HER2 gene-amplified tumor cells with and without HER2 protein overexpression). However, the both effects of genetic and epigenetic ITH on HER2-targeted therapy have not been clearly demonstrated. In order to implement ITH as a referenced factor for treatment selection, the ITH quantification is necessary. Gene-protein assay (GPA), in which immunohistochemistry and dual in situ hybridization are simultaneously performed on a single slide, allows bright-field analyses of both gene and protein status. We aimed to quantify HER2 ITH by the combination of gene and protein status and clarify its clinical significance. **Methods:** Fifty three patients with HER2-positive breast cancer, who underwent neoadjuvant trastuzumab with chemotherapy, were examined. Five representative microscopic images were captured from a GPA slide of a pretherapeutic biopsy material. All evaluable tumor cells in the images were scored according to the HER2 status determined by the combination of gene copy number and protein expression (Table). We investigated the relationship between the HER2 scores and pathological complete response (pCR) to the neoadjuvant treatment by the logistic analysis. **Results:** The average of HER2 scores, indicating the degree of the HER2 status, varied from 2.21 to 5.98. It was significantly related to pCR (Estimate: 1.21, Std. error: 0.46, RR: 3.34, P=0.009, 95%CI: 1.35-8.25). The standard deviation of HER2 scores, indicating the degree of the HER2 ITH, varied from 0.13 to 1.37. It was significantly related to pCR (Estimate: -2.09, Std. error: 0.83, RR: 0.12, P=0.012, 95%CI: 0.02-0.63). **Conclusions:** HER2 ITH, quantified by GPA, is a predictive factor for the therapeutic effect to trastuzumab-based treatment in HER2-positive breast cancer.

HER2 score by GPA.

1037 Poster Session (Board #29), Sun, 8:00 AM-11:30 AM

Phase II study of gemcitabine (G), trastuzumab (H), and pertuzumab (P) for HER2-positive metastatic breast cancer (MBC) after prior pertuzumab-based therapy. *First Author: Neil M. Iyengar, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The combination of taxanes with HP for first line treatment of HER2-positive MBC is associated with improved progression-free (PFS) and overall survival (OS). Treatment per physician's choice with anti-HER2 therapy after second line therapy is associated with a median PFS of 3 months. While continued use of H in therapeutic combinations after progression on H-based therapy is standard, the efficacy of continuing HP-based treatment after progression on P-based therapy is unknown. **Methods:** This is a single arm phase II trial of G with HP. Eligible patients (pts) had HER2-positive (IHC 3+ or FISH $>$ 2.0) MBC with prior HP-based treatment and $\leq$ 3 prior chemotherapies. Pts received G (1200 mg/m^2) on days 1 and 8 of a q 3 week (w) cycle, and H (8 mg/kg load $\rightarrow$ 6 mg/kg) and P (840 mg load $\rightarrow$ 420 mg) q3w. The primary endpoint is PFS at 3 months. Secondary endpoints include OS, safety and tolerability. An exploratory endpoint is to compare PFS by RECIST criteria versus 18-F FDG-PET response criteria. The study therapy will be considered successful if at least 27/45 (60%) patients are progression free at 3 months. **Results:** As of 1-27-17, 41 of 45 pts are enrolled; 34 are evaluable at 3 months and 7 have not had 3-month evaluation. At 3 months, 26/34 (76%) are progression free (1 CR, 8 PR, 17 SD); 8 pts progressed. There are no cardiac or febrile neutropenic events to date. 4 pts required G dose reduction (3 grade 3 neutropenia and 1 grade 3 vomiting) and the study was amended to lower initial G dose to 1000 mg/m^2. **Conclusions:** The preliminary 3 month-PFS is 76% in evaluable pts (95% CI 60% to 88%). The updated 3 month-PFS results will be presented. Continuation of P beyond progression is associated with apparent clinical benefit. A randomized trial is justified to confirm this clinically important observation. Clinical trial information: NCT02252887.

1038 Poster Session (Board #30), Sun, 8:00 AM-11:30 AM

Updated results from MONALEESA-2, a phase 3 trial of first-line ribociclib + letrozole in hormone receptor-positive (HR+), HER2-negative (HER2–), advanced breast cancer (ABC). *First Author: Gabriel N. Hortobagyi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Endocrine therapy (ET) is the basis of first-line (1L) treatment for HR+ ABC. However, ET resistance are almost universal. At the first interim analysis (IA) of MONALEESA-2 (NCT01958021), ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) + letrozole (LET) significantly prolonged progression-free survival (PFS) vs placebo (PBO) + LET in patients (pts) with HR+, HER2– ABC.[1] Here we report updated efficacy and safety data from MONALEESA-2 with a further ~11 months of follow-up. **Methods:** Postmenopausal women with no prior therapy for ABC were randomized 1:1 toRIB (600 mg/day, 3-weeks-on/1-week-off) + LET(2.5 mg/day, continuous) vs PBO + LET. The primary endpoint was locally assessed PFS. Secondary endpoints include overall survival (OS; key) and safety. OS significance was defined by a p-value threshold of 3.15 x 10^{-5}. Tumor assessments were performed every 8 weeks for the first 18 months, and every 12 weeks, thereafter. **Results:** 668 pts were enrolled (334 in each arm). At the second IA for OS (data cut-off Jan 2, 2017), the median duration of follow-up was 26.4 months; 116 deaths and 345 PFS events had occurred. OS data remain immature, with 15.0% vs 19.8% of pt deaths in the RIB + LET vs PBO + LET arm (HR = 0.746; 95% CI: 0.517–1.078; p= 0.059). Updated PFS analyses confirmed continued treatment benefit in the RIB + LET vs PBO + LET arm. The 24-month PFS rates (RIB + LET vs PBO + LET) were 54.7% vs 35.9%. Treatment benefit was consistent across pt subgroups. The most common Grade 3/4 laboratory abnormalities ($\geq$10% of pts; RIB + LET vs PBO + LET) were decreased neutrophils (62.6% vs 1.5%), decreased leukocytes (36.8% vs 1.5%), decreased lymphocytes (16.2% vs 3.9%), and elevated alanine aminotransferase (11.4% vs 1.2%). **Conclusion:** After 26+ months of follow-up, treatment benefit with 1LRIB + LET persists in postmenopausal women with HR+, HER2– ABC. The study remains immature for OS analysis. The safety profile of RIB + LET remains manageable. 1. Hortobagyi G, *et al. N Engl J Med* 2016;375:1738–48. Clinical trial information: NCT01958021.

1039 Poster Session (Board #31), Sun, 8:00 AM-11:30 AM

Palbociclib (PAL) + letrozole (L) as first-line (1L) therapy (tx) in estrogen receptor-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2−) advanced breast cancer (ABC): Efficacy and safety across patient (pt) subgroups. *First Author: Richard S. Finn, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Hormone tx (HT) is the primary 1L tx for ER+ ABC. In the PALOMA-2 study (NCT01740427), PAL+L as 1L ABC tx prolonged progression-free survival (PFS; hazard ratio [HR] 0.58; $P<.001$) (Finn et al, *NEJM*. 2016). **Methods:** Postmenopausal pts with ER+/HER2– ABC and no prior systemic treatment in the advanced setting were randomized 2:1 to PAL (125 mg/d oral [3 wk on, 1 wk off]) + L (2.5 mg QD) or placebo (P) + L. Key endpoints were investigator-assessed PFS and safety. **Results:** 666pts (444, PAL+L; 222, P+L) were enrolled. Pts were similarly distributed between arms for visceral (48%) and nonvisceral (52%) disease and prior HT (56%) and no prior HT (44%); more pts had disease-free interval (DFI) $>$12 mo (40%) than $\leq$12 mo (22%). Median PFS (mPFS) was improved in all subgroups by adding PAL to L (Table). Adverse events were consistent across subgroups, as described for the full study population. **Conclusions:** PAL+L improved mPFS vs P+L with manageable toxicity across all subgroups including those with visceral disease. PAL+L provides a 1L option that should be considered for all pts with ER+/HER2- ABC. Sponsor: Pfizer Clinical trial information: NCT01740427.

Assessment of ESR1 and ERBB2 mutations in estrogen receptor positive (ER+) metastatic breast cancers (MBC). *First Author: Gargi D. Basu, Ashion Analytics, Phoenix, AZ*

Background: Mutations (mut) in ESR1 have been reported in ER+ breast cancers (BC) as an acquired resistance mut to aromatase inhibitor (AI) therapy. Acquired ERBB2 mut have also been reported in MBC patients (pts) that cause activated ERBB2 signaling. The emergence of acquired secondary mut presents challenges in effective treatment approaches. **Methods:** Comprehensive genomic profiling was performed on 83 BC samples with 48 metastatic; 34 primary samples. Targeted next-generation sequencing was performed on 562 cancer associated genes in paired tumor and blood DNA (germline) samples. **Results:** ESR1-mut were found in 23%(11/48) of ER+ MBC tissues with no mut detected in primary ER+ BCs. Mutations-D538G, Y537S and E380Q in the ligand binding domain of ER were the most common alterations, found in 54.5%, 18% and 18% of ESR1 mut samples, respectively. An ER+ HER2- liver biopsy obtained after 20 mos on AI + everolimus had ESR1-D538G and TSC2 structural event. Protein array showed high expression of androgen receptor (AR) and p-AR and activation of ERBB1/2/3, p-SRC and p-4EBP1 in this sample. Further, a functionally uncharacterized ESR1 mut was found in ER+, HER2+ and a triple negative MBC tissue (the primary BC had been ER+). Mut in PI3K pathway (PIK3CA, ARID1A, TSC1/2, PTEN) were present in 8/11 samples with ESR1 mut. Activating mut in ERBB2 were found in 3/83 samples; all 3 were in ER+ MBC samples with one case harboring mut in both ERBB2 and ESR1 (E380Q – uncertain degree of constitutive activity). Interestingly, a BC sample with ER+ HER2- liver met harbored both ERBB2 (V777L) and ERBB3 (E928G) mut; this pt responded well to trastuzumab/pertuzumab (HP) therapy. A pt with ER+ HER2-ERBB2-L755S mut met to gallbladder found after 7 mos on letrozole/palbociclib therapy responded well to HP and T-DM1 therapy. All 3 ERBB2-mut cancers had a CDH1 frameshift mut suggesting enrichment in pretreated lobular MBCs (Ross J. CCR, 2013). **Conclusions:** This study shows a 23% and 6% ESR1 and ERBB2 mut rate in MBC samples. No ESR1 and ERBB2 mut were present in primary BC samples. Our findings suggest that pts with lobular MBC should be monitored for acquired ERBB2 mut, and that ERBB2 mut may not arise in BCs which harbor known constitutively active ESR1 mut.

1041 Poster Session (Board #33), Sun, 8:00 AM-11:30 AM

A phase II, randomized, open-label 3-arm clinical trial of fulvestrant (F) plus goserelin (G) versus anastrozole (A) plus goserelin (G) versus goserelin (G) alone for hormone receptor (HR) positive, tamoxifen (T) pretreated premenopausal women with recurrent or metastatic breast cance r(MBC) (KCSG BR10-04). *First Author: Ji-Yeon Kim, Samsung Medical Center, Seoul, Republic of Korea*

Background: Endocrine therapy(ET) is the preferred treatment for HR(+) MBC. For premenopausal patients who were pretreated with T, ovarian function suppression with G ± aromatase inhibitor(A.I.) is a reasonable option. Fulvestrant yields favorable outcomes in postmenopausal women with MBC. We investigated the efficacy and safety of F+G and A+G in comparison with G alone in premenopausal women with HR(+), T-pretreated MBC. **Methods:** In this multicenter, open-label, randomized phase 2 study, women > 18 years with HR(+), T-pretreated MBC were stratified by presence of visceral metastasis and recurrence within or after 1 year of completion of adjuvant T. Premenopausal women with T-pretreated MBC eligible for ET were randomly assigned (1:1:1) to F+G (F 500 mg IM + G 3.6 mg SC Q 4 wks), or A +G (A 1 mg P.O. qd + G 3.6 mg SC Q 4 wks) or G (G 3.6 mg SC Q 4 wks). The primary endpoint was time to progression(TTP), analyzed by intention to treat with log-rank test. Secondary endpoints included overall survival, overall response rate, clinical benefit rate and toxicities according to NCI CTCAE v3.0 (ClinicalTrials.gov, No. NCT01266213). **Results:** Of 138 eligible pts, 44 were randomly assigned to F+G, 47 to A+G, 47 to G. The median duration of follow-up was 28.8 months(mo) and median age was 43 (range; 23.0-55.0). The median TTP was 16.3 mo(95% C.I. 7.5-25.1) for F+G, 14.5 mo(95% C.I. 11.0-18.0) for A+G, and 13.5 mo(95% C.I. 10.3-16.8) for G alone, respectively. For the comparison of each experimental arm to control arm, 24-mo TTP were analyzed: F+G vs G(%±SE): 40.5±7.5 vs. 25.3±7.0, one-sided P = 0.048, A+G vs G(%±SE): 23.9± 7.2 vs. 25.3±7.0, one-sided P = 0.304. Grade 3/4 toxicities were rarely observed. Most common adverse events were grade 1 joint stiffness and arthralgia which were more frequently observed in F+G compared to A+G and G (P = 0.018 and 0.015, respectively). **Conclusions:** The combination of F+G as well as G ±A.I. might be a valid option for HR(+) premenopausal women with T-pretreated MBC and further investigation is warranted. Clinical trial information: NCT01266213.

1042 Poster Session (Board #34), Sun, 8:00 AM-11:30 AM

Is androgen receptor useful to predict the efficacy of anti-estrogen therapy in advanced breast cancer? *First Author: Andrea Rocca, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: The androgen receptor (AR) is widely expressed in breast cancers but its role in estrogen receptor (ER)-positive tumors is still controversial. However, the AR/ER ratio may impact prognosis and the response to antiestrogen endocrine therapy (ET). **Methods:** We assessed whether AR in primary tumors and/or matched metastases is a predictor of efficacy of first-line ET in advanced breast cancer (ABC). We evaluated patients treated with first-line ET (2002–2011), excluding those receiving concomitant chemotherapy or trastuzumab or pretreated with > 2 lines of chemotherapy. ER, progesterone receptor (PgR), Her2, Ki67 and AR expression was determined by immunohistochemistry. A cut-off of < 1% immunostained cells was used to categorize AR expression. AR expression was analyzed in relation to the other conventional biomarkers (ER, PgR, Her2 and Ki67), best response (CR, PR, SD, PD), and time to progression (TTP) (months). TTP was estimated using the Kaplan-Meier method and compared with the log-rank test. Hazard ratios and their 95% confidence intervals (95% CI) were estimated using the Cox regression model. The Chi-square test was used to evaluate correlations between categorical variables and best response. p values < 0.05 were considered statistically significant. **Results:** Of the 102 evaluable patients (93% were treated with an aromatase inhibitor), biomarkers were assessed in primary tumors in 70 cases, in metastases in 49 and in 17 in both). Median TTP was 17 months (95% CI 14-21.5, median follow-up 75 months). The overall concordance rate between primary tumors and metastases was 64.7% (95% CI 42%-87.4%) for AR expression. Differences in TTP according to AR status were not statistically significant. AR/PgR ≥ 0.96 was associated with a significantly shorter TTP (HR = 1.65, 95% CI 1.05-2.61, p = 0.030). AR status in primary tumors or metastases was not associated with PD as best response. In contrast, Ki67 > 20% and PgR < 10% showed a significant association with PD as best response. Using a cut off of ≤10% for AR expression, results did not change. **Conclusions:** AR expression does not appear to be useful to predict the efficacy of ET in ABC. Ki67 and PgR exert a greater impact on the efficacy of hormone therapy than AR.

1043 Poster Session (Board #35), Sun, 8:00 AM-11:30 AM

Evaluation of tumor and circulating cell free (cf) DNA mutations in women with hormone refractory metastatic breast cancer (MBC) enrolled in a phase I study of Z-endoxifen (MC093C). *First Author: Matthew P. Goetz, Mayo Clinic, Rochester, MN*

Background: In estrogen receptor (ER) positive MBC, mutations (e.g. *ESR1*), identified from tumor biopsies or cfDNA, confer resistance. The concordance between mutations observed in tumor and cfDNA and the implications for response to Z-endoxifen, a potent anti-estrogen, are unknown. **Methods:** We previously conducted a phase I trial of Z-endoxifen in endocrine refractory, ER positive MBC. Seven dose levels were considered ranging from 20 to 160 mg/day followed by expansion cohorts (EC) of 40, 80, and 100 mg/day. Pretreatment blood samples (all pts) and fresh tumor biopsies (EC) were collected prospectively. Tumor and cfDNA were evaluated by targeted NGS. **Results:** 41 pts (38 evaluable) were enrolled. Prior endocrine therapy included aromatase inhibitors (37/38, 97%), fulvestrant (22/38, 58%) and tamoxifen (26/38, 68%). Substantial endoxifen exposure without DLTs at doses above 80 mg/day led to a halt in dose escalation and opening of the EC. Overall clinical benefit (stable > 6 months [7 pts.] or partial response by RECIST criteria [3 pts.]) rate was 26.3% (95%CI: 13.4-43.1%). cfDNA was obtained from 36 pts and mutations were identified in 13 (36%) including *ESR1* [*Y537N* or *D538G*] (5), *PIK3CA* [*H1047R* or *E542K*] (8), *TP53* [*K132R*, *R248Q*, *R267Q*, or *H179Y*] (4), *AKT* (*Q79K*) (1), and *KRAS* (*G12D*) (1). In 5 pts with cf *ESR1* mutations, 4 had additional cfDNA mutations including *PIK3CA* (3), and *TP53* (1). PFS was shorter in pts with cfDNA mutations relative to those without (median: 61 vs.132 days; log-rank p = 0.021). Discordance was observed between tumor and cfDNA mutations where 3/7 *PIK3CA* tumor mutations were detected by cfDNA, 1/2 *TP53* tumor mutations were detected by cfDNA, and 0/1 *AKT* tumor mutations were detected by cfDNA. Conversely, 2 pts had cfDNA mutations (either *ESR1*, *TP53* or *AKT*) undetected in tumor. **Conclusions:** The absence of cfDNA mutations in patients with endocrine resistant, MBC treated with Z-Endoxifen was associated with significantly longer PFS. Given the discordance between tumor and cfDNA sequence data, future studies must determine which approach maximizes prognosis and prediction of benefit for estrogen-targeted therapy. Clinical trial information: NCT01327781.

1044 Poster Session (Board #36), Sun, 8:00 AM-11:30 AM

Safety and efficacy of the BCL2 inhibitor venetoclax in estrogen receptor (ER) and BCL2-positive metastatic breast cancer: The mBEP study. *First Author: Geoffrey John Lindeman, The Royal Melbourne Hospital, Parkville, Australia*

Background: The anti-apoptotic protein BCL2 is overexpressed in ~85% of ER^+ breast cancer (BC). Venetoclax (ABT-199), a BCL2 inhibitor approved for CLL (400 mg/day), synergizes with tamoxifen in preclinical patient derived xenograft models by increasing apoptosis. In the first study to evaluate venetoclax in solid tumors, we tested the safety and efficacy of this combination in ER^+BCL2^+ metastatic BC. **Methods:** A '3+3 design' dose escalation phase 1b study enrolled women with ER^+ (> 1%), $BCL2^+$ (> 10%, mod-high) and HER2 non-amplified metastatic BC. Patients received escalating doses of venetoclax 200, 400, 600 or 800 mg/day with tamoxifen 20 mg/day. The primary objective was to determine dose-limiting toxicity (DLT) and maximum tolerated dose (MTD) over 4 weeks. There was no limit to the number of prior lines of therapy. **Results:** Fifteen patients were enrolled (mean age 62 years, range 44-78; previous tamoxifen, 10 pts). Mean lines of prior therapy for metastatic BC was 2.5 (median 2, range 0-6) and included tamoxifen (6 pts). *ESR1* mutations were present in ctDNA of 4 patients. Treatment was well tolerated, with no DLT observed. MTD was not reached; 6 patients received the maximal planned dose (800 mg). The most common adverse event (AE) was lymphopenia (67% Grade 1-2; 13% Grade 3; No Grade 4), followed by nausea (46%, Grade 1-2), which was readily managed. Of 13 women with measurable disease (RECIST v1.1), 4 (31%) had a partial response and 5 (38%) had stable disease (clinical benefit rate, 69%). For patients with a partial response, tumor regression was rapid (evident at first restaging) and occurred in the 400-800 mg dose levels. Two patients with non-measurable bone-only disease had clinically stable disease (1 ongoing > 64 weeks). The median duration of response has not yet been reached (range, 12 to > 64 weeks). **Conclusions:** We demonstrated the safety of tamoxifen and venetoclax in ER^+BCL2^+ metastatic BC, with preliminary evidence of clinically relevant activity. A dose expansion study including serial biopsy, ctDNA and PET scans is ongoing at the 800 mg/day recommended phase 2 dose. Sponsor: Royal Melbourne Hospital Clinical trial information: ISRCTN98335443, ACTRN12615000702516.

1045 Poster Session (Board #37), Sun, 8:00 AM-11:30 AM

Efficacy and safety in elderly patient subsets across studies investigating endocrine monotherapy versus combination therapy in patients with HR+/HER2−advanced breast cancer. *First Author: Rachel A. Freedman, Dana-Farber Cancer Institute, Boston, MA*

Background: Combination of endocrine therapy and targeted agents in 1st and 2nd-line therapy prolong progression-free survival (PFS) in patients with hormone receptor–positive (HR+), HER2− advanced breast cancer (ABC). However, a greater risk of adverse events (AEs) and a greater possibility of drug-drug interaction, associated with combination therapy, present challenges in older patients. **Methods:** This study reviewed PFS and safety data in age-stratified subsets from Phase II or III clinical trials comparing endocrine monotherapy vs combinations of endocrine or targeted therapy in patients with HR+, HER2−ABC. **Results:** Among 9 identified studies, combination therapy that included ribociclib, palbociclib, and everolimus significantly reduced risk of disease progression vs monotherapy in older and younger patient subsets (Table). For combination therapy that included ribociclib or palbociclib, frequency of discontinuations due to AEs was similar between the subsets; more frequent discontinuations due to AEs were noted in the ≥70-year subset with everolimus. **Conclusions:** Combination endocrine therapies involving CDK4/6 or mTOR inhibitors have similar efficacy but vary in tolerability among older and younger patients with HR+, HER2− ABC.

Tumor genomics and response to CDK 4/6 inhibitors for patients with hormone receptor-positive (HR+) metastatic breast cancer (MBC). *First Author: Laura Spring, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: The combination of endocrine therapy with a cyclin-dependent kinase (CDK) 4/6 inhibitor, such as palbociclib, has changed the treatment paradigm of HR+ MBC, particularly as 1stline therapy. However, there are no predictive biomarkers at present, and little is known about the impact of tumor genomics on outcomes. For example, mutations in TP53 could impact the ability of p53 to negatively regulate p21, thereby promoting cell cycle progression despite CDK 4/6 inhibition. The aim of this study was to evaluate the association between tumor genomics, particularly PIK3CA and TP53 mutations, and response to CDK 4/6 inhibitors in HR+ MBC. **Methods:** All HR+/HER2- MBC patients at our institution receiving a CDK 4/6 inhibitor in the second line or beyond were identified. Tumor genomics were analyzed utilizing the institutional tumor genotyping next generation sequencing (NGS) assay known as "Snapshot-NGS assay" on DNA isolated from the tumor, covering key oncogenic driver mutations and tumor suppressor genes. The log-rank test was used for statistical analysis. **Results:** A total of 83 patients with HR+/HER2- MBC were identified, of which 61 had available tumor genotyping results available (52 metastatic specimens). The median line of therapy was three. Median progression-free survival (PFS) on CDK 4/6 inhibitor-based therapy, as second line or beyond, was 9.2 months (mo) overall. No significant difference in PFS was seen among patients with PIK3CA (n = 31) mutations (7.1 vs. 9.7 mo; p = 0.28) or with any alteration in the PI3K/Akt/mTOR (n = 36) pathway (8.2 vs. 9.3 mo; p = 0.40). The presence of a p53 mutation (n = 9) or complex tumor genomics (n = 14) demonstrated a trend towards shorter PFS (5.5 vs. 9.2 mo; 5.5 vs. 9.5 mo, respectively), although statistical significance was not reached due to small numbers (p = 0.76; p = 0.31). In a multivariable analysis adjusting for age and prior lines of therapy, similar results were observed. **Conclusions:** This study suggests patients with HR+ MBC harboring p53 mutations or complex tumor genomics may experience shorter PFS on CDK 4/6 inhibitor-based therapy in the second line and beyond, and these novel findings require validation in additional studies.

1047 Poster Session (Board #39), Sun, 8:00 AM-11:30 AM

First-line ribociclib plus letrozole for postmenopausal women with hormone receptor-positive (HR+), HER2-negative (HER2-) advanced breast cancer (ABC): MONALEESA-2 safety results. *First Author: Wolfgang Janni, University of Ulm, Ulm, Germany*

Background: In the randomized, phase III MONALEESA-2 study (NCT01958021), first-line therapy with ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor; 600 mg/day; 3-weeks-on/1-week-off) + letrozole (LET; 2.5 mg/day) in postmenopausal women with HR+, HER2– ABC significantly prolonged progression-free survival vs placebo (PBO) + LET (hazard ratio: 0.556; p = 0.00000329; Hortobagyi GN *et al. N Engl J Med* 2016;375:1738–48). Here we present further safety analyses from MONALEESA-2. **Methods:** Adverse events (AEs) were characterized per CTCAE v4.03. Analyses of key AEs included time to first event, duration (time to AE resolution), and the rate of associated dose interruptions or reductions. **Results:** Safety analysis included 664 patients (pts; RIB + LET: 334; PBO + LET: 330). Neutropenia was the most common all-grade (G) and G3/4 AE in the RIB + LET arm (Table); febrile neutropenia rates were low (RIB + LET arm: 1.5%) with no associated deaths. Median time to first event for G ≥2 neutropenia in the RIB + LET arm (based on neutrophil counts) was 16 days. Other common G3/4 AEs (increased by ≥5% in the RIB + LET vs PBO + LET arm) were leukopenia (21% vs 1%), elevated alanine aminotransferase (ALT; 9% vs 1%), lymphopenia (7% vs 1%), and elevated aspartate aminotransferase (AST; 6% vs 1%). Neutropenia was the most common AE leading to dose interruptions/reductions; G3/4 neutropenia led to dose interruptions in 48% vs < 1% and reductions in 30% vs 0% of pts in the RIB + LET vs PBO + LET arm. 7.5% vs 2.1% of pts (RIB + LET vs PBO + LET) discontinued due to AEs; common AEs leading to discontinuation (> 1% pts) were elevated ALT (5% vs < 1%), elevated AST (3% vs 1%), and vomiting (2% vs 0%). **Conclusions:** First-line RIB + LET had a manageable safety profile in postmenopausal women with HR+, HER2– ABC. Neutropenia was the most common AE in the RIB arm, and was transient and reversible with dose modifications. Additional AE analyses will be presented. Clinical trial information: NCT01958021.

1048 Poster Session (Board #40), Sun, 8:00 AM-11:30 AM

Health-related quality of life from a phase 3 randomized trial of fulvestrant 500 mg vs anastrozole for hormone receptor-positive advanced breast cancer (FALCON). *First Author: John Forsyth Russell Robertson, Division of Medical Sciences and Graduate Entry Medicine, University of Nottingham, Royal Derby Hospital Centre, Derby, United Kingdom*

Background: The Phase 3 randomized FALCON trial (NCT01602380) demonstrated improved progression-free survival with fulvestrant 500 mg (F) vs anastrozole 1 mg (A) in postmenopausal women with hormone receptor-positive (HR+) locally advanced or metastatic breast cancer (BC) without prior endocrine therapy (hazard ratio [HR] 0.797, 95% confidence interval [CI] 0.637-0.999; p = 0.0486; Robertson et al. Lancet 2016). Overall health-related quality of life (HRQoL) was maintained and similar for F and A. There was no evidence of a detriment with F vs A in time to deterioration for both Trial Outcome Index (TOI; HR 0.90, 95% CI 0.70-1.15; p = 0.4008) and Functional Assessment of Cancer Therapy for Breast Cancer (FACT-B) total score (HR 0.84, 95% CI 0.66-1.07; p = 0.1594). We present additional analyses of patient (pt)-reported HRQoL outcomes from FALCON. **Methods:** Women with HR+ BC were randomized 1:1 to F (Days 0, 14, 28, then every 28 days) or A (daily) until disease progression or discontinuation. HRQoL was assessed by FACT-B questionnaire (TOI [summary of physical and functional well-being and breast cancer subscale scores] and FACT-B total score) at randomization and every 12 weeks during treatment. HRQoL data post-treatment (with or without progression) were also collected. **Results:** 462 pts were randomized (F, n = 230; A, n = 232). Compliance to FACT-B during treatment ranged from 84.6-100.0%. Mean change from baseline in TOI (scale range 0-92) and FACT-B total score (scale range 0-144) remained broadly stable (approximately ±3 points to Week 132) and similar between arms during treatment. HRQoL was also maintained in FACT-B subscales. Approximately one third of pts had improved TOI (≥ +6 points) and FACT-B (≥ +8 points) total scores from baseline up to Week 144 of treatment with F (ranges 26.4-45.0%, and 20.0-35.8%, respectively) and A (ranges 18.6-32.9%, and 22.7-37.9%, respectively). **Conclusions:** Compliance to the FACT-B questionnaire on treatment with F and A for HR+ BC in the FALCON trial was good; mean change from baseline in TOI and FACT-B total score was maintained, and similar proportions of pts had improved TOI and FACT-B total score in both arms. Clinical trial information: NCT01602380.

1049 Poster Session (Board #41), Sun, 8:00 AM-11:30 AM

Characteristics of disease activity able to identify risk categories and probability to respond to first-line endocrine therapy (ET) in HR+ve/HER2-ve metastatic breast cancer (MBC) patients (pts): Dream or reality? Evaluation of a composite risk score in a subgroup population of the GIM 13-AMBRA study. *First Author: Giorgio Mustacchi, University of Trieste, Trieste, Italy*

Background: The appropriate choice of 1st-line therapy in HR+ve/HER2-ve MBC pts is becoming more complicated since the data of front-line Fulvestrant and CDK 4/6 Inhibitors have been released. In the absence of predictive biomarkers of tumor response, one possible option is the recently proposed "composite score" (Schmid, ESMO 2016), composed by visceral tumor burden (VTB) and Disease-Free-Interval (DFI) to identify risk categories and the probability of response to ET or chemotherapy (CHT). Aim of the present analysis is to describe the choices of 1st-line treatment and the response rate, according to the mentioned score in a population of HR+/HER2-ve MBC. **Methods:** We used data of the HR+ve pts of the AMBRA study, a longitudinal cohort study, describing the choice of first and subsequent lines of treatment in HER2-ve MBC pts (SABCS 2016 P5-15-07 & P5-14-09). Using median DFI and VTB three categories of risk have been identified: Low (DFI > 24 months & VTB-), Intermediate (DFI £ 24 months & VTB- or DFI > 24 months & VTB+) and High (DFI £ 24 months & VTB+). This analysis describes the choices of 1st-line therapy and relative response rate according to these risk categories. **Results:** So far, 791/1500 pts have been registered into the AMBRA study, 673 of them (85%) with HR+ MBC and 659 (83.3%) are evaluable for this analysis. Risk categories and response to therapy are detailed in the table below. **Conclusions:** No conclusion can be done regarding the "High Risk" group because of the low number of pts treated with ET alone. Regarding the "Low" and "Intermediate" risk categories, we can conclude that the proposed "composite risk score" doesn't seem to discriminate MBC patients who could be treated with ET alone or with a more aggressive treatment, at least in terms of response rate.

	Low risk (N=264)		Intermediate Risk (N=324)		High risk (N=42)	
	ET	CHT±ET	ET	CHT±ET	ET	CHT±ET
1st-line therapy (%)	43.6%	56.4%	20.7%	79.3%	11.9%*	88.1%
Disease Control Rate (CR+PR+SD) (%)	60%	71.1%	61.2%	73.5%	na*	59.5%

*only 5 pts treated with ET

1050 Poster Session (Board #42), Sun, 8:00 AM-11:30 AM

Predictors of prolonged benefit from palbociclib (PAL) plus fulvestrant (F) in women with endocrine-resistant hormone receptor–positive/human epidermal growth factor receptor 2–negative (HR+/HER2–) advanced breast cancer (ABC) in PALOMA-3. *First Author: Massimo Cristofanilli, Robert H. Lurie Cancer Center of Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: PAL+F improved progression-free survival (PFS) over F + placebo (P) in patients (pts) with endocrine-resistant HR+/HER2– ABC. We examined factors predictive of long-term benefit on PAL+F. **Methods:** Pre/postmenopausal pts with HR+/HER2– ABC that progressed on prior endocrine therapy (ET) were randomized 2:1 to PAL (125 mg/d oral [3 wk on, 1 wk off]) + F (500 mg) or P+F. Characteristics of pts with prolonged benefit (treatment [tx] duration ≥18 mo for PAL+F; ≥12 mo for P+F based on median PFS and tx duration) were compared with the intent-to-treat (ITT) population. **Results:** PAL+F improved PFS vs P+F (11.2 vs 4.6 mo; hazard ratio, 0.50). By Aug 2016, 138 pts had long-term benefit: 100/347 (29%) pts on PAL+F received tx for ≥18 mo, including 70 (20%) who received > 2 y (26–39 cycles). In contrast, 38/174 (22%) pts on P+F received ≥12 mo of tx; only 16 (9%) received > 2 y (27–38 cycles). No apparent differences in baseline characteristics of pts with long-term benefit were observed between groups except that a greater proportion of those on P+F had a single site of disease involvement (40% PAL+F vs 63% P+F). Pts with long-term benefit on PAL+F had lower rates of visceral disease (42% vs 60%), liver metastases (18% vs 40%), and ≥3 disease sites (27% vs 39%) at baseline vs the ITT population; no difference in sensitivity to prior ET was observed (84% vs 79%). Objective response rate (ORR) was higher among pts with prolonged benefit on PAL+F vs ITT (36% vs 26%). **Conclusions:** PAL+F is associated with prolonged benefit in about a third of pts treated with the combination in PALOMA-3. These pts achieve higher ORR compared to other study pts and the benefit is independent of baseline site and number of metastatic recurrences and prior endocrine sensitivity. Benefit from F alone is less prolonged and appears limited to those with 1 site of disease involvement. The analysis confirms the efficacy of PAL+F in HR+ ABC with visceral recurrence. Biomarker analyses are ongoing in pts with long-term benefit to understand molecular features predictive of tx sensitivity. Funding: Pfizer. Clinical trial information: NCT01942135.

1052 Poster Session (Board #44), Sun, 8:00 AM-11:30 AM

Assessment of multiple endocrine therapies for metastatic breast cancer in a multicenter national observational study. *First Author: Olivia Le Saux, Centre Léon-Bérard, Lyon, France*

Background: For HR+/HER2– metastatic breast cancer (mBC), International guidelines recommend multiple lines of endocrine therapy (ET) before starting chemotherapy. Few studies have assessed the efficacy of such strategy on large populations. Our objective was to evaluate multiple ET activity according to clinical and biological characteristics and type of ET. **Methods:** All patients (pts) who initiated treatment for a newly diagnosed mBC between January 2008 and December 2014 in all 18 French Comprehensive Cancer Centers were included in the real life ESME database. ESME collects retrospective data using a clinical trial-like methodology. Database lock was 8 Dec 2016. Primary endpoint of the current study was progression free survival (PFS) on successive ET lines. Only pts with ET alone were assessed (pts receiving ET after chemotherapy as maintenance therapy, or combined with targeted treatment were excluded). **Results:** 9921 pts out of 16703 in ESME, had HR+/HER2- mBC (median age 62.0 years[range 23-96]). 53.9% of pts had visceral and 80.1% non visceral disease at diagnosis. Median OS of HR+/HER2- pts was 42.15 months (95% CI, 40.93-43.27). As first-line therapy, 4123 pts (41.6%) received ET alone, while 2038 received chemotherapy alone (20.5%) and 3667 received both (37%). Median PFS for first-line ET (N=4123) was 11.3 months (95% CI, 10.6-11.9). Only 668 pts (16%) received subsequent lines of ET alone. Types of ET used are described in the table below. Successive PFS will be reported at the meeting. **Conclusions:** Those data show that ET is prescribed to less than 50% of patients with HR+/HER2- mBC in first line and only to a small minority in subsequent lines. This is not in line with existing guidelines (NCCN, ABC3). Real-life median PFS for first-line ET is consistent with median PFS reported in clinical trials (Nabholtz, 2000).

Type of ET prescribed.

Endocrine therapy (ET)	First-line N=4123	Subsequent lines N=668

1053 Poster Session (Board #45), Sun, 8:00 AM-11:30 AM

Palbociclib exposure-response analyses in second-line treatment of hormone-receptor positive advanced breast cancer (ABC). *First Author: Wan Sun, Clinical Pharmacology, Global Product Development, Pfizer Inc., San Diego, CA*

Background: Palbociclib (PAL) is an oral inhibitor of cyclin-dependent kinases 4 and 6 approved for ABC. Exposure-response analyses for efficacy and safety endpoints were performed to evaluate the current PAL clinical dosing regimen (125 mg daily, 3 weeks on and 1 week off) and dose modification strategy in 2nd-line ABC. **Methods:** The present analyses used data from PALOMA3, a phase 3 study comparing the safety and efficacy of fulvestrant plus either PAL or placebo in 2nd-line ABC patients (PTs). A Bayesian pharmacokinetic (PK) analysis was conducted to estimate PAL PK parameters for individual PTs. Average concentration of PAL over the entire treatment (C_{avg}) was derived from average daily dose intensity divided by post hoc estimates of clearance for each PT. Time varying C_{avg} (C_{avgt}) was also derived to account for dose modifications up to each observation point. Kaplan-Meier method and the Cox proportional hazards model were employed to explore relationship between progression-free survival (PFS) and C_{avg}, C_{avgt}, as well as other prognostic factors. A semi-mechanistic PK-pharmacodynamic (PD) model was built to quantify the relationship between PAL concentration and absolute neutrophil count (ANC). **Results:** The median PFS for low and high PAL exposure groups divided according to C_{avg} were similar (9.47 and 10.9 months, respectively) and significantly higher than that of the control arm (4.57 months). While $C_{avgt}$was found to be a significant predictor for PFS in univariate analysis (P-value < 0.05), this relationship was not significant in the multivariate analysis where other significant prognostic factors were also included. The PK-PD analysis for safety endpoint indicated higher PAL concentrations were associated with lower ANC, which is consistent with the fact that ANC profiles were well managed by dose modification strategies, i.e., dose interruption, delay and reduction. **Conclusions:** The analysis results suggested PTs were benefited similarly from fulvestrant plus PAL treatment with manageable safety profile, supporting a favorable benefit-risk profile of PAL under the current dosing regimen and dose modification strategy in 2nd-line ABC. Funding: Pfizer Inc. Clinical trial information: NCT01942135.

1054 Poster Session (Board #46), Sun, 8:00 AM-11:30 AM

Outcome of palbociclib based therapy in hormone receptor positive metastatic breast cancer patients after treatment with everolimus. *First Author: Ajay Dhakal, Roswell Park Cancer Institute, Buffalo, NY*

Background: Resistance mechanisms to CDK 4/6 inhibition are not well defined. Outcome data on hormone receptor positive (HR+) metastatic breast cancer patients (MBCP) treated with palbociclib (PA) after treatment with everolimus (EV) are lacking. The PALOMA 3 trial (P3) showing benefit of PA plus fulvestrant (FU) compared to FU in HR+ MBCP after progression on endocrine therapy excluded women previously treated with EV. The aim of our study was to investigate the outcomes of HR+ MBCP with prior EV treatment on PA based therapy. **Methods:** This is a retrospective, single institute review of HR+, HER 2 nonamplified MBCP from Jan 2014 - Nov 2016 treated with PA after treatment with EV. Women who received EV for $<$ 1 month or PA $<$ 14 days were excluded. Progression free survival (PFS) was defined as the time from the initiation of PA to the date of progression as determined by treating physician based on radiological, biochemical and/or clinical criteria. Response rates were determined based on available radiological data. Clinical benefit was defined as a complete response (CR), partial response (PR) or stable disease of at least 24 weeks. **Results:** 23 patients with mean age 67 years (42 to 81) were identified. 95% were postmenopausal, 81% had ECOG performance status 0 or 1, 83% had visceral metastases, 95% had $>$ 2 lines of prior endocrine therapy (ET), 82% shown prior sensitivity to ET, 82% received prior chemotherapy, of which 84% were in metastatic setting. Kaplan Meier estimate showed median PFS of 2.9 months (95% CI 2.0-4.2); median PFS of P3 PA cohort was 9.5 months (95% CI 9.2-11.0). Fisher's exact test comparing study cohort with P3 PA cohort showed statistically significant differences in objective response (CR or PR) rates of 0/23 (0%) vs. 66/347 (19%, p = 0.02) & clinical benefit ratio of 4/23 (17.4%) vs. 231/347 (66.5%, p = 0.00). **Conclusions:** Outcomes with PA in HR+ EV treated MBCP were worse when compared to the P3 PA cohort data. Treatment with EV may lead to resistance to CDK inhibition. Though limited by size, our data suggests that use of PA after EV is associated with low response & clinical benefit rates. Further studies are necessary to confirm the findings to determine sequencing of targeted therapies.

1055 Poster Session (Board #47), Sun, 8:00 AM-11:30 AM

The role of taxanes in HR+ve/HER2-ve metastatic breast cancer (MBC) patients (pts) from adjuvant to metastatic setting in the clinical practice: Results from GIM13-AMBRA study. *First Author: Giorgio Mustacchi, University of Trieste, Trieste, Italy*

Background: The molecular subtypes of BC have individual patterns of behavior, prognosis and sensitivity to treatment, with subsequent implications for the choice of, or indeed role, for adjuvant (Adj) and metastatic chemotherapy (CHT). Taxanes (T) play a central role in chemotherapy for BC. However, previous studies have reported that T are relatively ineffective in patients with Luminal (HR+ve) BC compared with other subtypes. Aim of the present analysis is to describe the use of T in the clinical practice in Italy in HR+ve pts. **Methods:** AMBRA is a longitudinal cohort study, aiming to describe the choice of first and subsequent lines of treatment in HER2-ve MBC pts receiving at least one CHT (SABCS 2016, P5-15-07 & P5-14-09) in the years 2012-2015. For the present analysis, we focused on the use of T from the AdJ to the metastatic setting. **Results:** So far, 791/1500 pts have been registered into the study, 651 of them (82,3%) evaluable with HR+ MBC. Main characteristics are: Mean age 52 years; pN: UK 64 (9.8%) N+=405 (62.2%); Adj CHT=397 (61 %), mean DFI=96,99 months. T were used in 60.3% of the cases in the Adj setting, alone or in combination with other drugs, mainly anthracyclines (82.6%), with a mean DFI of 56.9 months. In the metastatic setting, across 1st to 3rd line, 460 pts (70.6%) received T, alone (49.7%) or in combination with Bevacizumab (38.2%), or other CHT drugs (11.9%). Details of the use of T in MBC are described in the table below. **Conclusions:** T have been used in more than 60% of cases of Luminal tumours in the Adj setting. In this population DFS is significantly shorter as compared with the non-T treated luminal population, as previously suggested by different Authors. Re-challenge with T is very frequent across different lines for MBC. Paclitaxel is the most used T, Docetaxel the less used and Nab-paclitaxel, labelled for MBC only, shows an increasing use from 1st-to 3rd line of treatment.

Drug	1st-line %	2nd-line %	≥ 3rd-line %
Paclitaxel	79.5	60.7	44
Docetaxel	14.5	10.7	9.3
Nab-Paclitaxel	6.0	28.4	46.6

1056 Poster Session (Board #48), Sun, 8:00 AM-11:30 AM

Prospective study of UDP-glucuronosyltransferase (UGT) 2B17 genotype and exemestane (Exe) pharmacokinetics (PK) and pharmacodynamics (PD) in Asian, hormone receptor (HR) positive, metastatic breast cancer (MBC) patients. *First Author: Robert John Walsh, Department of Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore*

Background: The active metabolite of Exe, 17-dihydroexemestane (17DhExe), is glucuronidated by UGT2B17 to inactive exemestane-17-O-glucuronide (Exe17-*O*-glu). *UGT2B17*2/*2*null genotype is 7 times more common in Asians than Caucasians and leads to reduced Exe glucuronidation in vitro. We studied Exe PK and PD in MBC patients genotyped for UGT2B17. **Methods:** Eligible patients (HR+ MBC; ≥1 line of endocrine therapy) received Exe 25mg OD till progression. *UGBT2B17* genotype was correlated with day 29 (D29) steady-state PK (Exe and metabolites), change in PD biomarkers (estrone and androstenedione) at D29 *vs* baseline (BL), objective response rate (ORR) [sum of complete and partial responses], and clinical benefit rate (CBR) [response or stable disease ≥ 24 weeks]. **Results:** In 64 patients enrolled, CBR was 25%; ORR was 3%. Frequencies of *UGT2B17*2/*2, UGT2B17*1/*2* and *UGT2B17*1/*1* were 72%, 26% and 2%, respectively. PD and PK data were available for 54 and 53 patients respectively. Mean Exe17-*O*-glu AUC and C_{max} were significantly lower, and mean 17DhExe C_{max} numerically higher in patients with *UGT2B17*2/*2 vs* other genotypes (Table 1). 17DhExe C_{max} was higher in patients with clinical benefit *vs* none (5.6 *vs* 3.8 ng/ml, p=0.02). Frequency of desired PD effect (rise in androstenedione and fall in estrone at D29 *vs* BL) was 22%. Exe plasma active index (PAI) [Table 1] was higher in patients with a fall in D29 estrone *vs* those without (14.7 *vs* 9.5, *p*=0.05). **Conclusions:** *UGT2B17* genotype affects Exe PK and may have significant PD correlates. Larger studies to examine effects on clinical treatment efficacy are needed. Clinical trial information: NCT01655004.

D29 PK.

Parameter	*UGT2B17 *2/*2, n=41*	Non *UGT2B17 *2/*2, n=12*	p value
Exe C_{max} (ng/mL)	38.1 ± 3.4	34.1 ± 4.3	0.56
Exe AUC (hr*ng/mL)	100.3 ± 8.5	93.7 ± 13.7	0.71
17DhExe C_{max} (ng/mL)	4.5 ± 0.5	3.3 ± 0.4	0.08
17DhExe AUC (hr*ng/mL)	15.9 ± 1.5	13.1 ± 2.1	0.36

Exe17-*O*-glu AUC (hr*ng/mL)	11.0 ± 1.5	92.4 ± 9.9	<0.001
Glucuronidation ratio $AUC_{Exe17Oglu}/AUC_{17Dh\ Exe}$	0.7 ± 0.1	7.8 ± 0.9	<0.001
PAI $(AUC_{Exe}+AUC_{17DhExe})/AUC_{Exe17Oglu}$	14.7 ± 2.1	1.2 ± 1.4	<0.001

1057 Poster Session (Board #49), Sun, 8:00 AM-11:30 AM

Choice of treatment and adherence to international ESO-ESMO (ABC) guidelines in HR+/HER2-ve metastatic breast cancer (MBC) patients (pts). *First Author: Marina Elena Cazzaniga, ASST Monza Oncology Unit, Monza, Italy*

Background: ESO/ESMO recently developed consensus guidelines for MBC treatment, potentially applicable worldwide. Aim of the present analysis is to verify the adherence to ABC recommendations for HR+ve MBC in the context of the AMBRA study. **Methods:** AMBRA is a longitudinal cohort study, aiming to describe the choice of first and subsequent lines of treatment in HER2-ve MBC pts receiving at least one Chemotherapy (CHT) (SABCS 2016, P5-15-07 & P5-14-09). For the present analysis, we selected 6 statements from the ABC1 & ABC2 Conferences, comparing them with the clinical choices of 1st-line therapy in all evaluable cases. **Results:** So far, 791/1500 pts have been registered into the study, 673 of them (85%) with HR+ MBC. Main characteristics are: N+=422 (62.2%), adjuvant chemotherapy=288 (42.4%), median DFI=70 months. 26 pts were excluded due to change into HR-ve (26; 3.8%). Endocrine Therapy (ET) was the 1st-line of treatment in 187/647 (27.8%), CHT in 310 (47.9%) and CHT followed by ET in 135 (20.8%). Viscera was the main site of disease in 328 pts (48.7%): 56 (17%) received ET, 209 (63.7%) CHT alone, the remaining CHT followed by ET. Median DFI was similar in all the 3 groups. Selected recommendations and percentages of adherence are reported in the table below. **Conclusions:** The adherence to clinical recommendation about the use of ET as 1st-line treatment in HR+ pts is very low; a potential bias could be due to the selection of the study population. Visceral disease appears to be often a key factor for selecting CHT as 1st-line treatment. In pts receiving ET, the recommendation to use AIs, TAM or F is transposed in almost all the cases.

Adherence to ABC1 & 2 Recommendations for HR+ve pts.

	n/N (% of adherence)	
1 - In HR+ pts ET is preferential	187/647 (27.8%)	
- ET, visceral relapse	56/187 (29.9%)	
2 - The preferred 1stline ET for postmenopausal pts is an aromatase inhibitor (AIs) or Tamoxifen (TAM)	100/186 (53.7%) 6/186 (3.2%)	170/186 (91.4%)
3 - Fulvestrant (F) High-Dose is also an option	65/186 (34.9%)	
4 - The addition of Everolimus to an AI is a valid option for some postmenopausal pts with disease progression after a NSAI visceral relapse	15/186 (8.1%) 5/186 (2.7%)	

1058 Poster Session (Board #50), Sun, 8:00 AM-11:30 AM

Experience of implementing a novel random sampling BICR audit for investigator (INV)-assessed progression-free survival (PFS) in the PALOMA-3 trial. *First Author: Xin Huang, Pfizer Inc., La Jolla, CA*

Background: PFS has frequently been used as a primary endpoint for evaluating efficacy of anticancer therapies in randomized clinical trials. Given high correlation between INV and independent (BICR) assessments with respect to the relative treatment effect, a pre-planned BICR audit of INV progression assessment in a random subgroup of patients (pts) instead of a BICR review of all progression assessments can be an acceptable approach to verify the INV assessments and to evaluate the potential bias in INV PFS results. **Methods:** PALOMA-3 was a randomized, double blind, placebo (PCB) controlled, Ph 3 study with the primary objective of demonstrating the superiority of palbociclib (PAL) + fulvestrant (F) over PCB + F in women with HR+, HER2- metastatic breast cancer (MBC). The primary endpoint was INV assessed PFS. BICR assessment of PFS was performed with the use of a novel audit approach involving a random sample–based BICR to verify if the INV assessed PFS was accurate. A third-party core imaging laboratory performed the blinded review for a randomly selected subgroup of pts (~40%). NIH and PhRMA methods were used to evaluate the potential for bias in the INV PFS results. **Results:** PAL + F improved PFS in patients with HR+, HER2- MBC. The observed INV HR was 0.46 (95% CI: 0.36, 0.59; stratified 1-sided $p < 0.0001$) in favor of PAL + F. The median PFS was 9.5 mo (95% CI: 9.2, 11.0) in the PAL + F arm and 4.6 mo (95% CI: 3.5, 5.6) in the PCB + F arm (Lancet Oncol. 2016; 17: 425–39). The estimated HR of the complete BICR data incorporating the information from the complete INV assessed PFS and the random sample audited BICR subgroup was 0.33 with the upper bound of the 1-sided 95% CI of 0.47. The results confirmed the INV assessed treatment effect and detected no INV bias in favor of PAL + F. **Conclusions:** PALOMA-3 is the first registrational trial to use a BICR audit and has received positive reviews from regulatory agencies. The experience of implementing the random sampling BICR audit in PALOMA-3 demonstrates that this approach can be used for randomized, double blind oncology trials with solid tumors where INV assessed PFS is the primary endpoint and a large treatment effect is targeted. Sponsor: Pfizer. Clinical trial information: NCT01942135.

1059 Poster Session (Board #51), Sun, 8:00 AM-11:30 AM

RADICAL trial: A phase Ib/IIa study to assess the safety and efficacy of AZD4547 in combination with either anastrozole or letrozole in ER positive breast cancer patients progressing on these aromatase inhibitors (AIs). *First Author: Michael Seckl, Charing Cross Hospital, London, United Kingdom*

Background: Patients with metastatic ER positive breast cancer invariably experience disease progression whilst taking AIs. Fibroblast growth factor receptor inhibitors (FGFRI) such as AZD4547 can reverse endocrine resistance in breast cancer cells. Consequently, we designed the RADICAL trial to test the safety and efficacy of AZD4547 combined with letrozole (L) or anastrozole (A). **Methods:** Patients with prior disease progression on either AI were initially recruited to a Phase Ib study which showed that L 2.5mg or A 1mg daily continuously could be safely combined with AZD4547 80mg twice daily on a 1wk on/1 wk off schedule. Pharmacokinetic data showed no significant interactions. Subsequently, 52 patients progressing on these AIs were recruited, either continuing, or, if other therapies had subsequently been given, restarting their prior AI together with AZD4547. Primary endpoint was change in tumour size (RECIST v 1.1) at 12 weeks compared to baseline. **Results:** Enrolled patients had previously received a median of 4 (range: 1-11) systemic therapies, including endocrine treatments with a median of 2 (range: 1-6). The mean tumour size change at 12 and 28 weeks was 7% (95%CI: -4%, 17%) and 8% (95%CI: -4%, 20%), respectively. Clinical benefit assessed by partial response (PR) or stable disease (SD) occurred in 36.5% (1 PR and 18 SD) and 25% (2 PR and 11 SD) of patients at 12 and 28 weeks, respectively. The median progression free survival was 3.1 months (95%CI: 2.4-5.4). Most adverse events (AEs) were G1/2 (95.3%). 11 (21%) patients developed asymptomatic AZD4547-induced retinal pigment epithelial detachment, all resolved and 1 and 6 were able to continue on study medication at full and half dose, respectively. Among 34 G3/4 AEs, only 6 were probably/possibly related to AZD4547. Out of 13 unrelated serious AEs, 2 were fatal. **Conclusions:** Combined AZD4547 with L or A appears to be safe and shows anti-tumour activity in advanced ER+ patients resistant to these AIs. Development of a biomarker to select patients for this therapy will facilitate future studies. Clinical trial information: NCT01791985.

1060 Poster Session (Board #52), Sun, 8:00 AM-11:30 AM

Estimating the effects of patient-reported outcome (PRO) diarrhea and pain measures on PRO fatigue: Data analysis from a phase II study of abemaciclib monotherapy, a CDK4 and CDK6 inhibitor, in patients with HR+/HER2- breast cancer after chemotherapy for metastatic disease—MONARCH 1. *First Author: Mark Boye, Eli Lilly and Company, Greenwood, IN*

Background: Investigators reporting treatment-emergent adverse events (TEAEs) in the 3rd line or greater abemaciclib MONARCH1 Phase 2 study observed Grade 1-3 diarrhea, fatigue, and abdominal pain in 90, 65, and 39% of the patients (n = 132). Unknown is the extent that diarrhea and overall pain add to fatigue in this setting. Using patient-reported outcome (PRO) measures, we conducted cross-sectional and longitudinal multivariate analyses to estimate these effects. **Methods:** Data came from a single-arm, open-label study of previously-treated patients with mBC. Throughout the study, the Brief Pain Inventory and the EORTC QLQ-C30 v3 were co-administered. All constructs and items from these two questionnaires – except EORTC Items 25 and 28 (memory and financial difficulties) - were used to estimate the Structural Equation Model (SEM) and the direct and indirect effects of pain and diarrhea on fatigue. Extended pattern mixture modeling (ePMM) – a latent variable modeling method that allows the explicit analysis of missing data and identifies subgroups with differential changes over time – was used to explore these relationships from screening through cycle 8. **Results:** SEM results showed that at cycle 2 of treatment, pain was a significant predictor of fatigue ($b = 0.68$; $P < 0.001$; CI 0.48 – 0.90); diarrhea was not a significant predictor of fatigue ($b = 0.06$; $P = 0.12$; CI -0.04 – 0.17). ePMM results across eight 30-day cycles found three fatigue subgroups: no change, improvement, worsening then improvement. Belonging to a similar pain subgroup predicted belonging to the corresponding fatigue subgroup (ref class was no change; improving $b = 5.03$, $P = 0.004$; worsening $b = 22.01$, $P < 0.001$); the same was not true for diarrhea and fatigue (ref class was no change; improving $b = 0.213$, $P = 0.75$; worsening $b = 0.04$, $P = 0.97$). **Conclusions:** These results suggest that for patients undergoing 3rd line or greater mBC treatment, pain is a significant predictor of fatigue early and over the course of the trial. However, diarrhea is not a significant predictor of fatigue. Clinical trial information: NCT02102490.

1061 Poster Session (Board #53), Sun, 8:00 AM-11:30 AM

Analysis of everolimus starting dose as prognostic marker in HR+ mBC patients treated with everolimus (EVE) + exemestane (EXE): Results of the 3rd interim analysis of the non-interventional trial BRAWO. *First Author: Peter A. Fasching, Universitatsklinikum Erlangen, Erlangen, Germany*

Background: BRAWO is a German non-interventional study, which enrolled more than 2400 patients (pts) with advanced/metastatic, hormone-receptor-positive and HER2-negative breast cancer treated with EVE and EXE. Main objectives are a) the impact of physical activity on efficacy and quality of life, b) prophylaxis and management of stomatitis in clinical routine, and c) the sequence of therapy when EVE is used in daily clinical practice. **Methods:** In this update on the results of the 3rd interim analysis (data cut-off 18-Oct-2016) we analyzed under real world conditions the first 1.078 patients followed up until disease progression for their progression-free survival (PFS) events. A two-stage process based on a Cox regression model was used to check the relevance of the start dose on PFS. In the first step potentially relevant covariates defined by medical experts were evaluated for relevance. In the second step start dose and all covariates showing a p-value of at most 0.1 in first step including all two-interaction of start dose with these parameters were included into the model. **Results:** Our multivariate analysis support the evidence that predictive factors, such as body mass index (BMI, p-value: < 0.001), therapeutic line (1st vs. 2nd+3rd vs. $\geq$4th; p-value: 0.013), presence of visceral metastases (p-value: < 0.001) and ECOG (Eastern Cooperative Oncology Group, p-value: < 0.001) status at the beginning of the therapy correlated significantly with the PFS. 283 patients started with 5mg and 795 Patients started with 10 mg. Starting dose had no significant impact on the PFS (neither as main effect nor within interactions, p-value: 0.44-0.88). **Conclusions:** Even though the approved and recommended starting dose for treatment with EVE is 10 mg, physicians sometimes start EVE-treatment with a lower starting dose, trying subsequently to increase the dose to the recommended dose of 10mg to allow the patient's organism to adapt to the therapeutic. As the study was not powered to detect possible differences in PFS by starting dose, the result of showing no detrimental effect of a lower start dose may be the result of limited power. Clinical trial information: EUPAS9462.

1062 Poster Session (Board #54), Sun, 8:00 AM-11:30 AM

Combination of paclitaxel and LAG3-Ig (IMP321), a novel MHC class II agonist, as a first-line chemoimmunotherapy in patients with metastatic breast carcinoma (MBC): Interim results from the run-in phase of a placebo controlled randomized phase II. *First Author: Francois P. Duhoux, Department of Medical Oncology, King Albert II Cancer Institute, Cliniques universitaires Saint-Luc and Institut de Recherche Expérimentale et Clinique (Pôle MIRO), Université Catholique de Louvain, Brussels, Belgium*

Background: IMP321 is a recombinant soluble LAG3-Ig fusion protein that binds to MHC class II molecules and mediates antigen-presenting cell (APC) activation followed by CD8 T-cell activation. The activation of the dendritic cell network with IMP321 the day after a low dose injection of a single agent chemotherapy may lead to stronger anti-tumor CD8 T-cell responses. We report initial results of the safety run-in of a randomized, placebo-controlled phase IIb trial in patients (pts) with hormone receptor positive (HR^+) MBC receiving first-line weekly paclitaxel. **Methods:** In the safety run-in phase 15 pts with MBC received weekly paclitaxel (80 mg/m^2; D1, D8, D15) in a four week cycle in conjunction with either 6 mg (n = 6; cohort 1) or 30 mg (n = 9, cohort 2) IMP321 injections s.c. (D2 and D16) for 6 cycles. Patients without progressive disease could continue with a maintenance phase of 12 additional injections of IMP321 every 4 weeks. Blood samples for pharmacokinetics and immuno-monitoring were taken in cycle 1 and 4 just before and after IMP321 injection. **Results:** In total 15 pts (median age 53 years) were enrolled between Jan 2016 and Oct 2016. No dose limiting toxicities have been reported. Cytokine release syndrome grade 1 was the only serious adverse event (SAE) related to IMP321 and occurred twice in the same patient. Grade 1 and 2 injection site reactions were the most common related AEs and occurred in 14 pts (93 %). A dose-dependent increase in serum IMP321 concentration was observed among the two dose levels with a C_{max}between 4 and 24 hours. Increased number of circulating monocytes, dendritic cells and increased activation were observed at both dose levels of IMP321, supporting the working hypothesis. **Conclusions:** The 30 mg s.c. IMP321 given every two weeks in combination with weekly paclitaxel is the recommended phase 2 dose which is used in the ongoing randomized placebo controlled phase II part of the study. Clinical trial information: NCT02614833.

1063 Poster Session (Board #55), Sun, 8:00 AM-11:30 AM

Is incomplete estradiol suppression during aromatase inhibitor treatment in post-menopausal patients with breast cancer due to insufficient systemic drug concentrations? *First Author: Daniel Louis Hertz, University of Michigan, Ann Arbor, MI*

Background: Aromatase inhibitors (AI) suppress estrogen biosynthesis and are effective treatments for estrogen receptor (ER)-positive breast cancer. In a prospectively enrolled cohort we observed a subset of post-menopausal women who exhibit high plasma estradiol (E2) concentrations during AI treatment, which could potentially contribute to treatment failure. We tested the hypothesis that incomplete E2 suppression is due to insufficient systemic AI concentrations. **Methods:** Five hundred post-menopausal women with ER-positive breast cancer were randomized to daily exemestane (Exe) 25 mg or letrozole (Let) 2.5 mg. Plasma E2 was measured using GC/MS/MS (lower limit of quantification (LLOQ) = 1.25 pg/mL) at baseline and after 3 months. Let and Exe plasma concentrations measured after 1 or 3 months were compared with the magnitude of E2 depletion using four complementary statistical procedures to assess associations of drug concentrations with: 1) a binary outcome of E2 suppression below LLOQ (logistic regression), 2) 3-month E2 concentrations (linear regression), 3) absolute change from baseline in E2 concentrations (Spearman correlation), and 4) an ordinal outcome defined by E2: decreased to below LLOQ, decreased but not to LLOQ, stayed the same, or increased from baseline (cumulative logistic regression). **Results:** 397 patients with E2 and AI concentration measurements were evaluable (Exe n = 199, Let n = 198). Thirty (7.6%) patients (Exe n = 13, Let n = 17) had E2 concentrations above the LLOQ at 3 months (range: 1.42-63.8 pg/mL). Exe and Let concentrations were not associated with achievement of unmeasurable E2 concentrations, on-treatment E2 concentrations, E2 change from baseline, or ordinal groupings of E2 change (all $p > 0.05$). In a parallel analysis there was no association of estrone-sulfate and drug concentrations (data not shown). **Conclusions:** Our results suggest that circulating drug concentrations do not explain incomplete E2 suppression in women receiving AI therapy. Additional studies are underway to determine whether age, body mass and genetic variation in the aromatase enzyme influence AI treatment response.

1064 Poster Session (Board #56), Sun, 8:00 AM-11:30 AM

Safety and tolerability of the dual PI3K/mTOR inhibitor LY3023414 in combination with fulvestrant in treatment refractory advanced breast cancer patients. *First Author: Anna M. Varghese, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Thephosphatidylinositol 3-kinase (PI3K) /mammalian target of rapamycin (mTOR) pathway is frequently activated in breast cancer. LY3023414 (LY) is an oral ATP- competitive inhibitor that selectively and potently inhibits class I PI3K isoforms, mTOR, and DNA-PK. The recommended phase 2 dose (RP2D) of LY monotherapy was previously established to be 200 mg twice daily (BID). Here we present the safety and preliminary activity data of LY in combination with fulvestrant (F) for breast cancer patients (pts) as part of a multi-cohort Phase 1 study. **Methods:** Pts with advanced HR+, HER2- breast cancer refractory to standard treatment received 200 mg LY BID + 500 mg F (day 1 and 15, then once monthly). Eligible pts had measurable disease and baseline tumor tissue available. Primary objective was to determine a RP2D. Other objectives included assessment of pharmacokinetics (PK), antitumor activity, and biomarker analysis. **Results:** 9 pts received LY + F in the breast cancer expansion cohort. All pts had multiple lines of prior systemic therapy (range 3-12), including chemotherapy. Dose limiting toxicity was observed in one pt in the form of grade (Gr) 3 oral mucositis. Common possibly related adverse events included nausea (5 pts), vomiting (4 pts), oral mucositis (4 pts), decreased appetite (3 pts), fatigue (3 pts), mucosal inflammation (2 pts), and paresthesia (2 pts). No obvious impact of LY on F PK or of F on LY PK was observed. Median duration of treatment was 15 weeks (range 3-63). In the 6 pts evaluable for tumor response, there was 1 durable partial response according to RECIST (still on treatment for $\geq$11 months) and 4 further pts had a decrease in their target lesions for a disease control rate of 56%. The median progression-free survival for this cohort is 4.2 months (90% CI 1.8, NA). Of note, the partial response was observed in a pt harboring an activating PIK3CA mutation (H1047R). Further biomarker analysis is ongoing. **Conclusions:** The RP2D of LY in combination with F is 200mg BID and may cause tumor regression or stabilization in breast cancer pts. Clinical trial information: NCT01655225.

1065 Poster Session (Board #57), Sun, 8:00 AM-11:30 AM

Genetic causes of resistance to entinostat in luminal breast cancer model systems. *First Author: Maki Tanioka, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Based on promising phase II data, the histone deacetylase inhibitor Entinostat (ENT) is in phase III trials for patients with metastatic ER-positive breast cancer. Predictors of sensitivity and resistance, however, remain unknown. **Methods:** Luminal cell lines SKBR3 (ER-/HER2+), BT474 (ER+/HER2+) and MCF7 (ER+/HER2-) were treated with or without ENT at their IC50 doses and their gene expression profiles determined. In addition, a total of 27 MMTV-Neu mouse tumors (luminal) were untreated (N = 8), or treated with ENT at 12 mg/kg for 3 weeks (N = 5), 6 weeks (N = 6), or until progression after complete response (N = 8). We investigated their gene expression profiles by microarray and copy number (CN) by arrayCGH, and utilized the Dawnrank analysis, a network-based bioinformatics tool that integrates DNA and RNA data to identify driver genes, to find predictors of resistance to ENT. **Results:** Supervised analysis of gene expression data coming from the 3 treated cell lines showed significant upregulation of multiple *MYC* gene signatures. Therefore, we constitutively overexpressed *MYC* using lentiviral *MYC* shRNA in SKBR3 and MCF7, and *MYC* overexpression made cell lines more resistant to ENT. In MMTV-Neu mice, both *MYC* gene mRNA and gene signatures were downregulated while cells responded to ENT, and became upregulated when the tumors progressed. aCGH CN analysis revealed that a large portion of mouse Chromosome 4 had DNA CN loss and low gene expression in tumors that progressed while on ENT. Within this region, *JUN* was computationally identified to be a top driver gene associated with resistance. *JUN* was next knocked down using lentiviral *JUN* shRNA in BT474 and T47D, and *JUN* knock-down repeatedly made cell lines more resistant to ENT. *MYC* gene-expression was also upregulated in *JUN*-knockdown BT474 and T47D. Finally, *JUN* CN loss was found in 22% (132/588) of luminal tumors in The Genome Cancer Atlas breast cancer, and all the *MYC* signature scores were significantly higher in JUN-deleted TCGA samples. **Conclusions:** ENT was an effective drug for all of our luminal models, both in vitro and in vivo. Using these models, we selected for resistant variants and identified *MYC* signature expression, and *JUN* CN deletion as being associated with resistance.

1066 Poster Session (Board #58), Sun, 8:00 AM-11:30 AM

Fulvestrant as maintenance therapy after first-line chemotherapy in patients with hormone receptor-positive, HER2-negative advanced breast cancer (FANCY), a prospective, multicenter, single arm phase 2 study. *First Author: Shusen Wang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Fulvestrant is potent for treatment of hormone receptor (HR)-positive advanced breast cancer (ABC); however, few data exist for this regimen as maintenance endocrine treatment after chemotherapy (CT). In our phase 2 trial, we aimed to assess efficacy and tolerability of fulvestrant 500mg as maintenance therapy in patients with disease control after first-line CT. **Methods:** Simon's two-stage design was used. We enrolled post-menopausal women with histologically confirmed HR-positive, HER2-negative ABC, who achieved disease control after four to eight cycles of first-line CT. Fulvestrant 500 mg was intramuscularly injected on day 1, 15, 29, then every 28 (±3) days subsequently, until disease progression or unacceptable toxicity. The primary endpoint was clinical benefit rate (CBR), secondary endpoint included progression-free survival (PFS) since maintenance treatment, PFS since first-line CT, objective response rate (ORR) and safety. **Results:** Between Dec 10, 2013, and Sept 30, 2015, 58 patients were enrolled. 25 (43%) patients were deemed as resistance to endocrine treatment, 36 (62%) patients had a visceral disease. Median follow-up was 21 months. After fulvestrant maintenance treatment, 36 patients remained disease stabilising for at least six months, and eight (14%, 95% CI 6-25) patients achieved a response, resulted in a CBR of 76% (95% CI 63-86), which met its primary endpoint. The median PFS since fulvestrant treatment was 16·1 months (95% CI 10·3 to not reached), and median PFS since first-line CT was 19·5 months (95% CI, 15·6 to not reached). 39 (67%) of 58 patients reported at least one adverse event (AE), of which predominantly were grade 1 or 2. The most common grade 3 AEs were increased alanine aminotransferase in two (3%) patients, increased aspartate aminotransferase in one (2%) patient, and arthralgia in one (2%) patient. No patient discontinued treatment due to AE. **Conclusions:** Fulvestrant 500mg is active in maintenance therapy in non-progrssion patients with HR-positive ABC after first-line CT. Further study is needed to assess long-term outcome of maintenance therapy. Clinical trial information: NCT02000193.

1067 Poster Session (Board #59), Sun, 8:00 AM-11:30 AM

Treat ER$^+$ight: Canadian prospective observational study in post-menopausal HR$^+$HER2$^-$ advanced breast cancer women—First interim analysis (IA). *First Author: Cristiano Ferrario, Segal Cancer Centre, Jewish General Hospital, McGill University, Montreal, QC, Canada*

Background: Treat ER$^+$ight is the first Canadian real-world study enrolling patients (pts) previously exposed to NSAI therapy and currently receiving endocrine therapy (ET) alone or in combination with targeted therapy (ET+TT). **Methods:** This first planned IA describes baseline parameters and adverse event (AE) prevention strategies adopted by 16 centers since Feb 2016 upon enrolling pts initiating ET or ET+TT. **Results:** See Table. **Conclusions:** This IA suggests that pts initiating ET+TT are younger, have a better ECOG status, mostly visceral disease and receive more prophylactic/proactive AE prevention therapies. Insights into real-world dosing and sequence will be presented. Clinical trial information: NCT02753686.

Baseline characteristics	Overall (n=72)	ET (n=34)	ET+TT (n=38)

1069 Poster Session (Board #61), Sun, 8:00 AM-11:30 AM

Overall survival (OS) of men and women with breast cancer according to tumor subtype: A population-based study. *First Author: Julieta Leone, Grupo Oncologico Cooperativo del Sur (GOCS), Neuquén, Argentina*

Background: The outcomes of male breast cancer (MBC) and female breast cancer (FBC) according to tumor subtype are poorly known. Our group previously reported the prognostic significance of tumor subtypes in MBC. The aim of this study was to analyze differences in OS between MBC and FBC according to tumor subtype compared with other factors. **Methods:** We evaluated men and women with microscopically confirmed invasive breast cancer between 2010 and 2013 with known estrogen receptor (ER) and progesterone receptor (PR) (together hormone receptor [HR]) status and human epidermal growth factor receptor 2 (HER2) status reported to the SEER program. Patients (pts) with other primary either before or after breast cancer were excluded. Pt characteristics were compared between MBC and FBC. Univariate and multivariate analyses were performed to determine the effect of each variable on OS. **Results:** We included 1,187 MBC and 166,054 FBC pts. Median age for MBC was 65 years (range 26-97) and for FBC was 60 years (range 18-108). Median follow-up was 21 months (range 1-48) for both groups. OS at 3 years for MBC and FBC was 85.6% and 90.4%, respectively ($p = 0.0002$). MBC pts were more frequently ductal, had higher grade, presented with more advanced stage and were more often HR+/HER2- (all $p < 0.0001$). MBC had worse OS than FBC in HR+/HER2- (Hazard ratio [HaR] 1.5; $p = 0.0005$), HR+/HER2+ (HaR 2.8; $p < 0.0001$) and triple negative (TN) (HaR 4.3; $p < 0.0001$) (p for interaction < 0.02). MBC had significantly worse OS than FBC in stage I and II, but similar OS in stage III and IV (p for interaction < 0.01). In multivariate analysis adjusted for age, race, grade, stage, surgery, radiation and marital status; HR+/HER2+ was the only subtype with significant differences in OS between MBC and FBC (HaR 2.0; $p = 0.002$). **Conclusions:** In this cohort, we observed significant differences in the distribution of tumor subtypes between MBC and FBC. OS was significantly different in both groups. Men had worse OS in stage I and II while similar OS in stage III and IV. There were significant differences in OS according to tumor subtype; compared with women, men with HR+/HER2+ tumors had twice the risk of death.

1070 Poster Session (Board #62), Sun, 8:00 AM-11:30 AM

Prognostic significance of tumor subtypes in women with breast cancer according to stage: A population-based study. *First Author: Jose Pablo Leone, University of Iowa, Iowa City, IA*

Background: Tumor subtypes (TS) are an important prognostic tool in breast cancer patients (pts). However, with contemporary therapies the prognosis of different subtypes is unclear. Recently, the AJCC proposed to incorporate TS among other variables in the 8th edition of the staging manual. The aim of this study was to analyze differences in overall survival (OS) by TS according to stage compared with other factors. **Methods:** We evaluated women with microscopically confirmed invasive breast cancer between 2010 and 2013 with known estrogen receptor (ER) and progesterone receptor (PR) (together hormone receptor [HR]) status and human epidermal growth factor receptor 2 (HER2) status reported to the SEER program. Pts with other primary either before or after breast cancer were excluded. Pt characteristics were compared between TS. Univariate and multivariate analyses were performed to determine the effect of each variable on OS. **Results:** We included 166,054 pts. Median age was 60 years (range 18-108). Median follow-up was 21 months (range 1-48). TS distribution was: 72.5% HR+/HER2-, 10.8% HR+/HER2+, 4.8% HR-/HER2+ and 12% triple negative (TN). Pts with HR+/HER2- tumors were older, had lower grade and presented with earlier stage (all $p < 0.0001$). OS at 3 years for each subtype according to stage is shown in the table (p for interaction < 0.0001). These differences in OS by TS continued to be significant for each stage in multivariate analysis adjusted for age, race, grade, histology and marital status. **Conclusions:** In this cohort, we observed significant differences in pt characteristics according to TS. Although HR+/HER2- tumors had better clinicopathologic features, the HR+/HER2+ group had the best OS in most stages. OS was significantly different by TS in each of the 4 stages and these results remained significant in the multivariate model. Pts with TN stage 1 tumors had similar OS as pts with HR+/HER2+ stage 2 tumors. Our results support the incorporation of TS as part of the staging variables in breast cancer.

	Stage 1	Stage 2	Stage 3	Stage 4
HR+/HER2-	97.2%	93.6%	85.5%	46.6%
HR+/HER2+	97.1%	94.5%	87.8%	54.8%
HR-/HER2+	96.4%	90.8%	79.5%	46.2%
TN	94.7%	85.9%	60%	14.7%
p	< 0.0001	< 0.0001	< 0.0001	< 0.0001

1071 Poster Session (Board #63), Sun, 8:00 AM-11:30 AM

Retrospective-prospective blinded evaluation predicting efficacy of epirubicin by a multigene assay in advanced breast cancer within a Danish Breast Cancer Cooperative Group (DBCG) cohort. *First Author: Anna Sofie Kappel Buhl, Department of Oncology, Herlev Hospital, Herlev, Denmark*

Background: Epirubicin remains a cornerstone in the treatment of primary and advanced breast cancer. This study evaluated the predictive effect of a multigene mRNA-based Drug Response Predictor (DRP) in the treatment of advanced breast cancer (ABC). We applied a mathematical method combining *in vitro* sensitivity with gene expression patterns in tumors. Previously the DRP has been broadly validated[1, 2] including retrospective validation of epirubicin[3]. **Methods:** Among 838 consecutive patients from a DBCG cohort 137 patients were treated with epirubicin between May 1997 and November 2016 at one of the participating sites. Patients were examined every 9 to 12 weeks by CT scan and clinical evaluation. After patient informed consent, mRNA was isolated from formalin fixed paraffin embedded tumor tissue from diagnostic biopsies and analyzed using Affymetrix arrays. Blinded predictions of epirubicin efficacy were compared to clinical data collected retrospectively from patients' medical records. Statistical analysis was done using Cox proportional hazards model adjusted for treatment line. Primary endpoint was progression free survival (PFS). **Results:** Median time to progression was 9.3 months (95% CI: 7.2-13.2). Of the 137 patients, four received epirubicin more than once. Scoring the DRP as a continuous covariate demonstrated that the DRP was significantly associated to PFS (p = 0.02). The estimated hazard ratio was 0.56 (90% CI: 0.35-0.89) comparing two patients with DRP score differing by 50 percentage points. The estimated median time to progression for a patient with a DRP value of 25% was 7 months versus 13 months for a patient with a DRP value of 75%. No interaction with previous adjuvant chemotherapy was observed (p = 0.98). **Conclusions:** The current study demonstrates a potential clinical value by being able to select patients that benefit from epirubicin against patients predicted not to benefit sparing the last patients unnecessary toxicity. Studies evaluating the predictor in an adjuvant setting will follow. [1] Knudsen et al PLoS ONE 9(2): e87415; [2] Buhl et al PLoS ONE 11(5): e0155123; [3] Wang et al JNCI 105(17): 1284-91

1072 Poster Session (Board #64), Sun, 8:00 AM-11:30 AM

Characterization of bone only metastasis (BOM) patients (pts) with respect to tumor subtypes (TS). *First Author: Amanda Marie Parkes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Metastatic breast cancer (MBC) pts with BOM are a unique population with limited characterization. Our goal was to characterize the TS of BOM pts, evaluating differences in sites and types of bone metastases (BM), treatment, and survival. **Methods:** We identified pts followed at MD Anderson Cancer Center from 01/01/1997 to 12/31/2015 for at least 6 months with a BOM diagnosis as first site of metastasis (met). TS was assessed by initial biopsy immunohistochemistry (IHC) (Table 1) with hormone receptor (HR) + defined as ER or PR >10%. **Results:** We identified 1445 pts with BOM, 1049 with initial biopsy IHC available to group into TS (Table 1). Among BOM pts, the majority had multiple BM at diagnosis (1141/79%), most in both the axial (Ax) and appendicular (App) skeleton (53%). Of the 808 pts with BM categorized on imaging at diagnosis, the majority were lytic (389/48%), with 21% sclerotic, 18% mixed, and 12% blastic. Time from breast cancer diagnosis to first met differed significantly by TS, $\chi^2(3) = 94.33$, $P < .0001$, with median time to met longer for pts with blastic (3.08 years; 95% CI 2.03, 4.24) versus lytic lesions (1.75 years; 95% CI 1.27, 2.17). **Conclusions:** BOM patients are a unique MBC subpopulation, more commonly found in luminal TS patients. Our study demonstrates prognostic differences in BOM pts specific to TS and emphasizes the need for further study of BOM patients.

Tumor Subtype *n = 1049*	# BM at Diagnosis	BM Location at Diagnosis	Treatment	Median Time from Diagnosis to First Met *years (95% CI)*	Median OS *years (95% CI)*

NCI Breast Cancer Steering Committee Working Group (WG) report on meaningful and appropriate endpoints for clinical trials (CT) in metastatic breast cancer (MBC). *First Author: Andrew David Seidman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There is significant heterogeneity in the natural history of MBC. Several recent randomized CT have yielded statistically significant advantages for the experimental arm, but neither led to regulatory approval nor practice change. Formal guidance for industry on CT endpoints provided by the US FDA in 2007 was not disease-specific. Patient-focused drug development is mandated by Prescription Drug User Fee Act V. Our WG sought to create specific consensus on endpoints for MBC CT focusing on subtype and line of therapy, with sensitivity to various stakeholders. **Methods:** A WG composed of medical oncologists, statisticians, advocates, FDA and NCI liaisons performed a systematic literature review of MBC natural history, CT endpoints by subtype (HR+/HER2-, HR+/HER+, HR-/HER2-, HR-/HER2+), and line of therapy (n = 146 papers). External expertise was obtained on industry perspectives, big data and real world evidence (RWE), and patient reported outcomes (PROs). WG members voted anonymously on statements and positions generated from deliberation. **Results:** The WG reached consensus on definitions relevant to contemporary CT endpoints. WG recommendations on the appropriate choice of OS or PFS are sensitive to expected post progression survival (PPS), and proportional and absolute gains. Currently, for HR-/HER2- MBC, OS is preferred as the optimal primary endpoint regardless of line of therapy; PFS is preferred in settings where expected PPS is longer. Toxicity can outweigh modest gains in PFS; scant data exist to gauge how patients value PFS gain vs toxicity. Where new agents may prolong PFS without impacting OS, exploring/validating graphic approaches that capture grade and timing of toxicity and PROs is warranted. An overview of WG Consensus Statements will be presented in detail. **Conclusions:** CT design for MBC should be sensitive to natural history (PPS), availability of other effective agents, PROs and toxicity burden. As unique subtypes (e.g. AR+) and novel therapies (e.g. immunotherapy) emerge, reassessment of relevant benchmarks is indicated. Rigorous big data approaches providing insights from RWE may inform CT endpoints in the future.

1074 Poster Session (Board #66), Sun, 8:00 AM-11:30 AM

Primary surgery versus no surgery in synchronous metastatic breast cancer: Patient-reported outcomes of the ABCSG 28 Posytive trial. *First Author: Vesna Bjelic-Radisic, Department of Obstetrics and Gynecology, Medical University of Graz, Graz, Austria*

Background: The ABCSG 28 Posytive trial compared primary surgery versus primary systemic therapy without surgery in synchronous metastatic breast cancer. The primary aim of the study was to investigate whether immediate resection of the primary tumor followed by standard systemic therapy improves median survival compared with no surgical resection (NCT01015625). This report describes quality-of-life (QoL) results. **Methods:** Patients were randomized between 2011 and 2015. Patients completed the EORTC QLQ-C30 and EORTC QLQ-BR 23 before treatment and every 6 months during follow-up. **Results:** 90 patients (45 with surgery, 45 with primary systemic therapy without surgery) from 15 centers were included in the QoL analysis. At 6 months patients after surgery reported more insomnia, breast symptoms and arm symptoms than patients without surgery, but these differences were no longer present at later follow-up visits. In the univariate and multivariate analysis the global health status and physical functioning scales of EORTC QLQ C30 were statistically significant predictors for OS and TTP ($p < 0.05$). Over a 24-month follow-up, patients > 60 years showed more QoL impairments than those < 60 years, independent of treatment. Patients < 60 years had better physical functioning and less fatigue, appetite loss, constipation and breast symptoms than older patients. There were no differences in QoL between patients with bone metastases vs those with visceral ± bone metastases. **Conclusions:** In patients with primary metastatic breast cancer primary surgery does not appear to improve QoL. Global health status and physical functioning scales of EORTC QLQ-C30 appears to be a predictive factor for OS and TTP. Clinical trial information: NCT01015625.

1075 Poster Session (Board #67), Sun, 8:00 AM-11:30 AM

Trop2 gene expression (Trop2e) in primary breast cancer (BC): Correlations with clinical and tumor characteristics. *First Author: Neelima Vidula, Massachusetts General Hospital, Boston, MA*

Background: Trophoblast antigen 2 (Trop2) is a glycoprotein expressed by many cancers. A phase I study of the trop2 antibody drug conjugate (ADC) IMMU-132 has shown promising activity in triple negative (TN) BC. We studied associations of primary BC trop2e with clinical characteristics, outcomes, and selected genes in publically available databases. **Methods:** Trop2e was evaluated with microarray data from the neoadjuvant I-SPY 1 (n=149), METABRIC (n=1992) & TCGA (n=817) databases. Associations with clinical features were assessed with the Kruskal-Wallis test (all). Correlations with chemotherapy response were evaluated with the Wilcoxon rank sum test (I-SPY 1) & with recurrence free survival (RFS) by the Cox proportional hazard model (I-SPY 1 & METABRIC). Pearson correlations were used to study associations between trop2e & selected genes (all). **Results:** In all 3 datasets, trop2 was detectable and had a wide range of expression in all BC subtypes. In I-SPY 1, trop2e did not vary by hormone receptor (HR) & HER2 or intrinsic subtype; in METABRIC & TCGA trop2e was lower in HER2+ than HR+/HER2- & TNBC (METABRIC p=0.03, TCGA p=0.007) & in HER2+ enriched and luminal B BC ($p < 0.001$, METABRIC & TCGA). Trop2e was higher in grade I vs. II/III BC in METABRIC ($p < 0.001$). No association with chemotherapy response was seen (I-SPY 1) or with RFS (I-SPY 1 & METABRIC). The table below shows significant ($p<0.05$) gene correlations with trop2e in ≥2 datasets. **Conclusions:** Trop2e is seen in all BC subtypes, particularly luminal A and TNBC. Trop2e correlates with the expression of genes involved in cell epithelial transformation, adhesion, and proliferation and inversely with immune genes, which may contribute to tumor growth. These findings support the use of trop 2 directed ADC in all BC subtypes.

1076 Poster Session (Board #68), Sun, 8:00 AM-11:30 AM

The Metastatic Breast Cancer (MBC) project: Accelerating translational research through direct patient engagement. *First Author: Nikhil Wagle, Dana-Farber Cancer Institute, Boston, MA*

Background: The Metastatic Breast Cancer Project is a nationwide research study, launched in Oct 2015 in collaboration with patients (pts) and advocacy groups, that directly engages pts through social media and seeks to empower them to share their experiences, clinical information, and samples to accelerate research. **Methods:** MBC pts enroll by providing their information at mbcproject.org. Pts are sent a saliva kit and asked to mail back a sample which is used to extract germline DNA. We contact pts medical providers and obtain medical records (MRs) and stored tumor samples. Pts may also submit a blood sample, used to extract cell free DNA (cfDNA). Whole exome sequencing (WES) is performed on tumor, germline, and cfDNA; transcriptome sequencing is performed on tumor. Clinical and genomic data are used to generate genomic landscapes in pt subgroups and to identify mechanisms of response and resistance to therapies. Data are shared widely through public databases. Pts receive regular study updates. **Results:** In 12 months, 2908 MBC pts from 50 states enrolled. 95% completed the 16-question survey about their cancer, treatments, and demographics. 1730 (60%) completed the online consent form. 100-200 pts continue to enroll monthly. To date, 1539 saliva kits were mailed and 1120 samples were received (73%). 992 unique treating institutions were reported by pts, including 733 institutions reported by only 1 pt each and 5 institutions reported by more than 40 pts each. We have obtained MRs from 253 patients (67% yield) and tumor samples from 85 pts (67% yield). WES was successfully completed for 79 tumors of 88 attempted (90%). WES has been performed on initial cfDNA samples. **Conclusions:** A direct-to-patient approach enabled rapid identification of thousands of MBC pts willing to share MRs, saliva, and tumor samples, including many with rare phenotypes. Remote acquisition of MRs, saliva, tumor, and blood for pts located throughout the US is feasible. We estimate that for ~33% of consenting patients, we can obtain medical records, saliva, and tumor tissue. Genomic analysis of tumor and cfDNA from subgroups including young pts, pts with extraordinary responses, and pts with de novo MBC will be presented.

1077 Poster Session (Board #69), Sun, 8:00 AM-11:30 AM

The role of high-dose chemotherapy (CT) and stem-cell support in high-risk stage II, locally advanced, and responding stage IV breast cancer (BC): The Israeli experience with 20 years median follow-up. *First Author: Idit Peretz, Rabin Medical Center, Petah Tikva, Israel*

Background: Lately, updated data led the medical community to reconsider the use of intensive CT with stem-cell support for selected groups of BC patients (pts). Herein, we provide an update on a study investigating the efficacy, feasibility, and toxicity of high-dose CT with stem-cell support in pts with high-risk stage II, chemosensitive stage III and IV BC. **Methods:** The protocol offered adjuvant/neoadjuvant/induction doxorubicin-based CT, 75-90 mg/m^2 X 4 courses followed by high-dose CT (cyclophosphamide 6000 mg/m^2, carboplatin 800 mg/m^2, and thiotepa 500 mg/m^2) and autologous stem cell support with growth factors. Post-transplant local radiotherapy was delivered. Pts who were hormone receptor (HR) positive received Tamoxifen. **Results:** From 2/1994 to 11/1998, 292 BC pts were referred to the study from all Israeli oncology centers. Median follow-up from transplant was 20 (range, 18-22) years; 119 had stage 2 disease (42 with 4-9 positive nodes, 77 with ≥10 positive nodes); 87 had stage 3 disease, of whom 50 had locally advanced/inflammatory BC treated with neoadjuvant CT; and 86 had chemosensitive stage IV BC. Two acute transplant-related deaths and one death due to late transplant-related toxicity were reported. Median age at transplant was 45 (range, 24-63) years. Overall survival (OS) by HR status is presented in the table. In total, 167 of the 292 pts died (based on death status data retrieved from the Registry of the Ministry of the Interior), representing OS of 42%. The OS rates for stage II, III, and IV were 55%, 45%, and 23%, respectively. **Conclusions:** Long-term accurate follow-up of pts receiving well-defined treatments remains an important tool in cancer research. High-dose CT with stem-cell support could represent a therapeutic/curative option in select BC patients in all disease stages. Reintroduction of this approach should be re-examined.

	N (HR+/HR-)	OS: All pts, n/n (%)	OS: HR+ pts, n/n (%)	OS: HR-neg pts, n/n (%)	Missing data, n
Stage 2	119 (74/45)	66/119 (55%)	40/66 (60%)	26/66 (40%)	-
Stage 3	87 (36/33)	39/87 (45%)	14/39 (36%)	17/39 (43%)	18 (8 alive)
Stage 4	86 (49/29)	20/86 (23%)	14/20 (70%)	4/20 (20%)	8 (2 alive)

1078 Poster Session (Board #70), Sun, 8:00 AM-11:30 AM

Evolution of overall survival according to year of diagnosis (2008-2014) and subtypes, among 16703 metastatic breast cancer (MBC) patients included in the real-life "ESME" cohort. *First Author: Suzette Delaloge, Institut Gustave Roussy, Villejuif, France*

Background: Real-life data may help checking that public investments match closely medical needs. During the last decade, several drugs have been released on the market for MBC on the basis of a potential impact on overall survival (OS). Based on the large real-life ESME cohort, we aimed to describe the time evolution of MBC OS according to main phenotypes. **Methods:** ESME is a unique MBC national cohort including all consecutive patients (pts) who initiated treatment for MBC between 1/01/08 and 31/12/14 in the 18 French comprehensive cancer centres. ESME collects retrospective data using clinical trial-like methodology including quality assessments. Database lock was 8/12/2016. Primary objective was the impact of year of MBC diagnosis on OS. Multivariate Cox regressions were used with adjustment for main prognostic covariates. **Results:** 15170 out of 16703 pts in ESME had full IHC data allowing their classification as HR+HER2- (N=9922), HER2+ (N=2863), or HR-HER2- (N=2321) cases. Median FU and OS for the whole cohort are 4.05 yrs [95 CI: 3.98-4.12], and 3.1 yrs [95 CI: 3.03-3.18] respectively. In the adjusted multivariate analysis, year of MBC diagnosis, age at MBC, subtype (using HER2+ as reference), disease-free interval (DFI), visceral involvement, and number (nbr) of metastatic sites are significant OS predictors (table) although with low effect for the first item. Age at MBC, DFI, visceral involvement, and nbr of metastatic sites remained significant prognostic variables in subtypes. Year of diagnosis was no longer significant in HR+HER2- nor HR-HER2- cases (HR=0.997, p=0.71 and HR=0.997, p=0.84), while it was highly significant in HER2+ cases (HR=0.91, $p<0.0001$). **Conclusions:** Although OS of MBC has slightly improved over the past decade, this remains mostly confined to HER2+ cases, highlighting the need for new strategies for the luminal and triple negative populations.

	HR (95% CI)
Year of diagnosis	0.982 (0.969-0.994)
Older age	1.014 (1.012-1.016)
HR+ HER2-	1.179 (1.11-1.252)
HR- HER2-	3.122 (2.909-3.35)
Shorter DFI	0.975 (0.971-0.979)
Visceral metastasis	1.237 (1.171-1.306)
Nbr of metastatic sites	1.253 (1.226-1.281)

1079 Poster Session (Board #71), Sun, 8:00 AM-11:30 AM

Pharmacogenetics revisits bevacizumab in breast cancer patients: An ancillary analysis of the UCBG trial COMET—A French multicentric prospective study from R&D UNICANCER. *First Author: Gerard A. Milano, Oncopharmacology Unit, Centre Antoine Lacassagne, Nice, France*

Background: Bevacizumab (Beva) is no longer unanimously recommended in the management of breast cancer (BC). Given the absence of faithful predictors of Beva treatment outcome, we made the hypothesis that constitutional gene polymorphisms could play a role in this context. We report the pharmacogenetic ancillary study of the prospective COMET trial conducted in advanced BC patients (pts) receiving first-line Beva associated with paclitaxel. **Methods:** Relevant targeted gene polymorphisms were analyzed (blood) in 203 prospective pts (mean age 55.3, median follow-up 24 months). VEGFA at positions -2578C > A (rs699947), -1498T > C (rs833061), -634G > C (rs2010963), and 936C > T (rs3025039) were analyzed by PCR-RFLP. VEGFR1 319A > C (rs9582036), VEGFR2 at positions 604C > T (rs2071559), 1192C > T (rs2305948), 1416T > A (rs1870377), IL8 251T > A (rs4073), CYP2C8 139C > T (rs1572080), 399T > C (rs10509681) and ABCB1 at positions 1199 C > TA (rs2229109), 2677G > TAC (rs2032582) were analyzed by Mass-Array Agena. ABCB1 1236C > T (rs1128503) and 3435T > C (rs1045642) were analyzed by pyrosequencing. All fitted HWE. **Results:** Median progression-free survival (PFS) was 10.8 months. VEGFR1 319A allele was associated with longer PFS (p = 0.03). The VEGFA-1498T allele was significantly associated with both longer overall survival (OS) (p = 0.005) and PFS (p = 0.065). The VEGFA -2578C allele was associated with greater OS (p = 0.002) and PFS (p = 0.071). These two VEGFA polymorphisms were in linkage disequilibrium ($p < 0.0001$). Multivariate Cox analysis showed that VEGFA -2578 (p = 0.001) and VEGFR2 1416 (p = 0.025) were significant predictors of OS: the score of favorable alleles (VEGFA -2575C and VEGFR2 1416T) was highly associated with OS (p = 0.0003), with median survival at 24 months being 30% for score 0 (95%CI 15-61), 65% for score 1 (95%CI 55-75) and 90% for score 2 (95%CI 67-90). **Conclusions:** Application of an easy-to-perform low-cost genotyping test may identify strong predictors of Beva outcome in metastatic BC pts. In the current era of precision medicine, a pharmacogenetic-based personalized Beva therapy deserves to be prospectively validated in BC pts. Clinical trial information: 2012-A00244-39.

1080 Poster Session (Board #72), Sun, 8:00 AM-11:30 AM

Distribution of receptor tyrosine kinase (RTK) nsSNPs in breast cancer (BC) patients (pts) using next-generation sequencing (NGS). *First Author: Lindsay Kaye Morris, College of Medicine, The University of Tennessee Health Science Center, Memphis, TN*

Background: Non-synonymous SNPs (nsSNPs) discovered by NGS occurring in RTKs' conserved topology in pts with BC may promote oncogenic signaling and hence may be actionable. **Methods:** We analyzed BC pts for nsSNPs in 29 RTKs identified by tumor profiling with NGS from Caris during 2013-2015. Mutations were classified by location including the tyrosine kinase domain (TKD), extracellular domain (ECD), transmembrane domain (TM), juxtamembrane domain (JM) and carboxy-terminal (CT) regions. nsSNPs underwent *in silico* analysis using PolyPhen-2 (Harvard) to determine pathogenicity. **Results:** 79 pts were identified with a median age of 58 years (range 32-83); 99% female; 60% white, 38% black and 2% other. 77 pts were classifiable with 8 (10%) triple-positive, 35 (46%) ER+/PR+/HER2- (ER/PR+), 10 (13%) ER-/PR-/HER2+ (HER2+) and 24 (31%) triple-negative. 78 nsSNPs and 1 Caris-reported pathogenic substitution of *ERBB3* (TKD S846I) were found. 52/79 (66%) pts had ≥1 RTK nsSNP (range 0-4); 28/29 RTKs had ≥1 nsSNP with median of 2 (range 0-15). In 28 pts (35%), 40% of nsSNPs were predicted to be damaging (pnsSNP) and 3 pts had 2 pnsSNPs. 17/29 RTKs had pnsSNPs, median 1 (range 0-9). The most commonly mutated RTKs were *ROS1* (9/15 variants were pnsSNPs), *ALK* (3/4), *EPHA5* (3/3), *FLT4* (2/5), *cKIT* (2/4) and *ERBB4* (2/3). *ROS1* and *ALK* nsSNPs were most-frequently seen in ER/PR+ (9/15 pnsSNPs), triple-positive (3/3) and HER2+ (0/2) pts; no triple-negative pts had such variants. 100% triple-positive pts (6/8 pnsSNP), 69% ER/PR+ (18/35), 60% HER2+ (2/10) and 58% triple-negative (3/24) had RTK nsSNP. nsSNP were spread in all 5 RTK regions: 58% localized to the ECD (20/45 pnsSNPs), 17% TKD (8/13), 9% CT (2/7), 9% TM (1/7) and 8% JM (1/6) lesions were found. Of 9 *ROS1* pnsSNPs, 7 were ECD, 1 CT and 1 TKD. **Conclusions:** 35% of BC pts had pnsSNP in RTKs across various phenotypes including frequent mutations in potentially actionable genes such as *ROS1* and *ALK*. 26% of ER/PR+ pts had pnsSNPs in *ROS1* or *ALK*. nsSNPs in the ECD or TKD were most likely to be damaging.

1081 Poster Session (Board #73), Sun, 8:00 AM-11:30 AM

Immune microenvironment in brain metastases of breast cancer. *First Author: Rin Ogiya, Tokai University School of Medicine, Isehara, Japan*

Background: In patients with brain metastasis (BM) of melanoma or lung cancer, significant activity of immune checkpoint inhibitors has been reported. However, details of the immune microenvironment in BM has not been unveiled. In this study, we used immunohistochemistry (IHC) to compare primary breast tumors and BM tumor samples with respect to tumor infiltrating lymphocytes (TILs) and tumor characteristics related to the immune system. **Methods:** We retrospectively identified 107 patients with breast cancer, diagnosed with BM, who had undergone surgery between 2001 and 2012 at 8 institutions. We collected 191 samples which included both BM samples alone and pair-matched samples (primary and BM). Hematoxylin and eosin (H&E) stained slides were evaluated for stromal TILs in 10% increments (0–1%, > 1– < 10%, 10%–100%). IHC was performed using the following primary antibodies: CD4, CD8, Foxp3, PD-L1, PD-L2 and HLA class I. The cells positive for each antibody signal were counted automatically using ImageJ (NIH). The expression of PD-L1, PD-L2, and HLA on the tumor cells was scored as 0 (negative), 1 (weak or focal), or 2 (strong). **Results:** The median category of TILs of BM tumors was > 1– < 10% (range: 1–30%). Forty-six pair-matched samples were analyzed and the percentage of TILs in the primary breast tumor was significantly higher than that in BM samples (paired t-test, $P < 0.01$). The number of CD4/CD8/Foxp3 positive cells in primary breast tumor was also significantly higher than in BM samples (paired t-test, $P < 0.05$ for all categories). The negative/positive conversion occurred with the expression of HLA/PD-L2 on tumor cells (paired t-test, P = 0.03/0.06, respectively). No significant difference was observed in the overall survival (OS) of patients, from initial BM, based on high or low TILs (log-rank test, P = 0.131). However, triple negative breast cancer patients with low TILs had significantly shorter OS compared with patients with high TILs (log-rank test, P = 0.04). **Conclusions:** We demonstrated that TILs in BM tumors was significantly lower as compared to primary breast tumors. The expression of immune related molecules on tumor cells was converted in BM tumors.

1082 Poster Session (Board #74), Sun, 8:00 AM-11:30 AM

A phase II, multicenter, randomized trial of eribulin plus gemcitabine (EG) vs. paclitaxel plus gemcitabine (PG) in patients with HER2-negative metastatic breast cancer (MBC) as first-line chemotherapy (KCSG BR13-11, NCT02263495). *First Author: Kyung Hae Jung, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea*

Background: PG chemotherapy is one of the preferred chemotherapeutic regimens for patients with MBC. Eribulin mesylate is a non-taxane inhibitor of microtubule dynamics of the halichondrin class. A recent pooled analysis with eribulin showed improved overall survival (OS) in various patient subgroups. Furthermore, eribulin may have rational benefit compared with paclitaxel in terms of neurotoxicity. **Methods:** This study was a prospective randomized phase 2, open-label, two-arm, multi-center study comparing EG with PG chemotherapy for patients with HER-2 negative MBC as first-line treatment. Histologically confirmed breast cancer patients, at least 19 years of age, with no prior history of chemotherapy for MBC with evaluable lesions were included. Prior hormonal therapy as a treatment of Hormone Receptor (HR)-positive MBC was allowed. This design was hypothesized that EG chemotherapy would not be inferior to PG chemotherapy. The primary endpoint was Progression-Free Survival (PFS). Estimated 6 mo. PFS rate for each arm was 70%. The secondary endpoints were: Time to Treatment Failure (TTF); OS; neuropathic scale; toxicity; clinical benefit rate. **Results:** A total of 118 patients (median age: 50, 24-66) were enrolled between 2015 and 2016, and were randomly assigned to PG (n = 59) or EG (n = 59) chemotherapy. Mean number of metastatic sites was 3 (1-8). Six month PFS rates for both arms were 72% for EG and 73% for PG arm (p = 0.457). PFS in PG arm tends to be longer than in EG group (median PFS 12.6 for PG *vs.* 9.6 months for EG) without statistical significance. In addition, there was no significant difference in OS between the two groups (not reached *vs.* 21.2 months, p = 0.223). The median numbers of chemotherapy cycles of both groups were 8 for EG and 10 for PG (range 2-32). CBRs were 44% for EG and 45% for PG arm. Major toxicities were neutropenia and neurotoxicity. Grade II or more neurotoxicity was more common in PG than in EG group (40% *vs.*25%). **Conclusions:** EG chemotherapy showed similar clinical benefit with PG chemotherapy in terms of PFS but, more favorable neurotoxicity than PG chemotherapy. Clinical trial information: NCT02263495.

1083 Poster Session (Board #75), Sun, 8:00 AM-11:30 AM

A phase I trial of mifepristone (M), carboplatin (C), and gemcitabine (G) in advanced breast and ovarian cancer. *First Author: Erica Michelle Stringer, University of Alabama at Birmingham, Birmingham, AL*

Background: Glucocorticoid receptor (GR) activity inhibits chemotherapy-induced apoptosis, and GR antagonism with m enhances chemotherapy sensitivity in GR+ breast (B) and ovarian cancer (OC) cells. C+G is a commonly used regimen for B and OC. We report the results of a phase I trial of the GR antagonist m plus C+G in patients with advanced B and OC. **Methods:** A standard "3+3" dose escalation phase I study was performed. Objectives were to assess the safety and tolerability of the regimen, and to determine the recommended phase 2 (RP2D) dose of M+C+G. C+G was administered on days 1 and 8 of a 21 day cycle, and m was administered the day prior to and the day of chemotherapy. The starting dose level (DL) was 1, with additional DLs as follows in the table. **Results:** 31 patients (pts) with a median age of 54 years (range 32-76) were enrolled. 18 pts had BC (3 ER+, 15 triple-negative), and 13 had high grade serous OC (11 platinum-sensitive, 2 platinum-resistant). The median number of prior therapies for advanced BC was 1 (range 0-5) and for OC was 2 (range 1-3). Dose de-escalation was necessary due to the DLT of neutropenia. After DL -3, prophylactic G-CSF (PGF) was instituted. The RP2D was C AUC 2, G 600 mg/m2, m 300 mg with PGF administered on day 9. Of the BC pts, 2 had a complete response (CR), 2 had a partial response (PR), 8 had stable disease (SD), 4 had progressive disease (PD). Of the OC pts, there was 1 CR (CR2 lasted > 27 mos; CR1 lasted only 8 mos), 1 PR, 6 SD, and 3 PD. 4 pts were inevaluable for response. **Conclusions:** These data suggest that M+C+G is safe and tolerable, and the most common DLT is neutropenia. This was easily managed with the institution of PGF. Studies correlating tumor GR expression with response are ongoing, and may help identify patients who are most likely to benefit from this combination. Clinical trial information: NCT02046421.

	Dose				
DL	Carboplatin	Gemcitabine	Mifepristone	Pts Enrolled	Dose-limiting Toxicities (DLTs)

1084 Poster Session (Board #76), Sun, 8:00 AM-11:30 AM

A phase 2 study of napabucasin with weekly paclitaxel in previously treated metastatic breast cancer. *First Author: William Jeffery Edenfield, Greenville Health System Cancer Institute, Greenville, SC*

Background: Napabucasin is a first-in-class cancer stemness inhibitor, identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al PNAS 112 (6):1839, 2015). Napabucasin has shown potent synergistic preclinical anti-tumor activity with paclitaxel (PTX). In a phase Ib dose escalation study in patients (pts) with advanced solid tumors, Napabucasin plus weekly paclitaxel was well tolerated. A phase II expansion cohort was opened for pts with previously treated metastatic breast cancer (MBC). **Methods:** Pts with metastatic MBC for whom weekly PTX was a reasonable treatment option received Napabucasin 240, 480, or 500 mg orally, twice daily in combination with paclitaxel 80 mg/m2 IV weekly on 3 of every 4 weeks. Adverse events were evaluated using CTCAE v4.03 and objective tumor assessments were obtained every 8 weeks per RECIST 1.1 criteria. **Results:** A total of 50 pts were enrolled including 34 with triple-negative disease (negative for estrogen receptor [ER], progesterone receptor [PR], and Her2 and no prior history of positive receptor status). There were 9 pts positive for ER, PR, or Her2 and refractory to targeted agents, and 7 pts with conversion to triple-negative disease from pathology previously positive for ER, PR or Her2. Pts were heavily pre-treated, having received a median of 5 prior lines of systemic therapy. All but 3 patients had received previous systemic treatment with a taxane. Napabucasin + PTX was well tolerated. Grade 3 AE occurring in ≥ 5% patients was diarrhea (n = 4), and 1 pt had grade 4 diarrhea. The objective response rate (ORR), disease control rate (DCR), median progression free survival (mPFS), and median overall survival (mOS) for all pts and for each sub-group are summarized in the table. **Conclusions:** Napabucasin (BBI-608) plus weekly paclitaxel has demonstrated safety, tolerability, and encouraging signs of anti-cancer activity in pts with pretreated metastatic breast cancer. Further clinical evaluation of this combination regimen in controlled trials is warranted. Clinical trial information: NCT01325441.

	n	ORR	DCR (at 8 weeks)	mPFS (months)	mOS (months)
All MBC	50	20%	50%	2.5	9.1
Triple-Negative	34	18%	47%	2.3	7.2
Receptor Positive	16	25%	56%	5.5	not reached

1085 Poster Session (Board #77), Sun, 8:00 AM-11:30 AM

Extracellular matrix (ECM) protein fragments in serum and outcomes in two metastatic breast cancer cohorts. *First Author: Nicholas Willumsen, Nordic Bioscience, Herlev, Denmark*

Background: Extracellular matrix (ECM) is the non-cellular component of all tissues. Increased ECM formation and matrix metallo-protease (MMP) mediated ECM degradation are parts of tumorgenesis. The altered ECM remodeling generates specific ECM fragments that are released into the circulation. We evaluated the association of specific ECM/collagen fragments measured in serum with outcomes in two independent metastatic breast cancer (MBC) cohorts. **Methods:** C1M (MMP-degraded type I collagen), C3M (MMP-degraded type III collagen), C4M (MMP-degraded type IV collagen), and PRO-C3 (pro-peptide reflecting truetype III collagen formation) were measured by ELISA in pre-treatment serum from a phase III randomized clinical trial of 2nd-line hormone therapy (HR+, n= 153), and a 1st-line trastuzumab-treated cohort (HER2+, n=64). In both cohorts, all sites of metastases were included. The collagen-fragments were evaluated on continuous and categorical (75th percentile cut-off) bases by univariate Cox-regression analysis for their association with time-to-progression (TTP) and overall survival (OS). **Results:** In the HR+ cohort, Pro-C3 measured as a continuous variable was significantly associated with TTP; C1M, C4M and Pro-C3 were associated with OS. On a categorical basis, C1M and C3M were associated with TTP; all fragments were associated with OS (Table). In the HER2+ cohort, continuous measurements of all fragments were associated with TTP and OS. On a categorical basis (Table), all fragments were associated with TTP; C4M and Pro-C3 were associated with OS. **Conclusions:** ECM remodeling quantified in pre-treatment serum was associated with shorter TTP and OS in two independent MBC cohorts receiving systemic therapy. If validated, quantification of ECM remodeling in serum has potential as prognostic and/or predictive biomarkers in MBC.

1086 Poster Session (Board #78), Sun, 8:00 AM-11:30 AM

Association between insulin-like growth factor-1 receptor (IGF1R) expression in circulating tumor cells (CTCs) and prognosis in patients with metastatic breast cancer (MBC). *First Author: Alessandra Gennari, E.O. Galliera, Genova, Italy*

Background: CTCs are strongly associated with prognosis in MBC. In a recent metanalysis on 1944 patients, a CTC count > 5/7.5 ml was associated with a 2-fold increased risk of progression and death. Little evidence is available on the prognostic role of phenotypic CTC assessment, however. In this study, nested in a randomized clinical trial of Ist line chemotherapy ± metformin, we evaluated the prognostic role of IGF1R expression in CTCs, given its potential growth promoting effect. **Methods:** CTCs were isolated from blood samples of enrolled patients; an automated sample preparation and analysis system (CellSearch) was customized for detecting IGF1R positive CTCs. The prognostic role of total CTCs, IGF1R positive (+ve) and negative (-ve) CTCs was assessed by fitting different PFS and OS multivariate Cox's models. **Results:** CTC evaluation at baseline was performed in 72 of 126 patients, of whom 30 (42%) had CTCs ≥5/7,5ml and 41 (57%) had at least one IGF1R+ve CTC. In univariate analysis the prognostic role of total CTCs was confirmed: PFS (< 5 vs ≥5) HR = 1.69, 95%CI 1.01-2.69, p 0.042 and OS HR = 2.80, 95%CI 1.47-5.30, p 0.002).However, when total CTCs were split in IGF1R+ve and IGF1R–ve, a striking difference was seen in the prognostic effect of these cell types.While no association was detected between an increasing number of IGF1R+ve CTCs and PFS or OS (p = 0.56 and p = 0.99), the number of IGF1R-ve CTCs (< 4 vs ≥4) was strongly associated with an increased risk of progression and death: HR 1.93 (95%CI 1.15-3.23, p 0.013) and 3.65 (95%CI 1.88-7.09, p 0.001). In multivariate analysis, adjusted for metformin, the prognostic role of the number of IGF1R-ve CTCs was confirmed, while no residual prognostic role of total CTCs or number of IGF1R+ve cells was found (p = 0.55 and p = 0.64 for PFS; p = 0.86 in both cases for OS). **Conclusions:** In our study, the loss of IGF1R expression in CTCs exhibited a significant adverse prognostic effect, whereas no significant effect of total CTCs and IGF1R+ve CTCs was observed. This finding supports the biological characterization of CTCs as a critical step for further definition of their prognostic significance.

1087 Poster Session (Board #79), Sun, 8:00 AM-11:30 AM

Paclitaxel plus carboplatin versus paclitaxel plus epirubicin as first-line treatment for metastatic breast cancer: Efficacy and safety results of a randomized, phase III trial. *First Author: Zhongsheng Tong, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Paclitaxel/carboplatin combinations are highly active in metastatic breast cancer (MBC). We conducted a randomized, phase III, non-inferiority trial comparing paclitaxel/carboplatin (TP) with paclitaxel/epirubicin (TE) as first-line therapy for MBC. Progression-free survival (PFS) was the primary efficacy endpoint. Secondary endpoints included response rate, overall survival, tolerability, and quality of life (QoL). **Methods:** From June 2009 to January 2015, 231 patients were randomly assigned, 115 of whom were randomized to TP and 116 to TE. Baseline characteristics were relatively well-balanced in the two treatments. **Results:** After a median follow-up of 29 months, no significant difference was observed between the two treatments in objective response rate (ORR) (38.3% vs. 39.7%, respectively). Both the progression-free survival (p=0.158) and overall survival (p=0.369) were very similar between the two treatments. Both regimens were well tolerated. The main toxicities were myelosuppression, gastrointestinal reactions, and alopecia. TP showed higher grades 3–4 alopecia and higher nausea ($p<0.05$). TE showed higher incidence of myelosuppression than TP ($p<0.05$) (Table). Those patients whose epirubicin cumulative dose was more than 1000 mg/m^2 did not suffer worse cardiotoxicity. **Conclusions:** Our study suggests that TP arm is an effective therapeutic alternative for patients with MBC, especially in those previously exposed to epirubicin in the adjuvant setting. TP has some advantages, such as less cost and less side effects (myelosuppression and fatigue). Clinical trial information: NCT02207361.

Summary of adverse events per patient.

Phase 2 study of pembrolizumab as first-line therapy for PD-L1–positive metastatic triple-negative breast cancer (mTNBC): Preliminary data from KEYNOTE-086 cohort B. *First Author: Sylvia Adams, NYU Langone Medical Center, New York, NY*

Background: Standard first-line treatment for mTNBC is chemotherapy. However, outcomes are poor, and new treatment options are needed. Cohort B of KEYNOTE-086 (NCT02447003) assessed the safety and antitumor activity of pembrolizumab as first-line therapy for patients (pts) with PD-L1–positive mTNBC. **Methods:** Men and women with centrally confirmed mTNBC, no prior systemic anticancer therapy for metastatic disease, ECOG PS 0-1, and a tumor PD-L1 combined positive score (CPS) ≥1% received pembrolizumab 200 mg Q3W for 24 mo or until disease progression, intolerable toxicity, or investigator or pt decision. Tumor imaging was performed Q9W for 12 mo and Q12W thereafter. Clinically stable pts with PD could remain on pembrolizumab until PD was confirmed on subsequent assessment. Primary end point was safety. Secondary end points included ORR, DOR, and PFS (RECIST v1.1, central review). Planned enrollment was 80 pts. This analysis included all pts who had ≥18 wk of follow-up as of Nov 10, 2016. **Results:** 79 of the first 137 pts with PD-L1–evaluable tumors (58%) had PD-L1 CPS ≥1%. Of the first 52 pts enrolled, 100% were women, median age was 53 y, 40% had elevated LDH, 69% had visceral metastases, and 87% received prior (neo)adjuvant therapy. After a median follow-up of 7.0 mo (range 4.4-12.5), 15 (29%) pts remained on pembrolizumab. Treatment-related AEs occurred in 37 (71%) pts, most commonly fatigue (31%), nausea (15%), and diarrhea (13%). 4 (8%) pts experienced 5 grade 3-4 treatment-related AEs: back pain, fatigue, hyponatremia, hypotension, and migraine (n = 1 each). No pts died or discontinued pembrolizumab due to an AE. ORR was 23% (95% CI 14%-36%). Best overall response was CR in 4%, PR in 19%, SD in 17%, PD in 58%, and not assessed in 2%. Median time to response was 8.7 wk (range 8.1-17.7). Median DOR was 8.4 mo (range, 2.1+ to 8.4), with 8 (67%) responses ongoing at cutoff. Median PFS was 2.1 mo (95% CI, 2.0-3.9); estimated 6-mo PFS rate was 29%. **Conclusions:** Data from the first 52 pts enrolled in KEYNOTE-086 cohort B suggest that pembrolizumab monotherapy has a manageable safety profile and promising antitumor activity as first-line therapy for PD-L1–positive mTNBC. Clinical trial information: NCT02447003.

1089 Poster Session (Board #81), Sun, 8:00 AM-11:30 AM

Overall survival (OS) in patients (Pts) with diagnostic positive (Dx+) breast cancer: Subgroup analysis from a phase 2 study of enzalutamide (ENZA), an androgen receptor (AR) inhibitor, in AR+ triple-negative breast cancer (TNBC) treated with 0-1 prior lines of therapy. *First Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: The AR may be a novel therapeutic target for pts with AR-driven TNBC. ENZA, a potent AR inhibitor approved in men with metastatic prostate cancer, was evaluated in this phase 2 study of pts with AR+ TNBC. A genomic signature associated with AR-driven biology was identified; updated OS results in pts treated with 0-1 prior lines of therapy are presented. **Methods:** This is an open-label, Simon two-stage study (NCT01889238) of ENZA monotherapy in advanced AR+ TNBC (AR > 0% by IHC). Bone-only disease and unlimited prior regimens were allowed; CNS metastases or seizure history were exclusionary. The primary endpoint was clinical benefit rate at 16 weeks (CBR16) in evaluable pts (AR > 10% and ≥1 postbaseline assessment). OS was an exploratory endpoint. Results in intent-to-treat (ITT) and evaluable pts were presented previously (Traina TA et al. *J Clin Oncol*. 2015;33:1003). **Results:** 118 pts were enrolled (ITT). CBR16 in 78 evaluable pts was 33.3%. Of the 118 ITT pts, 56 were Dx+ and 62 were Dx–; ≥50% received 0-1 prior lines of therapy (28 Dx+, 37 Dx–). As of 26 Nov 2016 there were 83 deaths (median follow-up 28 mo); median OS (mOS) was 13 mo (95% CI; 8-18). In the Dx+ subgroup there were 32 deaths (mOS 20 mo [95% CI; 13-29]) vs 51 deaths in the Dx– subgroup (mOS 8 mo [95% CI; 5-11]). In pts with 0-1 prior lines of therapy, there were 13 deaths in the Dx+ subgroup (mOS 29 mo [95% CI; 19-not reached] vs 28 in the Dx– subgroup (mOS 10 mo [95% CI; 7-15]). The most common adverse events (AEs) were fatigue and nausea; fatigue was the only grade 3 related AE in > 5% of pts. A multi-covariate Cox analysis identified Dx status (+ vs –) and line of therapy (0-1 vs ≥2) as the only variables significantly associated with OS. **Conclusions:** In this study, the mOS of pts with Dx+ TNBC who received 0-1 prior lines of therapy appears longer than that of unselected historic controls. ENZA may represent a therapeutic option in pts with AR+ TNBC who would otherwise receive cytotoxic chemotherapy and is currently being evaluated in ENDEAR, a phase 3 study in pts with Dx+ advanced TNBC and 0-1 prior lines of therapy. Clinical trial information: NCT01889238.

1090 Poster Session (Board #82), Sun, 8:00 AM-11:30 AM

Whole exome sequencing of metaplastic breast cancer (MpBC): Effect of mutation status on survival. *First Author: Luis Baez Vallecillo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Metaplastic Breast Cancer (MpBC) is considered a chemorefractory, aggressive subtype that is characterized by squamous and/or mesenchymal differentiation and associated with a high rate of molecular aberrations that activate the PI3K pathway. The goal of this study was to correlate outcomes data with underlying genomic aberrations in MpBC. **Methods:** A cohort of 52 archived samples of MpBC collected from 1986 and 2016 that had clinical outcomes data available for central review underwent hybrid capture sequencing of 202 cancer-related genes (n = 52) and, when sufficient material was available, whole exome sequencing (n = 21). Relapse free (RFS) and overall (OS) survival analyses at 5 years were compared between patients having mutation vs. wild-type (WT) in the whole genome using Kaplan-Meier statistics. **Results:** The variant allele frequency (VAF) was relatively low with most mutations having a VAF of < 50%. *TP53* mutation was found in 33 tumors (63%) and was associated with improved RFS (HR = 2.4; p = 0.03) and OS (HR = 3.7; p = 0.006) compared to WT. Aberrations in the PI3K/AKT/mTOR pathway were present in 29% of tumors and associated with diminished OS (HR = 0.27; p = 0.02) but not RFS (HR = 0.67; p = 0.32). Though uncommon, the presence of an *AKT1* (6%) mutation was associated with worse RFS (HR = 0.006; p = 0.006) and OS (HR = 0.0005; p < 0.0001). **Conclusions:** Surprisingly, *TP53* mutation was associated with better prognosis in MpBC with increased RFS and OS. Mutations in *AKT1* were uncommon but associated with a significantly worse RFS and OS. Notably, all patients harboring an AKT1 mutation died within a year of diagnosis. Mutations activating the PI3K/AKT/mTOR pathway were associated with worse OS.

1091 Poster Session (Board #83), Sun, 8:00 AM-11:30 AM

Use of serial multi-template liquid biopsies in triple negative breast cancer monitoring. *First Author: Paul Y. Song, Cynvenio Biosystems, Inc., Westlake Village, CA*

Background: Triple negative breast cancer (TNBC) remains the most aggressive subtype of breast cancer in which up to 1/3 of all patients will relapse early and distantly. There remains no proven method to monitor and detect early recurrence. This study examines the utility of serial liquid biopsies using a multi-template approach (identification and analysis of cell-free DNA (cfDNA) and circulating tumor cells (CTCs)) as a solution. **Methods:** 210 patients (average 53 yrs.) with confirmed diagnosis of TNBC, within 3 years of completion of therapy (mean 25 mos.), and in full remission were enrolled. Liquid biopsies were performed quarterly to look for cancer specific genomic mutations not seen in germ line controls, but in cfDNA and CTCs using a custom 27-gene breast cancer panel. Prior validation of our gene panel demonstrated a false positive rate of 0.001-0.0007% in normal cfDNA and cell-based controls. **Results:** Each subject had on average 3.0 serial samples collected to date. 169 patients (80.4%) had evidence of mutations in at least one sample. Seventy-five percent of cfDNA and 36% of CTC samples examined have been found to bear mutations. The total number of samples with orthogonally (either between template or between draws) confirmed signal was 16.9%. Seven patients (3.3%) have developed documented evidence of recurrence, one in the axilla and the others with visceral/distant metastases. Of the patients that have recurred, all had a persistent mutation on consecutive blood draws or evidence of genomic mutations in both cfDNA and CTCs. **Conclusions:** The majority of TNBC patients in our study post-treatment were found to have genomic mutations on at least one liquid biopsy sample – either cfDNA or CTC. But, very few had a persistent presence of mutations in subsequent samples and 96.7% of our patients have remained NED. Unlike patients who remained NED, patients who recurred displayed persistent evidence of mutations on serial draws or in both cfDNA and CTC samples. To date our recurrence rate is lower than predicted. This study highlights the need for serial monitoring using a multi-template approach to better fully understand patient specific tumor biology and kinetics. The trial is ongoing. Clinical trial information: NCT02639832.

1092 Poster Session (Board #84), Sun, 8:00 AM-11:30 AM

Genome-wide copy number analysis of cell-free DNA from patients with chemotherapy-resistant metastatic triple-negative breast cancer. *First Author: Daniel G. Stover, Dana-Farber Cancer Institute, Boston, MA*

Background: Triple-negative breast cancer (TNBC) is a poor prognosis breast cancer subset characterized by relatively few mutations but extensive copy number alterations (CNAs). Cell-free DNA (cfDNA) offers the potential to overcome infrequent tumor biopsies in metastatic TNBC (mTNBC) and interrogate the genomics of chemotherapy resistance. **Methods:** 506 archival or fresh plasma samples were identified from 164 patients with mTNBC who had previously received chemotherapy. We performed low coverage sequencing to determine genome-wide copy number and estimate 'tumor fraction' of cfDNA (TFx). In patient samples with TFx >10%, we identified regions that were significantly gained or lost using GISTIC2.0. We compared CNAs of mTNBCs with primary TNBCs from a publicly-available dataset, METABRIC (TNBC n=277). **Results:** We successfully obtained high quality, low coverage whole genome sequencing data for 478 (94.5%) plasma samples from 158 patients, with 1 to 14 samples per patient. Archival samples had significantly higher average cfDNA per mL plasma and TFx than fresh samples, potentially due to later average line of therapy. Average TFx of first blood draw was significantly higher in patients with liver metastases (TFx 28.3% vs. 14.4%, p=1.1e-7). 101/158 patients (63.9%) had at least one sample with TFx >10%, our threshold for high confidence CNA calls. Most alterations significantly enriched in chemotherapy-resistant mTNBCs were chromosomal gains, including NOTCH2 and ERCC1. Median overall survival from time of first blood draw was 9 months, and TFx was highly correlated independent of metastatic line of therapy, age at metastatic diagnosis, BRCA status, and primary stage: adjusted hazard ratio between 4^{th} and 1^{st}quartiles = 4.29 (95% CI 1.66-11.1; p=0.0008). **Conclusions:** It is feasible to perform genome-level copy number analysis from cfDNA in both archival and fresh samples from patients with mTNBC. Copy number alterations enriched in mTNBC may have implications in the understanding of metastasis, therapeutic resistance, and novel therapeutic targets. 'Tumor fraction' of cfDNA is correlated with overall survival and may be an independent prognostic marker in mTNBC.

1093 Poster Session (Board #85), Sun, 8:00 AM-11:30 AM

Investigating tumoral and temporal heterogeneity through comprehensive -omics profiling in patients with metastatic triple negative breast cancer. *First Author: Christopher Szeto, NantOmics, LLC, Santa Cruz, CA*

Background: The "Intensive Trial of OMics in Cancer"-001 (ITOMIC-001; Clinicaltrials.gov ID: NCT01957514) enrolls patients with metastatic triple negative breast cancer (TNBC) who are platinum-naive and scheduled to receive cisplatin. Multiple biopsies (up to 7 metastatic sites) are performed under carefully controlled conditions prior to and upon completion of cisplatin treatment and following any subsequent therapies. Samples are chosen for DNA sequencing, RNA sequencing, and quantitative proteomics (GPS Cancer). Here we describe the -omic alterations acquired during treatment. **Methods:** We analyzed 74 biopsies from 17 patients taken at various clinical timepoints (e.g. initial diagnosis, initial trial recruitment, following cisplatin treatment, etc.) spanning 2 years on trial and over 8 years before recruitment. This dataset includes 64 whole genomes (with matched-normal blood samples), 44 RNAseq expression profiles, and 23 proteomic sets. GPS Cancer, which comprises whole genome sequencing, whole transcriptome sequencing, and targeted quantitative proteomics was used to detect somatic alterations, measure mutational burdens, and estimate expression profiles of both transcripts and proteins. PARADIGM pathway analysis was used to identify network-level changes through integration of all available data types. **Results:** While mutational profiles within patients were largely stable over time, we observed up to a 10-fold difference in the magnitude of mutational burden between patients. Following cisplatin treatment, the expression of over 300 genes were significantly perturbed, and an average of 270 mutations per patient were introduced. PARADIGM integrated pathway analysis shows differential activity in the MYC/MAX and ETS1 pathways during tumor progression. **Conclusions:** Using GPS Cancer we provide detailed characterizations of the molecular profiles of metastatic TNBC across space and over time. We demonstrate the potential for using this information to discover mechanisms underlying treatment resistance and disease progression. Our findings form the basis for molecularly informed QUILT trials for combination therapy.

1094 Poster Session (Board #86), Sun, 8:00 AM-11:30 AM

Validity of 1% hormonal positivity cutoff by American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) guidelines at Georgia Cancer Center. *First Author: Houssein Talal Abdul Sater, Georgia Regents University/Medical College of Georgia School of Medicine, Augusta, GA*

Background: Hormone Receptor Status (HS) in breast cancer (BC) is a universally accepted biomarker. ASCO/CAP 2010 guidelines set the threshold of Estrogen and Progesterone Receptor positivity to 1 %. BC with 1-9% HS expression remains controversial with recent data disputing these guidelines. The objective of this retrospective study was to validate these guidelines at Georgia Cancer Center (GCC) with high percentage of black race. **Methods:** All female patients with invasive BC diagnosed between 2005-2010 at GCC (11y follow-up) were chart reviewed. We used Cox proportional hazards model to explore survival among three HS groups (< 1%, 1-9%, ≥10%) adjusting for standard prognostic factors. Hazard ratios (HR) and 95% confidence intervals (CI) were also reported. 1-9 %, and ≥10% groups were further explored using same method to test survival difference with or without hormone therapy (HT). Fischer's Exact test was used to evaluate response to HT in these groups. **Results:** 400 patients (all stages) with mean age of 59, were 24.75% HS < 1%, 17.5% HS1-9%, and 57.75% HS≥10%. Race was 43.75% Black, and 54% White. Disease stages were 84.4% early (I-IIIA) and 15.56% late (IIIB-IV). Grades were 51.42% low (1-2) and 48.58% high (3). The 2 groups (1-9%, ≥10%) received chemotherapy (42.86%, 39.83%), and HT (58.57%, 80.52%) respectively while 70.71% of < 1% HS group had chemotherapy. Mortality in HS < 1% was significantly higher than HS ≥10% (HR 1.8, 95% CI 1.07-3.02), while mortality between HS 1-9% and HS ≥10% was not different (HR 1.05, 95% CI 0.48-2.30). Treated (HT) subjects had lower mortality than untreated subjects in the 1-9% group (HR 0.10, 95% CI 0.01-0.85). 100% of HT group had no evidence of tumor at last follow up compared to 87.5% in non-treatment group (p = 0.048). There was no significant difference in mortality between treated (HT) 1-9% and ≥10% groups. **Conclusions:** Hormone receptor expression as low as 1-9% was found to be equi-prognostic to ≥10% expression. It also predicted response to hormonal therapy. Whether other factors as lympho-vascular invasion, grade, and other parameters change the behavior of the 1-9% HS group remain to be explored.

1095 Poster Session (Board #87), Sun, 8:00 AM-11:30 AM

Phase II study of eribulin in combination with gemcitabine for the treatment of patients with locally advanced or metastatic triple negative breast cancer: ERIGE trial on behalf of the Gruppo Oncologico Italiano di Ricerca Clinica (GOIRC). *First Author: Antonino Musolino, Medical Oncology Unit, University Hospital of Parma, Parma, Italy*

Background: There are no well-established chemotherapy regimens for metastatic triple negative breast cancer. The combination of a microtubule inhibitor (eribulin) with a nucleoside analog (gemcitabine) may synergistically induce tumor cell death, especially in tumors like triple negative breast cancers (TNBC) characterized by high cell proliferation, aggressive tumor behavior, and chemo-resistance. **Methods:** We performed an open-label, national multicenter phase 2 study evaluating the combination of eribulin (0.88 mg/m^2) plus gemcitabine (1000 mg/m^2) on day 1 and 8, q21 as either first- or second-line treatment of locally advanced or metastatic TNBC. The Simon's optimal two-stage design was used for estimating objective response rate (ORR) as study primary endpoint. A prospective, molecular correlative study was carried out on germinal DNA of study population to assess the role of germinal DNA polymorphisms and BRCA mutations in predicting efficacy and toxicity of the combination regimen. **Results:** From July 2013 to September 2016, 83 (37 in the first stage, 46 in the second one) assessable patients were enrolled. Median age at baseline was 56 years. Sixty-six and 17 patients were in first or second-line treatment, respectively. All patients were previously treated with an anthracycline and/or a taxane. With regard to the first stage of study enrolment, patients received a median number of 6 cycles of treatment. The ORR (CR+PR) was 43.24% (90% CI 29.3-58.0) and the clinical benefit rate (CR+PR+SD) was 64.9% (90% CI: 50.1%-77.8%). The most common grade 3/4 AEs ($>$ 10% of patients) were neutropenia without febrile neutropenia and liver toxicity. Grade 1/2 AEs were fatigue, anemia, thrombocytopenia, diarrhea, alopecia, peripheral neuropathy, and oral mucositis. **Conclusions:** The combination of eribulin and gemcitabine shows promising activity and a moderate toxicity profile in metastatic TNBC. More mature toxicity and outcome data of the final study population and correlation with genome analysis will be presented at the meeting. Clinical trial information: 2012-003505-10.

1096 Poster Session (Board #88), Sun, 8:00 AM-11:30 AM

Immune gene signatures in triple-negative breast cancers characterized by varying levels of chromosomal instability. *First Author: Balazs Gyorffy, MTA TTK, Budapest, Hungary*

Background: Triple-negative breast cancer (TNBC) is generally characterized by high levels of chromosomal instability (CIN) and an intense immune infiltration. However, the link between these two hallmarks and its implications for clinical practice has not been fully elucidated. **Methods:** We generated eight immune metagenes representing various immune components: natural killer [NK], dendritic cells [DC], T-cells [TC], B-cells [BC], cytotoxic T-cells [CT], interferon [IFN], nuclear factor-κB [NF-kB], and macrophages [M]. Publicly available gene expression data from forty-two data sets, including 862 TNBC samples, were collected. TNBC tumors were clustered in three main subgroups (Basal-Like [BL1/2], Immunomodulatory [IM], and Mesenchymal/Mesenchymal Stem-Like [MS]) using transcriptomic profiling. The CIN70 signature was used to stratify TNBC patients according to the levels of CIN. Statistical analyses were performed using Mann–Whitney *U* test and Kaplan-Meier analyses. **Results:** The majority of TNBC samples showed a high level of CIN (83%), and several immune modules were differentially expressed between CIN-high and CIN-low tumors. Specifically, CT, NK, DC, M, and NF-kB signatures were overexpressed in CIN-low TNBC ($p < 1.0E-04$). We then evaluated the distribution of genomic instability among TNBC molecular subgroups. Noteworthy, the CIN-high group was composed by a comparable proportion of BL1/2 (39%) and MS (35%) tumors, while CIN-low TNBCs were consistently enriched for MS cancers (61%). Higher expression of the NK, M, and IFN metagenes lead to better survival in CIN-high tumors ($p = 1.9E-02$, $p = 2.1E-04$, and $p = 1.1E-03$, respectively). Only IFN had the same correlation to survival in CIN-low ($p = 1.4E-02$). **Conclusions:** TNBCs with low levels of CIN may principally enclose M/MSL tumors, which are characterized by an intense immune infiltration and overall good prognosis. Conversely, the TNBC CIN-high group is more heterogeneous in terms of both biological features and levels of immune infiltrates. Therapeutic strategies to promote and boost immune response in the genomically unstable TNBC subgroup warrant further investigation.

1097 Poster Session (Board #89), Sun, 8:00 AM-11:30 AM

Retinoblastoma (Rb) protein expression in triple-negative breast cancer. *First Author: Jaymin M Patel, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Expression of Rb, the protein product of the *RB* tumor suppressor gene, is required for cyclin D kinase (CDK) 4/6 inhibition in luminal breast cancers. Triple negative breast cancers (TNBC) frequently exhibit Rb loss and are thus believed to be poor candidates for CDK4/6 inhibition. However, the features associated with Rb loss in TNBC are poorly-defined. We aimed to assess whether TNBC that express the androgen receptor (AR) and resemble a more luminal subtype retain Rb more often than other TNBC. **Methods:** To assess the frequency and correlates of Rb expression in TNBC, we stained tissue microarrays (TMAs) containing 180 Stage I-III TNBC, 71 with germline *BRCA1* mutations (*BRCA1*+) and 109 without *BRCA1* mutation (sporadic), using a mouse monoclonal antibody to human Rb (clone G3-245, BD Biosciences). Assessment of tumor size, histologic type, grade, lymphovascular invasion and lymph node status were assessed on histologic review. The TMAs, containing three 0.6mm cores/tumor, had been previously stained for AR, CK5/6, CK14 and EGFR. Log-binomial regression was used to calculate risk ratios (RR). **Results:** Fifty percent of TNBC were Rb-positive (Rb+; $\geq$10% nuclei staining) of which 84.4% had $>$ 50% nuclei staining. Among TNBC that were Rb-negative, 76.6% had $<$ 1% nuclei staining for Rb. AR expression ($\geq$10% nuclei staining) was more common in Rb+ than Rb-negative TNBC (16.7% vs 4.5%; p = 0.01). In addition, Rb expression was significantly more common among sporadic than *BRCA1*+ TNBC (59.6% vs 35.2%, p = 0.001). Compared with Rb-negative TNBC, Rb+ tumors were associated with older age (mean 48.7 vs 45.7 years; p = 0.06) and lower histologic grade (grade 1 or 2: 9.2% vs 2.2%; p = 0.05). No other clinical or pathologic features were significantly associated with Rb status. In a multivariable model, both AR expression (RR, 1.65; 95% CI, 1.31-2.08) and lack of *BRCA1* mutation (RR, 1.63; 95% CI, 1.17-2.29) significantly predicted for Rb expression among TNBC. **Conclusions:** Sporadic TNBC is significantly more likely to be Rb+ than *BRCA1*+ TNBC. Among TNBC, AR expression significantly predicts for Rb expression. These results suggest clinically relevant biomarkers that may predict for Rb expression and potential targeted therapies in TNBC.

1098 Poster Session (Board #90), Sun, 8:00 AM-11:30 AM

Influence of marital status on risk of mortality for 23,493 cases of triple negative breast cancer for four mutually exclusive race/ethnicities. *First Author: Carol Parise, Sutter Institute for Medical Research, Sacramento, CA*

Background: Marital status has been associated with better breast cancer survival. However, breast cancer is a heterogeneous disease and it has not been determined whether marital status is a survival advantage for women with triple negative breast cancer (TNBC) and if this advantage holds for all race/ethnicities. The purpose of this study was to determine if being unmarried resulted in an increased risk of mortality for TNBC for four mutually exclusive race/ethnicities. **Methods:** We identified 23,493 cases of TNBC from the California Cancer Registry 2000-2014. Marital status at time of diagnosis was defined as: 1) married, 2) single, never married; 3) separated; 4) divorced; 5) widowed. Race/ethnicity was defined as white (n = 13,241), black (n = 2,775), Hispanic (n = 5,059), and Asian/Pacific Islander (API) (n = 2,418). Kaplan-Meier Survival Analysis and Cox Regression were used to assess the risk of mortality associated with marital status using married as the reference category. Marital status was considered a risk for mortality and hazard ratios (HR) and 95% confidence intervals reported if the Wald χ^2 was statistically significant ($p < 0.05$). Models were adjusted for AJCC stage, age, grade, socioeconomic status, and treatment. Separate analyses were conducted for each race/ethnicity. **Results:** For allraces, single women had statistically significantly worse unadjusted survival ($p < 0.05$) than married women. However adjusted analyses showed that single (HR = 1.13; 1.01-1.27) and widowed (HR = 1.43; 1.27-1.61) white women had increased mortality when compared with married women. Single (HR = 1.50; 1.14-1.96) and divorced (HR = 1.75; 1.23-2.48) API women had an increased risk of mortality compared with married women. For black and Hispanic women, marital status was not associated with risk of mortality. **Conclusions:** Being married at the time of diagnosis of TNBC is a survival advantage only for white and API women but not for black and Hispanic women.

1099 **Poster Session (Board #91), Sun, 8:00 AM-11:30 AM**

BRAF: An emerging target for triple-negative breast cancer. *First Author: Joan Albanell, Medical Oncology Department, Hospital del Mar, Barcelona, Spain*

Background: A series of reports demonstrating the successful use of BRAF and MEK inhibitors in clinically advanced non-melanoma cancers has recently emerged. *BRAF* alterations in metastatic breast cancer (mBC) are rare and BRAF is not currently considered a target for the disease. **Methods:** DNA was extracted from 40 microns of FFPE sections from a series of 10,428 cases of metastatic breast cancer (mBC). Comprehensive genomic profiling (CGP) was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of > 550X for up to 315 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer. **Results:** 135 (1.2%) of the mBC featured alterations in *BRAF*. The median age of the 135 female patients was 66 years (range 27 to 83 years). The primary tumor was used for CGP in 50 (37%) and from metastatic sites including lymph nodes, liver, bone, lung, brain, adrenal and soft tissue in 85 (67%). Using *CDH1* mutation as the definition of lobular mBC, 126 (93%) were ductal and 9 (7%) were lobular histology. Activating *BRAF* alterations included amplifications (48%), SV mutations (39%) and rearrangements (13%). No (0%) mBC had multiple *BRAF* GA in the same case. 34% of *BRAF* SV were V600E and 66% were a wide variety of non-V600E GA. 10 (7.4%) of 135 BRAF mutated mBC featured *ERBB2* amplification with 1 (1%) having an *ERBB2* SV mutation and 1 (1%) having both *ERBB2* amplification and SV GA. Of the 115 *BRAF* GA cases with known hormone receptor status 71 (62%) were ER negative, 44 (38%) were ER positive and 63 (55%) were triple negative (TNBC). Other targetable genes enriched in mBC with *BRAF* GA included *CDK6* ($p = 0.001$), *HGF* ($p < 0.001$) and *MET* ($p < 0.001$). The median TMB was 4.5 with 17 (13%) of cases with TMB > 10 mut/Mb and 7 (5%) of cases with > 20 mut/Mb. **Conclusions:** *BRAF* alterations, although uncommon in mBC representing only 1.2% of cases, are enriched in TNBC and feature both targetable base substitutions and rare fusions. *BRAF* GA may be a rare cause of anti-HER2 therapy resistance in a subset of *ERBB2* driven mBC. Targetable genes co-altered with *BRAF* in mBC include *CDK6*, *HGF* and *MET*. The TMB in *BRAF* altered mBC is significantly higher than that for mBC in general and indicates potential role for immunotherapy for these patients.

1100 **Poster Session (Board #92), Sun, 8:00 AM-11:30 AM**

Dynamic relationship between cycling kinetics of triple-negative breast cancer and tumor infiltrating immune cells. *First Author: Ishita Choudhary, Georgia State University, Atlanta, GA*

Background: Recent studies show strong correlation between tumor infiltrating lymphocytes (TILs) and triple-negative breast cancer (TNBC) patient survival. CD8+ T cells serve as a favorable prognostic marker for TNBC. In addition, other cells such as CD4+ T cells, macrophages, B cells, and Tregs also infiltrate tumors. In this study, we delineate a strong relationship between the cycling kinetics of proliferating cells in TNBCs and antitumor immune response. **Methods:** A multi-institutional study performed by our group has previously shown that KAMS (Ki67-Adjusted Mitotic Score) provides a measure of the cycling kinetics of proliferating tumor cells and robustly stratifies TNBC patients into slow cycling (low KAMS) cyclophosphamide-methotrexate-fluorouracil (CMF)-responsive and fast cycling (high KAMS) CMF-resistant subgroups. In this study, we reviewed clinical data from 124 CMF-treated TNBC patients from Nottingham Hospital and sought correlations between cycling kinetics (High/Low KAMS) and tumor infiltrating immune cells. **Results:** We found that slow cycling TNBCs had higher mean expression of tumor infiltrating immune cells than fast cycling TNBCs. Intratumoral CD68 ($p = 0.003$), CD3 ($p = 0.006$), CD20 ($p = 0.01$), FOXP3 ($p = 0.01$), and total numbers of intratumoral and stromal CD68 ($p = 0.01$) and CD3 ($p = 0.03$) expressing cells were found to be significantly higher in low KAMS tumors than in high KAMS tumors. Of these biomarkers, CD68 was significantly associated with patients' breast cancer-specific survival (BCSS): (a) low KAMS, high CD68 TNBCs had better BCSS than low KAMS, low CD68 ($p = 0.01$) TNBCs, and (b) high KAMS, low CD68 cases had better BCSS than high KAMS, high CD68 cases. **Conclusions:** Our observation that there are more TILs in slow cycling TNBCs suggests that there may be a dynamic cross-regulation between cycling kinetics and antitumor immune response. From our surprising observation that CD68 exerts polar roles in low/high KAMS subgroups, we propose that distinctions in M1 and M2 macrophage subsets in slow and fast cycling TNBCs may correlate with distinct outcomes. In addition, metabolic competition between tumor and immune cells may determine the level and function of TILs.

1101 **Poster Session (Board #93), Sun, 8:00 AM-11:30 AM**

Beyond triple-negative breast cancer and African ancestry: Tumor phenotypes among internationally diverse patient populations. *First Author: Evelyn Mawunyo Jiagge, University of Michigan, Ann Arbor, MI*

Background: Population-based incidence rates of breast cancers that are negative for estrogen receptor (ER), progesterone receptor (PR), and HER2/*neu*(triple negative breast cancer {TNBC}) are higher among African American (AA) compared to White American (WA) women. Several studies show higher TNBC frequency among selected populations of African patients. The colonial-era trans-Atlantic slave trade resulted in shared West African ancestry between contemporary AA and Ghanaian (Gh) populations. The extent to which TNBC susceptibility is related to East African versus West African ancestry, and whether these associations extend to expression of other biomarkers such as Androgen Receptor (AR) and mammary stem cell marker ALDH1 is unknown. **Methods:** We used immunohistochemistry to assess ER, PR, HER2/*neu*, AR and ALDH1 among WA (n = 153); AA (n = 76); Ethiopian (Eth)/East African (n = 90) and (Gh)/West African (n = 286) breast cancers through an IRB-approved international research program. **Results:** Mean age at breast cancer diagnosis was 43; 49; 60; and 57 years for the Eth; Gh; AA; and WA patients, respectively. Frequency of TNBC was significantly higher for AA and Gh patients (54% and 41%, respectively) compared to WA and Eth patients (23% and 15%, respectively); $p < 0.001$. These associations were unchanged when limited to patients age 50 and younger (47% and 49% for AA and Gh, respectively; versus 18% and 16% for WA and Eth, respectively); $p < 0.001$. Frequency of ALDH1 positivity was also higher for tumors from AA and Gh patients (32% and 36%, respectively) compared to those from WA and Eth patients (23% and 17%, respectively); $p = 0.007$. Significant differences were observed for distribution of AR positivity, which was 71%; 55%; 42% and 50% for the WA; AA; Gh; and Eth cases, respectively ($p = 0.008$). **Conclusions:** We found a correlation between extent of African ancestry and risk of particular BC phenotypes. West African ancestry was associated with increased risk of TNBC and breast cancers that are positive for ALDH1. Future studies of hereditary TNBC susceptibility among women with African ancestry are warranted.

1102 **Poster Session (Board #94), Sun, 8:00 AM-11:30 AM**

Phase (Ph) 2 stage 1 clinical activity of seviteronel, a selective CYP17-lyase and androgen receptor (AR) inhibitor, in women with advanced AR+ triple-negative breast cancer (TNBC) or estrogen receptor (ER)+ BC: CLARITY-01. *First Author: Ayca Gucalp, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Seviteronel (Sevi), an oral selective CYP17-lyase and AR inhibitor that blocks testosterone and estradiol production and competitively antagonizes the AR, is in Ph 2 clinical development for BC and prostate cancer. The primary objective of this ongoing Ph 2 study (NCT02580448) is to estimate the activity of once daily Sevi in women with AR+ TNBC and ER+ BC as measured by clinical benefit rate (CBR) at 16 and 24 weeks (wk), respectively. **Methods:** Patients (pts) with ER+/HER2-normal metastatic BC following progression of ≥1 prior line of endocrine therapy or TNBC were enrolled with no limit of prior therapies in either cohort. Evaluable pts had AR ≥10% via central IHC staining (TNBC only) and 1 post-baseline scan. Sevi was administered at 450 mg oral daily. Scans were performed every 8 wk. Circulating tumor cell (CTC) enumeration was performed by EPIC CTC analysis. A Simon's 2-stage design was employed to determine activity (≥2 of 13 CBR16 in TNBC and ≥2 of 12 CBR24 in ER+ BC allow for accrual to Stage 2). **Results:** As of 4 Oct, 2016, 16 pts with AR+ TNBC (6 evaluable) and 14 pts with ER+ BC (11 evaluable) were enrolled. 67% had visceral metastases; 10% had stable brain metastases. 60% had ≥2 lines of prior therapy for advanced disease. 13 of 14 (93%) TNBC pts who underwent central AR testing had AR ≥10%. Four pts in the TNBC cohort and 8 pts in the ER+ cohort remain on therapy. CBR16 (TNBC) and CBR24 (ER+) was 2 of 6 (33%) and 2 of 11 (18%) allowing Stage 2 accrual in both cohorts. 7 of 10 evaluable pts with CTCs present at baseline had a CTC decline at C2D1, including all that met CBR (-94.3% [-27.5, -100] median [range]). The most common adverse events (≥ 25%) were fatigue (50%), nausea (43%) and decreased appetite (33%); all Grade 1/2. Updated CBR data will be presented at the time of presentation. **Conclusions:** Sevi Stage 1 activity is suggested by CBRs, along with associated CTC declines in heavily pretreated pts with high disease burden. The observed safety profile is consistent with on-target pharmacology. Stage 2 enrollment is ongoing. Sevi may provide a novel treatment option for women with AR+ TNBC or ER+ BC. Clinical trial information: NCT02580448.

1103 Poster Session (Board #95), Sun, 8:00 AM-11:30 AM

Efficacy/safety of epacadostat plus pembrolizumab in triple-negative breast cancer and ovarian cancer: Phase I/II ECHO-202 study. *First Author: Alexander I. Spira, Virginia Cancer Specialists Research Institute, Fairfax, VA*

Background: Epacadostat is an oral, potent, and selective inhibitor of indoleamine 2,3-dioxygenase 1, a tryptophan-catabolizing enzyme that induces immune tolerance via T-cell suppression and is associated with poor patient (pt) survival when overexpressed in some cancers. The ongoing, open-label, phase 1/2 (P1/2) ECHO-202/KEYNOTE-037 study is evaluating the efficacy, safety, and tolerability of epacadostat plus PD-1 inhibitor pembrolizumab (E + P) in pts with advanced/recurrent cancers. We report P1/2 study outcomes for triple-negative breast cancer (TNBC) pts and P2 outcomes for ovarian cancer (OVC; no P1) pts as of a 29OCT2016 data cutoff. **Methods:** Eligible pts were ≥18 years old with no prior checkpoint inhibitor treatment (tx); prior platinum/taxane tx was required for OVC pts. As part of P1 dose escalation, TNBC pts received E (300 mg BID) + P (200 mg Q3W). In P2, TNBC and OVC pts received E (100 mg BID) + P (200 mg Q3W). Response (RECIST v1.1) was assessed in evaluable pts. Safety and tolerability were assessed in pts with ≥1 dose of E + P. **Results:** A total of 39 pts with TNBC and 37 with OVC were enrolled. The majority of TNBC pts (56%, n = 22) and OVC pts (78%, n = 29) received ≥3 prior lines of tx. For TNBC pts, ORR (CR+PR) was 10% (n = 4; all PR) and DCR (CR+PR+SD) was 36% (n = 14; 10 SD); ORR and DCR for pts with ≤2 prior tx were 12% (n = 2) and 29% (n = 5), respectively, and for ≥3 prior tx were 9% (n = 2) and 41% (n = 9). For OVC pts, ORR was 8% (n = 3; all PR) and DCR was 35% (n = 13; 10 SD); ORR and DCR for pts with ≤2 prior tx were 13% (n = 1) and 25% (n = 2), and for ≥3 prior tx were 7% (n = 2) and 38% (n = 11). The most common TRAEs (≥15% of pts) were rash (18%), fatigue (15%), and nausea (15%) in the 39 TNBC pts, and fatigue (19%) in the 37 OVC pts. Grade ≥3 TRAEs occurred in 13% of TNBC pts (n = 5; none in > 1 pt) and 19% of OVC pts (n = 7; only rash occurred in > 1 pt [n = 3]). TRAEs led to discontinuation in 1 TNBC pt (grade 3 ascites) and 1 OVC pt (grade 2 arthralgia). **Conclusions:** E + P tx was generally well tolerated and showed antitumor activity consistent with previously reported P monotherapy in pts with advanced TNBC or OVC. Biomarker analysis is ongoing to characterize pt populations enrolled in this study. Clinical trial information: NCT02178722.

1104 Poster Session (Board #96), Sun, 8:00 AM-11:30 AM

Phase I study of olaparib (O), in combination with oral cyclophosphamide (C), in patients (pts) with metastatic triple negative breast cancer (TNBC) and recurrent high grade serous ovarian cancer (OVCA). *First Author: Chee Khoon Lee, St George Hospital, Sydney, Australia*

Background: Poly (ADP-ribose) polymerase (PARP) inhibitors can potentiate chemotherapy induced DNA damage, through synthetic lethality, leading to increased tumor death. We hypothesized that O+C would increase antitumor activity of O through increased DNA damage induced by C. This study (ANZCTRN12613000924752) evaluated the safety and activity of O+C. **Methods:** Eligible patient (pts) had performance status 0-2, with ≤3 lines of therapy (including platinum for OVCA and anthracycline and taxane for BC). Pts received O+C with a dose escalations strategy using a 3+3 design with cohort expansions once maximal tolerated dose (MTD) was determined. Dose level 1 (DL1); O, 300 mg bid continuously, C, 50mg on days 1,3 and 5 weekly, 21 day cycle. Dose level 2 (DL2); O, 300 mg bid continuously, C, 50mg days 1-5 weekly 21 day cycle. Dose limiting toxicity was evaluated during 1st two cycles. Safety was assessed by CTCAEv4.0 and efficacy with RECISTv1.1 and GCIC criteria. **Results:** Of the 32 pts (median age 56, 9 had BC (*BRCA*1 22%, *BRCA*2 44%) and 23 had HGSOC (*BRCA*1 39%, *BRCA*2 26%). 4 pts were treated at DL1 and 28 pts at DL2. DL2 was the MTD. At the time of analysis, 16 of 29 pts had 8 cycles of O+C, with 14 of 16 pts continued with O beyond the 8th cycle. One pt stopped because of adverse events (AEs) and the remaining 12 stopped due to disease progression. The median treatment duration of O+C was 4.3 months (0.7-23.5). Common AEs were nausea (Grade (Gr) 1/2: 88%, Gr 3: 3%), fatigue (Gr 1/2: 81%), constipation (Gr 1/2: 38%, Gr 3: 3%), and vomiting (Gr 1/2: 38%, Gr 3: 3 %). There were no grade (Gr) 4 or 5 AE. 50% required blood transfusion for anemia. Unconfirmed disease control rate (DCR) was 73% (N = 30; CR = 1, PR = 9, SD = 12). DCR for BC and HGSOC were 56% and 81% respectively. In the *BRCA* cohort (N = 19), DCR was 79%. GCIG CA125 response rates were 70% and 92% for all HGSOC and *BRCA* cohort respectively. **Conclusions:** In HGSOC and BC pts, the recommended phase II dose (O 300 mg bid continuously, C 50mg on days 1-5 weekly) is tolerable and active, particularly in those with germline *BRCA* mutation, supporting our hypothesis. A randomised phase II study in *BRCA* mutant HGSOC is planned. Clinical trial information: ACTRN12613000924752.

1105 Poster Session (Board #97), Sun, 8:00 AM-11:30 AM

Combined peripheral natural killer (NK) cell and circulating tumor cell (CTC) enumeration to enhance prognostic efficiency in patients (pts) with triple-negative breast cancer (TNBC). *First Author: Xiao-ran Liu, Peking University Cancer Hospital and Institute, Beijing, China*

Background: CTCs have emerged as an independent prognostic factor for metastatic breast cancer. However, the prognostic value of baseline CTCs regarding PFS in TNBC is still controversial, especially beyond first-line. We evaluated a novel combined NK cell/CTC detection system for enumeration to better understand the impact of cell count on prognosis in TNBC. **Methods:** 83 consecutive patients with metastatic TNBC were enrolled and received a new line of therapy (median=2, range: 1~5). Baseline circulating CTCs and NK cells were isolated and enumerated simultaneously prior to starting a new line of therapy using our previously published method targeting EpCAM (Bai et al. *J Mater Chem B*, 2014) and flow cytometry (antibodies against $CD3^-$, $CD45^+$, $CD56^+$) respectively. The NK cell level was expressed as the proportion of total lymphocytes (%). Patients with normal to high NK cell proportion (≥ 9.15%) and > 2 CTC/2 ml were defined as NK resistant CTC, the rest were defined as non-NK resistant CTC. **Results:** 33 out of 83 TNBCs had first-line of therapy. Pts with ≤ 2 CTC/2 ml had a significantly longer median PFS than those with > 2 CTC/2 ml (P = 0.028). The differences in median PFS were not significant (P=0.110) for the entire group of pts with TNBC receiving different lines of therapy. Pts with non-NK resistant CTCs had a significantly longer median PFS than those with NK resistant CTCs (P= 0.025), regardless of line of therapy. **Conclusions:** Including peripheral NK cell level into consideration can improve CTC prognostic efficiency in predicting PFS for TNBCs receiving different line of therapy. Further analysis of the unique biological features of NK-resistant CTCs and associated clinical consequence holds promise in guiding clinical practice.

Association of baseline CTC enumeration with PFS in 83 TNBCs.

	First-line TNBCs classified by CTC status[a] (n=33)		Total TNBCs classified by CTC status[b] (n=83)		Total TNBCs classified by NK-resistant CTC status[c] (n=62)	
	PFS (n)	P	PFS (n)	P	PFS (n)	P
Positive	6 (n=15)	0.028	6 (n=45)	0.110	5 (n=24)	0.025
Negative	25 (n=18)		9 (n=38)		9 (n=38)	

[a,b]Threshold: 2 CTC/2 mL. [c]Threshold: NK cell frequency ≥9.15% while > 2 CTC/2 mL.

TPS1106 Poster Session (Board #98a), Sun, 8:00 AM-11:30 AM

Trastuzumab emtansine (T-DM1) and ribociclib, an oral inhibitor of cyclin dependent kinase 4 and 6 (CDK 4/6), for patients with metastatic HER2-positive breast cancer: Phase 1b clinical trial. *First Author: Laura Spring, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Despite the availability of multiple effective therapies, most patients with metastatic HER2-positive breast cancer will experience disease progression and death. While traditionally the focus has been targeting the HER receptor family itself, combinations involving targets downstream of the HER2 pathway, particularly CDK 4/6, could potentially enhance therapeutic efficacy. In pre-clinical models of acquired resistance to HER2-targeted therapies, inhibition of CDK4/6 has been shown to result in tumor inhibition. Trial Design: This phase Ib, single arm, open-label clinical trialis investigating the combination of Trastuzumab emtansine (T-DM1) and the CDK4/6 inhibitor, ribociclib (LEE011). Eligible patients include patients age ≥ 18 years with HER2-positive metastatic breast cancer. Prior treatment with at least one regimen containing trastuzumab and a taxane is required. Ribociclib is given orally for two weeks of a 21-day cycle (days 8-21), with T-DM1 given at standard dose every 3 weeks on day 1. Trial Objectives: 1. To estimate the MTD and/or RP2D of ribociclib in combination with T-DM1. 2. To assess the safety and tolerability of ribociclib in combination with T-DM1. 3. To explore the clinical activity of T-DM1 and ribociclib in HER2-positive metastatic breast cancer. 4. To assess potential biomarkers of response to ribociclib in combination with T-DM1. Statistical Methods: A standard 3+3 dose escalation design is being used to evaluate various doses of ribociclib in combination with T-DM1 to determine the maximum tolerated dose (MTD) and/or recommended phase-2 dose (RP2D). Once MTD/RP2D is determined there will be a dose-expansion cohort (N = l5) to confirm the safety profile and evaluate preliminary evidence of efficacy, including objective response rate (ORR) by RECIST 1.1 and progression-free survival (PFS). Clinical trial information: NCT02657343.

TPS1107 Poster Session (Board #98b), Sun, 8:00 AM-11:30 AM

A randomized, double-blinded, controlled study of tucatinib (ONT-380) vs. placebo in combination with capecitabine (C) and trastuzumab (Tz) in patients with pretreated HER2+ unresectable locally advanced or metastatic breast carcinoma (mBC) (HER2CLIMB). *First Author: Carey K. Anders, University of North Carolina, Chapel Hill, NC*

Background: Tucatinib (ONT-380) is a highly selective small molecule inhibitor of HER2 kinase with nanomolar potency. Unlike dual HER2/EGFR agents, it does not inhibit EGFR at clinically relevant concentrations, decreasing the potential for EGFR-related toxicities (severe skin rash and diarrhea). In preclinical studies, tucatinib demonstrated synergistic activity with Tz, and was active in HER2+ models of brain metastases (mets). In a Phase 1b study, tucatinib was combined with C and Tz in pts with HER2+ MBC previously treated with trastuzumab emtansine (T-DM1) and Tz. Objective responses were seen, including in pts with brain mets. The combination was well tolerated, with low rates of Gr 3 diarrhea at the recommended dose (300 mg PO BID, equivalent to the single agent MTD). Based on these data, tucatinib is now being evaluated in a study in combination with C and Tz (HER2CLIMB). **Methods:** The primary study objective is to assess the effect of tucatinib vs. placebo given with C + Tz on progression-free survival (PFS) based on independent central review. Additional objectives include PFS in patients with brain mets, overall survival, ORR, duration of response, clinical benefit rate, and safety. The study population includes adult patients with progressive HER2+ locally advanced or MBC who have had prior treatment with a taxane, Tz, pertuzumab and T-DM1. Patients with brain mets, including untreated or progressive brain mets, may be enrolled. 480 patients will be enrolled in North America, Europe, Israel, and Australia. Patients are receiving C (1000 mg/mg^2 PO BID for 14 days of a 21-day cycle) and Tz (6 mg/kg IV once every 21 days), and are being randomized in a 2:1 ratio to tucatinib 300 mg PO BID or placebo. Patients with isolated CNS progression may continue on study treatment after undergoing local CNS therapy. An independent Data Monitoring Committee is monitoring patient safety. Clinical trial information: NCT02614794.

TPS1109 Poster Session (Board #99b), Sun, 8:00 AM-11:30 AM

A phase II randomized study to compare abemaciclib plus trastuzumab with or without fulvestrant to standard of care chemotherapy plus trastuzumab in hormone receptor positive, HER2-positive advanced breast cancer (monarcHER). *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Inhibition of CDK4 in preclinical models, demonstrated efficacy in HER2+ breast cancer and enhanced activity of HER2-targeted therapy suggesting a crosstalk between HER2 signaling and the cyclin D/CDK4 signaling pathway in which CDK4 & CDK6 inhibitors may re-sensitize resistant tumors to HER2 blockade.Abemaciclib is a selective inhibitor of CDK4 & CDK6 inhibitor that demonstrates single-agent anti-tumor activity on a continuous dosing schedule in women with hormone receptor positive (HR+) advanced breast cancer. Triple regimens with abemaciclib have been tolerable. **Methods:** monarcHER is an ongoing Phase 2, open-label, study in postmenopausal women with HR+, HER2+ locally advanced or metastatic breast cancer. Eligible patients (pts) are those previously treated with ≥2 HER2-directed therapies in advanced disease setting; T-DM1 and a taxane in any disease setting; no prior treatment with fulvestrant or any CDK4 & CDK6 inhibitor or with ECOG PS ≤1; LVEF ≥50%; no visceral crisis and no CNS metastases that are untreated, symptomatic or requiring steroids. Pts are randomized 1:1:1 to Arm A (abemaciclib [150mg PO Q12H] plus trastuzumab [IV infusion Q3 weeks] plus fulvestrant [IM injection on D1, 15, 29 then Q4 weeks]), Arm B (abemaciclib plus trastuzumab), or Arm C (trastuzumab plus SOC single-agent chemotherapy of physician's choice); stratified based on number of prior systemic regimens (excluding single agent endocrine therapy) and disease status (measurable vs nonmeasurable). The primary objective evaluates investigator-assessed progression-free survival (PFS). Secondary objectives include overall survival, objective response rate, duration of response, disease control rate, clinical benefit rate, safety and tolerability, efficacy, health outcomes and pharmacokinetics. Analysis is planned at 165 PFS events, providing ≥80% power to detect superiority of Arm A and Arm B over Arm C, assuming a hazard ratio of 0.67 at a one-sided alpha of 0.10. First pt visit occurred in May 2016; with a target enrollment of 225 pts. Contact information: 1-877-CTLILLY (1-877-285-4559) Clinical trial information: NCT02675231.

TPS1110 Poster Session (Board #100a), Sun, 8:00 AM-11:30 AM

A pilot study of palbociclib in patients with HER2-positive breast cancer with brain metastasis. *First Author: Cesar Augusto Santa-Maria, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: HER2+ breast cancers have the propensity to metastasize to the CNS. Most systemic therapy does not cross the blood-brain barrier (BBB) effectively, limiting treatment options. Palbociclib is a small molecule inhibitor of cyclin dependent kinases (CDK) 4 and 6, which has been studied in hormone positive breast cancers and found to have significant anti-tumor activity. Preclinical models demonstrate HER2+ tumors require cyclin D1 and CDK4 for progression and maintenance, and palbociclib has been found to have single agent activity in transgenic HER2+ models. Preclinical studies have also found that palbociclib crosses the BBB and exerts anti-cancer effects; indeed, clinical trials investigating its activity in primary brain tumors are ongoing. The summary of these data provide rationale for investigation of palbociclib in patients with HER2+ breast cancer and brain metastasis. **Methods:** A single arm study of palbociclib in patients with metastatic HER2+ breast cancer with brain metastasis was designed. The primary objective is to determine overall radiographic response rate in the CNS using modified RANO-BM criteria. Secondary objectives include PFS, OS, systemic response rates, safety, and tolerability. Exploratory objectives include assessment of mutational profiles in tissue and ctDNA, and quality of life endpoints using FACT-Cog and FACT-Br. Eligible patients must have metastatic HER2+ breast cancer with measurable brain metastasis (at least 1 lesion > = 5mm). Patients with rapidly progressive symptoms or with leptomeningeal disease are excluded. Concurrent therapy with trastuzumab is allowed. Eligible patients are treated with palbociclib 125mg PO (21 days on, 7 days off) until progressive disease or unacceptable toxicity. Available archival tissue will be obtained, ctDNA/FACT-Cog/Br will be assessed at baseline, 2, and 4 months. A total of 20 patients will be enrolled. To detect a radiographic response rates increase from 23% to 40%, a Bayesian posterior probability will be calculated after the response status in 20 patients has been assessed. The goal is that there is at least an 80% probability that the response rate exceeds 40%. Clinical trial information: NCT02774681.

TPS1111 Poster Session (Board #100b), Sun, 8:00 AM-11:30 AM

A phase 3 study of alpelisib (ALP) plus fulvestrant (FUL) in men and postmenopausal women with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) ABC progressing on or after aromatase inhibitor (AI) therapy: SOLAR-1. *First Author: Hope S. Rugo, University of California San Francisco Comprehensive Cancer Center, San Francisco, CA*

Background: Patients (pts) with HR+ breast cancer (BC) often havedysregulatedphosphatidylinositol 3-kinase (PI3K)/mammalian target of rapamycin (mTOR) pathway, which further leads to resistance to endocrine therapy (ET). In a phase 1 study, alpelisib (BYL719), a PI3Kα-specific inhibitor in combination with fulvestrant (FUL) has demonstrated antitumor activity in pts with estrogen receptor-positive, HER2– advanced BC (ABC) with *PIK3CA*-altered tumors. SOLAR-1 (NCT02437318) aims to assess the efficacy of ALP + FUL in *PIK3CA*-mutant and non-mutant tumors in HR+, HER2– ABC setting. **Methods:** SOLAR-1 is a phase 3, randomized, double-blind study conducted in men and postmenopausal women with HR+, HER2– ABC. Pts are randomly (1:1) allocated to oral alpelisib/placebo (300 mg qd) and intramuscular FUL (500 mg) until disease progression or treatment (tx) discontinuation. Stratification factors are presence of liver and/or lung metastases and prior use of CDK4/6 inhibitors. The eligibility criteria for the targeted BC patient population are shown in the Table. The primary endpoint is progression-free survival (PFS; RECIST v1.1; local assessment), while overall survival (OS) is a key secondary endpoint in the *PIK3CA*-mutant cohort. Other secondary endpoints are PFS and OS in the *PIK3CA* non-mutant cohort, the association between PFS and baseline *PIK3CA*status in ctDNA, overall response rate, clinical benefit rate, and safety. Recruitment of the planned 560 pts is currently ongoing. Clinical trial information: NCT02437318.

Inclusion criteria	Exclusion criteria
• Locally advanced or metastatic HR+, HER2− BC • Recurrence or progression on or after AI therapy • Identified PI3K mutational status • ≥1 measurable lesion (RECIST v1.1) or predominantly lytic bone lesion • ECOG-PS ≤1	• Ineligibility for ET due to symptomatic visceral disease or other disease burden • Prior tx with FUL, chemotherapy (except [neo] adjuvant), or PI3K/AKT/mTOR inhibitors • Premenopausal status

TPS1112 Poster Session (Board #101a), Sun, 8:00 AM-11:30 AM

A randomized phase II trial of fulvestrant with or without ribociclib after progression on aromatase inhibition plus cyclin-dependent kinase 4/6 inhibition in patients with unresectable or metastatic hormone receptor positive, HER2 negative breast cancer. *First Author: Kevin Kalinsky, Columbia University Medical Center, New York, NY*

Background: CDK4/6i, including palbociclib and ribociclib (R), have demonstrated remarkable benefit in progression free survival (PFS) in patients (pts) with HR+, HER2- MBC with anti-estrogen therapy. Switching between anti-estrogen therapies at disease progression is standard of care in the treatment of HR+ MBC. We evaluate the strategy of switching anti-estrogen therapy to fulvestrant (F) and maintaining CDK4/6 inhibition with R in pts with HR+, HER2- MBC who have progressed on an AI + CDK4/6i. **Methods:** Trial Design Phase II, multi-center, randomized, double-blind, placebo-controlled trial to evaluate F +/- R in pts with HR+, HER2- MBC who have previously progressed on any AI + CDK4/6i: Screened at 2 different scenarios: Scenario 1: Before receiving any CDK4/6i Scenario 2: Time of progression of disease (POD) while being treated with an AI + CDK4/6i Intervention At randomization, pts assigned 1:1 to either a) F + R or b) F + placebo, with treatment given in 4-week cycles. Major Eligibility Criteria 1, Metastatic BC, 2. HR+ HER2-, 3. Measurable or unmeasurable disease Specific Aims Primary: PFS. Secondary: Objective response rate, clinical benefit rate, overall survival, and duration of response. Biomarker assessment: amplification of cyclin D1 and cyclin E, phosphoRb and TK1 expression, Rb1 and p16 loss, and ctDNA for ESR1 and PIK3CA mutations. Statistical Methods Assuming a median PFS of 3.8 months with F alone, we predict that F + R will lead to a median PFS of at least 6.5 months. A one-sided log-rank test with a sample size of N = 120 and alpha = 0.025, achieves 80% power to detect a difference in PFS of 2.7. With a 10% dropout, n = 132. Clinical trial registry number NCT02632045.

TPS1113 Poster Session (Board #101b), Sun, 8:00 AM-11:30 AM

Phase Ib study to assess the safety, tolerability, and clinical activity of gedatolisib in combination with palbociclib and either letrozole or fulvestrant in women with metastatic or locally advanced/recurrent breast cancer (B2151009; NCT02684032). *First Author: Andres Forero-Torres, University of Alabama at Birmingham, Birmingham, AL*

Background: Hormone receptor positive (HR+) disease is the most common subset of both early and late stage breast cancer (BC). The majority of women with HR+ metastatic BC (MBC) ultimately develop resistance to endocrine therapy, with a median survival of ~2-3 years. A new standard-of-care strategy to treat HR+ metastatic disease involves the combination of hormone therapy and cyclin-dependent kinase (CDK) 4/6 inhibition, which has demonstrated improved progression-free survival (PFS) in both the first- and later-line metastatic setting. More recently, preclinical data with the dual phosphatidylinositol-3-kinase (PI3K)/mammalian target of rapamycin (mTOR) inhibitor gedatolisib (PF-05212384) suggest synergy with the combination of hormone therapy, CDK 4/6 inhibition, and inhibition of the PI3K/mTOR pathway. **Methods:** This phase Ib study includes a dose escalation portion to evaluate dose-limiting toxicities (primary endpoint) and determine the recommended phase II dose for triplet therapy with gedatolisib combined with palbociclib/letrozole or palbociclib/fulvestrant in women with HR+ HER2-negative MBC or locally advanced/recurrent BC, in the first- and later-line setting. Thereafter, a 3-arm expansion for early signals of efficacy will investigate objective response rates (primary endpoint) with gedatolisib combined with palbociclib/letrozole (n = 26), palbociclib/fulvestrant in patients without prior CDK 4/6 inhibition (n = 28), and palbociclib/fulvestrant in patients who have previously received palbociclib (n = 27). The rates of objective response will be compared to historical controls. Secondary endpoints include safety, tumor response, PFS (expansion portion only), pharmacokinetics, and biomarker correlations associated with the PI3K/mTOR pathway. This trial is now recruiting. Clinical trial information: NCT02684032.

TPS1114 Poster Session (Board #102a), Sun, 8:00 AM-11:30 AM

A phase I/II dose escalation and expansion study to investigate the safety, pharmacokinetics, pharmacodynamics and clinical activity of GSK525762 in combination with fulvestrant in subjects with ER+ breast cancer. *First Author: Joseph A. Sparano, Montefiore Medical Center, Bronx, NY*

Background: Advanced or metastatic ER+BC (estrogen receptor positive breast cancer) is an incurable illness that will prove fatal for most afflicted women. Current standards of care include endocrine, targeted, and chemotherapy. Preclinical data suggest that reducing expression of the estrogen receptor (ER) as well as other ER-responsive genes may provide therapeutic benefit for women for whom endocrine therapy alone has proven inadequate. The bromodomain (BRD) and extra-terminal (BET) family of proteins (BRD2, BRD3, BRD4 and BRDT) bind to acetyl-histone residues and epigenetically control transcription of genes driving cell survival and proliferation. In preclinical models, BET proteins reduce ER expression and down regulate ER-dependent gene expression and may be a novel therapeutic target in multiple tumors e.g. ER+BC. GSK525762 is a pan-BET inhibitor showing strong synergistic activity with fulvestrant in killing ER+BC cells in vitro and in xenograft models. The combination of BET agents with endocrine therapy may provide therapeutic benefit and restore sensitivity to ER targeting agents like fulvestrant. **Methods:** The study is a Phase I/II dose-escalation, expansion (Phase I) and randomized control (Phase II) study with oral administration of GSK525762 in combination with fulvestrant in advanced or metastatic ER+BC subjects, whose disease has progressed on prior treatment with $\geq$ 1 line of endocrine therapy. Phase I of the study is designed as parallel single arms to determine the recommended Phase 2 dose based on safety, tolerability, PK, and efficacy profiles in two distinct populations of ER+ BC: 1. Subjects with disease that progressed on anti-estrogen and/or $\geq$ 1 AIs, OR. 2. Subjects with disease that progressed on CDK4/6 inhibitor plus letrozole. Phase I will employ a Bayesian predictive adaptive design. Phase II of the study is a randomized, double-blind, placebo-controlled study, the composition of which will be selected at the end of Phase I. Patients must have received $<$ 3 lines of anticancer therapy ($\leq$1 line of chemo), measurable disease, and PS 0-1. Funding: GSK. Clinical trial information: NCT02964507.

TPS1115 Poster Session (Board #102b), Sun, 8:00 AM-11:30 AM

A randomized, open-label, multicentre, phase IV study evaluating palbociclib plus endocrine treatment versus a chemotherapy based treatment strategy in patients with hormone receptor positive/HER2-negative metastatic breast cancer in a real world setting. *First Author: Sibylle Loibl, German Breast Group, Neu-Isenburg, Germany*

Background: Although endocrine based therapy is recommended as first-line treatment in metastatic breast cancer (MBC) in patients with an HER2-/HR+ tumour up to 50% of the patients receive chemotherapy. Palbociclib (P) a CDK4/6 inhibitor improves PFS by 42% in endocrine sensitive and resistant HER2-/HR+ MBC when added to an endocrine therapy (ET). Patients included in clinical trials are often criticised not to be representative for real world breast cancer patients. **Methods:** Patients with first-line HER2-/HR+ MBC who are candidate for mono-chemotherapy will be eligible to be randomised 1:1 to receive either P plus ET per label or mono-chemotherapy per investigator´s choice with or without maintenance ET. In both study arms, treatment will be given until disease progression, unacceptable toxicity, withdrawal of consent of the patient or change of initial treatment plan (either planned six chemotherapy cycles followed by maintenance ET or chemotherapy until disease progression). Primary objective is to compare the time-to-treatment failure (TTF), defined as time from randomization to discontinuation of treatment for any reason, including disease progression, treatment toxicity and death. Secondary objectives are progression free survival, overall survival at 36 months, amongst other time to event endpoints; investigator assessed overall clinical response; toxicity and compliance; patient well-being and health care utilization by daily monitoring treatment impact. Aim: 360 patients will be accrued to show an improved TTF for P in combination with ET. Recruitment will start in QII/2017 and is planned for approximately 18 months in 100 sites in Germany, Spain, Poland, Italy, France, UK and Canada. Conclusions: The aim of the trial is to demonstrate that an endocrine based strategy consisting of ET plus P is superior to a chemotherapy based strategy as first-line therapy in women with HER2-/HR+ breast cancer in a real world setting.

TPS1116 Poster Session (Board #103a), Sun, 8:00 AM-11:30 AM

Phase 1/2, multicenter, non-randomized, open-label, multiple-dose first-in-human study of U3-1402 (anti-HER3 antibody drug conjugate) in subjects with HER3-positive metastatic breast cancer. *First Author: Takahiro Kogawa, National Cancer Center Hospital East, Chiba, Japan*

Background: There is a need for effective late-line treatments in metastatic breast cancer. HER3 overexpression in breast cancer is associated with poor prognosis, but there is as yet no approved targeted treatment against HER3. U3-1402 is a novel antibody-drug conjugate (ADC) comprised of a fully humanized anti-HER3 antibody (patritumab) covalently conjugated via a cleavable peptide linker to a derivative of the topoisomerase I inhibitor exatecan. After U3-1402 binds to HER3 on the tumor cell surface, it is internalized and leads to apoptosis via inhibition of topoisomerase I. This ADC achieves a high drug-to-antibody ratio of ~8:1. **Methods:** This is a Phase 1/2, multicenter, non-randomized, open-label, multiple-dose, first-in-human study in subjects with HER3-positive metastatic breast cancer. The study consists of 3 parts: Dose Escalation, Dose Finding, and Phase 2. In Dose Escalation, safety and tolerability of U3-1402 are evaluated and the maximum tolerated dose is determined using the modified continuous reassessment method with escalation with overdose control. In Dose Finding, the recommended phase 2 dose (RP2D) of U3-1402 is determined using continued assessment of safety and efficacy as well as pharmacokinetic data of U3-1402. Efficacy and safety of the RP2D are further evaluated in Phase 2 part. Patients with locally advanced or metastatic breast cancer who have disease refractory to standard treatment, who cannot tolerate standard treatment, or for whom no standard treatment is available, will be enrolled. Key inclusion criteria include HER3-positive tumor, ECOG performance status 0–1, and measurable disease based on RECIST version 1.1. HER3 expression in tumor tissue will be evaluated with immunohistochemistry at a central laboratory. Prior chemotherapy regimens are restricted to 6 or fewer in Dose Finding and Phase 2, but not in Dose Escalation. Patients will receive U3-1402 intravenously every 3 weeks until unacceptable toxicity or disease progression. Enrollment of an estimated 80 patients is ongoing. Clinical trial information: 02980341.

TPS1117 Poster Session (Board #103b), Sun, 8:00 AM-11:30 AM

An open-label, phase II study of rucaparib, a PARP inhibitor, in HER2- metastatic breast cancer patients with high genomic loss of heterozygosity: RUBY. *First Author: Anne Patsouris, Institute of West Cancerology Paul Papin, Angers, France*

Background: *BRCA1* and/or *BRCA2* mutations confer sensitivity to poly (ADP-ribose) polymerase (PARP) inhibitors (PARPi). In addition to BRCA1/2, alterations of other genes (PALB2, RAD51C….) implicated in homologous recombination repair (HRR) pathways leads to a BRCAness phenotype that is also associated with PARPi sensitivity. Rucaparib, a potent oral PARP-1, -2 and -3 inhibitor, has shown activity in a phase 1 study of patients (pts) with homologous recombination deficient (HRD) breast cancer (Kristeleit, RS. J Clin Oncol 32:5s, 2014 [suppl; abstr 2573]). This single arm, open-label, multicenter phase II study (NCT02505048) is evaluating the efficacy and safety of rucaparib in pts with HER2- metastatic breast cancer (MBC) associated with a BRCAness phenotype determined by "high tumor genomic LOH" score and/or a somatic *BRCA*mutation. **Methods:** Pts with HER2- MBC exhibiting a BRCAness phenotype will receive oral rucaparib 600 mg BID continuously in 21-day cycles until disease progression. The primary endpoint is clinical benefit rate (CBR), defined by complete and partial response and stable disease lasting for at least 16 weeks and, if CBR is significant, the objective response rate (ORR). Secondary endpoints include progression-free survival, overall survival, safety, and the prognostic value of the BRCAness signature. Targeted enrollment is 41 pts using a Simon two-stage design. Eligibility: Women with HER2- MBC with a BRCAness phenotype who received 1-4 prior chemotherapy regimens are eligible. ECOG PS 0-1 and adequate organ function is required. The BRCAness phenotype is defined by high tumor genomic LOH (LOH cutoff of 18%) that can identify HRD tumors, including both known *BRCA1* methylation and unknown genetic/epigenetic mechanisms and somatic *BRCA1/2* mutations. Pts with a known *BRCA1* and/or *BRCA2* germline mutation are excluded. "high tumor genomic LOH" score will be generated from the CytoScan HD SNP array, which is available from the SAFIR02 protocol or other molecular programs. To date, 13 pts have been enrolled, with enrollment ongoing. This trial design is intended to establish proof-of-concept that rucaparib can improve ORR in HER2- MBC with HRD. Clinical trial information: NCT02505048.

TPS1118 Poster Session (Board #104a), Sun, 8:00 AM-11:30 AM

A phase 2 study of investigational TORC1/2 inhibitor TAK-228 with fulvestrant in women with ER+/HER2–advanced or metastatic breast cancer (mBC) that has progressed during or after aromatase inhibitor (AI) therapy. *First Author: Jose Angel Garcia Saenz, Hospital Clínico San Carlos, Madrid, Spain*

Background: Antiestrogen therapy, including AI, is standard for ER+ tumors in the adjuvant and metastatic setting; however, resistance is common. These tumors may respond to alternative second-line anti-estrogen therapies such as fulvestrant but response durations are often short. Preclinical and clinical studies suggest that simultaneous inhibition of ER and PI3K/mTOR could prevent/delay the emergence of hormone-independent cancer cells, thereby improving patient (pt) outcomes. This study will test whether fulvestrant plus TAK-228, a dual TORC1/2 inhibitor, can overcome endocrine therapy resistance in ER+ mBC. This is an open-label, randomized, phase 2 study of continuous once-daily TAK-228 (4 mg) or once-weekly TAK-228 (30 mg) plus fulvestrant (per label), vs fulvestrant alone, in pts with ER+/HER2– advanced or mBC that has progressed during/after AI therapy (EudraCT 2015-003612-20). **Methods:** 153 pts will be randomized 1:1:1 and stratified (presence or absence of visceral metastasis, prior hormonal therapy sensitivity, and prior exposure to CDK 4/6 inhibitors). Pts will receive study drug(s) until progressive disease (PD), unacceptable toxicity, or consent withdrawal. Pts with histological confirmation of ER+/HER2– advanced or mBC with measureable disease, ECOG 0–1, PD during/after prior AI therapy (progression $\leq$12 mos after discontinuation of adjuvant therapy or $\leq$1 mo after discontinuation in the metastatic setting) and adequate organ function, but not prior therapy with mTOR, PI3K, dual PI3K-mTOR or AKT inhibitors, or fulvestrant, $>$ 1 prior line of chemotherapy for mBC or recurrent or progressive disease on $>$ 2 endocrine therapies for mBC are eligible. This study aims to determine the efficacy (primary endpoint: PFS; secondary endpoints: OS, TTP, ORR), safety and tolerability of TAK-228 plus fulvestrant vs fulvestrant alone. The primary hypothesis (TAK-228 plus fulvestrant can improve median PFS to 8 mos [hazard ratio, HR 0.5] vs fulvestrant-alone median PFS of 4 mos) is to be tested at the 0.10 significance level (2-sided; dropout rate 10%). To date, 24 pts have been enrolled. Clinical trial information: EudraCT 2015-003612-20.

TPS1119 Poster Session (Board #104b), Sun, 8:00 AM-11:30 AM

SANDPIPER: Phase III study of the PI3-kinase (PI3K) inhibitor taselisib (GDC-0032) plus fulvestrant in patients (pts) with estrogen receptor (ER)-positive, HER2-negative locally advanced or metastatic breast cancer (BC) enriched for pts with *PIK3CA*-mutant tumors. *First Author: Jose Baselga, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: As one of the most frequent genomic alterations in BC, *PIK3CA* mutations occur in ~40% of ER-positive, HER2-negative breast tumors. *PIK3CA* mutations may mediate resistance to endocrine therapies and promote growth and proliferation of tumors in BC. Taselisib is a potent and selective PI3K inhibitor that preferentially degrades mutant versus wild-type PI3Kα via a unique mechanism not seen with alpelisib and pictilisib. In *PIK3CA*-mutant BC cell lines, taselisib had enhanced activity. Confirmed partial responses were reported in pts with *PIK3CA*-mutant BC treated with taselisib either as a single agent or in combination with fulvestrant. **Methods:** SANDPIPER is a double-blind, placebo-controlled, randomized, phase III study, designed to evaluate the efficacy and safety of taselisib plus fulvestrant in pts with ER-positive, HER2-negative, *PIK3CA*-mutant locally advanced or metastatic BC. Postmenopausal pts will be randomized 2:1 to receive either taselisib (4 mg qd) or placebo in combination with fulvestrant (500 mg intramuscular on Days 1 and 15 of Cycle 1, and on Day 1 of each subsequent 28-day cycle). Pts must have had disease recurrence or progression during or after aromatase inhibitor treatment. Randomization will be stratified by visceral disease, endocrine sensitivity, and geographic region. SANDPIPER enriches for pts with *PIK3CA*-mutant tumors and a centrally assessed, valid cobas PIK3CA Mutation Test result in tumor tissue is required prior to enrollment; pts with *PIK3CA*-mutant tumors are randomized separately from those with non-mutant tumors. The primary efficacy endpoint is investigator-assessed progression-free survival in pts with *PIK3CA*-mutant tumors (estimated by Kaplan–Meier methodology). Other endpoints include overall survival, objective response rate, clinical benefit rate, duration of objective response, safety, pharmacokinetics, and patient-reported outcomes. Enrollment is open for pts with *PIK3CA*-mutant tumors. Target enrollment is 600 pts and $>$ 300 patients have been enrolled. Clinical trial information: NCT02340221.

TPS1120 Poster Session (Board #105a), Sun, 8:00 AM-11:30 AM

ATTAIN: Phase 3 study of etirinotecan pegol (EP) vs treatment of physician's choice (TPC) in patients (pts) with metastatic breast cancer (MBC) who have stable brain metastases (BM) previously treated with an anthracycline, a taxane, and capecitabine (ATC). *First Author: Debu Tripathy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EP is a next generation topoisomerase I inhibitor-polymer conjugate that provides continuous exposure to SN-38, the active metabolite. A BM mouse model showed high penetration and retention of SN-38 in CNS lesions, resulting in decreased size of CNS lesions and improved survival (OS) at concentrations achieved at the recommended dose in pts (Adkins BMC Cancer 2015). A Phase 3 trial (BEACON) of EP vs TPC in 852 pts with advanced BC did not meet its primary endpoint of OS (HR 0.087; p = 0.08); a subset of 67 pts with stable BM showed improved OS (HR 0.51 [95% CI 0.30-0.86]; $p < 0.01$) (Perez Lancet Oncol 2015). The current Phase 3 trial (ATTAIN) was designed for this subpopulation of pts having high unmet medical need. **Methods:** Pts with MBC with locally treated stable BM will be randomized 1:1 to EP vs TPC in an open-label, randomized Phase 3 study. Eligibility includes ECOG PS 0 or 1; adequate organ function who received prior ATC (in neo/adjuvant or locally advanced/MBC setting); pts must have had ≥1 prior cytotoxic regimen for MBC (triple negative BC); ≥2 prior cytotoxic regimens and either 1 prior hormone therapy (HR+ BC) or 1 prior HER2 targeted therapy (HER2+ BC). Pts must have undergone definitive local therapy of BM (whole brain radiation [RT]; stereotactic RT or surgical resection as single-agent or combination); signs/symptoms of BM must be stable with steroids unchanged or decreasing for ≥7 days prior to randomization. Primary endpoint is OS. Key secondary endpoints: ORR and PFS by RECIST v1.1 and RANO-BM, clinical benefit rate (ORR+SD ≥ 6 months) and QoL. Pts randomized to TPC will receive 1 of 7 IV cytotoxic agents. Pts are stratified by region, PS and receptor status. 350 pts will be randomized to obtain number of events required at 90% power to detect a statistically significant improvement in OS (hypothesizing HR = 0.67); 1 interim analysis at 50% of deaths (130 events) will be performed. PK sampling and UGT1A1 testing will be performed in the EP arm; plasma ctDNA will be assessed for potential predictive markers of efficacy. Enrollment will begin early 2017. Clinical trial information: NCT02915744.

TPS1121 Poster Session (Board #105b), Sun, 8:00 AM-11:30 AM

An open label, phase II trial of continuous low-irradiance photodynamic therapy (CLIPT) using verteporfin for the treatment of cutaneous breast cancer metastases. *First Author: Steven J. Isakoff, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Cutaneous metastases occur in approximately 20% of patients (pts) with metastatic breast cancer (mBC) and can be highly symptomatic and distressing. Radiation is frequently offered, but progression often occurs quickly. Photodynamic therapy is a promising approach with encouraging results in small studies. Here we will evaluate a novel Continuous Low-Irradiance Photodynamic Therapy (CLIPT) system that emits 690nm LED via a handheld powerpack attached to a single-use sterile light patch to deliver a total energy level of 10J/cm2. Verteporfin (Visudyne) is a photosensitizer approved for ophthalmological use that when combined with CLIPT generates activated oxygen species which can destroy tumor cells with limited normal tissue reaction. **Methods:** This open label, phase 2 study will evaluate the efficacy and safety of CLIPT with verteporfin in 15 pts with cutaneous lesions from mBC. Pts will receive a single IV injection of verteporfin on day 1. The 9x9cm patch with an adhesive border is placed over the treatment site and attached to the CLIPT portable power pack. The pt turns the device on at home 6 hours after the verteprofin injection and it automatically turns off after 24 hours. The pt will remove the patch and return to clinic on day 3. The primary endpoint is objective response rate (RR) at 3 weeks following CLIPT using a modified RECIST which accounts for nodular or diffuse plaque-like lesions. Secondary endpoints include RR at 2, 8 and 12 weeks, toxicity, and quality of life (using FACT-B, a Participant Symptom Scale, and Brief Pain Inventory). Pts who derive clinical benefit may be retreated up to 3 times to the same or different region. Eligible pts will have: cutaneous metastases from mBC with measurable disease by protocol defined modified RECIST 1.1, ≥ 1 line of prior systemic or local therapy for mBC, ≥ 14 days from prior systemic therapy or 60 days from radiation to target lesion, and no expectation for systemic therapy for ≥ 14 days after CLIPT. RR will be reported with 95% CI. If ≥ 3 responses (RR ≥ 20%) are observed, the null hypothesis of RR ≤ 5% will be rejected. At the time of abstract submission, 1 patient has been accrued. Clinical trial information: NCT02939274.

TPS1122 Poster Session (Board #106a), Sun, 8:00 AM-11:30 AM

A randomised phase 2 study of 3 weekly cabazitaxel vs weekly paclitaxel chemotherapy in the first-line treatment of HER2 negative metastatic breast cancer. *First Author: Amit Bahl, University Hospitals Bristol NHS Foundation Trust - Bristol Haematology and Oncology Centre, Department of Oncology, Bristol, United Kingdom*

Background: Breast cancer (BC) represents 25% of all cancers in women. Whilst the majority have early stage disease approximately 30% will develop metastatic breast cancer (MBC). In HER2 negative MBC, palliative chemotherapy is one of the main treatment options. It remains to be seen whether the use of adjuvant taxane chemotherapy leads to an increase in taxane resistance at the onset of MBC, although for patients with a relatively short disease free interval this may be the case. Cabazitaxel (CBZ) is a novel taxoid selected for development from preclinical evidence in cell lines resistant to docetaxel and paclitaxel including activity in a HER-2 positive BC tumour xenograft, with innate resistance to docetaxel. Clinically CBZ is licensed for metastatic castration-resistant prostate cancer following progression during or after docetaxel chemotherapy. A phase 3 RCT in this patient group showed a 3 month overall survival benefit for patients receiving CBZ and prednisolone compared with mitoxantrone and prednisolone. **Methods:** CONCEPT is an open label randomised phase 2 trial of first line chemotherapy in patients with HER-2 negative MBC where paclitaxel would be considered the standard treatment. Patients are randomised to cabazitaxel 25 mg/m^2 every 21 days for 6 cycles or paclitaxel 80 mg/m^2 weekly for 18 weeks. Eligibility includes patients who are PS 0 or 1 who may have received prior docetaxel in the adjuvant setting or be taxane-naïve. The primary endpoint is progression free survival (PFS), defined as the time between the date of randomisation and progression (according to RECIST version 1.1) or death from any cause. Secondary end-points include safety, overall survival and assessment of quality of life factors by FACT-B and EQ-5D-5L. For the current phase 2 study 90 patients will be recruited, with a 1:1 randomisation, proceeding to phase 3 of 160 patients, if the interim analysis does not show futility. To date 38 patients have been recruited from 10 centres. The IDMC met in Oct 2016 and recommended the study continue recruitment.

TPS1123 Poster Session (Board #106b), Sun, 8:00 AM-11:30 AM

Phase II study of apatinib plus vinorelbine, a novel combination of all-oral regimen in heavily pretreated patients with metastatic HER2-negative breast cancer. *First Author: Anjie Zhu, Chinese Academy of Sciences and Peking Union Medical College, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Beijing, China*

Background: Antiangiogenic therapy in combination with chemotherapy is effective in control advanced breast cancer(ABC). Apatinib is an oral, highly potent tyrosine kinase inhibitor targeting vascular endothelial growth factor receptor 2(VEGFR-2). Phase II clinical trials of Apatinib single agent had presented objective response and manageable toxicity in heavily pretreated, metastatic breast cancer. The median progression free survival (PFS) and median overall survival (OS) of single agent in both triple-negative and non-triple-negative breast cancer were 3.3-4.0 months and 10.3-10.6 months, respectively. The overall response rate and disease control rate (DCR) reached 16.7% and 66.7%, respectively. This all-oral phase II study aims to investigate the efficacy and safety of the oral vinorelbine-Apatinib combination in pre-treated metastatic breast cancer(MBC). **Methods:** This single arm prospective study enrolled patients with HER2(Human epidermal growth factor receptor-2) negative advanced breast cancer, pretreated with anthracycline and taxanes, and who failed in the metastatic setting at least one prior chemotherapy regimen. The estimated Enrollment was 40 patients. The primary end point of this study was PFS. Secondary end points included objective response rate (ORR), DCR, OS and safety. Patients were treated with apatinib 500/425mg daily plus oral vinorelbine 60-80 mg/m2 day1,8,15 every 3 weeks/cycle. Starting doses of Apatinib were chosen according to age, weight and patient status. Patients eligible were evaluated by CT or MRI scan at baseline and every 2 cycles (6 weeks) there after until disease progressed. Adverse events (AEs) were assessed and graded in accordance with the Common Terminology Criteria for AEs, version 4.0. Clinical trial information: NCT02768415.

TPS1124 Poster Session (Board #107a), Sun, 8:00 AM-11:30 AM

Phase II trial of pembrolizumab in combination with nab-paclitaxel in patients with metastatic HER2-negative breast cancer. *First Author: Maryann J. Kwa, New York University Cancer Institute, New York, NY*

Background: Immunotherapy has shown therapeutic promise in several cancers, including breast cancer. Monotherapy with anti-PD-1/anti-PD-L1 antibodies has demonstrated durable responses in patients with metastatic triple-negative breast cancer (mTNBC) (Nanda et al, JCO 2016) and metastatic estrogen receptor-positive (mER+)/HER2-negative breast cancer (Rugo et al, SABCS 2015). Furthermore, response rates have been increased with combination approaches with chemotherapy (Adams et al, ASCO 2016). Based on these results, we seek to study the anti-tumor efficacy and safety of pembrolizumab (anti-PD-1 antibody) and nab-paclitaxel, the impact of therapy on the tumor microenvironment, and predictive markers of response. **Methods:** This is an ongoing single-arm open-label multi-cohort phase II study of pembrolizumab and nab-paclitaxel in patients treated with ≤2 prior lines of therapy for metastatic HER2-negative breast cancer (n = 50) (ClinicalTrials.gov: NCT02752685). Thirty patients with mTNBC and 20 patients with mER+/HER2-negative breast cancer will be enrolled. Enrollment of patients with metaplastic breast cancer is encouraged. Patients will receive pembrolizumab 200 mg IV on day 1 plus nab-paclitaxel 100 mg/m^2 IV on day 1 and 8 (21-day cycle). Prior taxane therapy given > 3 months before cycle 1 is allowed. Primary objective is treatment efficacy, as determined by overall response rate (RECIST 1.1). Secondary objectives include safety, progression-free survival, overall survival, and duration of response. Serial tumor biopsies will be performed to assess changes in the tumor microenvironment from baseline with chemotherapy alone (cycle 1) and then with chemoimmunotherapy (cycle 2 and subsequent cycles). Mutational and neoantigen load, TILs by histopathological assessment, TCR by immunosequencing, and immune gene profiles in tumors will be evaluated. PD-L1 expression in tumor tissue is not required for enrollment but will be assessed as a predictive marker. The potential role of the gut microbiome in modulating the immune response will also be evaluated by 16S rRNA. An initial safety run-in with 12 subjects has been completed with no unexpected toxicity. Clinical trial information: NCT02752685.

TPS1125 Poster Session (Board #107b), Sun, 8:00 AM-11:30 AM

LCCC 1525: Combination immunotherapy with cyclophosphamide plus pembrolizumab in patients with advanced triple negative breast cancer (TNBC). *First Author: Benjamin Garrett Vincent, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Immunotherapy is a promising strategy to treat advanced TNBC, an aggressive subtype of BC lacking expression of estrogen and progesterone receptors and HER2. TNBC response to antibodies targeting programmed cell death protein 1 (PD-1) or its ligand (PD-L1) are modest (< 20%); high expression of PD-L1 is associated with enhanced response. The presence of intratumoral regulatory T cells (Tregs), potent suppressors of the immune response, dampens response to checkpoint inhibitors. The capacity of cyclophosphamide (Cy), a cytotoxic with known activity in BC, to deplete Tregs is well-established. Preclinical mouse models of TNBC illustrate Treg depletion with improved outcome when Cy is administered prior to PD-1 inhibition. We are testing the hypothesis that a single dose of Cy given prior to pembrolizumab (pembro) will improve progression free survival (PFS) beyond historical control in advanced TNBC. **Methods:** This phase II, single-arm, multicenter study will evaluate pembro 200 mg IV every 3 weeks following a single priming dose of Cy 300 mg/m2 IV in patients (pts) with advanced TNBC who have received ≥1 prior therapy in the metastatic setting. The primary objective is to estimate PFS for Cy + pembro in advanced TNBC pts. A co-primary objective is to describe reduction in circulating Tregs. Secondary objectives include overall response rate (ORR, RECIST 1.1), duration of response (DOR), disease control rate (DCR) and overall survival (OS). Determination of ORR based on immune response criteria (irRECIST) and association of immunogenomic features with PFS are exploratory. Statistical considerations: A sample size of 36 pts has an 80% power to detect change in median PFS from 1.9 (null) to 2.9 (alternative hypothesis) months at a 0.05 significance level. Assuming 10% dropout rate, we will enroll 40 pts. We will also be able to detect a 67% reduction in Tregs with 80% power and one-sided alpha = 0.05. Correlative studies: Archival primary and/or metastatic tissues are required of all pts to evaluate molecular subtype, gene signature expression, T and B cell receptor repertoires, and PD-1 and PD-L1 expression; correlations with outcome will be performed. Clinical trial information: NCT02768701.

TPS1126 Poster Session (Board #108a), Sun, 8:00 AM-11:30 AM

A phase 1b study of safety and immune response to PVX-410 vaccine alone and in combination with durvalumab (MEDI4736) in HLA-A2+ patients following adjuvant therapy for stage 2/3 triple negative breast cancer. *First Author: Steven J. Isakoff, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Stage 2-3 triple negative breast cancer (TNBC) remains at high risk for recurrence despite modern adjuvant therapy. An important role for the immune system in TNBC has recently emerged. Tumor infiltrating lymphocytes (TILs) are correlated with improved prognosis and several PD-1/PD-L1 checkpoint inhibitors, including Durvalumab (DUR), demonstrated activity in metastatic TNBC. Vaccines are a promising approach to further enhance the immune response in many cancers including TNBC. PVX-410 (PVX) is a novel tetra-peptide vaccine against XBP1 (2 splice variants), CD138 and CS1 that was safe and induced immune responses in a phase 1b study in smoldering myeloma. XBP1 and CD138 are also over-expressed in TNBC. **Methods:** This Phase 1b multi-center, single arm study will enroll 20 HLA-A2+ female patients (pts) following completion of all adjuvant therapy for stage 2-3 TNBC. Pts will receive 6 doses of 800ug PVX (emulsified in Montanide (SC) and co-administered with Hiltonol (IM)) at 2-week intervals, and 2 doses of DUR 1500mg IV at the 4th and 6th vaccine visits. Eligible pts must be between 1-6 months from completing adjuvant therapy, have no prior autoimmune disease, and have residual disease if neoadjuvant therapy was used. The primary objective is to determine the safety and tolerability of the combination, and the key secondary objective is to determine the immune response to PVX + DUR. If ≤1 pt in the first 6 has a protocol defined dose limiting toxicity within 4 weeks after the first DUR dose, accrual will continue to 20 pts. Immune response will be assessed at baseline, pre-dose 4 PVX/dose 1 DUR, and 4 weeks after completing protocol therapy. Paired data in 20 pts provides 90% power to see a shift of 0.75 standardized units from baseline to 4 weeks post treatment with the signed rank test. Immune response will be determined by a FACs based assay of antigen specific CD3+CD8+ T lymphocyte response and IFN-γ production (intracellular staining) in patient PBMCs. Additional correlative studies, including T-cell PD-1 and tissue PD-L1, XBP1, and CD138, are planned. Currently 4 pts are enrolled. Clinical trial information: NCT02826434.

TPS1127 Poster Session (Board #108b), Sun, 8:00 AM-11:30 AM

Phase Ib study of heat shock protein 90 inhibitor, onalespib in combination with paclitaxel in patients with advanced, triple-negative breast cancer (NCT02474173). *First Author: Robert Wesolowski, The Ohio State University Comprehensive Cancer Center, Arthur G. James Cancer Hospital, Columbus, OH*

Background: Heat shock protein 90 (HSP90) is a molecular chaperone which is necessary for proper folding and stabilization of proteins. Client proteins of HSP90 include many oncogenic proteins known to be over-activated in triple negative breast cancer such as AKT, EGFR, members of RAS/MAPK signaling pathway and androgen receptor. High expression of HSP90 in breast cancer has been associated with poor outcome. In addition, over-expression of HSP90 client proteins such as AKT and c-RAF has been implicated in paclitaxel resistance. Onalespib (AT13387) is a synthetic non-ansamycin small molecule that acts as an inhibitor of HSP90 by binding to the amino terminal of the protein and has dissociation constant (Kd) of 0.71 nM. **Methods:** Patients with inoperable or metastatic, triple negative or < 10% hormone receptor positive breast cancer are treated with onalespib and paclitaxel on days 1, 8, 15 every 28 days. Paclitaxel is given at a standard dose of 80 mg/m2 while the dose of onalespib is gradually increased using standard 3+3 design (see table). In order to assess the effect of each drug on pharmacokinetics of the other drug, onalespib is given on day -7 prior to cycle 1 and skipped on day 1 of cycle 1 during which paclitaxel is administered alone. The primary objective of the study is to determine recommended phase II dose and assess the toxicity profile of the combination. The secondary objectives include pharmacokinetic of each agent. Overall response rate, response duration and progression-free survival will also be assessed. The study is currently enrolling patients to dose level 2. Clinical trial information: NCT02474173.

Dose escalation schedule.

	Dose	
Dose Level	**Onalespib (mg/m^2 IV on days 1, 8, 15)**	**Paclitaxel (mg/m^2 IV on days 1, 8, 15)**
Level -1	100	80
Level 1	120	80
Level 2	150	80
Level 3	200	80
Level 4	260	80

1500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Enrichment of germline DNA-repair gene mutations in patients with colorectal cancer. *First Author: Saud H Aldubayan, The Broad Institute of MIT and Harvard, Cambridge, MA*

Background: Twin studies showed that 30% of all colorectal cancer (CRC) patients have an inherited genetic susceptibility. Several CRC predisposition genes have been described to date. However, mutations in these genes explain the risk in only 5-10% of CRC cases. In this study, we hypothesized that some of the CRC heritability may be explained by excess disruptive germline mutations in DNA repair genes (DRGs). **Methods:** Exome sequencing data of 716 in the discovery cohort (CanSeq and NHS/HPFS studies) and 1609 CRC patients in the validation cohort (TCGA and NSCCG studies) were used to evaluate germline variants in a pre-selected group of 42 DRGs and 12 known CRC risk genes. Frequencies of disruptive mutations in our cohorts were examined relative to 27173 non-Finnish European cancer-free adults from the ExAC cohort to evaluate for enrichment. **Results:** Of 716 patients in the discovery cohort, 27 (3.8%) patients harbored germline mutations in *APC* (n = 11), *MSH6* (n = 2), *MUTYH* (n = 11), CHEK2 (n = 1) and *TP53* (n = 2). Interestingly, germline mutations in *ATM* and *PALB2* were significantly enriched in our CRC discovery cohort (OR = 2.7; P = 0.044; and OR = 4.8; P = 0.026, respectively). Evaluation of germline data from another 1609 CRC patients (validation cohort) also showed significantly higher rates of *ATM* mutations (5; 0.7%; OR = 2.1; P = 0.044), and a trend for enrichment of *PALB2* mutations (3; 0.4%; OR = 2.8; P = 0.056). Secondary analysis of actionable germline mutations in a highly penetrant cancer risk gene set (*ATM, BRCA1, BRCA2, BRIP1* and *PALB2*) suggest a broader enrichment trend in CRC patients for these genes (Discovery: OR = 1.7; P = 0.06; Validation: OR = 2; P = 1.96e-04). **Conclusions:** Our analysis of germline variants in 2325 CRC patients showed the first robust evidence for germline *ATM* mutations to confer a higher risk of developing CRC. We also presented evidence to support *PALB2* as a potential novel CRC risk gene. Overall, our study shows that mutations in some DRGs may explain some of the missing CRC heritability. It also indicates that a significant percentage of CRC patients, who carry mutations in highly actionable genes where cancer screening recommendations for patients and families do exist, are not captured with current testing recommendations.

1501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Germline genetic testing in unselected pancreatic ductal adenocarcinoma (PDAC) patients. *First Author: Mary Linton Bounetheau Peters, Beth Israel Deaconess Medical Center, Cambridge, MA*

Background: The aim of this study is to assess the prevalence of known heritable germline mutations in unselected PDAC patients and to determine how well current guidelines for genetic testing identify mutation carriers. **Methods:** Consecutive, unselected patients with recently diagnosed PDAC from three centers were enrolled from May to December 2016 in an ongoing prospective study. A three-generation pedigree was obtained. Germline mutations in 12 genes associated with PDAC risk (*APC, ATM, BRCA1, BRCA2, CDKN2A, EPCAM, MLH1, MSH2, PALB2, PMS2, STK11, TP53*) and in 19 genes related to other cancer risks were screened for by NGS. American College of Gastroenterology and NCCN criteria for genetic testing for *BRCA1/2*, Lynch syndrome, and Familial Pancreatic Cancer (FPC) were assessed. **Results:** Among 183 patients, 46% are female, 79% are Caucasian and 10% are Ashkenazi Jewish, with median (IQR) age 68 (62,75) years at diagnosis. 41% of patients met [3]1 criteria for genetic testing (35.5% *BRCA1/2*, 2.7% Lynch, 9.3% FPC). Twenty patients (11%) were found to have a total of 21 pathogenic mutations (table). Mutation status was not associated with age at diagnosis, sex, or personal history of cancer (all $p > 0.05$). Six mutation carriers (30% of positives) did not meet current criteria for genetic testing. **Conclusions:** Preliminary results show that 6.6% of unselected PDAC patients carry a germline mutation in a gene known to increase PDAC risk and 4.3% have a mutation in genes not previously linked to PDAC. Existing testing criteria did not identify 30% of carriers. Continued refinement of guidelines is necessary to align genetic testing with inherited PDAC risk. Clinical trial information: NCT02790944.

1502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Prevalence of homologous recombination deficiency among all tumor types. *First Author: Arielle Lutterman Heeke, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Triple negative breast and ovarian cancer are known to have a high frequency of homologous recombination deficiencies (HRDef). The prevalence of HRDef among all tumors is unknown. **Methods:** Molecular profiles of 48,733 tumors obtained from pts with bladder, breast, ovarian, pancreas, prostate, thyroid, cervical, hepatobiliary, colorectal (CRC), endometrial, gastric/esophageal (GE), head/neck, renal, non-small cell lung (NSCLC), small cell lung (SCLC), GIST, glioma, melanoma, sarcoma and unknown 1° cancers were reviewed to identify somatic pathogenic mutations (mut) in HR genes *ATM, ATRX, BARD1, BLM, BRCA1/2, BRIP1, FANCA/C/D2/E/F/G/L, MRE11A, NBN, PALB2, PTEN, RAD50, RAD51, RAD51B,* or *WRN*. Molecular profiles were generated from tumors submitted to Caris Life Sciences using multiple technologies including next generation sequencing (average read depth 500X). **Results:** Overall frequency of HR mut among all tumors is 11.61% (5658/48733). Cancer lineages with highest frequency of HR mut are endometrial (38.08%, 1956/5137), glioma (15.90%, 265/1667), ovarian (12.99%, 1151/8862), prostate (11.21%, 77/687), cervix (10.06%, 79/785) & breast (9.66%, 562/5818). Least commonly mutated lineages include GIST (1.50%, 3/200), sarcoma (3.12%, 55/1763), head/neck (3.70%, 24/648), hepatobiliary (4.72%, 39/827) & pancreas (5.05%, 102/2022). Frequencies of HR gene mutations are depicted in Table 1. **Conclusions:** HR mutations were seen in 11.61% of tumors. While the percentage of HRDef in pancreatic cancer pts is lower than what has been seen in other datasets, the percentage in breast and ovarian cancer, as well as the percentage of other tumors with HRDef, provide a path to employ HRDef-directed therapies such as platinums, but especially PARP inhibitors and newer agents such as ATRX inhibitors.

Frequency of HR gene mutations.

HR Mutation	Frequency (%)	Lineages Mutated
ATM	14.24	All except (ex) head/neck
ATRX	0.91	Breast, cervix, CRC, endometrial, GE, GIST, glioma, melanoma, SCLC, NSCLC, ovarian, sarcoma, unknown 1°
BLM	0.21	CRC, GE, melanoma, NSCLC
BRCA1	2.70	All ex GIST, renal
BRCA2	2.88	All ex renal
BRIP1	0.17	Melanoma, pancreas
NBN	0.15	Breast, hepatobiliary, CRC, GE, glioma, NSCLC, ovarian
PALB2	0.55	All ex GIST, head/neck, prostate, renal, thyroid
PTEN	6.10	All ex GIST

1503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Genetic counseling and testing in endometrial cancer: Are we capturing high-risk women? *First Author: Jessica Lee, New York University School of Medicine, New York, NY*

Background: Lynch syndrome accounts for the majority of inherited endometrial cancers and the identification of probands presents a unique opportunity to treat and prevent multiple cancers. This is now even more relevant with the potential of novel immunotherapy agents for women with germline mutations. The diagnosis of endometrial cancer (EC) can provide the indication for women with specific risk factors to undergo genetic testing (GT). We sought to evaluate genetic counseling referrals (GCR) and subsequent GT rates. **Methods:** All women with EC between 2012 and 2015 were identified. Statistical analyses were performed to evaluate risk factors including age, body mass index (BMI), positive family history defined as two or more family members with Lynch-related cancers, and tumor mismatch repair (MMR) protein expression loss. **Results:** A total of 447 women were diagnosed with EC and of these, 107 (24%) were given GCR by their gynecologic oncologist based on their discretion. Compared to non-GCR, GCR women were significantly younger (median 54 vs 65, $p < 0.0001$) and had lower BMI (median 28.2 vs 30.8, $p = 0.007$). Of the 107 GCR women, 71 (66%) underwent GT. Of the 71 GT women, 8 (11%) were found to have a germline mutation in one of the MMR genes. Table 1 lists GCR, GT and positive germline mutations among specific high-risk cohorts. Of these cohorts, 56% under 50 years of age, 28% with family history, and 61% with loss of tumor MMR proteins had GCR. **Conclusions:** Many young, thin EC women with a family history or a tumor MMR deficiency are not given GCR. Among GCR women, 66% underwent GT, despite there being a high rate of germline mutations among these women. It is imperative that high-risk women receive GCR with subsequent GT to capture the maximum number with Lynch syndrome to screen and prevent additional cancers as well as enable cascade testing in family members. Facilitated pathways may be helpful in increasing GCR, as well as GT in EC women.

Cohort	GCR / all women	GT / GCR women	Lynch syndrome / GT women
Age < 50 years	40/71 (56%)	25/40 (63%)	4/25 (16%)
BMI < 25kg/m^2	33/109 (30%)	22/33 (67%)	3/22 (14%)
Positive family history	28/101 (28%)	23/28 (82%)	6/23 (26%)
MMR protein expression loss on tumor immunohistochemistry	25/41 (61%)	17/25 (68%)	5/17 (29%)

1504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Extended follow-up in the COGENT study: A randomized study of in-person versus telephone disclosure of cancer genetic test results. *First Author: Angela R. Bradbury, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Alternative delivery models are needed in the era of Precision Medicine given a shortage of genetic providers and increasing utilization of genetic testing. Telephone disclosure (TD) of genetic test results, including multi-gene panel testing, is non-inferior to usual care in-person disclosure (IPD) for short-term distress but failed non-inferiority for knowledge. Longitudinal data including health behaviors are needed. **Methods:** 970 patients undergoing clinical genetic testing at 5 centers were randomly assigned to usual care IPD (n = 497) or TD (n = 473) of results in the COGENT Study (NCT01736345). Participants completed surveys after pretest counseling, post-disclosure and at 6 and 12 months. We used non-inferiority tests for primary analyses and T-tests and logistic regressions for secondary analyses. **Results:** TD was not worse than IPD for anxiety both post-disclosure and at 6 months, but did not reach the non-inferiority threshold for knowledge at either time point. In secondary analyses there were no significant differences in anxiety, depression, or cancer worry between arms, but there was less knowledge gain at 6 (-0.41 v. +0.11 in IPD, p = 0.05) and 12 months (-0.34 v. +0.31 in IPD, p = 0.05) in the TD arm. In the TD arm, 195 (50%) returned for clinical follow-up with a physician to discuss medical management. Not returning for follow-up varied by site and was associated with a negative result, being male and non-white. Knowledge gain at 6 months was lower for those who did not return for follow-up (-0.77) compared to those who returned (-0.17, p = 0.08). There were no significant differences by arm at 6 and 12 months in performance of mammogram, breast MRI, colonoscopy or prophylactic surgeries. **Conclusions:** Distress is not unacceptably worse with TD, but knowledge failed the test for non-inferiority. Longitudinal knowledge declined more for those who did not return for medical follow-up, but uptake of screening and risk reducing behaviors did not differ by arm. Telephone disclosure of genetic test results, even MGPT, may be a reasonable alternative to in-person disclosure for patients who agree to return to meet with a provider for medical management recommendations. Clinical trial information: NCT01736345.

1505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Effects of lifestyle and diet as modifiers of risk of breast cancer (BC) in *BRCA1* and *BRCA2* carriers. *First Author: Marina Pollan, National Center of Epidemiology, Instituto Salud Carlos III, Madrid, Spain*

Background: Mutations in the *BRCA1/2* genes confer a high lifetime risk of BC. Penetrance varies among populations and individuals suggesting that non-genetic factors may modify the inherited risk. Knowledge of modifiable factors will help to develop preventive strategies. **Methods:** Information on physical activity (PA) (current PA and in the adolescence) and smoking was collected in 892 women (W) with a *BRCA1/BRCA2* germ-line mutation (582 with BC, 45,62% *BRCA2*) from 279 families, followed at three Spanish Genetic Counseling Units, 481of these W also answered a food frequency questionnaire. Participants gave their consent and the study was approved by the ethics committee. The association between BC, lifestyle factors and dietary patterns (Mediterranean and Western) associated with BC were studied using logistic regression. Huber-White robust estimators of variance were employed to take into account correlations between family members. Age, menopausal status, specific mutated gene, BMI, parity and oral contraception were included as co-variables. BC was classified as HR+/+,- or HR-. **Results:** W who did PA daily had half the risk of BC than sedentary W (OR:0,53;p=0,043 for current PA;OR:0,40;p=0,007 for PA in the adolescent) and no differences were observed between *BRCA1* and *BRCA2* carriers. Also, W who daily exercised in both periods had a reduction of their BC risk (OR:0,22;p<0,001). The effect of PA was particularly important among premenopausal W (p-het<0,05). PA in the adolescent decreased the risk of all type of tumors. Nevertheless, alcohol intake, smoking habit and type of diet, did not significantly modify BC risk in this *BRCA* W. **Conclusions:** Our preliminary data suggest a clear reduction in BC risk among *BRCA1/2* carriers who exercise regularly, mainly during the adolescence, and could be considered as potential modifiable factor for BC prevention in these group of W.

1506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Lung cancer screening patient navigation for current smokers in community health centers: A randomized controlled trial. *First Author: Sanja Percac-Lima, Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA*

Background: Annual chest computed tomography (CT) can decrease lung cancer mortality in high risk individuals. Patient navigation (PN) has been shown to improve cancer screening rates in underserved populations. We evaluated the impact of PN on lung cancer screening (LCS) in current smokers in community health centers (CHC). **Methods:** Current smokers aged 55-77 receiving care in five CHC affiliated with an academic medical center were randomized to intervention (n = 400) or control (n = 800) groups. In the intervention arm, patient navigators (PNs) determined eligibility for LCS, provided brief smoking cessation counseling, introduced shared decision making about LCS, scheduled appointments with the primary care provider (PCP), reminded patients about appointments and PCPs to order CTs, and helped patients attend testing and follow-up any abnormal results. Control patients received usual care. The primary outcome was the proportion of patients in each group who had any chest CT during the study period. Secondary outcomes included proportion of patients receiving lung screening CTs and the number of lung cancers diagnosed in each group. **Results:** Baseline patient characteristics were similar between randomized groups. From March 2016-January 2017, PNs contacted 332 (83%) of intervention patients; 76 refused further participation. Of participating patients, 130 (51%) were eligible for LCS. Exclusions included insufficient smoking history (n = 117), competing comorbidities (n = 5), moved (n = 2), and died (n = 2). In intention-to-treat analyses, 124 intervention patients (31%) had chest CT vs. 138 control patients (17.3%, p < 0.01). Lung cancer screening CTs were performed in 94 intervention patients (23.5%) vs. 69 control patients (8.6%, p < 0.01). Eight lung cancers were diagnosed in intervention patients (2%) vs. 4 in controls (0.5%). **Conclusions:** A patient navigation program implemented in community health centers significantly increased lung cancer screening among current smokers. PNs may help underserved low-income current smokers complete LCS and improve equity in care while decreasing lung cancer mortality. Clinical trial information: 2015P002239.

1507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

High risk genetic screening program in a community hospital breast imaging center. *First Author: Anne C. Kushwaha, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The NCCN has published guidelines for screening and testing of Hereditary Breast and Ovarian Cancer (HBOC) that is typically used by the primary physician or oncologist. Little data exists on the value of genetic screening at a major health care access point: the breast imaging center (BIC). Using BICs as potential clinics to identify high risk women could increase the number of appropriate referrals for genetic risk assessment. Therefore, at our hospital-based BIC serving mostly low to middle income patients in a major metropolitan center, we developed a practical screening tool based on the HBOC guidelines and prospectively screened women receiving screening and diagnostic mammography. **Methods:** A questionnaire based on the NCCN HBOC genetic referral guidelines was added to the intake forms of all patients (pts) obtaining breast imaging at our BIC from 2012 to 2015. Forms were reviewed by the radiologists and flagged if the patient met the guidelines of the tool. Identified pts were contacted by letter and/or telephone and a nurse navigator or genetic counselor verified data, and provided information about genetic counseling to the patient prior to scheduling genetic counseling appointments. **Results:** Almost 35, 000 pts were seen during the study period. 1214 pts (3.5%) were flagged as possibly high risk, of which 189 pts. had received prior genetic testing. Of the 1025 remaining pts identified as candidates for genetic counseling, 258 (25%) made a genetic counseling appointment and 163 (16%) received genetic counseling. 106 pts. were tested for BRCA1/2. 9 pts (8.5%) tested positive for a BRCA1/2 pathogenic mutation and 8 pts (7.5%) had a Variant of Unknown Significance. **Conclusions:** Screening for HBOC syndromes at the time of annual breast imaging in a community-based middle to low income metropolitan breast imaging center is practical. Our screening tool identified women with BRCA mutations who would have been otherwise missed. This will have immediate implications for the patient and their family members in regards to increased surveillance and risk reductive surgery discussions.

1508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Survival outcomes of screening with breast MRI in high-risk women. *First Author: Min Sun Bae, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mammography is the only imaging modality proven to reduce mortality from breast cancer. Over the past decade, magnetic resonance imaging (MRI) screening of women with increased risk of breast cancer ($>$ 20% cumulative life time risk) has been recommended. However, there is little evidence that supplemental screening with MRI improves survival. The purpose of this study was to compare survival outcomes of combined screening with MRI and mammography to screening mammography alone in women at increased risk for breast cancer. **Methods:** A total of 3,002 women at increased risk underwent at least two screening rounds between 2001 and 2005, with at least 5 years of follow-up. 1,534 women had combined screening (MRI and mammography), and 1,468 had screening mammography alone. Cancer detection yield and survival were determined in the two groups. **Results:** 60 women were diagnosed with breast cancer, 38 patients in the combined screening group and 22 in the mammography-only group. Cancer yield was 24.8 per 1000 (95% CI, 17.6-33.8) combined screening and 15.0 per 1000 (95% CI, 9.4-22.6) mammography-only. No interval cancers occurred in women undergoing combined screening, while 9 interval cancers were found in women undergoing only mammography screening. During a median follow-up of 10.8 years (range, 0.7-15.2), a total of 11 recurrences and 5 deaths (4 breast cancer cause and 1 unknown cause) were found. Of the 11 recurrences, 6 were in the combined screening group and 5 were in the mammography-only group. All deaths were in the mammography-only group. The Kaplan-Meier estimate for disease-free survival showed no statistically significant difference between the two groups (P = .325). However, patients in the combined screening group had a significantly better overall survival compared with patients in the mammography-only group (P= .002). **Conclusions:** Combined screening with MRI and mammography in women with increased risk of breast cancer resulted in not only a higher cancer detection yield but also better overall survival.

1509 Poster Discussion Session; Displayed in Poster Session (Board #167), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Variation in screening rates in a multi-ethnic population-based study in Chicago. *First Author: Brisa Aschebrook-Kilfoy, The University of Chicago, Chicago, IL*

Background: We initiated the Chicago Multiethnic Prevention and Surveillance Study (COMPASS) in 2013. Here, we present screening rates for key cancers with known disparities in risk/and or outcomes in Chicago, considering the effect health care access and race/ethnicity, and we compare the findings in COMPASS to rates reported by the CDC. **Methods:** COMPASS participant responses to a health interview were analyzed. The analysis of colorectal cancer screening (CRCS) was limited to persons 50-75, mammography screening (MS) was restricted to women ages 50-74, and cervical screening (CS) by pap smear testing was restricted to women ages 21-65. Frequency statistics and linear regression models were run to evaluate associations. **Results:** A total of 2,967 COMPASS participants were included in the analysis from 18 communities. We found ever CRCS rates in Chicago are lower than the national average (52.3% vs. 58.6%; $p < .01$) and that CRCS is lower in blacks (50.3%) and Hispanics (52.1%) compared to whites (65.8%), and that those with health insurance (HI) report a CRCS rate of 56.8% compared to 25.5% without insurance. Mammography within the last 2 years was 70.8% in COMPASS women compared to 72.4% nationally, with black women reporting higher rates of MS in the past 2 years (73.0%) compared to white women (65.4%) and Hispanic women (62.9%); and higher MS among women with HI (74.2%) compared to women without HI (47.2%). Pap screening within the last 5 years was 84.3% in COMPASS women compared to 83.0% nationally (last 3 years), with both black (85.3%) and Hispanic (83.2%) women reporting non-significantly higher CS compared to white women (80.9%) in COMPASS, and significantly higher CS among women with HI (86.2%) compared to women without HI (77.7%). **Conclusions:** Our results reinforce the fact that differences in cancer screening reflect the larger problem of access to care. We further found racial disparities in CRC screening in COMPASS to be consistent with disparities in incidence. However, our results do not support the notion that the disproportionate burden of breast and cervical cancer in black and Hispanic women in Chicago are primarily due to a lack of screening.

1510 Poster Discussion Session; Displayed in Poster Session (Board #168), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Incidence, persistence and determinants of human papillomavirus: A prospective cohort study of 10,000 HIV-negative Nigerian women. *First Author: Sally Nneoma Adebamowo, University of Maryland School of Medicine, Baltimore, MD*

Background: Cervical cancer is the second commonest cancer in Africa. Persistent High-risk HPV (HRHPV) infection is a necessary cause but little is known about the persistence and associated risk factors of HRHPV infection in African women. The aim of this study was to determine risk factors and incidence of HPV infection in Nigerian women. **Methods:** ACCME is a multicenter prospective cohort study of host germline, cervical somatic and HRHPV genomics, epigenomics, and vaginal microenvironment; and their association with HPV. From February/2014 to January/2016, 10,000 HIV-negative women were enrolled into the cohort and are being followed up every 6 months. We used SPF_{25}/$LiPA_{10}$to characterize HPV infection and defined persistent infection as 2 consecutive positive tests done at least 12 months apart. Logistic regression models were used to estimate the associations between risk factors and persistent HPV. **Results:** The mean (SD) age of the study participants at baseline was 40 (10) years and the mean (SD) vaginal pH was 5.2 (0.6). About 42% of the participants were positive for any HPV positive and 21% had persistence of any HPV infections. Some, 35% of the participants had multiple infections with any HPV. About 54% of those with persistent any HPV infections had HRHPV; HPV types 52 (25%) and 18 (15%) were the most prevalent and persistent HRHPV types. The incidence of any HPV infection was 6.6/1,000 person-months while that of HRHPV was 2.6/1,000 person-months. Age, body mass index, level of education, marital and socio-economic status and total number of lifetime sexual partners were associated with HPV infection in these women. **Conclusions:** We defined the incidence, risk factors and commonest types of HRHPV in a large cohort of women in West Africa.

A randomized trial of selenium and vitamin E for primary prevention of non-melanoma skin cancer: Trial results and experience from a low-resource setting. *First Author: Maria Argos, Division of Epidemiology and Biostatistics, School of Public Health, University of Illinois at Chicago, Chicago, IL*

Background: Selenium and vitamin E supplementation previously have shown some evidence of a beneficial effect in the secondary prevention of non-melanoma skin cancer (NMSC). More than 100 million people worldwide are at increased risk of NMSC and other cancers due to arsenic exposure from drinking water and diet – a risk that persists for several decades even after the exposure has terminated. Here, we report on the design, methods and main results of the Bangladesh Vitamin E and Selenium Trial (BEST) – a population-based chemoprevention study conducted among 7,000 adults with visible arsenic toxicity. **Methods:** BEST is a 2×2 full factorial, double-blind, randomized placebo controlled trial of 7,000 adults having manifest arsenical skin lesions evaluating the efficacy of 6-year supplementation with alpha-tocopherol (100 mg daily) and L-selenomethionine (200 μg daily) for the prevention of NMSC incidence. **Results:** Excellent compliance was maintained through the course of the trial, based on data from pill counts, self-reported compliance, and bioadherence. Among participants on treatment through the end of the 6-year intervention period, $>$ 85% were adherent to at least 80% of study supplements. More than 500 new NMSC cases were ascertained using a three-tiered biopsy protocol. No significant beneficial effects were observed on NMSC incidence during the study period for selenium or vitamin E. Among more than 500 observed deaths (including 182 cancer-related deaths), there were also no significant treatment effects on total mortality, cancer-related mortality or arsenical cancer-related mortality. **Conclusions:** This large population-based trial does not support any beneficial effect of vitamin E or selenium supplementation for the primary prevention of NMSC or mortality in an arsenic-exposed population. With the rapidly increasing burden of preventable cancers in low- and middle-income countries, efficient and feasible chemoprevention study designs and approaches, such as employed in Bangladesh, may prove impactful in conceiving large scale cancer chemoprevention trials in low-resource settings. Clinical trial information: NCT00392561.

1512 Poster Discussion Session; Displayed in Poster Session (Board #170), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Multi-gene panel testing of patients with multiple primary malignancies suspected with hereditary cancer syndrome. *First Author: Gloria HJ Chan, National University Hospital, Singapore, Singapore*

Background: Developing multiple primary cancers is an indicator of underlying hereditary cancer predisposition, but there is a paucity of data regarding the characteristics and clinical genetic testing outcome of these patients. **Methods:** We compared cancer index patients with 1 vs > 1 primary malignancy who underwent evaluation and clinical testing with multi-gene panels comprising up to 49 genes in a cancer genetics clinic in a tertiary cancer centre in Asia from 1998-2016. **Results:** Among 1191 cancer index patients, 960 (80.6%), 205 (17.2%), and 26 (2.2%) respectively had 1, 2, and ≥3 primary malignancies. Among patients with > 1 primary cancers (n = 231), the most common cancer pairs were breast-breast (35.4%), breast-ovary (12.1%), endometrium-ovary (8.2%), colon-colon (2.4%) and, colon-endometrium (2.4%). The mean age at diagnosis of the first, second and third cancers were 46.0 (21 to 87), 52.1 (21 to 89) and 57.7 (41 to 83) respectively. The mean duration between first and second cancers is 6.0 years (0 to 32). The most commonly suspected syndromes in patients with 1 vs > 1 primary cancer were hereditary breast and ovarian cancer 63.8% vs 53.6%, Lynch 24.8% vs 31.1%, Li-Fraumeni syndromes 1.8% vs 1.7%, and others 9.3% vs 13.4% (p = 0.03). Patients with > 1 primary cancer were more likely to have > 20% a priori risk of suspected hereditary cancer syndrome (42.8% vs. 26.5%; p < 0.001). 504/1191 (42.3%) patients underwent gene testing, including 394/960 (41.0%) and 110/231 (47.6%) patients with 1 vs > 1 cancer. Deleterious mutations were more likely to be identified in patients with > 1 vs 1 cancer (34.5% vs. 25.8%; p = 0.073), with causative genes being BRCA1 38.5%, BRCA2 17.9%, MLH1/MSH2/MSH6 20.5%, TP53 7.7%, and others (ATM [n = 2], MUTYH, APC, PALB2, RAD51 [n = 1 each]) for patients with > 1 cancer. VUS rates were 31.7% vs.31.8% in patients with 1 vs > 1 cancer, and were identified in genes including BRIP1, CHEK2, PALLD, POLE, PTEN, STK11, SMARCA4, and VHL. **Conclusions:** Patients with > 1 primary cancer comprised one-fifth of cancer index patients evaluated at a cancer genetics clinic, and were more likely to be found with deleterious mutations than patients with only 1 cancer on multi-gene panel testing.

Routine tumor next-generation sequencing (NGS) to identify rare germline lung cancer risk mutations in EGFR and ERBB2. *First Author: Ruthia Chen, Dana-Farber Cancer Institute, Boston, MA*

Background: New insights into lung cancer genomics has required a new look at genetic determinants of inherited lung cancer risk. There are now four germline mutations in lung cancer oncogenes (EGFR T790M, V843I, R776H; and ERBB2 G660D) which have been reported in kindreds with a high prevalence of lung cancer in nonsmokers. We hypothesized that routine tumor NGS could be used to find rare kindreds with inherited lung cancer risk. **Methods:** An institute-wide database of tumor NGS results was queried for cases positive for one of the reported germline risk alleles in EGFR or ERBB2. At our center, tumor NGS is performed using a hybrid-capture platform spanning exons and key introns of ~400 cancer related genes, and is available for patients (pts) with consent to a research protocol. For living pts with a mutation detected at an allelic fraction (AF) > 25%, and excluding acquired T790M, genetic counseling and CLIA germline testing was provided. For pts with EGFR T790M, testing was performed on the INHERIT EGFR study (NCT01754025; ALCMI). **Results:** 51 cases were identified from a total of 13,488 cancers with NGS results: 45 with EGFR T790M (all lung cancer), 4 with EGFR R776H (NSCLC, endometrial cancer, and 2 glioma), 2 with ERBB2 G660D (NSCLC and glioblastoma). 34 pts with T790M detected after EGFR inhibitor were excluded, leaving 17 pts of interest. Germline testing was performed on 9 living pts with > 25% AF on NGS, and was positive in 8; 6 of these had germline EGFR T790M. Additionally, germline EGFR R776H was found in a never-smoker with metastatic endometrial cancer; she had a prior a history of NSCLC, and family history was notable for multiple members with lung, breast, and colon cancer. Germline ERBB2 G660D was found in a young never-smoker with metastatic NSCLC and a family history significant for lung cancer in multiple first-degree relatives. **Conclusions:** Rare germline lung cancer risk mutations in EGFR and ERBB2 can be identified on routine tumor NGS, and may indicate a risk of inherited lung cancer. Our study includes the second known report of a germline EGFR R776H or ERBB2 G660D mutations. Commercial germline NGS assays could be expanded to cover these rare but potentially high-penetrance variants.

Identification of putative germline mutations in 10,288 patients undergoing circulating tumor DNA testing. *First Author: Thomas Paul Slavin, City of Hope, Duarte, CA*

Background: No studies have yet described incidental detection of germline cancer predisposition mutations using circulating cell-free DNA (cfDNA). **Methods:** Deidentified cfDNA sequencing data from 10288 advanced cancer patients (pts) undergoing clinical circulating tumor DNA testing (Guardant360, 73 genes) were included in this study. CfDNA was extracted from plasma and quantified. A DNA library was prepared and sequenced to 15,000X average read depth. Using Ingenuity Variant Analysis, point mutations and small indels suspicious for germline origin (allele fraction 40-60%) were classified following American College of Medical Genetics and Genomics guidelines. **Results:** More than 50 cancer types were studied, including lung (40%), breast (20%), CRC (8%), prostate (6%), and pancreas (3%). Average age was 63.6 years (range:18-95), 42% were male. Of 34,873 putative germline variants identified, 520 (1.5%) were pathogenic or likely pathogenic (PV), 16,939 (49%) were of uncertain significance, and 17,414 (50%) were benign or likely benign. Of the 250 pts (2.4%) with hereditary cancer syndrome gene PVs, 83 were excluded due to high level of somatic tumor burden leaving 167 (1.6%) with putative germline PVs; rates were higher in pts <50 vs >50 overall (3.3% vs 1.4%, p=0.02) and in breast cancer pts (4.3% vs 1.5%, p=0.03). **Conclusions:** The observed frequency of incidentally identified putative germline PVs is expectedly lower than the true germline rate; however, these findings illustrate that detection from cfDNA is clinically feasible. Importantly, incidental germline findings could impact oncology treatment planning (e.g. PARP inhibitors for *BRCA1/2* mutations) and could benefit families via increased surveillance/primary prevention. Further research is needed to explore how to report potential germline results to clinicians using a systems-based approach.

Effects of gene penetrance on adherence to breast cancer screening recommendations (BCSR) among high-risk women. *First Author: Jacqueline Talea Desjardin, University of California, San Francisco, San Francisco, CA*

Background: Adherence to cancer screening depends on the interplay between risk perception and convenience. For instance, high perceived risk is likely what motivates high-risk mutation carriers (HRMC) to adhere well to rather inconvenient BCSR. While the NCCN offers BCSR for moderate-risk genes, adherence in moderate-risk mutation carriers (MRMC) and non-carriers with negative multigene panels (NC) is unknown. **Methods:** Screening behavior was examined in 120 women (15 HRMC, 20 MRMC, 85 NC) 20-65 years old (y) without cancer who received genetic testing and counseling. The groups did not differ in age or family history (fhx). Medical records were reviewed pre- and post-testing to determine adherence. Average follow up was 15 months. Data were analyzed by Chi-squared test. **Results:** Prior to genetic testing, 93% of women were adherent to general population BCSR, and 58% were already screening in accordance with post-test counseled BCSR. Testing altered adherence to counseled BCSR for HRMC (p<0.01), but not for MRMC (p=0.21) or NC (p=0.86). HRMC had better post-test adherence than MRMC (p<0.05). **Conclusions:** MRMC are often told to follow similar BCSR to HRMC, namely annual mammogram and MRI, but MRMC may be less motivated to adhere to these BCSR due to lower risk perception. We found adherence was high in HRMC, likely due to high risk perception; intermediate in NC, likely due to manageable BCSR; and comparably low in MRMC, possibly because their risk perception was insufficient to motivate biannual imaging studies. Understanding how genetic testing influences adherence is essential to ensuring proper surveillance in high-risk women.

Knowledge and understanding of genetic test results in men undergoing multigene testing for inherited prostate cancer. *First Author: Veda N. Giri, The Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

Background: Genetic counseling (GC) for prostate cancer (PCA) risk is an emerging field, with limited insights regarding needs of males considering genetic testing (GT). Genetic Evaluation of Men is a prospective multigene testing study to identify inherited mutations linked to PCA, with testing following GC. We surveyed men pre-GT and post-GT on knowledge of cancer risk and genetics (KCRG) and understanding of personal GT results to identify GC needs. **Methods:** Eligibility for males affected or high-risk for PCA encompass age, race, family history (FH), and PCA stage/grade. Demographic, clinical, and FH data were obtained from participants and medical records. Pre-GT survey included questions on KCRG (15 items) and health literacy/numeracy (6 items). Post-GT survey additionally included understanding of GT results (9 items). Personal and FH were categorized into three hereditary cancer syndromes (HCS) linked to PCA. Factors associated with baseline KCRG were assessed by univariable models followed by multivariable linear regression. McNemar's test was used to assess concordance of understanding GT results vs. actual results. **Results:** Among 109 men (mean age 63 years, 81% White, 59% PCA diagnosis) who completed pre- and post-surveys, factors associated with higher pre-test KCRG included meeting HCS criteria ($p = 0.006$) and higher numeracy ($p = 0.025$). On multivariable analysis, HCS remained significantly predictive of higher KCRG ($p = 0.040$). However, of 101 men who responded definitively regarding understanding of personal GT results, 13 responded incorrectly on mutation status indicating significant disagreement with actual results (McNemar's $p < 0.001$). Of these 13 men, 12 had $> = 1$ variant of uncertain significance (VUS). Additionally, 6 men were unsure whether they carried a mutation when their GT results found VUS but no mutations. **Conclusions:** This is the first report of knowledge and understanding of genetics and cancer risk in the context of multigene testing for PCA. While personal/FH of HCS was associated with higher KCRG, understanding of personal GT results was lacking, and warrants tailored GC strategies for multigene testing for inherited PCA.

Optimizing somatic genomic reporting and physician interpretation with web-based, interactive technologies. *First Author: Stacy W. Gray, City of Hope, Duarte, CA*

Background: The increased availability of tumor genomic profiling is revolutionizing oncology. However, the promise of precision care will not be realized if providers misinterpret complex genomic data. **Methods:** We created web-based, interactive reports with enhanced data visualization elements and embedded decision support for $>$ 300 gene panels. We conducted a randomized vignette-based survey study to determine whether exposure to the interactive reports, as compared to static reports, improves physicians' genomic understanding and report-based satisfaction. Overall comprehension and satisfaction scores were calculated across three vignettes (possible range 0-18 and 1-4 respectively, higher score correspond to improved endpoints). **Results:** 105 physicians at a major cancer center participated (29% participation rate); 67% medical, 20% pediatric, 7% radiation and 7% surgical oncology; 37% female. Prior to viewing the case-based vignette reports, 34% of physicians reported that they found it difficult to make treatment recommendations based on the standard report in their routine practice. After viewing the case-based vignettes, physicians' overall comprehension scores did not differ significantly by report type (mean score interactive 11.6 vs. static 10.5, difference = 1.1, 95% CI -0.3, 2.5, $p = 0.13$). However, physicians who viewed the interactive report were more likely to correctly assess sequencing quality ($p < 0.001$) and understand when reports needed to be interpreted with caution (e.g., if low tumor purity, $p = 0.02$). Overall satisfaction scores were significantly higher in the interactive group than the static group (mean score 2.5 vs. 2.1, difference = 0.4, 95% CI 0.2, 0.7, $p = 0.001$). Of the 92 physicians who endorsed the need for additional genomic support for providers, 66% reported that interactive genomic reports would be helpful. **Conclusions:** Interactive, genomic reports may improve physicians' ability to accurately assess genomic data and increase physician satisfaction. To advance the field, further research in representative provider populations is warranted and efforts to integrate interactive genomic reports into electronic health records are needed.

Multigene hereditary cancer testing in sarcoma patients. *First Author: Sarah A. Jackson, Genedx, Inc., a Wholly-Owned Subsidiary of Opko Health, Inc., Elmwood Park, NJ*

Background: In multi-gene hereditary cancer testing, multiple syndromes may be interrogated simultaneously, increasing the likelihood of detecting an underlying cancer predisposition. We characterized the yield and distribution of pathogenic or likely pathogenic variants (PV/LPV) in patients with a personal history of sarcoma undergoing panel testing through our clinical diagnostic laboratory. **Methods:** We retrospectively reviewed panel test results, demographic data, and personal/family history information from patients reporting a personal history of sarcoma. Patients included in this study underwent panel testing (NGS and del/dup) of up to 61 genes at this laboratory and concurrent or prior *TP53* analysis at this or an outside laboratory. Chi-square and Fisher's exact tests were used to compare groups. **Results:** Among 374 sarcoma patients, 53 (14.2%) harbored one or more PV/LPV in 14 genes: *TP53*, *BRCA2*, *CHEK2*, *BRCA1*, *ATM*, *MSH6*, *MLH1*, *NBN*, *BAP1*, *BRIP1*, *FLCN*, *MSH2*, *PTEN*, and *RB1*. Thirty-nine (10.4%) individuals reported both a personal and family history of sarcoma; however, PV/LPV were not more likely to be detected among this group than those with personal history alone ($p = 1.0$). PV/LPV were most often detected in *BRCA1/2* (15/374, 4.0%) or *TP53* (12/374, 3.2%). Notably, four probands with *BRCA1/2* PV/LPV reported a family history of sarcoma, including one kindred in which the variant was present in two brothers, both affected with sarcoma. Additionally, seven patients were found to have PV/LPV (1.9%) in genes causative for Lynch syndrome. Among patients with PV/LPV in genes other than *TP53,* nearly half (17/41, 41.5%) met National Comprehensive Cancer Network *TP53* testing criteria. **Conclusions:** The majority of PV/LPV were identified in genes for which association with sarcoma risk is not well-established. While several of these genes have been implicated in somatic pathways related to sarcoma development, it is unclear whether these germline findings are causative, play no role, or modify sarcoma risk. Although these data do not inherently associate non-*TP53* genes with sarcoma risk, they suggest a potential clinical benefit can be gained from performing hereditary cancer risk assessment and multi-gene panel testing in sarcoma patients.

The Angiosarcoma Project: Generating the genomic landscape of a rare cancer through a direct-to-patient initiative. *First Author: Corrie Painter, Broad Institute of MIT and Harvard, Cambridge, MA*

Background: Angiosarcoma (AS) is a rare soft tissue sarcoma, with an incidence of 300/yr and a 5-year DSS of 30%. The low incidence has impeded large-scale research efforts that may lead to improved clinical outcomes. To address this, we launched a nationwide study, which seeks to empower patients (pts) to accelerate research by sharing their samples and clinical information remotely. **Methods:** With pts and advocacy groups we developed a website to allow AS pts to participate across the US. Pts are mailed a saliva and blood draw kit for germline and cell free (cf) DNA analysis. We then obtain medical records and stored tumor samples. Whole exome sequencing will be performed on tumor, cfDNA and saliva samples. Transcriptome analysis will be performed on tumor samples. A clinically annotated genomic database will be generated and shared widely to identify genomic drivers and mechanisms of response and resistance to therapies. Study updates will be shared with pts regularly. **Results:** We conducted a 3-week pilot study to test the feasibility of enrolling geographically dispersed AS pts through a direct-to-patient (DTP) approach. Through social media, we identified 100+ pts willing to participate, 90 within the first day of outreach. We enrolled 15 pts from 10 states to test our ability to remotely obtain pt reported data, online consent, and samples. The average age of pts is 48, ranging 23-71 yrs. Primary locations of AS are breast 6 pts (40%), cardiac 4 pts (27%), scalp 2 pts (13%), liver 1 pt (6%), bladder 1 pt (6%), forehead 1 pt (6%). 9 pts (60%) reported being disease free, 4 pts (27%) reported having AS spread to lung, lymph, bone, and hip. Requests for medical records and tissue samples are underway, and initial saliva samples have been received. We are now opening this study to all AS pts in the USA. **Conclusions:** A DTP approach enabled rapid identification of an initial cohort of AS pts willing to share tumors, saliva, blood and medical records. We were able to obtain detailed clinical experiences and samples to perform genomic analysis. This study serves as proof of principle that DTP genomics efforts can democratize cancer research for exceedingly rare cancers, which to date have been disproportionately understudied.

Baseline screening and psychosocial results from the UK SIGNIFY study: A whole-body MRI screening study in *TP53* mutation carriers and matched controls. *First Author: Ros A. Eeles, The Institute of Cancer Research, Sutton, United Kingdom*

Background: In the United Kingdom, current screening guidelines for *TP53* germline mutation carriers solely recommends annual breast MRI, despite the wide spectrum of malignancies typically seen in this group. Some centres employ family specific screening with most centres having an "open-door" policy. Recent evidence suggests there may be a survival benefit with more intensive screening, including whole-body MRI. There are no published data on the psychological impact of such screening programmes. **Methods:** This study sought to investigate the role of one-off non-contrast whole-body MRI (WB MRI) in the screening of asymptomatic *TP53* mutation carriers aged over 18 years. Clinical and psychological endpoints were assessed. Scans were read by radiologists blinded to participant carrier status. The incidence of malignancies diagnosed in *TP53* mutation carriers against general population controls was calculated. The incidences of non-malignant relevant disease and irrelevant disease were measured, as well as the number of investigations required to determine relevance of findings. A series of questionnaires is used to assess the psychological impact of screening. **Results:** 44 *TP53* mutation carriers and 44 population controls were recruited. In *TP53* mutation carriers, six of 44 (13.6%, 95% CI: 5.2%-27.4%) participants were diagnosed with cancer during the study, all of which would be considered life threatening if untreated. Two were found to have two primary cancers. Two participants with cancer had abnormalities on the MRI which were initially thought to be benign (a pericardial cyst and a uterine fibroid) but transpired to be sarcomas. No controls were diagnosed with cancer. Fifteen carriers (34.1%, 95% CI: 20.5%-49.9%) and 7 controls (15.9%, 95% CI: 6.6%-30.1%) underwent further investigations following the WB MRI for abnormalities that transpired to be benign (p = 0.049). To date, there is no evidence of clinically significant adverse psychosocial effects. **Conclusions:** The cancer detection rate in this group justifies a minimum baseline non-contrast WB MRI in germline *TP53* mutation carriers. Clinical trial information: NCT01737255.

1521 Poster Session (Board #179), Mon, 1:15 PM-4:45 PM

Impact of *PIK3CA* tumor mutation on the association of aspirin or NSAID use and time to breast cancer recurrence. *First Author: Anne Marie McCarthy, Massachusetts General Hospital, Boston, MA*

Background: Aspirin or NSAID (A/N) use post diagnosis is associated with lower risk of breast cancer recurrence and mortality in cohort studies. A potential mechanism is that A/Ns may suppress cell growth and induce apoptosis in tumors driven by phosphatidylinositol 3 kinase (*PIK3CA*), the most common oncogene mutation in breast cancer. An interaction of A/Ns and *PIK3CA* mutation has been observed for colorectal cancer prognosis, but has not been studied in breast cancer. The objective was to assess time to breast cancer recurrence (TTR) with respect to A/N use and *PIK3CA* mutation. **Methods:** Patients with HR+/HER2- breast cancer treated at Massachusetts General Hospital in 2009-2014 who received tumor genotyping were included. *PIK3CA* mutations, including 8 common hotspot mutations, were assessed by a high-throughput tumor genotyping assay using DNA from formalin-fixed, paraffin-embedded tumor tissue. A/N use beginning 6 months post diagnosis through metastasis was extracted from electronic medical records using coded data and natural language processing. Patients with de novo metastatic disease or progressive disease within 6 months of primary diagnosis were excluded. TTR was estimated using Cox proportional hazards models. **Results:** Among breast cancer patients (N=212), 60 (28%) used A/Ns and 69 (33%) had *PIK3CA* mutation (see Table). After adjusting for age, stage, adjuvant endocrine therapy, radiation, and chemotherapy, A/N users had significantly longer TTR (HR=0.65 p=0.01). The association was similar for wild type (HR=0.58 p=0.01) and *PIK3CA* mutated tumors (HR=0.60 p=0.06), with no significant interaction of A/N use and *PIK3CA* (p=0.34). **Conclusions:** Among HR+ breast cancer patients, those who used A/Ns following primary diagnosis had longer TTR than non-users, regardless of tumor *PIK3CA* mutation status. The study provides a model for how tumor genomics could be integrated into secondary chemoprevention studies.

Time to recurrence adjusted for age, stage, treatment.

1522 Poster Session (Board #180), Mon, 1:15 PM-4:45 PM

Comparison of epigenetic aging in normal breast tissue from women with and without breast cancer. *First Author: Erin Wysong Hofstatter, Yale School of Medicine, New Haven, CT*

Background: Age is one of the most important risk factors for developing breast cancer. However, why increasing age is associated with increasing incidence of breast cancer remains poorly understood. We hypothesize that accumulated epigenetic alterations in the breast contribute to the development of breast cancer, and that such changes accumulate more rapidly in the breast during the lifetime of women who develop breast cancer as compared to their healthy peers. We therefore sought to identify an epigenetic pattern of accelerated breast tissue "aging" in women with breast cancer. **Methods:** Samples of normal breast tissue were collected from four cohorts of women: age $<$ 50 years with and without breast cancer, and age $\geq$50 years with and without breast cancer (BC). Samples were obtained from the Susan G. Komen Tissue Bank at IU Simon Cancer Center, reduction mammoplasties and adjuvant mastectomy specimens at Yale. The Illumina Human 450K BeadChip microarray was used to generate DNA methylation profiles. Data was analyzed using the "Epigenetic Clock", a published biomarker of aging based on 353 specific CpGs in the human genome. Clinical data collected for each subject included: age, height, weight, ethnicity, medical and reproductive history, tobacco and alcohol use, family history of breast cancer, current medications, and tumor characteristics. **Results:** Normal breast tissue samples from 90 subjects were analyzed (age $<$ 50 with BC = 22, age $<$ 50 without BC = 30, age $\geq$50 with BC = 15, age $\geq$50 without BC = 23). Age range was 24-82 years and 18-82 years for cohorts with and without BC respectively. In the cohort with BC, 95% of tumors were estrogen receptor-positive. Overall, DNA methylation tissue age (DNAmAge) was strongly correlated with chronologic age (r = 0.88, p $<$ 0.001). However, normal breast tissue from women with breast cancer demonstrated significantly accelerated DNAmAge as compared to healthy peers (p $<$ 0.001). **Conclusions:** Normal breast tissue from women with breast cancer demonstrates evidence of an accelerated epigenetic "aging" process. DNAmAge of normal breast tissue may prove to be a useful tool in identifying those women at highest risk, and lend insight into novel mechanisms of breast cancer prevention.

1523 Poster Session (Board #181), Mon, 1:15 PM-4:45 PM

Performance of mutation risk prediction models in a racially diverse multi-gene panel testing cohort. *First Author: Gregory Idos, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Mutation carrier prediction models are clinically useful tools for identifying candidates for genetic counseling and testing. Consensus guidelines recommend germline genetic testing for those with a carrier probability (CP) of approximately 5% or higher. However, prediction models may perform less well among racial/ethnic minorities. Our hypothesis is that pathogenic mutations (PM) are identifiable in a clinically meaningful fraction of racially/ethnically diverse patients with a CP of $<$ 5%. **Methods:** We conducted a multicenter prospective clinical trial of patients undergoing cancer-risk assessment using a 25 gene panel, which include *APC, ATM, BARD1, BMPR1A, BRCA1, BRCA2, BRIP1, CDH1, CDK4, CDKN2A, CHEK2, EPCAM, MLH1, MSH2, MSH6, MUTYH, NBN, PALB2, PMS2, PTEN, RAD51C, RAD51D, SMAD4, STK11, TP53*. Patients were recruited from August 2014 to November 2016 at three centers. Patients were enrolled if they met standard clinical criteria for genetic testing or were predicted to have a $\geq$2.5% probability of inherited cancer susceptibility using validated prediction models. We evaluated the CP of patients with a PM in *BRCA1*, *BRCA2*, and/or a mismatch repair (MMR) gene using the following models: (1) BRCApro, (2) MMRpro and (3) $PREMM_{1,2,6}$. **Results:** Of 2000 patients enrolled in this cohort, 80.6% are female (n = 1612). Regarding race/ethnicity, the cohort is 40.1% Non-Hispanic White (n = 802), 37.4% Hispanic (n = 748), 11.5% Asian (n = 230), 3.9% Black (n = 78), and 7.1% Other (n = 142). Among 241 (12.1%) patients who tested positive for a pathogenic mutation, 76 (31.5%) patients had a *BRCA1* or *BRCA2* mutation. Of those, 52 (68.4%) patients had a BRCApro CP of $<$ 5%. Thirty-eight (15.8%) patients had a pathogenic mutation in an MMR gene: 19 (50.0%) had an MMRpro CP of $<$ 5%, while 13 (34.2%) had a $PREMM_{1,2,6}$ CP of $<$ 5%. The racial/ethnic distribution of *BRCA1/2* or MMR mutation carriers is similar to that of the whole cohort. **Conclusions:** In a diverse cohort of patients undergoing 25-gene multiple-gene panel testing, half or more carriers of *BRCA1/2* or MMR mutations had a CP of $<$ 5%, the consensus guideline-recommended cutoff for genetic testing. These results support a lower threshold for genetic testing guidelines. Clinical trial information: NCT02324062.

1524 Poster Session (Board #182), Mon, 1:15 PM-4:45 PM

Prevalence of incidental germline pathogenic (PV) and likely pathogenic (LPV) variants in hereditary cancer-related genes identified in matched tumor/normal sequencing of advanced solid tumors. *First Author: Ecaterina Elena Ileana Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Next-generation sequencing (NGS) for tumor molecular profiling can reveal germline incidental mutations in hereditary cancer-related genes. The American College of Medical Genetics and Genomics (ACMG) has recommended that laboratories performing clinical sequencing seek and report PV and LPV in 56 genes. We assessed the prevalence of incidental germline LPV and PV in other cancer-related genes among patients undergoing hybrid capture sequencing of 201 cancer-related genes. **Methods:** Matched tumor and germline DNA NGS of a targeted panel of 201 genes was performed in 1000 patients (pts) with advanced or metastatic solid tumors enrolled in a molecular testing protocol (NCT01772771) in a research laboratory. We previously reported germline alterations in the putative most actionable genes as designated by ACMG (PMID: 26787237). We assessed the germline LPV and PV in 54 additional cancer-related genes. **Results:** Among the 1000 patients who underwent tumor and normal DNA sequencing, 37 patients (3.7%) were found to have a germline PV or LPV in the following genes: ATM (4); BAP1 (1); CDH1 (1); CDKN2A (1); CHEK1 (2); CHEK2 (10); EGFR (1); ERCC3 (4); ERCC5 (1); HNF1B (1); HRAS (1); MLL3 (1); NF1 (3); PKHD1 (4); PTCH1 (1) and SMARCA4 (1). Eight pts (22%) had previous genetic counseling and testing for various reasons, but only 3 pts (8%) had previously identified alterations (all with NF1 mutations). After discussion in our return of germline results board, it was decided to return the findings in established hereditary cancer predisposition genes with high penetrance: BAP1 (p.Y401X), CDH1 (p.C688X), CDKN2A (p.G101W), EGFR (p.T790M) and SMARCA4 (p.S332FfsX55) after validation in a CLIA laboratory. **Conclusions:** Return of the previously unrecognized germline LPV or PV in patients with advanced or metastatic cancers who undergo somatic profiling is of great interest. The exact genes for which the germline results should be returned is controversial. Broader genomic testing is likely to identify additional incidental germline alterations with potential clinical utility to patients and their relatives.

1525 Poster Session (Board #183), Mon, 1:15 PM-4:45 PM

Expanded yield of multiplex panel testing in fully accrued prospective trial. *First Author: Gregory Idos, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Genetic testing is a powerful tool for stratifying cancer risk. Multiplex gene panel (MGP) testing allows simultaneous analysis of multiple high- and moderate- penetrance genes. However, the diagnostic yield and clinical utility of panels remain to be further delineated. **Methods:** A report of a fully accrued trial (N = 2000) of patients undergoing cancer-risk assessment. Patients were enrolled in a multicenter prospective cohort study where diagnostic yield and off-target mutation detection was evaluated of a 25 gene MGP comprised of *APC*, *ATM*, *BARD1*, *BMPR1A*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CDK4*, *CDKN2A*, *CHEK2*, *EPCAM*, *MLH1*, *MSH2*, *MSH6*, *MUTYH*, *NBN*, *PALB2*, *PMS2*, *PTEN*, *RAD51C*, *RAD51D*, *SMAD4*, *STK11*, *TP53*. Patients were enrolled if they met standard testing guidelines or were predicted to have a ≥2.5% mutation probability by validated models. Differential diagnoses (DDx) were generated after expert clinical genetics assessment, formulating up to 8 inherited cancer syndromes ranked by estimated likelihood. **Results:** 1998/2000 patients had reported MGP test results. Women constituted 81% of the sample, and 40% were Hispanic; 241 tested positive for at least 1 pathogenic mutation (12.1%) and 689 (34.5%) patients carried at least 1 variant of uncertain significance. The most frequently identified mutations were in *BRCA1* (17%, n = 41), *BRCA2* (15%, n = 36), *APC* (8%, n = 19), *CHEK2* (7%, n = 17), *ATM* (7%, n = 16). 39 patients (16%) had at least 1 pathogenic mutation in a mismatch repair (MMR) gene (*MLH1*, n = 10; *MSH2*, n = 10; *MSH6*, n = 8; *PMS2*, n = 11). 43 individuals (18%) had *MUTYH* mutations – 41 were monoallelic. Among 19 patients who had mutations in *APC* – 16 were *APC* I1307K. Only 65% (n = 159) of PV results were included in the DDx, with 35% (n = 86) of mutations not clinically suspected. **Conclusions:** In a diverse cohort, multiplex panel use increased genetic testing yield substantially: 35% carried pathogenic mutations in unsuspected genes, suggesting a significant contribution of expanded multiplex testing to clinical cancer risk assessment. The identification of off-target mutations broadens our understanding of cancer risk and genotype-phenotype correlations. Follow-up is ongoing to assess the clinical utility of multiplex gene panel testing. Clinical trial information: NCT02324062.

1526 Poster Session (Board #184), Mon, 1:15 PM-4:45 PM

NGS-based multi-gene panel analysis in *BRCA1/2*-negative breast and ovarian cancer families. *First Author: Esther Pohl, Center for Familial Breast and Ovarian Cancer and Center for Integrated Oncology (CIO), Medical Faculty, University of Cologne and University Hospital Cologne, Cologne, Germany*

Background: 24% of familial breast cancer (BC) and/or ovarian cancer (OC) cases analyzed within the framework of the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC) are due to pathogenic mutations in the *BRCA1* or *BRCA2* genes. The population-specific mutation prevalence of non-*BRCA1/2* genes associated with familial BC and/or OC is largely unknown and was determined in a large German cohort. **Methods:** Here, we present next-generation sequencing (NGS) data established from TruRisk (GC-HBOC-designed) or TruSight cancer gene panels. A cohort of 6,507 *BRCA1/2*-negative index cases fulfilling the inclusion criteria of the GC-HBOC for germline testing was analyzed. Illumina sequencing platforms were used and data analysis was carried out at each individual center using different analysis pipelines. Analysis of copy number variations (CNV) was not included in the present data evaluation. **Results:** By focusing on 8 confirmed BC/OC risk genes (*ATM, CDH1, CHEK2, NBN, PALB2, RAD51C, RAD51D, TP53*), the 6,507 cancer patients revealed 165 different deleterious variants in 378 unrelated mutation carriers (5.8%). We found a high prevalence of *CHEK2* (n = 150, 2.3%), *ATM* (n = 89, 1.4%), and *PALB2* (n = 72, 1.1%) mutations while *RAD51C* (n = 21, 0.3%), *TP53* (n = 16, 0.2%), *NBN* (n = 15, 0.2%), *CDH1* (n = 10, 0.2%), and *RAD51D* (n = 5, 0.1%) were less frequently mutated. **Conclusions:** The high frequency of pathologic mutations in the genes *ATM, CDH1, CHEK2, NBN, PALB2, RAD51C, RAD51D,* and *TP53,* together accounting for almost 6% of familial BC/OC risk, highlights the importance of these genes to be included in BC/OC routine diagnostics. The relevance of these mutations in a clinical setting for early detection of breast and ovarian cancer needs to be established.

1527 Poster Session (Board #185), Mon, 1:15 PM-4:45 PM

PALB2 mutations in high-risk women with breast or ovarian cancer. *First Author: Kelly A. Metcalfe, University of Toronto, Toronto, ON, Canada*

Background: In Canada, genetic testing for *BRCA1* and *BRCA2* is available free of charge to women who meet eligibility criteria, based on personal and family history of cancer. Less than 10% of women are identified with a *BRCA* mutation, despite features of hereditary cancer. *PALB2* has been identified as a moderate penetrance gene in various populations. In the current study, we examined the frequency of *PALB2* mutations in women with breast or ovarian cancer who met criteria for genetic testing for *BRCA1* and *BRCA2*and tested negative. **Methods:** DNA samples from women with breast or ovarian cancer, who met criteria for provincial *BRCA1* and *BRCA2* genetic testing and tested negative between the years of 2007 and 2014 were included in this study. All 13 coding exons of *PALB2* plus 20 base pairs from the exon boundaries were amplified using Wafergen SmartChip technology. The amplified DNA were paired-end sequenced at 2x250 cycles using an Illumina MiSeq sequencer. **Results:** 2,225 women with breast cancer and 429 women with ovarian cancer were tested for *PALB2* mutations. No *PALB2* mutations were found in women with ovarian cancer. Seventeen deleterious *PALB2* mutations were detected in women with breast cancer (0.8%). The frequency of *PALB2* mutations was significantly higher in women with bilateral breast cancer (2.4%) compared to women with unilateral breast cancer (0.6%) (p = 0.01). There was no significant difference in age at diagnosis between those with and without a *PALB2*mutation (50.9 years vs 53.8 years; p = 0.34). **Conclusions:** Genetic testing for *PALB2* should be considered for high-risk women with breast cancer, especially those who present with bilateral breast cancer. However, *PALB2* does not appear to contribute to ovarian cancer which has implications for counselling women who are identified with a *PALB2* mutation.

1528 Poster Session (Board #186), Mon, 1:15 PM-4:45 PM

Pathogenic germline mutations in emerging cancer genes: What happens after panel testing? *First Author: Evan Thomas Hall, Stanford University School of Medicine, Stanford, CA*

Background: Next-generation sequencing technology enables more comprehensive germline genetic testing, including genes whose cancer risks are less well-characterized (particularly among patients with less striking family histories). Little is known about patient outcomes, particularly adherence to risk-reducing recommendations and family testing. **Methods:** We attempted a phone interview ≥3 times with each adult patient who had a germline pathogenic or likely pathogenic mutation found in an emerging cancer gene (defined as any gene other than *BRCA1/2* or the Lynch Syndrome genes *MLH1, MSH2/6, PMS2*) at a single academic cancer genetics clinic from January 2013-July 2016. **Results:** Of 143 eligible patients, 53 (37%) were successfully contacted and all consented to participate. Median follow-up was 677 days (range 247–1401) and age was 52 years (21-82). Two-thirds (68%) had personal cancer history and 93% had a first-degree relative with cancer. Mutations in genes associated with named syndromes (*APC*=5, *CDH1*=3, *TP53*=3, *PTEN*=2) were found in 23% (many of whom lacked family history typical of these syndromes) whereas 77% had mutations in less well-characterized genes (*MYH*=10, *CHEK2*=10, *ATM*=6, *PALB2*=6, *NBN*=3, *RAD51C*=2, *RAD51D*=2, *SDHB*=1, *CDKN2A*=1, *MRE11A*=1, *RAD50*=1, *FLCN*=1). **Conclusions:** Two years after panel testing, patients with germline mutations in less well-characterized genes reported high rates of adherence to recommendations, family communication and testing. Limitations include a relatively low response rate and a single academic center; this may bias toward a "best-case" scenario. Larger, population-based studies will be crucial to understand the real-world outcomes of germline multiple-gene panel testing and its contribution to precision oncology.

Patient-reported experiences (N=53)	N (%)
Any risk-reducing intervention recommended (change in screening, preventive surgery, chemoprevention)	48 (84%)
Change in screening recommended	46 (81%)
Preventive surgery recommended	8 (14%)
Chemoprevention recommended	6 (11%)
Patient adhered to recommendations	45 (79%)
Patient shared genetic results with ≥1 relative	52 (91%)
≥1 relative had genetic testing based on patient's results	36 (63%)

1529 Poster Session (Board #187), Mon, 1:15 PM-4:45 PM

Pathogenicity of mutation analyzer (PathoMAN): A fast automation of germline genomic variant curation in clinical sequencing. *First Author: Vijai Joseph, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A challenge in clinical oncology is interpretation of multiplexed gene sequencing of patients at risk. The plethora of variants to be curated for pathogenicity or actionability poses a growing burden for cancer care professionals. Current guidelines by the ACMG requires the aggregation of multiple lines of genomic data evidences from diverse resources. A computational tool that automates, provide uniformity and significantly speed the interpretive process is thus necessary. **Methods:** The *Pathogenicity of Mutation Analyzer* (PathoMAN), is a tool that automates germline genomic variant curation from clinical sequencing based on ACMG guidelines. PathoMAN aggregates multiple tracks of genomic, protein and disease specific information from public sources such as ClinVar, ExAC, UniProt, 1000 genomes, dbNSFP and locus specific databases. Variant specific and gene specific annotations are used to classify variants to model the ACMG rubric. We analyzed 2500 manually curated and classified, high quality variants in 180 genes from 3 large, published studies to quantify the performance of PathoMAN; analyzing 242 pathogenic/likely pathogenic (P/LP), 1272 benign/likely benign (B/LB) and 1261 variants of uncertain significance (VUS). We report the summary of PathoMAN classifications in four categories contrasted against the manual curation. **Results:** PathoMan achieves an average of 75% concordance and 1.5% discordance for P/LP mutations and 60% and 0.1% for B/LB variants. PathoMAN is able to resolve 12% of reported VUS as either P/LP or B/LB. It loses resolution to classify 25% of P/LP and B/LB variants due to lack of information and due to inconsistencies in available data from public resources. **Conclusions:** PathoMAN provides a breakthrough in rapid classification of genetic variants by generation of robust models using a knowledgebase of diverse genetic data. It is easily accessible, web-based resource that allows the community to rapidly test a large number of variants for pathogenicity. Such bioinformatic tools are essential to reduce manual workload of a domain level experts. We propose, a new nosology for the 5 ACMG classes to facilitate better reporting to ClinVar.

1530 Poster Session (Board #188), Mon, 1:15 PM-4:45 PM

Germline mutations of PALB2 gene in a sequential series of Chinese patients with breast cancer. *First Author: Jiaojiao Zhou, Department of Surgical Oncology, the Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: PALB2 (Partner and Localizer of BRCA2) is recently recognized as a breast cancer predisposition gene, which plays a critical role in genome maintenance via interacting with BRCA1/2 and RAD51 when DNA break. Germline loss-of-function mutations in PALB2 lead to increased breast cancer risk. Since the germline mutation frequency of PALB2 is much less than BRCA1/2, the distinct mutation spectrum of PALB2 is still obscure. Therefore, we assessed the mutational frequency, spectrum and predictors of the PALB2 gene in a sequential series of Chinese breast cancer patients from our Research DNA Bank, to verify the utility of PALB2 genetic testing in Chinese population. **Methods:** We examined Chinese breast cancer cases (n = 2279) who agreed to participate in research DNA banking, recruited from 1990 through 2016. To identify the mutations, complete coding sequence and intron–exon boundaries of PALB2 were screened with Next Generation Sequencing. Personal and family histories were synchronously collected for mutation identification. **Results:** Among the 2279 breast cancer patients, 307 patients were familial breast cancer cases and the rest 1972 patients were sporadic breast cancer cases. PALB2 mutation carriers accounted for 7.8% (n = 24) and 4.8% (n = 95) in familial and sporadic breast cancer cohort separately. In total, 31 missense, 4 nonsense, 3 frameshift, 3 splicing and 1 codon mutations of PALB2 were identified in this study. Among the pathologic variants, PALB2 c.1744C > T, c.2748+1G > A, c.2749-1G > C, c.3114-1G > A were newly identified in sporadic breast cancer, and c.3271delC newly found in familial breast cancer. Based on in silico analysis, a total of 6 potential damaging missense variants were novelly found in this study, among which the PALB2 c.3035C > T was detected in both sporadic and familial breast cancer. **Conclusions:** Our data presents the germline mutation status of PALB2 in Chinese patients with breast cancer, suggesting that loss-of-function germline mutations of PALB2 are important in both familial and sporadic breast cancer. Clinically, this information may be helpful in genetic counseling of breast cancer patients with PALB2 germline mutation.

1531 Poster Session (Board #189), Mon, 1:15 PM-4:45 PM

Clinical implementation of whole genome multi-omics analyses for patients with refractory cancers. *First Author: Milan Radovich, Indiana University School of Medicine, Indianapolis, IN*

Background: Relative lack of prior success of genomic technology has been a function of suboptimal target detection and poor timely implementation. We set out to improve patient access to targeted therapy through use of whole genome sequencing (WGS) to optimize targets and operational implementation to identify clinical trials and secure off-label drugs. **Methods:** We performed a retrospective analysis of our first 100 patients (Feb-Nov 2016) with metastatic disease whose tumors and matched blood were analyzed using whole genome (WGS) and transcriptome sequencing, as well as targeted proteomic analysis in a CLIA setting (NantOmics). Most common tumor types were Colorectal (20%), Breast (15%), and Ovarian (10%). Patients were seen in dedicated precision genomics clinics with results reviewed by a multi-disciplinary molecular tumor board. A dedicated service line with staff to match patients to clinical trials, medication acquisition, and genetic counseling for germline findings was provided. **Results:** 85% of patients had a finding either on WGS or proteomic analysis that pointed to an FDA approved drug or clinical trial. Common findings included: mutations in the PI3K pathway (15%), BRCA1&2/ATM (15%), and cell cycle genes (11%). Other markers of note include: HER2, TMB/MSI for immune checkpoint therapy, IDH1/2, and MET. WGS also enabled identification of rare actionable findings, particularly translocations, and viral integration for trials requiring HPV-positivity. Cancer predisposition germline findings were observed in 3 patients. Of the 85 patients with actionable findings, 22 went on to be treated with a genomically-directed agent, 13 did not follow recommendations or were sent to hospice, 4 were lost to follow-up, and 46 still remain on their therapy prescribed prior to sequencing. **Conclusions:** A higher proportion of patients in our program went on to be treated with a genomically-directed agent than previously reported in the literature secondary to comprehensive whole genome multi-omics profiling and a clinical service line dedicated to medication acquisition and matching to clinical trials.

1532 Poster Session (Board #190), Mon, 1:15 PM-4:45 PM

Multi-gene hereditary cancer testing among men with breast cancer. *First Author: Krystal Brown, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

Background: All men with a personal diagnosis of breast cancer (BC) are candidates for *BRCA1/2* genetic testing, as pathogenic variants (PVs) in these genes have a known association with BC risk in both men and women. As additional genes with known BC risk in women are now routinely included in multi-gene panel testing, we evaluated the outcomes of multi-gene panel testing in a large cohort of men with BC. **Methods:** This analysis includes the results of commercial genetic testing for 1,358 men with BC usinga multi-gene pan-cancer panel between September 2013 and January 2017. Clinical information was obtained from provider-completed test request forms. Age at diagnosis, personal, and family history were compared for men with PVs in *BRCA1/2* versus non-*BRCA1/2* genes. **Results:** Overall, 207 (15.2%) men with BC were found to carry a PV, where 147 (10.8%) men had a PV in *BRCA1/2* (*BRCA1*, 0.7%; *BRCA2*, 10.2%) and 60 (4.4%) men had a PV in a non-*BRCA1/2* gene (*CHEK2*, 2.0%; *ATM*, 1.0%; *PALB2*, 1.0%; *BARD1*, 0.2%; *NBN*, 0.2%; *MSH6*, 0.1%; *BRIP1*, 0.1%; *CDH1*, 0.1%; *CDKN2A*, 0.1%; *MLH1*, 0.1%, *TP53*, 0.1%). There were no substantial differences in the median age-at-diagnosis for men without a PV (65) compared to those with a *BRCA1/2* PV (66) or a non-*BRCA1/2* PV (63). Prostate cancer was the most common additional malignancy among all men with BC (9.0%), with a similar incidence among men with a *BRCA1/2* PV (9.2%) and a non-*BRCA1/2* PV (8.3%). In addition, 1.4% of men with a *BRCA1/2* PV and 3.3% of men with a non-*BRCA1/2* PV had a second BC. A family history of breast and/or ovarian cancer was present in 44.4% of the testing cohort, 66.7% of men with a *BRCA1/2* PV, and 48.3% of men with a non-*BRCA1/2* PV. This is consistent with the relative penetrance of *BRCA1/2* and other genes included here. There were no other substantial differences in family history among *BRCA1/2* PV carriers versus non-*BRCA1/2* PV carriers. **Conclusions:** Close to a third of all PVs identified here in men with BC were in a gene other than *BRCA1/2*. There were no obvious differences in the clinical presentation of men with a *BRCA1/2* PV compared to men with a PV in another gene or no PV at all. Collectively, this suggests that multi-gene panel testing is appropriate for all men with BC, regardless of other personal or family history.

1533 Poster Session (Board #191), Mon, 1:15 PM-4:45 PM

Underutilization of multigene panels among Ashkenazi Jewish patients. *First Author: Jessica Fields, New York Presbyterian Hospital, Weill Cornell Medical Center, New York, NY*

Background: Approximately one in forty Ashkenazi Jewish (AJ) individuals carry a *BRCA1/2* mutation and genetic screening in this population has largely focused on these two genes. With the recent rapid uptake of multigene panel testing for cancer genetic assessment, we sought to explore multigene panels in our cohort which is comprised of AJ and non-AJ patients. **Methods:** The results of all patients with known ancestry who underwent genetic testing and counseling at the hereditary breast and ovarian cancer center at a single institution between 7/1/2013-12/31/2016 were reviewed. **Results:** One thousand six hundred and fifty patients with known ancestry underwent genetic testing over the study period, including 681 AJ patients. The median age was 49 (range 20-86). AJ patients were more likely to undergo targeted testing than non-AJ patients (74% vs. 61 %, $P<0.001$). The use of multigene panels in AJ patients increased over time (2013 – 3.2%, 2014 – 18.7%, 2015 – 27.4%, 2016 – 48.4%, $P<0.001$). Mutations were more common in AJ patients (75, 11% vs. 66, 7%, $P=0.003$). Variants of uncertain significance (VUS) were less common in AJ patients (40, 6% vs. 124, 13%, $P<0.001$), even when excluding patients with single gene testing (32, 19% vs. 98, 27%, $P=0.05$). Among all patients, mutations in *BRCA1/2* were most common (75%). The majority (69%) of non-*BRCA1/2* mutations were identified on multigene panels. Rates of mutations in non-*BRCA*1/2 genes were the same among AJ and non-AJ patients (16, 21% vs. 20, 30%, $P=0.3$, Table 1). **Conclusions:** AJ patients have equivalent rates of non-*BRCA1/2* mutations and on multigene panels have lower rates of VUS compared to non-AJ patients. However, the majority of AJ patients underwent targeted gene testing. These findings suggest consideration of a change in paradigm for genetic assessment of AJ patients with a focus on *BRCA* and non-*BRCA*associated cancer genes through multigene panel testing.

Mutation frequency among Ashkenazi and non-Ashkenazi Jewish patients.

Gene	AJ Patients N (%)	NonAJ Patients N (%)
APC	3 (4)	1 (1%)
ATM	0 (0%)	4 (6%)
BRCA1	34 (46%)	20 (30%)
BRCA2	25 (34%)	27 (40%)
CHEK2	7 (9%)	12 (18%)
FANCC	3 (4%)	0 (0%)
MSH6	1 (1%)	0 (0%)
PALB2	0 (0%)	1 (1%)
PMS2	0 (0%)	1 (1%)
PTEN	0 (0%)	1 (1%)
RAD51D	1 (1%)	0 (0%)

1534 Poster Session (Board #192), Mon, 1:15 PM-4:45 PM

Knowledge outcomes in a randomized trial of telephone vs. in-person disclosure of genetic testing: The COGENT study. *First Author: Nina Beri, University of Pennsylvania, Philadelphia, PA*

Background: Telephone disclosure (TD) of genetic testing is non-inferior to in-person disclosure (IPD) for most outcomes but did not meet non-inferiority for knowledge change. We sought to understand which concepts patients don't understand and factors associated with lower knowledge. **Methods:** Patients were recruited to a multi-center, randomized trial (NCT01736345) comparing TD to IPD of genetic test results. 819 patients were randomized (IPD = 418; TD = 401); 165 declined randomization and requested IPD. Knowledge was assessed after pre-test counseling (V1) and test disclosure (V2). **Results:** There were no significant differences in genetic or multi-gene (MG) knowledge between disclosure groups after V1 and V2. On average, patients answered 73% (SD 1.19) of genetic knowledge and 57% (SD 1.78) of mg knowledge items correctly.After V1, most understood implications of a positive result (87%), that results are not deterministic (84%) and risks for their children (91%). Understanding of uninformative negative, true negative and variant of uncertain significance (VUS) results was lower (post-V1: 33%, 65%, 29%; post-V2 : 37%, 65%, 25%). In multivariable analyses, lower genetic knowledge after V1 was associated with study site, being older ($p < 0.01$), single ($p < 0.01$), non-white ($p < 0.01$), not Ashkenazi Jewish ($p = 0.01$), and not having a mutation in the family ($p = 0.03$), having more relatives with cancer ($p < 0.01$) and not graduating college ($p < 0.01$). Lower mg knowledge after V1 was associated with site and being non-white ($p = 0.01$). Lower genetic knowledge after V2 was not associated with disclosure method but associated with study site, being older ($p < 0.01$), not graduating college ($p < 0.01$) and being non-white ($p < 0.01$). Lower mg knowledge after V2 was only associated with not graduating college ($p = 0.02$). **Conclusions:** While there were no significant differences in genetic knowledge by disclosure method, understanding of several concepts (e.g. VUS and negative results) were lower regardless of arm. Several factors, including age, education and race/ethnicity were associated with lower knowledge. Interventions to improve genetic knowledge in real-world and diverse populations are needed. Clinical trial information: NCT07136345.

1535 Poster Session (Board #193), Mon, 1:15 PM-4:45 PM

Novel germline risk loci in familial melanoma (FM). *First Author: Esther Kazlow, New York University School of Medicine, New York, NY*

Background: While about 10% of cutaneous melanoma (CM) clusters in families, known high-risk loci explain not more than 40% of expected inherited risk. Besides the most frequently mutated genes in FM (e.g. *CDKN2A*), it is estimated that the remaining 60% of FM susceptibility is due to the interaction of environment with specific pools of rare known loci and yet unknown high-risk genes. In our study, we report the discoveries of novel germline genetic risk factors in FM in a recently developed FM cohort at New York University Langone Medical Center (NYULMC) consisting of CM and multiple primary melanomas (MPM) of Ashkenazi Jewish (AJ) and non-AJ European ancestries. **Methods:** As part of an ongoing ascertainment of FM at NYULMC, we assessed the status of *CDKN2A* mutations using Sanger sequencing, examining the coding regions of 47 AJ FM families and 81 non-AJ FM kindreds. In high-risk mutation-negative families, we applied whole-exome sequencing (WXS) and an innovative hot-spot mutational analysis of non-coding regions to identify novel high-risk loci associated with FM susceptibility. **Results:** We found that frequencies of *CDKN2A* deleterious mutations in our FM cohort (13%) are comparable with observations from previous studies. We have also identified a specific *CDKN2A* coding mutation in FM kindreds of AJ ancestry, which is particularly interesting as *CDKN2A* mutations in AJ cohorts have been sparsely reported in prior studies. The WXS/targeted non-coding sequencing of mutation-negative families identified putatively deleterious mutations in regulatory regions in the vicinity of several novel loci, including *SMAD4* and *PAX8*, co-segregating in FM kindreds. **Conclusions:** Our unique FM ascertainment, including > 50% AJ kindreds, provides an excellent platform for mapping high-risk genetic susceptibility in FM. Novel deleterious mutations identified in non-coding regulatory regions of *SMAD4* and *PAX8* genes, some with increased frequency in AJ families, suggest a need for a more thorough investigation of the non-coding genome using a founder FM population, as we propose here. As our ongoing ascertainment expands, we are pursuing validation of our observations through comprehensive sequencing efforts.

1536 Poster Session (Board #194), Mon, 1:15 PM-4:45 PM

Localization of non-receptor tyrosine kinase (nRTK) variants in solid tumor patients using next-generation sequencing (NGS). *First Author: Srishti Sareen, Department of Internal Medicine, The University of Tennessee Health Science Center, Memphis, TN*

Background: Non-synonymous SNPs (nsSNPs) in nRTKs may serve as oncologic targets and predictive biomarkers, with significant lesions described in various nRTK regions including the tyrosine kinase domain (TKD). NGS allows the entire coding sequence to be evaluated, facilitating the identification of novel lesions. **Methods:** We searched all nsSNPs in 14 nRTKs in the tumors of patients (pts) at our institution that received NGS with Caris from 2013-2015 with a diagnosis of advanced breast, colon or lung cancer. Substitutions were classified as either within or extra-TKD; in the case of *JAK1-3*, pseudokinase domain lesions were also identified. In order to predict the pathogenicity of nsSNPs, *in silico* analysis with PolyPhen-2 (Harvard) was completed. **Results:** 356 pts (79 breast, 110 colon and 165 lung (156 NSCLC, 11 small cell)) were identified with a median age of 61 years (range 26-86); 58% female; 62% white, 35% black. 245 variants were found, with 200 nsSNPs and 45 known pathologic mutations (Pmut); Pmut were *PIK3CA* (21 breast, 13 colon, 5 NSCLC) and *AKT1* (6 breast). 169/356 (47%) pts had ≥1 nRTK lesion (0-8). 52/200 (26%) nsSNPs were predicted-damaging (pnsSNPs) with *in silico* analysis among 49 pts (6 breast, 13 colon and 30 NSCLC). pnsSNPs were found in 14/14 nRTKs with median 3 (1-10). The most frequently mutated nRTKs in breast were *SRC* (2/2 variants were pnsSNPs) and *ABL2* (1/5); in colon *ABL1* (5/10), *JAK3* (3/27) and *CDK12* (2/8); and in NSCLC *JAK3* (6/20), *BTK* (5/8), *ABL1* (3/12), *JAK2* (3/11), *CDK12* (3/9) and *JAK1* (3/3). Of 180 nsSNPs with *in silico* results, 68% were extra-TKD (29/122 variants were pnsSNPs), 23% within the TKD (13/42) and 9% in pseudokinase domains of *JAK1-3* (10/16). Notably, 8/10 pseudokinase domain pnsSNPs were in NSCLC pts (3 *JAK1*, 2 *JAK2* and 3 *JAK3*). **Conclusions:** > 13% solid tumors held an nRTK nsSNP that was predicted-damaging by *in silico* analysis, with 69% of these mutations occurring outside of the TKD-proper. Further work is needed to determine how these pnsSNPs affect function and if they are clinically actionable.

1537 Poster Session (Board #195), Mon, 1:15 PM-4:45 PM

The frequency of a novel *KANK1* and *NTRK3* translocation and BRAF^{V600E} mutation in patients diagnosed with metanephric adenoma utilizing molecular mechanisms. *First Author: Aida Catic, ACL Laboratories, Department of Cytogenetics, Rosemont, IL*

Background: Renal metanephric adenoma (MA) is a very rare benign renal tumor, which is frequently misclassified when microscopic features alone are applied. Despite the classification of adenoma as a benign tumor, it is difficult to differentiate from other renal carcinomas such as malignant papillary renal cell carcinomas and in children it can be mistaken with Wilms tumor. The correct classification of a renal tumor is critical for diagnostic, prognostic, and therapeutic purposes. Despite the advancements in cancer genomics, there is limited data available regarding the genetic alterations critical to the metanephric adenoma development. Recent data suggest that 90% of MA have *BRAF*^{V600E}mutations; the genetics of the remaining 10 % are unclear. **Methods:** This study was conducted on 13 FFPE specimens from patients who were diagnosed with renal metanephric adenoma. H&E stained slides from all cases were reviewed by study pathologist, and representative tissue blocks were further selected for *BRAF*^{V600E} sequencing and fluorescent *in situ* hybridization was adapted to detect chromosomal rearrangement between *KANK1* on chromosome 9 (9p24.3) and *NTRK3* on chromosome 15 (15q25.3). **Results:** In this study, we identified a novel chromosomal translocation t(9;15)(p24;q24) between *KANK1* and *NTRK3*, and provided new insights into molecular mechanisms which might identify a subset of metanephric adenomas. Such findings imply that recurrent cytogenetic aberrations may be of prognostic significance as well. Interestingly, our data suggested mutual exclusivity of *BRAF*^{V600E}and t(9;15) aberrations. **Conclusions:** Molecular and cytogenetic analyses have allowed us to elucidate a genetic aberration, which may be specific to metanephric adenoma. Aberrant expression of the *KANK1-NTRK3* gene fusion may be one mechanism by which functionally relevant genes are altered in the development of metanephric adenoma, and thus mark a subgroup of metanephric adenomas with particular clinicopathological features. Also, our study adds *KANK1* and *NTRK3* to the list of candidate genes that may play a role in the 10% of renal metanephric adenomas that lack a *BRAF*^{V600E} mutation.

1538 Poster Session (Board #196), Mon, 1:15 PM-4:45 PM

A clinical and genomic profile of inflammatory myofibroblastic tumors. *First Author: Sugganth Daniel, Foudation Medicine, Inc., Morrisville, NC*

Background: Inflammatory Myofibroblastic Tumors (IMT) are tumors that morphologically traverse the neoplastic and inflammatory realms. With a predilection for children and young adults, many patients present with systemic symptoms and the tumors demonstrate local invasiveness and even metastasis. IMTs are composed of fascicles of myofibroblastic spindle cells with a marked lymphoplasmacytic infiltrate. **Methods:** Integrated genomic profiling of DNA and RNA from IMTs in 30 patients was performed using a hybrid capture, paired-end NGS sequencing method and customized pipeline analysis. **Results:** 23 patients were children or young adults (< 30y), overall the age ranged from 7 months to 72 years. The tumor was clinically aggressive in 10 patients; 3 metastatic, 5 multifocal and 2 locally invasive. Epithelioid morphology was documented in 2 cases, one demonstrated the ALK-RANBP2 fusion. ALK rearrangements were detected in 13 patients, with 7 different fusion partners. ALK IHC or FISH was performed in 23 patients and were all concordant with the genomic results. 22 gene fusions were detected in 21 patients, 4 tumors had ROS1-TFG fusions, 2 had NTRK3-ETV6 fusions. 3 had novel fusions in JAK1-PML, PDGFRB-NOTCH1 and MUTYH-TESK2 respectively. Intact tyrosine kinase domains (TKD) in JAK1 are transposed to the promoter coiled-coil motif in PML, in the rearrangement. While the TKDs are preserved in the PDGRB and TESK2 rearrangements, the functional roles of their partners are yet to be elucidated. The prevalence of rearrangements was higher in patients below 30 years of age (20/23) compared to that above 30y (3/7). All 10 aggressive tumors were detected to have rearrangements. **Conclusions:** IMTs are seen predominantly in younger age groups. Gene rearrangements are seen more frequently in patients with younger age and also in more aggressive tumors, in a statistically significant manner. Alterations in genes associated with hematopoietic neoplasms such as JAK1 among others, are interesting, given the hematologic component of the lesion, and the presence of novel tyrosine kinase rearrangements warrant further investigations to elucidate mechanistic models.

1539 Poster Session (Board #197), Mon, 1:15 PM-4:45 PM

Genetic, clinical and pathological characteristics of BRCA-associated breast cancer (BC) in Hispanic patients in the United States (US) and Latin America (LatAm). *First Author: Yanin Chavarri Guerra, Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico City, Mexico*

Background: Hispanic women with BC present at a younger age, have a higher frequency of BRCA mutations and show a worse incidence-to-mortality ratio than non-Hispanic women. Information regarding the characteristics of BRCA-associated BC in Hispanics is limited. Here, we assess differences in BRCA-associated BC between Hispanic patients in the US and in LatAm. **Methods:** Hispanic patients from the US and LatAm (Mexico, Colombia, Peru, and Puerto Rico) with a history of BRCA-associated BC enrolled in the Clinical Cancer Genomics Community Research Network registry were included. We compared the genetic, demographic, clinical and pathologic characteristics between Hispanics from the US and LatAm using Fisher's exact test and x^2statistics. **Results:** Between 1997 and 2016, 3670 Hispanic patients with a history of BC from LatAm (n = 1341) and the US (n = 2329) were identified, of which 490 (13.3%) had a deleterious BRCA mutation. The frequency of BRCA mutations was similar in Hispanics from LatAm (13.8%, n = 185) and the US (13.1%, n = 305). No significant differences were found in the frequency of BRCA1 vs BRCA2 mutations between patients from LatAm (BRCA1 68%, BRCA2 31.8%) and the US (BRCA1 61.3%, BRCA2 39%) (p = .12). The most frequent mutations found in BRCA1 were: ex 9-12del (LatAm n = 24, US n = 15), 185delAG (LatAm n = 13, US n = 18) and 943ins10 (LatAm n = 3, US n = 8), and in BRCA2 3492insT (LatAm n = 3, US n = 28). Mean age at BC diagnosis was 39.1 (SD 9.5) in LatAm and 41.7 (SD 10.6) in the US (p = 0.01). US patients were significantly more likely to present with Stage 0-II BC than those from LatAm (77.1% vs. 47.6%, p < .001). We found no differences in the proportion of hormone receptor positive tumors between patients from LatAm (45%) and the US (47%) (p = .78). **Conclusions:** The frequency of BRCA-associated BC was similar between Hispanics in LatAm and the US. Women from LatAm with BRCA mutations present at a younger age, as seen for sporadic BC; the causes for this finding warrant further research. Women with BRCA-associated BC in LatAm are more likely to have advanced BC at presentation, which may be a reflection of disparities and barriers in access to care.

1540 Poster Session (Board #198), Mon, 1:15 PM-4:45 PM

The relationship between statins and colorectal cancer stage in the Women's Health Initiative. *First Author: Brian Rutledge, Wayne State University School of Medicine, Detroit, MI*

Background: Statins are the most widely prescribed cholesterol-lowering drugs in the United States. The anti-carcinogenic effect of statins may reduce the metastatic potential of cancer cells leading to 'stage migration' with users more likely diagnosed with early rather than late stage cancer. We evaluated the relationship between prior statin use and colorectal cancer (CRC) stage at diagnosis in the Women's Health Initiative (WHI). **Methods:** The study population included 132,322 post-menopausal women aged 50-79 years, among which there were 2,628 pathologically confirmed cases of insitu (3.3%), local (43.6%), regional (40.4%) and distant (12.7) stage CRC, after an average of 13.9 (SD = 4.7) years of follow-up. To reduce the possibility of detection bias among women more likely to be prescribed statins, we excluded women who did not report a mammogram within 5 years of study entry and who had no health insurance or medical care provider (n = 28,237). Stage was coded using criteria implemented in the Surveillance, Epidemiology and End Results (SEER) Program into early (in situ and local) vs. late (regional and distant) stage disease. Information on statin use prior to diagnosis was collected by self and interviewer-administered questionnaires at baseline and at one, three, six and nine years post-baseline. Self- and interviewer-administered questionnaires were used to collect risk factor information. Hazards ratios (HR) and 95% confidence intervals (CIs) evaluating the relationship between statin use at baseline only, and in a time-dependent manner, and diagnosis of late-stage CRC were computed from multivariable-adjusted Cox proportional hazards analyses. Statistical tests were two-sided. **Results:** Statins were used by 10,868 women (8%) at baseline. There was no significant relationship between statin use at baseline and late stage CRC cancer (HR = 1.03, 95% CI (0.82-1.30) and no significant association by type of statin or duration of use. In the multivariable-adjusted time-dependent model, use of statins was associated with a reduction in diagnosis of late-stage colorectal cancer (HR 0.79, 95% CI 0.67-0.94, p = 0.007). **Conclusions:** Prior statin use may have an influence on colorectal cancer stage at diagnosis.

1541 Poster Session (Board #199), Mon, 1:15 PM-4:45 PM

The scientific impact and value of large, NCI-sponsored randomized phase III cancer prevention trials. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The cooperative cancer research groups of the National Cancer Institute's National Clinical Trials Network have a history of successful conduct of large randomized phase III trials of prevention for cancer. An important question for funding agencies is whether the conduct of large prevention trials provides strong scientific return on investment. **Methods:** We used study data from a single NCI-sponsored cooperative group (SWOG) over a 20-year period (1990-2009, inclusive). During this time, SWOG conducted two large prevention trials (the Prostate Cancer Prevention Trial and the Selenium and Vitamin E Cancer Prevention Trial) and numerous treatment trials. Scientific impact for prevention and treatment trials was examined using citation analysis. Average annual citation counts were compared using t-tests. Scientific impact was also assessed as a function of trial costs. **Results:** Twenty-six treatment trials with 16,391 patients and two prevention trials with 54,415 patients were examined. The mean annual citation rate for primary articles was higher for prevention trials compared to treatment trials (173.6 vs. 41.7, p = .003). For both primary and secondary article publications, mean annual citations for articles associated with prevention trials were also higher (557.2 vs. 67.6, p < .0001). Large prevention trials were estimated to provide 70% greater scientific impact on a cost-adjusted basis. **Conclusions:** Based on these criteria, the scientific impact of large phase III cancer prevention trials was very high in absolute terms and after accounting for trial costs. For appropriate scientific questions, large prevention trials provide a strong scientific return on investment for federal funding agencies.

1542 Poster Session (Board #200), Mon, 1:15 PM-4:45 PM

Soft palatal melanosis as a predictor for neoplasia in the upper aerodigestive tract. *First Author: Kenro Hirata, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: Squamous cell dysplasia and carcinoma in the upper aerodigestive tract (UAT) was frequently accompanied by melanosis in the UAT. Soft palatal melanosis can be detected by visual inspection during routine physical examination or even personally in a mirror. **Methods:** We reviewed digitalized records of high-quality endoscopic images of the soft palate of 1786 Japanese alcoholic men who underwent endoscopic screening combined with esophageal iodine staining and evaluated to what extent the presence of soft palatal melanosis combined with other risk factors can predict the risk of UAT neoplasia. **Results:** Soft palatal melanosis was observed in 381 (21·3%) of the subjects (mild, 15·0%; distinct, 6·3%). An older age, an inactive heterozygous aldehyde dehydrogenase-2 genotype, smoking, and a high mean corpuscular volume (MCV) were positively associated with the presence of soft palatal melanosis. The age-adjusted odds ratio (OR [95% CI]) for neoplasia in the UAT was 1·92 [1·40–2·64] in the group with melanosis and 2·51 (1·55–4·06) in the group with distinct melanosis, compared with the melanosis-free group. A multiple logistic analysis including the alcohol and aldehyde dehydrogenases genotypes and non-genetic risk factors showed that the presence of soft palatal melanosis was independently associated with a high risk of neoplasia in the UAT. We calculated the individual number of risk factors out of four easily identifiable and significant factors: age ≥55 years, current/former alcohol flushing, MCV ≥106 fl, and distinct soft palatal melanosis. Compared with the risk-factor-free condition, the OR (95% CI) values of UAT neoplasia for one, two, three and four risk factors were 1·49 (0·97–2·30), 3·14 (2·02–4·88), 4·80 (2·71–8·51) and 7·80 (2·17–28·1), respectively. **Conclusions:** Soft palatal melanosis combined with other simple risk assessments provides a simple new strategy for identifying heavy drinkers with a high risk for UAT neoplasia.

1543 Poster Session (Board #201), Mon, 1:15 PM-4:45 PM

Breast cancer risk assessment and chemoprevention use among VA primary care. *First Author: Joseph Merriman, Hematology/Oncology, Vanderbilt University Medical Center, Nashville, TN*

Background: Despite recommended guidelines and available medicationsto reduce breast cancer risk by up to 50-65%, <5% of the 10 million eligible women are offered chemoprevention in the U.S. The comfort level, practice patterns, and barriers to breast cancer risk assessment and chemoprevention use within the VA have not been reported. **Methods:** We assessed VA primary care providers using a REDcap survey. We obtained provider demographics, use and comfort level with breast cancer risk models and chemoprevention and knowledge about chemoprevention. Data was analyzed with Fishers exact or chi-square tests. **Results:** Of the 200 survey respondents, 167 were included for analysis. Overall, 30% used the Gail model monthly or more often, and 1.5 % prescribed chemoprevention in the last 2 years. Fewer than 30% correctly answered chemoprevention knowledge questions. Designated women's health providers were more comfortable with risk assessment and chemoprevention (p<.046, p<.004) and used risk models more often (p<.045). 63% expressed interest in education about breast cancer prevention. **Conclusions:** Breast cancer risk assessment and chemoprevention use by VA primary care is limited by lack of comfort and familiarity. Women's health providers are more comfortable and knowledgeable about breast cancer risk models and chemoprevention, offering an opportunity for partnership with high-risk oncologists to improve breast cancer risk assessment and chemoprevention use among female Veterans.

Survey responses by demographics.

		VA WOMEN'S HEALTH PROVIDER

Does the extent of therapy differ between breast cancers detected by screening mammogram and non-screening methods? *First Author: Wendie-Lou D. Den Brok, BC Cancer Agency, Vancouver, BC, Canada*

Background: There is ongoing debate about the role of screening mammography and its impact on overall survival in breast cancer. We hypothesized that women with screen-detected breast cancers (SDBC) receive less surgery, regional radiotherapy (RRT), and chemotherapy (CH) than women with non-screen-detected breast cancers (NSDBC). Less therapy equates to less personal and societal burden, including less time away from work, fewer side effects, lower health care and disability costs, and reduced psychosocial distress. These may be adequate justification for screening programs even in the absence of an overall survival benefit. **Methods:** Women aged 40-79 years with stage 0-III breast cancers diagnosed between 2007-2012 and referred to the British Columbia Cancer Agency were identified using the Breast Cancer Outcomes Unit database. Clinical and tumor characteristics and type/extent of treatment were extracted. Linkage with the Screening Mammography Program of British Columbia segregated cases into SDBCs and NSDBCs. Interval breast cancers arising in regularly screened women (minimum 2-year interval) were excluded. **Results:** We identified 12,393 women; 7807 with SDBC and 4586 with NSDBC. Compared with NSDBCs, SDBCs were lower stage, less often treated with mastectomy and CH, and occurred in slightly older women (Table 1). SDBC received more radiation than NSDBC. **Conclusions:** Women with NSDBC are more likely to present with higher stage breast cancer. Rates of mastectomy and CH were 20% higher in NSDBC whereas SDBC had a modest 5% higher rate of RRT. These findings suggest that screening mammography decreases the extent of local and systemic treatment for breast cancer.

Tumor and treatment characteristics.

	SDBC	NSDBC	p-value
N (%)	7807 (63)	4586 (37)	
Median age	60	57	<0.0001

1545 Poster Session (Board #203), Mon, 1:15 PM-4:45 PM

Immune profiling of oral pre-malignant lesions (OPLs): An Erlotinib Prevention of Oral Cancer (EPOC) study biobank analysis. *First Author: William Nassib William, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We previously demonstrated that high-risk loss of heterozygosity (LOH) profiles (i.e., 3p14/9p21 LOH) and EGFR gene copy number gain (CNG) in OPLs were associated with inferior oral cancer-free survival (OCFS) in patients enrolled in the randomized EPOC trial. Herein, we performed comprehensive immune profiling of OPLs and correlated the findings with molecular features and outcomes, using the prospectively collected and clinically annotated EPOC biobank. **Methods:** We evaluated OPL specimens by multiplex immunofluorescence using the Opal 7-color fIHC Kit and the Vectra multispectral microscope / inForm Cell Analysis software. Markers included AE1/AE3 pancytokeratins, PD-L1 (clone E1L3N), CD3, CD8, and CD68. Wilcoxon rank-sum and Fisher's exact tests were used to assess the associations between binary markers and continuous and categorical variables, respectively. Cox model was used to investigate associations of markers with OCFS. **Results:** The cohort included 188 OPL patients with hyperkeratosis/hyperplasia (18%), mild/moderate (44%), or severe dysplasia (5%); 65% had high-risk LOH profiles. The 5-year OCFS was 72.3% (median follow-up of 50 months). PD-L1 expression in $>$ 1% of epithelial cells occurred in 28% of OPLs. Intraepithelial CD3+, CD3+/CD8+, CD68+, and CD68+/PD-L1+ cells were detected in 100%, 88%, 88%, and 54% of the samples, respectively. OPLs with high-risk LOH profiles had increased epithelial PD-L1 expression (P = 0.007), intraepithelial CD68+/PD-L1+ cells (P = 0.002), and a trend towards more CD3+/CD8+ cells in the stroma (P = 0.06) but not in the epithelium (P = 0.97), compared with low-risk LOH OPLs. Increased epithelial PD-L1 expression was associated with inferior OCFS on univariate (P = 0.023), and multivariate analysis including LOH status and EGFR CNG as co-variates (P = 0.018). **Conclusions:** High-risk OPLs defined by LOH profiles had increased PD-L1 expression in epithelial cells and intraepithelial macrophages, as well as stromal CD3+/CD8+ immune infiltration. Higher PD-L1 expression was associated with increased oral cancer risk. The findings may support evaluation of (PD-1-targeted) immunoprevention strategies in high-risk OPLs.

1546 Poster Session (Board #204), Mon, 1:15 PM-4:45 PM

Association of baseline plasma levels of 25OH vitamin D and breast cancer risk in a chemoprevention trial. *First Author: Bernardo Bonanni, European Institute of Oncology, Milan, Italy*

Background: Observational studies have shown a correlation of higher serum 25-hydroxyvitamin D (25OHD) concentrations and reduced cancer risk, including breast cancer (BC). We assessed the association of 25OHD and Vitamin D Receptor (VDR) polymorphisms (SNPs) with breast cancer events within a chemoprevention trial in premenopausal women at risk for BC. **Methods:** Premenopausal women with history of intraepithelial neoplasia (IEN) or at risk women according to the Gail model were included in a 4 arm phase II prevention trial (low dose tamoxifen vs fenrerinide vs their combination vs placebo). Level of 25OHD were measured at baseline. VDR SNPs (*Fok*I, *Bsm*I, *Taq*I, *Apa*I, and *Cdx2)* were determined using the Applied Biosystems' Taqman Allelic Discrimination Assay according to manufacturer's instructions. Survival analysis for breast cancer events was performed using competing risk models, adjusted for BMI, age, season and risk strata. **Results:** Plasma samples were available for 228 subjects. At baseline the median plasma 25OHD concentrations were slightly higher in 53 unaffected women, 19.6 ng/ml (IQR 12.7-27.3 ng/mL) than in 175 women with IEN, 18.8 ng/ml (11.7-25.8). After a median follow up of 15 years, 79 women developed a breast cancer event, 12 had different neoplastic events. The median level of 25OHD was 19.7 ng/ml (IQR 12.8-26.1) in subjects free from oncological events and 17.8 ng/ml (9.7-23.9) in subjects with breast events. Women in the lowest 25OHD quartile ($\leq$12 ng/ml) had an increased risk of breast cancer events: HR = 1.79 (95%CI, 1.07-2.99, p = 0.03). Considering all cancer events, the associations with 25OHD were confirmed (P = 0.005). Among the VDR SNPs the *Apa*I variant in homozygote or heterozygote versus wild type showed an HR of 1.83 (95%CI, 1.04-3.21 p = 0.03). **Conclusions:** Our results support a role of plasma vitamin D levels in breast cancer risk. Subjects in the lowest quartile had a two-fold increased risk of a cancer event. Our findings support trials of 25OHD supplementation to prevent breast cancer in 25OHD insufficient subjects.

1547 Poster Session (Board #205), Mon, 1:15 PM-4:45 PM

Impact of patient-provider race/ethnicity and gender concordance on cancer screening: Findings from medical expenditure panel survey. *First Author: Jyoti Malhotra, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Racial/ethnic minority groups experience lower rates of cancer screening compared to non-Hispanic (NH) whites. Previous studies evaluating the role of patient-provider race/ethnicity and gender concordance in cancer screening have been inconclusive. **Methods:** We conducted a cross-sectional study of 18,690 patient-provider pairs using the 2003-2010 Medical Expenditure Panel Survey (MEPS) data. We assessed association between patient-provider race/ethnicity and gender concordance and, screening adherence for breast, cervical, and colorectal cancer using American Cancer Society guidelines. Separate multivariable logistic regression adjusting for demographics, self-reported health and MEPS survey year were conducted to examine relationships of interest. **Results:** Seventy percent of patients were NH-white, 15% were NH-black and 15% were Hispanic. Patients adherent to cancer screening were more likely to be non-Hispanic, better educated, married, wealthier, and privately insured. Among NH-black and NH-whites, patient-provider racial/ethnic concordance was not associated with screening adherence. Among Hispanics, patient-provider racial/ethnic discordant pairs had higher colorectal cancer screening rates as compared to concordant pairs (OR 1.48; 95% CI 1.28-1.71). This association was significant even on adjusting for gender concordance and survey language (English vs. Spanish). Conversely, patient-provider gender discordance was associated with lower rates of breast (OR 0.81; 95% CI 0.74-0.89), cervical (OR 0.79; 95% CI 0.72-0.87) and colorectal cancer (OR 0.86; 95% CI 0.80-0.93) screening adherence in all patients. This association was also significant on restricting analysis to racial/ethnic concordant pairs. **Conclusions:** Patient-provider gender concordance positively impacts adherence to cancer screening and this finding may guide future interventions. Patient-provider racial/ethnic concordance is not associated with screening adherence among whites and blacks but Hispanic patients seen by Hispanic providers have lower colorectal cancer screening rates. This counter-intuitive finding requires further study.

1548 Poster Session (Board #206), Mon, 1:15 PM-4:45 PM

Use of a marketing plan for recruitment to a lung cancer screening study. *First Author: John R. Goffin, Juravinski Cancer Centre, Burlington, ON, Canada*

Background: Recruitment to clinic trials is typically poor. Among barriers to recruitment may be the limited knowledge of trialists with respect to marketing techniques. Improvements in marketing could decrease recruitment time and shorten the time to access new interventions. We hypothesized that a marketing plan would improve recruitment to a lung cancer screening study. **Methods:** The Pan-Canadian Early Detection of Lung Cancer Trial recruited subjects from 8 centres to a screening study of low-dose CT scan and autofluorescence bronchoscopy. Recruitment processes were undertaken independently at each centre. One centre (M) used marketing expertise and a marketing plan, including surveying study candidates for motivators, resulting in specific newsprint advertisements. Screened trial candidates provided demographic and tobacco use data and indicated how they had heard about the study (bus, friend/family, MD, mail, newsprint, radio, TV, other). No site paid for radio or TV time. We used regression analyses to assess whether newsprint advertisements were more effective for recruitment at site M compared with all other sites. **Results:** From 2008 to 2010, 7059 candidates contacted all centres for eligibility screening, including 779 at centre M. Overall, 50.2% were female; median age was 59 yrs. Compared with other centres, candidates at centre M had less education ($p < 0.001$), a higher median 3-year lung cancer risk (2.3 vs 2.0%, $p < 0.001$), but were more likely to have learned of the study by newsprint (58.8 vs 53.3%, chi-squared $p = 0.004$), and were more likely to be recruited (44.0 vs 34.9%, $p < 0.001$). It was more likely that newsprint was the driver for screening contact among candidates with higher education level (OR 1.05/level), higher age (OR 1.03 / yr) and contact at site M (OR 1.31) (all < 0.001). Recruitment after eligibility screening was higher when newsprint was the driver for contact on univariable but not multivariable analysis. **Conclusions:** The effectiveness of newsprint advertising in motivating study contact may be improved by the formal use of marketing expertise. Newsprint advertising may improve the likelihood of recruitment after study screening, possibly through improved initial self-screening by the candidate. Clinical trial information: NCT00751660.

1549 Poster Session (Board #207), Mon, 1:15 PM-4:45 PM

Ten year experience of an integrated cancer prevention center screening for multiple cancer types. *First Author: Ido Wolf, Tel Aviv Sorasky Medical Center, Tel Aviv, Israel*

Background: Cancer is the leading cause of mortality worldwide. Prevention and early detection are pivotal tools for reducing cancer burden. **Methods:** We describe the 10 year experience (2006-2016) of an integrated cancer prevention center that provides screening for prevention and early detection of 11 most common cancer types. Healthy individuals (20-80 yr) were included. Extensive clinical and epidemiological data was obtained. DNA was extracted from all participants and genotyped for APC I1307K and E1317Q. Patients were examined by specialists in internal medicine, surgery, plastic surgery, OBGYN, urology, oncology, oral surgery, gastroenterology, and others. Women underwent vaginal US and pap smear and (40yr) mammography and US/MRI with a clinical indication. PSA and free PSA for Men ($>$ 40yr). LDCT for heavy smokers. Colonoscopy was recommended to all subjects ($>$ 40yr). **Results:** A total of 6258 (49%) men and 6461 (51%) women mean age 47.0 ± 11.5 year were screened. New malignant lesions were detected in 389 (1.75%) of screeners. The most common cancers were of skin (74, 0.6%), prostate (62, 0.5%), thyroid (51, 0.4%), breast (36, 0.3%), colorectal (22, 0.2%), ovarian (19, 0.1%), uterus (14, 0.1%), testis (12, 0.09%) urinary (9, 0.07%) and lung (10, 0.08%). In 28 patients (0.22%) more than one cancer was detected. Twenty eight of the cancer patients (7.2%) died after 32.4 ± 28.1 months at a mean age of 69.4 ± 14.2 years. Significantly, better than the expected cancer mortality. The APC I1307K and E1317Q variants were detected in 572 (4.8%) and 182 (1.5%) subjects respectively. First degree family member with cancer (OR = 2.02), I1307K carrier ship (OR = 1.53), female gender (OR = 1.23) and advanced age (OR = 1.06) were all associated with statistically significant ($P < 0.05$) increased cancer risk. Advanced age and first degree family history were also associated with detection of more than one cancer types. **Conclusions:** One stop shop screening, in the setting of a multidisciplinary outpatient clinic, is feasible and can prevent and detect cancer at an early stage. It significantly improve morbidity and mortality. Impressively the APC I1307K carries an overall increase cancer risk.

1550 Poster Session (Board #208), Mon, 1:15 PM-4:45 PM

Breast cancer screening practices with high-risk women: A cross-sectional survey. *First Author: Anne Hudson Blaes, University of Minnesota, Minneapolis, MN*

Background: Little literature exists on primary care providers' knowledge and preferences towards breast cancer screening for high-risk women. While guidelines recommend MRI and mammography, it is unclear how frequently these recommendations are used. **Methods:** This web-based survey of providers licensed to practice in Minnesota was conducted. This analysis focuses on breast cancer screening practices for high-risk women. Data were summarized using descriptive statistics; professional characteristic comparisons were conducted using Chi-squared tests. **Results:** 805 of 10,392 (8%) invitees completed the survey. 72.2% were female. 43.9% were physicians (20.8% internists, 71.7% family medicine, 6.3% gynecology), 11.4% physician assistants (PAs), 44.8% advanced practice registered nurses (APRNs). 84.8% were in community practice, 38% $>$ 20 years of experience and 27.1% $<$ 10 years. When asked how effective screening was for reducing cancer mortality in high risk women, mammography was thought to be very effective (48.8%) or effective (46.8%) in women ages 40-49 years, for women ages 50+ years, 60.8% and 35.7%, respectively. 62.4% thought breast MRI was very effective in reducing cancer mortality in high risk women. There was no difference in breast MRI recommendation based on professional background, experience or practice setting. Female practitioners, less experience, and those working in gynecology or women's health were more likely to recommend breast MRI. A case vignette for high risk screening cancer survivors is provided (Table). **Conclusions:** Most primary care providers believe mammography is helpful in women at high risk for developing breast cancer. Less than half of practitioners, however, are following guideline specific recommendations of both mammography and MRI for breast cancer screening in high-risk patients.

Providers' recommendations for breast cancer screening of 40 y/o treated with mantle radiation for Hodgkin lymphoma at age 20 years*.

	Recommendation

Prospective randomized biomarker study of metformin and lifestyle intervention for prevention in obese postmenopausal women at increased risk for endometrial cancer. *First Author: Melinda S. Yates, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Obesity significantly increases risk of endometrial cancer (EC) through systemic metabolic effects and local tissue action, driven by estrogen and dysregulated insulin signaling. EC is most commonly diagnosed in postmenopausal women. Metformin, an antidiabetes drug, and lifestyle intervention were evaluated for effects on endometrial proliferation and serum biomarkers, in parallel with weight loss. **Methods:** Obese postmenopausal women were randomized into 4 groups for a 16 week intervention using a 2 (metformin 1700 mg/day vs placebo) x 2 (lifestyle intervention vs no lifestyle intervention) factorial design based on the Diabetes Prevention Program. Pre- and post-intervention endometrial biopsies were assessed for proliferation (% Ki67+). Body weight and serum markers were measured pre- and post-intervention (estrone, FSH, DHEA-S, SHBG, IGF-1, adiponectin, omentin, insulin, glucose, A1C, ALT, triglycerides, and others). **Results:** Of 576 women approached for the study, 29 women were randomized and 26 completed the study. Similar adherence was seen for placebo and metformin, with 88% and 94% of doses taken, respectively. Adverse events were grade 1 or 2, most commonly flatulence, headache, and diarrhea. Metformin+lifestyle group lost the most weight (-7.4%), followed by lifestyle (-5.2%), metformin only (-3.1%), and placebo (+0.1%). Endometrial proliferation was not changed. Overall proliferation was low (7.1% at baseline) with substantial variability even in this postmenopausal cohort. Biopsies produced limited endometrium, precluding evaluation of other tissue markers. Metformin significantly increased serum DHEA ($p = 0.002$). SHBG increased ($p = 0.031$) and insulin decreased with lifestyle intervention ($p = 0.035$) but were not statistically significant after multiple comparisons correction. **Conclusions:** Metformin and lifestyle intervention produced positive changes in serum markers and weight loss. While it is known that obese postmenopausal women are at increased risk for EC, improved biomarkers are needed to stratify risk and test prevention strategies, particularly at the endometrial tissue level. Clinical trial information: NCT01697566.

1552 Poster Session (Board #210), Mon, 1:15 PM-4:45 PM

What puts physicians and patients discussing cancer screening on the same page? *First Author: Danielle Seiden, Mount Sinai Beth Israel, New York, NY*

Background: Shared decision making requires effective provider-patient communication. We studied concordance in recalled discussions and factors that affected it. **Methods:** In a cluster-randomized trial of educational supports for providers (MDs), we are enrolling an age-(30-89 years) and sex-stratified sample of 216 patients (PTs) who underwent a physical examination at 2 urban hospitals, 18 for each of 12 primary care MDs. Screening guideline formatting (colorcoding) and academic detailing were randomly assigned in a 2x2 design. Immediate post encounter surveys recorded PT and MD recall of screening discussions. **Results:** The first 174 participants were diverse (63% white) and highly educated (77% college degree). PTs and MDs differed in recall of screening discussions, and the differences varied by screening test. When MDs reported a colorectal cancer (CRC) screening discussion, 21% of PTs did not; 20% of MDs disagreed when PTs reported the discussion. The discrepancies were greater for prostate specific antigen (PSA) screening, 29% and 29%, respectively, but much less for mammograms (MAM), 8% and 5%, respectively. Recall of the MD recommendation also differed: 15% of PTs disagreed when their MD reported it, and 33% of MDs when their PT reported it. For PSA, disagreement was 26% and 33%, respectively, and for MAM, disagreement was 17% and 10%, respectively. Overall, agreement between all PTs and MDs on whether screening was recommended was fair for CRC, PSA and MAM: kappa = 0.33, 0.34 and 0.29, respectively. For PTs $>$ 70 agreement was nonexistent on recalled CRC and PSA recommendations (kappa = -0.02 and -0.03, respectively) but preserved for MAM (kappa = 0.39). Sex did not affect CRC agreement. Recall concordance improved when SDM was recalled. For CRC, kappa rose from -0.12 to 0.52 if the MD recalled any MDM element. **Conclusions:** In a highly educated, diverse patient population, patients and physicians often disagreed on recalled cancer screening discussions. Discordance was greatest with PSA and least with MAM. Discordance was greater in older patients. If MDs recalled any shared decision making, agreement increased significantly. Communication varies by cancer screen, PT age and elements of shared decision making. Clinical trial information: NCT02430948.

1553 Poster Session (Board #211), Mon, 1:15 PM-4:45 PM

Awareness of cervical cancer and screening among rural Nepalese women. *First Author: Anju Shrestha, Nepal Cancer Hospital and Research, Kathmandu, Nepal*

Background: Cervical cancer is leading female cancer in Nepal. Despite the existence of effective screening using Pap smear, the uptake of screening is poor. Objectives of this study were to determine the baseline information about the knowledge of cervical cancer and explore attitude and practice of Pap smear screening among the women of rural community of Nepal. **Methods:** A cross sectional population based descriptive study of female attending free cervical cancer screening camp in different rural community of Nepal organized by Nepal cancer Support group and Nepal cancer Hospital, funded by Direct Relief was conducted from 1/06/2016 to 31/12/2016- using self- administered questionnaire to elicit information on demographic characteristics, knowledge, screening behaviors and determinants of cervical cancer. **Results:** A total of 2529 women participated in nine screening camp, out of which 55.95% (1416) were illiterate whereas only 4.95% (129) were graduate. Mean age of participates were 40.5± 11.97 (17-83)yrs. 31.63% (800) of women married before age of 16 and 32.08% (811) women had their first childbirth before age of 18 years. Only 6.88% (174) women were working outside and rest were working in household work and farming. 76.24% (1928) women knew nothing about cervical cancer. Although 38.71% (979) women heard about Pap smear, only 10.36% (262) knew about eligibility of screening, 1.58% (40) knew about screening interval and 16.57% (419) know that Pap smear is used for detections of cancerous and precancerous lesions of cervix. However, knowledge of risk factors for cervical cancer was found in 5.9% (150). Of the female respondents, 78.09% (1975) did not feel susceptible to cervical cancer and 82.25% (2080) had never been screened before. The most common reason for not doing Pap test is they never heard about it (59.99%: 1516). The other reason includes do not have any symptoms (17.79%:450); embarrassment (2.49%:62); do not know where to do (1.27%:32); fear of finding out cancer (0.51%:13) and never advised by doctor (0.4%:10). **Conclusions:** The study revealed very low cervical cancer knowledge and poor screening behavior among the women. This may be due to lack of awareness, education and low priority of women's health issue.

1554 Poster Session (Board #212), Mon, 1:15 PM-4:45 PM

Risk factors of colorectal adenoma recurrence among individuals under 50 years of age compared to those 50 years of age or older. *First Author: Christine Louise Sardo Molmenti, Northwell Health/Hofstra Northwell School of Medicine, Great Neck, NY*

Background: Colorectal cancer incidence and mortality are increasing among individuals $<$ 50 years of age. Data are limited regarding the epidemiology of colorectal adenomas in this younger age group. This study investigated and compared risk factors associated with recurrence of adenomas in individuals under and over 50 years of age. **Methods:** Pooled analyses from the Wheat Bran Fiber and Ursodeoxycholic Acid phase III, randomized, controlled clinical trials included 1,623 participants, aged 40-80 years. Each completed baseline questionnaires related to family history and lifestyle habits, had one or more colorectal adenomas removed at baseline, and had a follow-up colonoscopy during the trial (mean follow up 36 months). Univariate and multivariate logistic regression modeling estimated the association between age and colorectal adenoma recurrence, and evaluate multiple risk factors, while controlling for confounding factors. **Results:** A statistically significant increased trend was found for colorectal adenoma recurrence with increasing age (P_{trend}= $<$ 0.001). Multivariate logistic regression revealed that risk factors significantly associated with adenoma recurrence in the ≥50 age group (n = 1,523) included history of previous polyps, characteristics of adenomas removed at baseline (multiple adenomas and villous feature), current smoking, and an increased waist circumference. Although risk profile in the $<$ 50 age group (n = 95) shared similarities with that in the ≥50 age group (e.g., current smoking), there were a few notable differences: history of previous polyps was a more prominent predictor for recurrence for the $<$ 50 ($OR_{<50}$ = 4.76 and $OR_{\geq 50}$ = 1.33, $P_{interaction}$ = 0.042), whereas baseline characteristics of adenomas were more important for the ≥50 (multiple adenomas: $OR_{<50}$ = 0.40 and $OR_{\geq 50}$ = 2.28, $P_{interaction}$ = 0.043). **Conclusions:** Predisposition to colorectal adenoma is a more important risk factor for recurrence in the $<$ 50 as compared to the ≥50. Future studies need to identify susceptibility factors contributing to the increasing incidence of colorectal cancer in this younger age group.

1555 Poster Session (Board #213), Mon, 1:15 PM-4:45 PM

Health4Families: An intervention to improve weight and health behaviors in families with hereditary breast/ovarian cancer or Lynch syndrome. *First Author: Susan K. Peterson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Physical activity, diet, and healthy weight may reduce cancer risk in hereditary breast and ovarian cancer (HBOC) and Lynch syndrome (LS) families. Evidence-based programs to help affected families make these behavioral changes are lacking. We evaluated data from a 16-week family-centered lifestyle intervention trial for individuals with HBOC or LS germline gene mutations and their relatives. **Methods:** Index cases with HBOC- or LS-associated mutations were recruited from an institutional registry and advocacy organizations, and identified relatives to participate with them in the study. Those eligible had BMI$>$25 and/or did not meet recommendations for exercise or fruit/vegetable consumption. Participants were randomized to multiple conditions including text messaging, online weight/diet monitoring, an online social network, and E-mail or telephone coaching. All monitored activity using Fitbits. Behavioral outcomes were assessed online at baseline and 8 weeks. **Results:** 65 HBOC index cases with 63 family members, and 35 LS index cases with 36 family members participated in the study. At 8 weeks, participants lost 3.2 pounds on average (p$<$.0001) and increased weekly physical activity from 126 to 172 minutes (p=.0012). LS participants decreased self-reported sedentary time (p=.0126). Program effects did not differ between index cases and family members. Participants reported high program satisfaction; 78% would recommend it to a family member. **Conclusions:** Hereditary cancer families can benefit from behavioral interventions to improve weight and physical activity. Data show that distance-based methods are effective, and are ideally suited for families with a hereditary predisposition to cancer but who are often geographically dispersed. Clinical trial information: NCT02194387.

Baseline body composition and physical activity in index cases and family members.

	HBOC index cases	HBOC family members	LS index cases	LS family members
BMI (M±SD)	29.6 ± 7.2	29.3 ± 6.9	29.3 ± 6.6	29.7 ± 6.1
Weekly min MVPA*	127 ± 140	129 ± 195	107 ± 119	82 ± 94
Weekly hours sedentary time	49.5 ± 28.3	48.5 ± 29.4	45.6 ± 26.4	48.4 ± 30.0
≥ 150 min MVPA/week (%)	42	33	31	22

*MVPA = moderate-vigorous physical activity

Effect of metformin chemoprevention on metabolomics profiles in Li-Fraumeni Syndrome (LFS). *First Author: Farzana L. Walcott, George Washington University, Washington, DC*

Background: LFS is a highly-penetrant, autosomal dominant, cancer predisposition disorder characterized by early onset cancer; germline mutations in *TP53*are present in 70% of LFS. We previously observed metformin inhibition on mitochondrial function in LFS patients. Metformin may reduce TCA cycle and glycolytic intermediates during cellular transformation, indicating inhibition of complex I of the mitochondria. To further explore this, we performed untargeted metabolomics profiling on stored serum of study participants. To our knowledge, there are no previous studies of metabolomics profiling in LFS patients treated with metformin. **Methods:** Adult LFS patients (≥18 years old) were enrolled for 20 weeks. Metformin was initiated at 500 mg per day and increased in 500 mg dose increments every two weeks to a maintenance dose of 2000 mg of metformin. Patients were taken off metformin for the last six weeks of the study (week 20). Global biochemical profiles were determined in human serum samples collected in 21 patients, each providing one sample at baseline, week 14 (on 2000 mg metformin) and week 20 (off metformin). Metabolomics analyses were performed by Metabolon, Inc. **Results:** Treatment with metformin induced a strong metabolic signature of increased fatty acid beta-oxidation in LFS patients. Acylcarnitines, long chain fatty acids, and 3-hydroxy fatty acids were significantly elevated following metformin treatment. TCA cycle intermediates, aconitate, malate, and fumarate were also increased as were levels of ketone body 3-hydroxybutyrate (BHBA)indicating robust β-oxidation, presumably to support increased energy production via the TCA cycle. Clearance of metformin results in normalization of levels to comparable baseline values, indicating a causal role of metformin in these changes. **Conclusions:** Global metabolomics profiling suggests an increase in TCA cycle intermediates and a strong signature of fatty acid oxidation with metformin treatment in LFS, suggesting metformin effect on the mitochondria and TCA cycle is more dynamic than previously shown. LFS patients may have distinct metabolic profiles which may be altered by treatment with metformin. Funding: ASCO Young Investigator's Award 2016. Clinical trial information: NCT01981525.

1557 Poster Session (Board #215), Mon, 1:15 PM-4:45 PM

High accumulation of metformin in colonic tissue of subjects with diabetes or metabolic syndrome. *First Author: Andrea De Censi, Division of Medical Oncology, E.O. Galliera Hospital, Genova, Italy*

Background: Epidemiological studies consistently observed an association between metformin use in diabetic patients and decreased colon cancer incidence and mortality at clinical doses (1500-2250 mg day), corresponding to plasma levels of 0.003-0.045 mM. Preclinical models report much higher doses of metformin, ranging between 1 and 40 mM for *in vitro* and 0.006-0.145 mM for *in vivo* studies. A recent trial using a low dose of metformin (250 mg/day, Higurashi T et al. Lancet 2016;17:475) showed a 40% reduction of colorectal adenoma recurrence. We performed a pilot study to measure metformin in plasma and colonic tissue of subjects with diabetes or metabolic syndrome and to explore their correlation with different tissue biomarkers, including Ki-67, pS6k, a mTOR effector protein, and EGFR expression. **Methods:** We used LC-MS/MS to quantify metformin in plasma and colonic tissues from 13 volunteers with diabetes or metabolic syndrome undergoing screening colonoscopy. All patients had received metformin at 1000-1850 mg/day for a median of 6.5 yrs (range 2-15), except for one who served as untreated control. Tissue quantifications were performed on specimens derived from right and left colon biopsies with or without washing to exclude a potential contamination due to lumen accumulation by the drug. Biomarker assessment was performed by standard IHC assay. **Results:** The mean plasma metformin was 0.025 mM/L (range $5x10^{-5}$-0.017), whereas the colonic tissue was ~100 fold higher in right [0.39 mM/Kg (range 0.034-1.75)] and left colon [0.46 mM/Kg (range $5x10^{-3}$-1.86)]. There was no significant difference between washed and unwashed biopsies. No significant correlations were detected between metformin levels in plasma/tissue and tissue biomarkers. **Conclusions:** Metformin can attain ~100 fold higher colonic tissue levels than in plasma. These levels are in the range of a direct antitumor effect observed in *in vivo* preclinical models. A two-by-two clinical trial of metformin and aspirin in colon cancer patients is underway by our group to further elucidate independent and synergistic antitumor effects.

1558 Poster Session (Board #216), Mon, 1:15 PM-4:45 PM

Risk of breast or ovarian cancer in family members who do not carry the *BRCA1* or *BRCA2* family mutation: Findings from the EMBRACE study. *First Author: Fabio Girardi, Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom*

Background: *BRCA1/BRCA2* true-negatives are proven non-carriers of the *BRCA* mutation segregating within their family. Currently, there is no conclusive evidence on the risk of developing breast or ovarian cancer in these individuals, potentially leading to non-uniform clinical practices. The purpose of this study was to estimate breast and ovarian cancer risks for true-negatives from the EMBRACE prospective cohort study. **Methods:** Risks were calculated separately for incident invasive breast cancer and epithelial ovarian cancer (EOC). We used cohort analysis to estimate incidences, cumulative risks and standardised incidence ratios (SIRs). **Results:** A total of 1895 unaffected women were eligible for inclusion in the breast cancer analysis and 1736 for the ovarian cancer analysis. There were 23 incident invasive breast cancers and 2 EOCs diagnosed during follow-up. The cumulative risk of invasive breast cancer was 9.4% (95% CI 5.9%-15%) by the age of 85-years, whilst the corresponding risk of EOC was 0.6% (95% CI 0.2%-2.6%). The SIR for breast cancer was 0.93 (95% CI 0.62-1.40) in the overall cohort, 0.85 (95% CI 0.48-1.50) in non-carriers from *BRCA1* families and 1.03 (95% CI 0.57-1.87) in non-carriers from *BRCA2* families. The SIR for EOC was 0.79 (95% CI 0.20-3.17) in the overall cohort and 1.74 (95% CI 0.44-6.98) in non-carriers from *BRCA2* families. **Conclusions:** This is the largest cohort to date of prospectively ascertained true-negatives from *BRCA1/BRCA2* families. Our results did not provide evidence for elevated risks of invasive breast cancer or EOC in proven non-carriers. Risk-reducing bilateral mastectomy and risk-reducing salpingo-oophorectomy may not be appropriate for these individuals. Female relatives of a known *BRCA1/BRCA2* mutation carrier should be advised towards genetic testing to avoid unnecessary surgical procedures. However, we were not able to investigate variation in risks by cancer family history. Therefore, we cannot rule out that risks may be slightly higher for close relatives of affected mutation carriers. In such cases, model-based estimates incorporating family history, such as those given by BOADICEA, can be used in the counselling process.

1559 Poster Session (Board #217), Mon, 1:15 PM-4:45 PM

Breast cancer in male veterans: The Veterans Affairs (VA) informatics and computing infrastructure (VINCI) big data analysis. *First Author: Anita Aggarwal, VAMC-DC, Potomac, MD*

Background: Male breast cancer (MBC) management from diagnosis to treatment is generalized from female breast cancer (FBC) because of its rarity and paucity in literature. VINCI is a unique database for cross sectional and longitudinal analysis. The objective of this retrospective analysis was to compare characteristics and outcome of MBC with FBC in veterans. **Methods:** Detailed demographics, diagnosis, treatment and outcome of all patients diagnosed with breast cancer between 1998 and 2016 at 152 VA medical centers were obtained and analyzed with Chi-square and t-test univariate statistics. **Results:** In total 9765 patients' records were reviewed, 1613 MBC were compared with 8152 FBC. The mean age at diagnosis is 68.5 and 57.3 years for MBC and FBC, respectively (Table1). After a median follow up of 3.5 years, 48% MBC and 22% FBC died. Breast cancer mortality is 18% and 9% in MBC and FBC, respectively. A cox regression survival analysis indicates that males were 33% (Hazard Ratio 1.33, P=<0.0001) more likely to die from breast cancer than females. **Conclusions:** This is the largest comparison series of MBC with FBC to date in the Veteran population to author's knowledge. Males have higher breast cancer specific mortality than females most likely because of older age and higher stage at the time of diagnosis. Differences in the biology and pathology may be contributing factors which needs further prospective studies.

Demographics and outcome comparison analysis of male and female veterans with breast cancer.

	Total Sample N=9,765

The clinical impact of the Prognostic Nutritional Index (PNI) and Controlling Nutritional Status (CONUT) score on breast cancer patients survival. *First Author: Nami Yamashita, Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan*

Background: Recent reports show that the preoperative immunonutritional status correlate with the survival rate in cancer patients. The Prognostic Nutritional Index (PNI) and Controlling Nutritional Status (CONUT) score are used as screening tools for immunonutritional status and reported to be a predictor of postoperative recurrence in patients with various gastrointestinal cancers. However, the clinical importance of the PNI and CONUT in breast cancer has not been elucidated. The aim of this study is to investigate the clinical impact of preoperative PNI and CONUT on long-term survival of breast cancer patients. **Methods:** We retrospectively analyzed 653 consecutive stage I-III breast cancer patients who were treated from January 2002 to December 2013. The PNI score was calculated as 10 x serum albumin (g/dl) + 0.005 x total lymphocyte count (per mm^3). The CONUT score is calculated from three parameters, serum albumin, cholesterol, and total lymphocytes count. The patients were divided into two groups according to the PNI and CONUT score. The uni- and multivariate Cox regression analyses were performed to evaluate the prognositic value of the PNI and CONUT in breast cancer. **Results:** The malnutritional status was observed in 170 (26%) and 131 (20%) patients as low-PNI and high-CONUT, respectively. The relapse-free survival (RFS) and overall survival (OS) rates were significantly lower in the low-PNI group (RFS: $p < 0.0001$, OS: $p < 0.0001$) and high-CONUT group (RFS: $p = 0.0009$, OS: $p = 0.0018$). In the multivariate analysis, low-PNI was independent prognostic factors for both RFS and OS (RFS: HR2.33, $p = 0.032$, OS: HR5.01, $p = 0.0009$). In the subset analysis, the low-PNI group showed poor prognosis especially in the postmenopausal, hormone receptor negative patients. The low-PNI also had poorer prognosis in post-recurrence survival. **Conclusions:** The preoperative PNI is a strong independent predictor of long-term survival among breast cancer patients.

1561 Poster Session (Board #219), Mon, 1:15 PM-4:45 PM

Hormone replacement therapy (HRT) among *BRCA* mutation carriers. *First Author: Nicole Centers, Florida Hospital Celebration Health, Celebration, FL*

Background: BRCA mutation carriers are often offered risk-reducing surgery (oophorectomy, hysterectomy) and medication regimens (hormone modulators, chemotherapy) in a preventative format. These therapies cause premature menopause and associated symptoms including reduced libido and sexuality. Hormone replacement therapy (HRT) is beneficial in alleviating climacteric symptoms of menopause. However, due to high risk for breast cancer in BRCA mutation carriers, many within the healthcare community oppose the use of HRT, despite recent studies that fail to demonstrate an adverse effect on oncologic outcomes. The purpose of this study was to identify current HRT practices among BRCA1,2 mutation carriers. **Methods:** The study population included 763 BRCA1,2 mutation carriers (52% previvors, 48% survivors) who are members of Facing Our Risk of Cancer Empowered, a support, education, and advocacy group for individuals with gene mutations. Data was collected via an online survey that included questions pertaining to patient characteristics, preventative procedures, menopausal status and symptoms, HRT use, and provider recommendations. **Results:** According to the survey findings, 73% of BRCA mutation carriers were postmenopausal (59% previvors, 88% survivors) and, among these, 81% had become menopausal prematurely due to risk-reducing surgery or medications. Major postmenopausal concerns of BRCA mutation carriers involved low libido/sexuality (78%) and an increased risk for weight gain (83%), cardiovascular disease (77%), and osteoporosis (65%). Despite the high incidence of premature menopause and associated symptomatology of the population, HRT usage was low (13% previvors, 28% survivors). According to the survey respondents, only 26% of healthcare providers for the previvors and 8% for the survivors favored HRT use. **Conclusions:** High rates of premature menopause with related symptoms occur among BRCA1,2 mutation carriers in association with cancer preventative therapies. Despite the young age of this postmenopausal population, only a small percentage are on HRT. These findings suggest the need for improved education to patients and providers regarding HRT and cancer risk, as well as the exploration of HRT options.

1562 Poster Session (Board #220), Mon, 1:15 PM-4:45 PM

The association between proton pump inhibitors (PPI) use for gastro-esophageal reflux disease (GERD) and lung cancer (LC): A nested case-control study. *First Author: Hadas Dresler, Meir Medical Center, Kfar-Saba, Israel*

Background: Data suggests that GERD with recurrent reflux and micro-aspiration of stomach contents, may be associated with lung injury, inflammation, activation of proliferative signals, and eventually DNA damage and malignant transformation. Recently, a large population based cohort study found that GERD may increase the risk of lung cancer in Asians. In the present nested case control study, we aimed to evaluate the association between PPI use as a surrogate for GERD and lung cancer in a large western population. **Methods:** We conducted a matched case-control study within a population-representative database from the United Kingdom. Study cases were defined as individuals with any diagnostic code of lung cancer. For every case, four eligible controls were matched on age, gender, practice site, time and duration of follow-up. Exposure of interest was PPI use prior to cancer diagnosis. Adjusted odds ratios (ORs) and 95% confidence intervals (CIs) for lung cancer were estimated using conditional logistic regression. Adjustment was performed for smoking. **Results:** The study population included 19143 lung cancer cases and 74473 matched controls. PPI use was associated with a significantly increased lung cancer risk (adjusted OR 1.70, 95%CI 1.64-1.77, $p < 0.001$). In a sensitivity analyses we observed similar associations when PPI use was initiated more than one year prior to cancer diagnosis (adjusted OR 1.18, 95%CI 1.13-1.23, $p < 0.001$) and more than two years prior to cancer diagnosis (adjusted OR 1.15, 95%CI 1.10-1.20, $p < 0.001$) **Conclusions:** ChronicPPI use, as a surrogate for symptomatic GERD, may be associated with a higher lung cancer risk.

Socio-demographic variations in lung cancer screening before and after USPSTF recommendation: Results from national health interview surveys (NHIS). *First Author: Qian Wang, Department of Internal Meidicine, Icahn School of Medicine at Mount Sinai St. Luke's, New York, NY*

Background: In 2013, USPSTF recommended low-dose CT screening (LCS) for lung cancer in high-risk adults. The change in real-world practice is largely unknown, as well as the association with socio-demographic factors. **Methods:** Data were extracted from the population-based 2010 and 2015 NHIS. LCS was defined as a chest CT to check for lung cancer within the past year. We included adults aged 55 to 80 years who 1) have 30+ pack-year smoking history; 2) are currently smokers or have quitted within the past 15 years. We excluded adults who 1) have lung cancer; 2) had not seen a physician in the past year. We used weighted analyses to estimate national lung cancer screening rates. **Results:** A total of 874 and 1041 high-risk smokers responded to the LCS questions for lung cancer in 2010 and 2015, respectively. The screening rate more than doubled from 4.1% to 9.1% ($P < 0.01$) in all respondents. The increase was greater in women (2.9% to 9.5%, $p < 0.01$) than men (5.2% to 8.8%, $p = 0.03$) and in age 65-80 (4.7% to 12.3%, $p < 0.01$) than age 55-64 (3.8% to 6.3%, $p = 0.16$). White saw the largest increase and highest rate in 2015 (4.0% to 9.3%, $p = < 0.01$). Those with some college or above education had the highest rate in 2010, but the lowest in 2015. Household income above 75,000 dollars was associated with the lowest rate in both 2010 and 2015. **Conclusions:** Since the recommendation of USPSTF, LCS rate for lung cancer has doubled but remains less than 10%. Higher education and household income are associated with lower screening rate, in contrast to studies of other cancers.

LCT screening rates for lung cancer in 2010 and 2015.

	2010 (%)	2015 (%)	p-value

Breast cancer screening in transgender patients: Findings from the 2014 BRFSS survey. *First Author: Anand Narayan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Transgender patients undergoing transitions often receive cross sex hormonal therapies, placing them at uncertain risk for developing breast cancer. There is limited population-based information about the extent to which transgender patients undergo mammography screening. Our purpose was to determine the extent to which transgender patients undergo mammography screening using nationally representative survey data. **Methods:** Transgender participants in the 2014 Behavioral Risk Factor Surveillance System survey were included. Proportions undergoing mammography screening in the last year or two years were calculated stratified by age category and transition status (male to female(MtF), female to male(FtM), non-conforming(people who do not follow societal notions how they should look or act based on the sex they were assigned at birth)). For each transition status, predictors of mammography screening (demographics, indices of access to health care) were calculated using logistic regression. **Results:** 656 transgender patients were included (343 were MtF, 203 were FtM and 110 classified themselves as gender non-conforming). For MtF respondents, 61.5% of women underwent mammography screening within the last year (71.9% within last two years). For FtM respondents, 66.1% underwent mammography screening within the last year (74.2% within the last two years). For gender non-confirming transgender patients, 57.9% underwent mammography screening within the last year (74.4% within the last two years). For all transgender patients, income category (OR 1.16, 0.82 - 1.64), higher education category (OR 1.09, 0.31 - 3.86) and health insurance (OR 0.38, 0.10 - 1.41) were not associated with increased adherence to mammography screening. Adjusted for age, education, race and income, transgender patients were comparably likely to undergo mammography screening compared with non-transgender patients (OR 0.97, 0.58 – 1.62). **Conclusions:** High proportions of transgender survey respondents undergo mammography screening (57.9 – 66.1% within the last year, 71.9 – 74.4% within the last two years), proportions comparable to non-transgender survey respondents.

1565 Poster Session (Board #223), Mon, 1:15 PM-4:45 PM

Effects of physical condition and body composition on cancer risk in a nationwide cohort of 31,158 men from Finland. *First Author: Jorma Tauno Juhani Sormunen, University of Tampere, Tampere, Finland*

Background: Regular physical activity seems to protect men from colorectal cancer and possibly also from prostate cancer. In the case of other cancers the evidence is adding up, and physical activity seems to have a small protective effect to its incidence. The aim of this study was to analyse the effects of physical condition (PC) in early adulthood on cancer incidence later in life. **Methods:** We collected data on general health, anthropometry and PC for 31,158 Finnish men born in 1958 from the time of their military service between the ages of 17 and 30 years. Using linkage with the Finnish Cancer Registry, all men were followed-up for cancer incidence up to 2014. **Results:** Overweight and obesity (body mass index (BMI) $\geq$ 25 kg/m^2) were associated with an increased overall cancer risk [hazard ratio (HR): 1.08, 95% confidence interval (CI): 0.89-1.30] when compared to those with BMI $<$ 25 kg/m^2. Those with normal weight but bad PC had an increased risk of all cancers combined as compared to those with normal weight and good PC (HR 1.18, 95% CI: 1.01-1.38), which further increased in those who were also overweight (HR 1.30, 95% CI: 1.01-1.69). We noticed an increased overall cancer risk in men in who entered service with minor health problems (HR 1.46, 95% CI 1.19-1.80), when compared to those that were completely healthy. This was especially observed for advanced prostate cancer (HR: 3.35, 95% CI: 1.14-9.90). Increased HRs, yet statistically insignificant, were also seen for colorectal and other obesity-related cancers. **Conclusions:** Good PC at young age seems to protect men from cancer later in life. Early adulthood obesity, when combined with bad PC, seems to further increase cancer risk.

1566 Poster Session (Board #224), Mon, 1:15 PM-4:45 PM

Anti-cancer effect among patients with familial Mediterranean fever: Outcome of 258,803 person-years analysis. *First Author: Ronen Mordechay Brenner, Wolfson Medical Center, Tel Aviv, Israel*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease that causes recurrent serosal inflammation. The association between FMF and malignancy has not been previously described. We estimated cancer risk in a large single-institution cohort of FMF patients. **Methods:** The study cohort consisted of 8,534 FMF patients registered in the Israel National FMF Center at Tel Hashomer, Israel. We linked the study cohort to the database of the Israel National Cancer Registry using the national identity number. Cancer incidence in FMF patients was determined and stratified by age and gender. Standardized incidence ratios (SIR) for cancers were calculated. **Results:** Among 8,534 FMF patients (4,400 men, 4,134 women), 350 developed cancer during the years 1970-2011. Overall cancer risk among patients with FMF was significantly lower than that expected in the following gender and population groups, based on cancer incidence rates in those groups in the Israeli population: males of Jewish ethnicity SIR 0.66, CI 95% [0.55-0.77], $p< 0.001$; females of Jewish ethnicity SIR 0.75 CI 95% [0.64-0.86], $p< 0.001$; males of Arabic ethnicity SIR 0.34, CI 95% [0.07-0.99], $p= 0.024$. **Conclusions:** FMF patients have a significantly lower incidence of cancer than the general population. This pattern was demonstrated in two different ethnic populations, Jewish and Arabic. We speculate that the lower cancer incidence could be attributed to the direct physiological effect of FMF or to the anti-FMF treatment.

1567 Poster Session (Board #225), Mon, 1:15 PM-4:45 PM

Incidence and survival trends of cancers diagnosed in young adults (20-39 years): A population-based study. *First Author: Husson Olga, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Cancer in young adults (YAs; 20–39 years) is rare but its incidence is increasing globally. In The Netherlands, care for YA cancer patients is mostly dispersed, in contrast to centralized care for all pediatric cancer patients. Aim of this population-based study was to examine trends in YA cancer incidence and survival. **Methods:** Data from all YAs diagnosed between 1989-2015 (n = 89,675) were obtained from The Netherlands Cancer Registry. Age-standardized incidence rates with estimated annual percentage of change and five-year relative survival rates were calculated. **Results:** Cancer incidence in YAs increased significantly from 48 to 67 per 100,000 person years in males (1.7%) and from 78 to 97 per 100,000 person years in females (1.1%). In both males and females, significant rising incidence trends were found for melanoma (2.3%), skin (2.3%) and thyroid cancer (3.2%), CML (7.2%), Hodgkin (1.3%) and Non-Hodgkin lymphoma (0.9%). In females, the incidence of breast cancer increased (1.2%), while it decreased for lung (-1.3%) and ovarian cancer (-4.3%). In males, testicular cancer incidence increased significantly (4.1%). The most common cancers in male YAs were testicular cancer (33%), melanoma (15%), gastrointestinal cancer (8%), Non-Hodgkin and Hodgkin lymphoma (both 7%), whereas in females breast cancer (34%), melanoma (19%), gynecological (14%), thyroid and gastro-intestinal cancer (both 5%) were most frequently diagnosed. Over time, the five-year relative survival increased significantly from 72% to 85%. Survival improved for almost all tumor types, except for pediatric tumors: medulloblastoma (~60%), Ewing sarcoma (~43%) and rhabdomyosarcoma (~41%). A $<$ 80% five-year survival rate was also found for tumors of the lung (36%), gastro-intestinal tract (61%), ALL (60%), AML (65%) and soft tissue sarcomas (77%). **Conclusions:** Over the last 26 years, a marked increase in the incidence of a diverse spectrum of hematological and solid malignancies, pediatric and adult-type cancers was found for YAs. Survival improved over time, however remains poor for certain tumor types. Our data underpin the importance of knowledge of tumors at YA age to guide centralization of care and clinical research.

1568 Poster Session (Board #226), Mon, 1:15 PM-4:45 PM

The age specific genomic landscape of cancer. *First Author: Caitlin F. Connelly, Foudation Medicine, Inc., Cambridge, MA*

Background: The frequency of genomic alterations in cancer is known to differ based on a patient's age. Many studies have characterized the genomic characteristics of pediatric cancers; however, less is known about how the genomic landscape of mutations changes with age in adult patients. Accurately characterizing these differences will help guide personalized treatment strategies and illuminate differences in the genetic etiology of cancer at different ages of onset. **Methods:** Comprehensive genomic profiling was performed on > 100,000 patients in the course of routine care for patients with predominantly relapsed, refractory or metastatic cancer. For 117 types of cancer with ≥ 100 cases, logistic regression was used to identify genomic features with statistically significant dependence on patient age. **Results:** Many known associations with age were identified, including increased prevalence of BRCA1/2 mutations in younger breast and ovarian cancer patients and increased prevalence of mismatch repair mutations in younger colorectal and endometrial adenocarcinoma patients. In lung adenocarcinoma, we identified 19 genes for which alteration prevalence was significantly associated with patient age. The genes *ALK, ROS1,* and *RET* were more commonly altered in younger patients, *KRAS* and *MET* were altered more frequently in older patients, and *TP53* was most frequently altered at intermediate ages (40-60). Interestingly, a set of genes that have previously been associated with clonal hematopoiesis (CH) were found to be more frequently detected in older patients across a wide variety of cancer types. Based on the statistical power provided by this large cohort, several novel age based differences in gene alteration rates across multiple tumor types were detected and will be presented. **Conclusions:** Clear differences in genomics based on patient age were observed. This methodology can be used to identify novel associations between germline alterations and cancer types and somatic alterations that occur predominantly in young or elderly patients. These results also highlight the importance of accurately identifying and properly reporting somatic CH mutations during tumor genomic profiling.

1569 Poster Session (Board #227), Mon, 1:15 PM-4:45 PM

Association of dietary fiber intake and gut microbiota in healthy adults. *First Author: Daniel Lin, NYU Langone Medical Center, New York, NY*

Background: Increasing evidence has shown that gut microbiota alterations may play a role in colorectal cancer risk. Diet, particularly fiber intake, may modify gut microbiota composition, which may consequently impact cancer risk development. We investigated the relationship between dietary fiber intake and gut microbiota in healthy humans. **Methods:** Using 16S rRNA gene sequencing, we assessed gut microbiota in fecal samples from 151 healthy adults in two independent study populations: Study A, n = 75 (healthy controls from a colorectal cancer case-control study), and Study B, n = 76 (polyp-free subjects from a cross-sectional colonoscopy study). We calculated energy-adjusted total dietary fiber intake of participants based on food frequency questionnaires. For each study population, we evaluated the relationship between quartiles of higher fiber intake as a continuous ordinal variable, and global gut microbiota community composition (via PERMANOVA of weighted UniFrac distance) and specific taxon abundance (via DESeq2). **Results:** We found that fiber intake was significantly associated with overall microbial community composition in Study B ($p = 0.003$) but not Study A ($p = 0.68$), after adjustment for age, sex, race, body mass index, and cigarette smoking. In a taxonomy-based meta-analysis of these two study populations, higher fiber intake was associated with lower abundance of genus *Actinomyces* (fold change [FC] = 0.769, p = 0.003), and higher abundance of genera *Faecalibacterium* (FC = 1.153, p = 0.03), *Lachnospira* (FC = 1.167, p = 0.04), and *SMB53* (FC = 1.201, p = 0.05). A species-level meta-analysis showed an association between higher fiber intake and higher abundance of *Faecalibacterium prausnitzii* (FC = 1.165, p = 0.03) and lower abundance of *Ruminococcus bromii* (FC = 0.828, p = 0.08). **Conclusions:** Our results suggest that higher intake of dietary fiber may alter gut microbiota in healthy adults. Given the potentially modifiable nature of the gut microbiota through diet, these findings warrant further study of diet-microbiota based colorectal cancer prevention strategies.

1570 Poster Session (Board #228), Mon, 1:15 PM-4:45 PM

The epidemiology of metaplastic breast cancer: A review of 2,500 cases from the national cancer database. *First Author: Brittany Morgan Campbell, Duke University School of Medicine, Durham, NC*

Background: Metaplastic breast cancer (MBC) is a rare, aggressive, sarcomatoid breast cancer that was first described in 1973 but only became recognized as a histologically distinct entity in 2000. Given the paucity of data on the epidemiology of MBC, we performed a population-based analysis to delineate sociodemographic and clinicopathological characteristics associated with increased likelihood of MBC diagnosis. **Methods:** Adult female breast cancer patients with stage I-III MBC and non-MBC histology diagnosed between 2010 and 2013 were identified in the National Cancer Database (NCDB). Multivariate logistic regression was used to identify factors associated with diagnosis of MBC, and Cox proportional hazards modeling was used to estimate the effect of MBC on overall survival. **Results:** 2,451 MBC and 568,057 non-MBC patients were identified. After adjusting for receptor status (ER, PR, HER2), age, stage, grade, and treatment variables, MBC patients had worse survival than non-MBC patients (HR 1.45, $p < 0.001$). Compared to non-MBC patients, a higher proportion of MBC patients were non-Hispanic black (16.7% vs 10.5%), had an annual income < $35k (29.0% vs 25.5%), had lower high school completion rates (36.7% vs 33.9%), were treated at academic centers (35.5% vs 30.8%), and had government-sponsored insurance (48.8% vs 43.7%, all $p < 0.01$). MBC diagnosis was more likely in patients with triple-negative breast cancer (OR 20.71), higher clinical T stage (cT4 vs cT1: OR 6.18), and lower clinical N stage (cN1 vs cN0: OR 0.38, all $p < 0.001$). MBC patients were also more likely to be diagnosed based on pathology from their first operation rather than preoperatively (OR 1.41, $p < 0.001$). **Conclusions:** Black women and women of low socioeconomic status were at increased risk for diagnosis with MBC. Though MBC was more likely to be treated at academic centers, MBC was less likely to be diagnosed prior to surgical intervention. Many of the sociodemographic factors associated with MBC have also been associated with triple-negative breast cancer. Additional research is needed to determine the contribution of sociodemographic factors to the epidemiology of MBC independent of receptor status.

1571 Poster Session (Board #229), Mon, 1:15 PM-4:45 PM

PD-L1 expression in patients with metastatic gastric cancer in South Korea. *First Author: Hyo Song Kim, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea*

Background: Data are limited and conflicting regarding programmed death ligand 1 (PD-L1) expression as prognostic of clinical outcomes in patients (pts) with metastatic gastric cancer (mGC) treated with standard of care (SOC). Factors affecting the association between PD-L1 expression and outcomes include type of assay and antibody, scoring system for PD-L1 expression, and method of tissue collection. We analyzed the association between tumor PD-L1 expression and clinical parameters in Korean pts with inoperable mGC. **Methods:** A retrospective study was performed in 201 pts with inoperable mGC from Yonsei Cancer Center in Seoul, South Korea. Biopsy samples were collected at diagnosis. Tumor PD-L1 expression was measured by IHC using the 22C3 PD-L1 antibody pharmDx kit (Dako North America, Carpinteria, CA, USA). PD-L1 positivity was defined as a combined positive score (CPS) of ≥1%, where CPS is PD-L1$^+$ cells (tumor cells, macrophages, lymphocytes) over the total number of tumor cells, expressed as a percentage. Survival was analyzed using Kaplan-Meier methods, log-rank test, and Cox proportional hazards models, adjusting for age, sex, and ECOG performance status. **Results:** A total of 189/201 (94%) pts received chemotherapy as SOC and were included in this analysis. Median age was 56 years (range, 21-82), 37% of pts were women, and 28% had a BMI ≥24. All pts had stage IV metastatic disease and 27%, 49%, and 24% had well to moderately differentiated, poorly differentiated, and signet ring cell tumors, respectively. Prevalence of PD-L1 positivity was 72.5%. PD-L1 positivity was not associated with age, BMI, or histologic grade. Median overall survival (OS) for the PD-L1$^+$ and PD-L1$^-$ groups was 10.9 and 10.2 months, respectively (P= 0.92). The hazard ratio for the PD-L1$^+$ vs the PD-L1$^-$group was 1.02 (95% CI, 0.74-1.39) before adjusting for age, sex, and ECOG performance status and 1.08 (95% CI, 0.77-1.51) after adjusting. **Conclusions:** Based on this preliminary assay and cutoff, results suggest that PD-L1 expression is not a prognostic factor for mGC. Additional biomarker analyses (eg, immune gene expression profile and microsatellite instability) are planned.

1572 Poster Session (Board #230), Mon, 1:15 PM-4:45 PM

BROCA gene panel testing in African descendants from northeastern Brazil: Genetic susceptibility profile of an admixed population. *First Author: Gabriela Espirito Santo Felix, Centro de Pesquisas Gonçalo Moniz, Fundação Oswaldo Cruz Bahia, Salvador, Brazil*

Background: The rising global burden of breast cancer (BC) in developing countries demands innovative interventions to accelerate progress in cancer control and prevention. Given the high rates of aggressive young onset breast cancer in Brazil, we sought to examine genetic susceptibility to the disease in the State of Bahia in the Northeast of Brazil, which has the largest population of African descendants. **Methods:** We screened cases, high-risk breast cancer patients with and without family history of breast cancer, and controls (cancer-free women) for twenty-eight breast cancer susceptibility genes using a validated targeted capture and multiplex sequencing approach – the BROCA panel. Each participant gave informed consent under IRB approved protocols and provided clinical-pathological and epidemiological data. **Results:** A total of 292 consecutive and unrelated individuals (173 cases and 119 controls) were included. Nearly 2/3rds of the cases (116/173) and about 90% of the controls (108/119) self-reported as African-descendant. Mutations considered pathogenic were identified in 37 (21.4%) cases and in one control (0.84%, RAD51C c.266insA), OR = 27.75 and p = 0.008. The mutated genes in cases were *BRCA1* (in 12 patients), *BRCA2* (10), *ATM* (3), *PALB2* (3), *BRIP1* (3), *BRCA2*/*BARD1* (1), *FAM175A* (1), *FANCM* (1), *NBN* (1), *SLX4* (1) and *TP53* (1). Three recurrent mutations accounted for 12.4% (9/37) of the total: 3 *BRCA1* c.3331_3334delCAAG (known European mutation), 3 *BRCA1* c.211A > G (known Galician mutation), and 3 *PALB2*c.1671_1674delTATT (novel mutation). **Conclusions:** Mutations in *BRCA1* and *BRCA2* (64.85%) or another breast cancer gene (35.15%) occur in one in five high-risk breast cancer patients in the largest study of Northeastern Brazil to date, and a significant proportion were recurrent mutations of European origin, which can be explained by the admixture pattern of the Brazilian population. This result underscores the importance of using multigene panel in cancer genetic epidemiologic research of understudied populations where unexpected findings, such as the recurrent and novel variant in *PALB2* c.1671_1674delTATT, can be detected.

1573 Poster Session (Board #231), Mon, 1:15 PM-4:45 PM

Smoldering Waldenström's macroglobulinemia (SWM): Analysis from the National Cancer Database (NCDB). *First Author: Priyanka Avinash Pophali, Hematology and Medical Oncology, Mayo Clinic, Rochester, MN*

Background: There are no epidemiologic studies of SWM due to lack ofICD codes specific for smoldering status. **Methods:** The NCDB represents ~70% of cancer cases in the US. It records the time to initial treatment or reasons for not receiving treatment. Using the 2004-2012 database, we estimated the overall proportion of new adult WM cases that are smoldering and analyzed outcomes according to socio-geo-demographic subgroups. Patients who were recommended treatment (irrespective of administration status) or died within 120 days of diagnosis were considered to have active WM while those who did not require treatment and had follow-up ≥120 days after diagnosis were considered to have SWM. **Results:** 2322 (28%) of 8302 patients diagnosed with WM were SWM. Median age at diagnosis was 71 (range 28-90) years. Median age did not change significantly during 2004-2012 (P = 0.83) but the proportion of smoldering disease decreased with time (P = 0.02). The proportions of SWM according to socio-geo-demographic subgroups are shown in the Table. Conditional survival (given survival to 4 months) at 5-years was 66% vs. 70% and at 10-years was 38% vs. 46% for active WM vs. SWM, respectively. The OS for SWM was significantly better among females and those who were younger, privately insured, with less co-morbidities and residing closer to a health facility. However, the OS did not differ by racial groups or era of diagnosis 2004-2008 vs 2009-2012. On multivariate analysis, sex, age group and co-morbidity index were significant factors affecting OS while race, insurance, distance from health facility and era of diagnosis were not. **Conclusions:** Approximately 28% of WM cases in the US are smoldering at diagnosis. The prevalence of SWM varied among socio-geo-demographic subgroups. Sex, age and co-morbidities significantly affect survival of SWM.

	Proportion of SWM	P-value
Sex	Males : 27.72% Females : 28.31%	0.13
Race	White, non-hispanic : 28.97% White, Hispanic: 24.79% Black : 21.01% Asian: 20.41% Other: 26.08%	0.0007

Travel distance (miles)	< 12.5 : 28.84% 12.5-49.9 : 26.21% ≥ 50 : 28.18%	0.0005

1575 Poster Session (Board #233), Mon, 1:15 PM-4:45 PM

Major stressful life events and risk of developing lung cancer. *First Author: Syed Hasan Raza Jafri, The University of Texas, Houston, TX*

Background: Lung cancer is the leading cause of cancer-related mortality linked with smoking, though only 6-18% of heavy smokers die of lung cancer. We hypothesized that major stressful life events are a risk factor for developing lung cancer. **Methods:** In our matched case-control study, cases (CA) were lung cancer patients diagnosed within past 12 months. Controls (CO) were patients without a prior history of malignancy. CA and CO were matched for age, gender and smoking status. Smokers had at least 10 packs/years history of smoking. Data was collected using standardized research questionnaire on 11 major stressful life events using Holmes and Rahe stress scale. The primary endpoint was odds of having a major stressful life event. A sample of 360 patients (120 CA and 240 CO), was needed to achieve 80% power to detect an odds ratio (OR) of 2.00 using Chi-Square test with a P = 0.05 significance. The study was IRB approved at each institution. **Results:** Between May 2015 and December 2016, 324 patients were enrolled (23 were excluded due to prior cancer history or incomplete information). 301 (CA = 102; CO = 199) were included in the final analysis. The two groups were well matched in median age (CA = 64.4 years; CO = 63.9years), gender (CA-Male = 48%; CO-Male = 49.2%) and smoking status (ever smoker, CA = 86%; CO = 85%). There was no difference in lifetime stressful life event between CA and CO (95% vs 93.9% P = 0.68%). However, CA were significantly more likely to have had a major stressful life event within the past 5 years than controls (CA = 77.4% vs CO = 65.8%, P = 0.03, (OR = 1.78). Serious life-threatening illness of an immediate family member (P = 0.04) and retirement (P = 0.07) within the past 5 years were noticeably more common among CA. Holmes-Rahe stress score in the last 5 years was higher in men (86.3 vs 63.3, P = 0.07) and those > 65 years old (82.4 vs 57.2,P = 0.04) as compared with CO and in those with squamous histology than with adenocarcinoma (115.6 vs 63.4, P = 0.005). **Conclusions:** Patients with lung cancer (CA) were significantly more likely to have had a major stressful life event within the past 5 years than the matched controls (CO), especially in older men with squamous histology. Major stressful life events should be considered a risk factor for developing lung cancer.

1576 Poster Session (Board #234), Mon, 1:15 PM-4:45 PM

Safety of multiplex gene testing for inherited cancer risk in a fully accrued prospective trial. *First Author: Allison W. Kurian, Stanford School of Medicine, Stanford, CA*

Background: Sequencing more genes increases the chance of finding a pathogenic mutation and/or a variant of uncertain significance (VUS). Little is known about potential harms of multiplex testing for cancer risk, such as unwarranted surgery or adverse psychological effects. **Methods:** We conducted a prospective trial of sequencing 25 genes*: APC, ATM, BARD1, BMPR1A, BRCA1, BRCA2, BRIP1, CDH1, CDK4, CDKN2A, CHEK2, EPCAM, MLH1, MSH2, MSH6, MUTYH, NBN, PALB2, PMS2, PTEN, RAD51C, RAD51D, SMAD4, STK11, TP53*. Patients were eligible if they met standard testing guidelines or predictive models estimated ≥2.5% mutation probability. Participants were surveyed 3 months post-test: the Multidimensional Impact of Cancer Risk Assessment (MICRA) scale measured distress, uncertainty and positive experiences. We report on the fully accrued trial (N = 2000). **Results:** 1998/2000 (99.9%) participants currently have reported results: 12.1% tested positive for a pathogenic mutation (Pos), 34.5% had VUS only and 53.5% tested negative (Neg). Median age was 51, 81% were female, 40% Hispanic, and 72% had a cancer history. Self-reported preventive surgery rates were low (mastectomy 9.3%, hysterectomy 1.5%, oophorectomy 1.6%), with no difference between VUS and Neg patients (p = 0.346). Most patients never or rarely had thoughts of cancer affecting daily activities (Pos 59.5%, VUS 66.9%, Neg 71.0%), never regretted testing (Pos 84.1%, VUS 90.0%, Neg 93.6%), and wanted to know all results, even those that doctors do not fully understand (Pos 81.7%, VUS 78.8%, Neg 77.1%). Pos patients had higher MICRA distress and uncertainty scores than VUS and Neg patients, whose distress and uncertainty scores did not differ significantly (p = 0.165, p = 0.129). Relatives of Pos patients completed genetic testing (30.4%) more often than VUS (5.8%) or Neg patients (5.1%, p < 0.001). **Conclusions:** After multiplex testing of 2000 diverse patients, few reported preventive surgery at 3 months; VUS patients had no more distress, regret or uncertainty than Neg patients. Pos patients most often advised relatives to test, suggesting that participants understood the implications of test results. Longer-term follow-up of test-related outcomes is underway. Clinical trial information: NCT02324062.

1577 Poster Session (Board #235), Mon, 1:15 PM-4:45 PM

Determining the clinical value of germline genetic testing coupled with tumor mutation profiling. *First Author: Edward Esplin, Invitae, San Francisco, CA*

Background: Somatic mutation analysis by next-generation sequencing (NGS) is an expanding clinical assessment offered to cancer patients. Studies report that 4–12% of patients have a positive tumor mutation profiling (TMP) result in a known cancer predisposition gene also identified in their germline, which has potential implications for the patient's acute treatment, ongoing surveillance, and the screening of family members. We report a series of patients with TMP coupled with germline genetic testing and include yield of pathogenic germline mutations, discordance between germline and TMP findings, and potential clinical impact. **Methods:** Our study used de-identified data from 182 consecutive patients who underwent TMP followed by germline testing with an NGS-based hereditary cancer gene panel. **Results:** 50/182 cases (27%) had one or more likely pathogenic or pathogenic (LP/P) germline variants, which is higher than previous reports. Among these 50, 28 (56%) met guidelines for germline testing by personal or family history criteria, 10 (20%) met recently established NCCN criteria for germline testing of patients with BRCA1/2 tumor variants, and 12 (24%) had TMP results that suggested a germline mutation but did not meet any guidelines for germline testing. We identified 52 LP/P germline variants in BRCA2 (17), BRCA1 (7), PALB2 (6), MUTYH (5), CHEK2 (2), and 15 other genes, all with established guidelines that would impact the clinical management of patients and their family members. In 9/50 cases, germline testing revealed variants that were absent in TMP results and provided new information with clinical implications for patients and their families, including variants in BRCA1 and CHEK2. **Conclusions:** In TMP patients, 50 of 182 had a medically actionable germline mutation with established management guidelines. Among these 50, 12 (24%) met neither current personal or family criteria nor the latest NCCN guidelines for germline testing in patients with TMP. Also striking were nine patients whose germline LP/P mutations were absent in TMP results. These data suggest that indications for germline testing of cancer patients must be expanded to avoid missing important germline findings in patients undergoing TMP.

1578 Poster Session (Board #236), Mon, 1:15 PM-4:45 PM

Does race play a role in genetic screening for hereditary cancer syndromes? *First Author: Sudeshna Chatterjee, New York Presbyterian Hospital, Weill Cornell Medical College, New York, NY*

Background: Molecular analysis of cancer predisposition genes may influence cancer screening, prevention strategies and options for targeted therapy. We sought to identify ethnic differences in patterns of genetic testing. **Methods:** Results of all patients with known ancestry who underwent genetic testing at the hereditary breast and ovarian cancer center at a single institution between 7/1/2013-12/31/2016 were reviewed. Race was stratified as Black, White, Asian, and Hispanic. Ashkenazi Jews were excluded from the White subgroup because of their higher rates of testing for deleterious founder mutations. White patients were utilized as the reference population for all statistical analysis. **Results:** 894 patients were included: 139 Black, 613 White, 33 Hispanic and 108 Asian. Black patients were more likely to undergo genetic testing for a personal history of cancer rather than family history risk assessment compared to White patients ($p = 0.002$). There was no difference in genetic testing rates based on personal or family history of cancer between Asians or Hispanics and Whites ($p = 0.398$;$p = 0.366$). Black patients were more likely than White patients to undergo testing with targeted-gene rather than multigene panels ($p = 0.026$). The use of targeted and multigene panels were not different among Asians or Hispanics ($p = 1.0$). Blacks, Asians and Hispanics had a lower rate of known deleterious mutations but a higher rate of variants of unknown significance (VUS) than Whites (15.1% $p = 0.048$; 22.2% $p = .001$; 33.3%$p = .002$ respectively). *BRCA1/2* mutations accounted for 100% of identified mutations across all the non-White populations. Among Blacks, *BRCA1/2* accounted for 38.1% of VUS compared to 27.9% in Whites ($p = .2114$). VUS in the *ATM* gene accounted for 28.6% in Blacks compared to 8.2% in Whites ($p = 0.028$). **Conclusions:** Black patients were less likely to undergo testing based on family history, suggesting a missed opportunity for cancer prevention. They were more likely to undergo targeted testing and100% of identified mutations were in *BRCA1/2* genes. Non-white patients had higher rates of VUS, emphasizing the need for improved VUS reclassification in non-White populations.

1579 Poster Session (Board #237), Mon, 1:15 PM-4:45 PM

Development and validation of a residual risk score to predict breast cancer risk in unaffected women negative for mutations on a multi-gene hereditary cancer panel. *First Author: Elisha Hughes, Myriad Genetics, Inc., Salt Lake City, UT*

Background: Women who are unaffected with cancer but have a significant family history of breast cancer (BC) are frequently referred for hereditary cancer testing with multi-gene panels; however, $< 10\%$ test positive for clinically actionable mutations. Large-scale genotyping studies have identified common variants (primarily single-nucleotide polymorphisms) that individually confer modest BC risk, but together may explain the genetic susceptibility for BC in many women without monogenic mutations. Here, we describe the development and validation of a polygenic residual risk score in a large, consecutive cohort of women who tested negative for mutations in known BC susceptibility genes. **Methods:** This IRB-approved study includes women of European ancestry tested with a multi-gene hereditary cancer panel who were negative for mutations in 11 genes associated with BC (*BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, PALB2, CHEK2, ATM, NBN, BARD1*). Clinical information was collected from provider-completed test request forms. The dataset was divided into a training (July – November 2016) and validation cohort (November 2016 – April 2017). Multivariable logistic regression models were used to evaluate 94 common variants and develop candidate residual risk scores as predictors of personal BC history (invasive ductal carcinoma, IDC) in the training cohort. Independent variables included age, personal/family cancer history, and ancestry. An optimal subset of the 94 common variants and a residual risk score will be selected through cross-validation followed by independent validation. **Results:** The training cohort includes 11,838 women (median age 47 years), 18% of whom reported a personal history of IDC and 36% of whom reported BC in a first-degree relative. Results from validation of the residual risk score in an independent cohort of approximately 12,000 women will be completed at the time of presentation. **Conclusions:** The validation and clinical implementation of a residual risk score for women at risk for hereditary BC may offer significant potential for the management of high-risk, unaffected women who test negative for monogenic BC mutations.

1580 Poster Session (Board #238), Mon, 1:15 PM-4:45 PM

Patterns of genetic screening for hereditary cancer syndromes: Effect of Supreme Court's ruling invalidating single gene patent rights. *First Author: Zhen Ni Zhou, New York Presbyterian Hospital, Weill Cornell Medical College, New York, NY*

Background: In 6/2013 the Supreme Court ruled that isolated DNA sequences found in nature could not be patented, resulting in rapid uptake of multigene panels. We sought to explore trends in genetic testing since this ruling. **Methods:** Results of all patients undergoing genetic testing and counseling at a single institution between 7/1/13 and 12/31/16 were reviewed. Associations between categorical variables were evaluated by chi-square tests or Fisher's exact tests as appropriate for category size. **Results:** 1663 patients underwent genetic testing over the study period. The median age was 49 years (range 18-86). Use of multigene panels versus targeted gene testing increased significantly in the years following the Supreme Court ruling (Table 1, $P<0.001$). While the percentage of patients found to have pathogenic mutations remained stable over the study period (9%), detection of variants of uncertain significance (VUS) increased significantly (Table 1, $P<0.001$). In 2013 *BRCA1/2* mutations accounted for 91% of identified mutations; however this number decreased over time (2014-83%, 2015-70%, 2016-58%, P=0.01). Use of multigene panels detected 71% of mutations in non-*BRCA1/2* genes such as *CHEK*(19), *APC* (44), *MSH6*(1), *P53*(1), and *PTEN*(1). Patients with a personal history of breast and/or ovarian cancer were more likely to have targeted testing than patients with other cancer types (590, 66% vs. 9, 33%, P=0.001). **Conclusions:** The uptake of multigene panels has increased since the 2013 Supreme Court ruling. While this technology allowed for the identification of many cancer-related genes that would be missed on targeted *BRCA1/2* testing, it also resulted in a significantly increased detection of VUS, a finding with unknown clinical implications.

Percentage of patients undergoing single gene testing versus multigene panel testing and identified mutations versus variants of uncertain significance (VUS) following the Supreme Court invalidation of exclusive gene patents.

Year	Targeted gene testing (%)	Multigene panel testing (%)	Mutations detected (%)	VUS detected (5)
2013	92.5	7.5	9.9	2.3
2014	76.6	23.4	8.7	9.7
2015	61.7	38.3	6.6	13.1
2016	44.6	55.4	10.9	10.9

Germline mutations in cancer predisposition genes among patients with thyroid cancer. *First Author: Junne Kamihara, Dana-Farber Cancer Institute, Boston, MA*

Background: Thyroid cancers are known component tumors of both well-described and emerging hereditary cancer syndromes. To assess the contribution of germline variants in thyroid cancer predisposition, we examined the prevalence of germline mutations among individuals with a history of thyroid cancer, compared to those with thyroid and breast cancer or breast cancer alone. **Methods:** Clinical histories and molecular results were reviewed for individuals with a history of thyroid and/or breast cancer, ascertained from a cohort of > 140,000 patients who underwent hereditary cancer multigene panel testing at a single commercial laboratory. Clinical history information was obtained from test requisition forms completed by ordering clinicians and from pedigrees/clinic notes, if provided. **Results:** Among 2,678 thyroid cancer patients, the majority were Caucasian (66.9%), female (92.3%), and/or had an additional cancer primary (71.9%), with nearly half reporting an additional breast cancer primary (49.1%). Among those with available pathology information, 4.1% had medullary thyroid cancer. The median (IQR) age at diagnosis was 38 (26,48) years, and while 94.1% had a family history of cancer, 78.8% had at least one affected 1st degree relative. Overall, 11.1% were identified as mutation carriers, defined as ≥1 pathogenic or likely pathogenic variant. Among those with thyroid cancer alone, 9.7% had a mutation, similar to those with breast cancer alone (9.7%) and those with breast and thyroid cancer only (10.5%). Genes most frequently mutated in the thyroid only group included *CHEK2* (3.1%), *MUTYH* (monoallelic) (2.4%), *APC* (2.0%), *ATM* (1.6%), and *PALB2* (1.2%). *CHEK2* was the most frequently mutated gene observed in all groups, with a higher frequency seen among those with thyroid and breast cancer (5.5%) compared to breast cancer (2.5%) or thyroid cancer (3.1%) alone ($p < 0.001$). **Conclusions:** A high rate of germline mutations is observed among individuals with thyroid cancer presenting for clinical genetic testing, even in the absence of other primary cancer diagnoses. Thyroid cancer may be an under-recognized component tumor of hereditary cancer predisposition syndromes suggesting the need for further investigation.

1582 Poster Session (Board #240), Mon, 1:15 PM-4:45 PM

Melanoma genetic testing to promote reductions in tanning: Results from the Utah BRIGHT project. *First Author: Lisa Aspinwall, University of Utah, Salt Lake City, UT*

Background: Predictive genetic testing for familial cancer may alert people to highly elevated risk prior to disease onset. Genetic test reporting has been shown to improve uptake of prophylactic screening and procedures, but whether test reporting also promotes increased performance of primary preventive behavior is unknown. **Methods:** Unaffected adult participants (N= 124) from high-risk melanoma families, ages 16-69 (mean = 35.24, 52% men) were enrolled. Participants from families that carried a *CDKN2A/p16* mutation received a personal genetic test result *and* counseling about management recommendations whereas control participants from families without a *CDKN2A/16* mutation received equivalent counseling and management recommendations based on family history alone. Photoprotection outcomes were compared between *CDKN2A/p16* participants (31 carriers, 44 noncarriers) and the no-test control group (n= 49), allowing the effects of receiving a genetic test result to be distinguished from the effects of counseling alone. Assessments were seasonally timed to capture tanning during the summer months. Melanin Index (MI) scores, measures of skin tanning obtained through reflectance spectroscopy, were assessed at the dorsal wrist and face. Tanning of the dorsal wrist and face were calculated by subtracting baseline MI scores at an unexposed site on the same individual. **Results:** Multilevel model analyses examined changes in tanning over time while controlling for clinician-rated skin type, age, gender, date of assessment, and group differences in phenotypic factors and family medical history. Participants who received positive test results were significantly less tan at the wrist one year after their previous summer baseline (b= -.11, p< .001). No-test controls and noncarriers had no change in tanning. The magnitude of decrease in tanning measurements observed among *CDKN2A/p16* carriers approximated one skin type. Facial tanning did not differ from baseline for any group. **Conclusions:** A positive melanoma genetic test result promotes reduced UVR exposure. Future research should examine why positive genetic test reports were more motivating to patients than equivalent counseling based on family history.

1583 Poster Session (Board #241), Mon, 1:15 PM-4:45 PM

BRCA1 and BRCA2 mutations in ovarian cancer patients from China: Association of ethnic-specific mutations in BRCA1 with an increased risk of ovarian cancer. *First Author: Tingyan Shi, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: *BRCA1/2* are cancer predisposition genes involved in hereditary breast and ovarian cancer (HBOC). Mutation carriers display an increased sensitivity to inhibitors of poly (ADP-ribose) polymerase (PARP). Despite a number of small-size hospital-based studies being previously reported, there is not yet, precise data of *BRCA1/2*mutations among Chinese epithelial ovarian cancer (EOC) pts. **Methods:** We performed a multicenter cohort study including 916 unselected consecutive EOC pts from eastern China, to screen for *BRCA1/2*mutations using the next-generation sequencing approach. **Results:** 153 EOC pts were found to carry pathogenic germline mutations in *BRCA1/2*, accounting for an overall mutation incidence of 16.7% with the predominance in *BRCA1* (13.1%) compared with *BRCA2* (3.9%). We identified 53 novel pathogenic mutations, among which the c.283_286delCTTG and the c.4573C>T of *BRCA1* were both found in two unrelated patients. More importantly, the most common mutation, c.5470_5477del8 was most likely to be Chinese population-related without an apparent founder origin. This hot-spot mutation was presumably associated with an increased risk of EOC. Taken together, germline *BRCA1/2*mutations were common in Chinese EOC pts with distinct mutational spectrum compared to Western populations. **Conclusions:** Our study contributes to the current understanding of *BRCA1/2* mutation prevalence worldwide. We recommend *BRCA1/2*genetic testing to all Chinese women diagnosed with EOC in order to identify HBOC families, to provide genetic counselling and clinical management for at-risk relatives. Mutation carriers may also benefit from PARP-targeted therapies.

	Total (%)	Mutation (%)	P	Pathogenic mutation (%)	P
Cases	916 (100)	194 (21.8)		153 (16.7)	
Histology			0.005		0.004

Unexpected germline mutations in a pan-cancer analysis including sarcoma, renal, and other cancers. *First Author: Shan Yang, Invitae, San Francisco, CA*

Background: Multi-gene testing for cancer predisposition is increasingly utilized in clinical care. Although the diagnostic yield and management implications of such testing in breast, ovarian and colorectal cancer are relatively well understood, data for other cancer types are still emerging. In this study we retrospectively examined 39,147 patients referred for hereditary cancer syndrome testing for pathogenic germline variants in 80 cancer risk genes, focusing on those patients with renal, sarcoma, paraganglioma, melanoma, and pancreatic cancers. **Methods:** Test results and personal/family history were extracted from a sequential series of de-identified clinical test reports. Data for genes not clinically ordered were analyzed under an IRB approved research protocol. Common low penetrance risk alleles were excluded. **Results:** Overall, 14.3% (5,589) of patients carried germline pathogenic mutations in 80 cancer risk genes. Of the 949 patients with renal cancer 20% (190) were positive, and 44% of these findings were "unexpected", meaning they appeared in genes that are not commonly requisitioned in renal cancer patients. Of the 423 sarcoma patients, 16% (68) had positive findings, 45% of which were "unexpected". For both cancer types, greater than 90% of these "unexpected" findings were in genes with published management recommendations. Similar results were observed in melanoma, paraganglioma and pancreatic cancer patients. A second or third pathogenic variant, many of which were also "unexpected", were found in 3.6% of positive cases. **Conclusions:** In this series of patients we estimate almost 12% of pathogenic variants across cancer indications are "unexpected". These data suggest many actionable pathogenic variants are being missed due to adherence to overly restrictive, narrowly constructed tumor-specific panels. Clinicians should expand the scope of their test panels in order to capture variants with the potential to impact patients and their family members by informing implementation of established management guidelines.

1585 Poster Session (Board #243), Mon, 1:15 PM-4:45 PM

Are we still adjusting to multigene panel testing? An NCI-designated cancer center's 2-year experience. *First Author: Chethan Ramamurthy, Fox Chase Cancer Center, Philadelphia, PA*

Background: Genetic testing for hereditary cancer predisposition has rapidly changed over the past few years with the introduction of multigene panel testing. Multigene testing has evolved from disease-agnostic comprehensive (C) panels alone to include disease-specific but expanded (DSE) panels as well as guideline-based (GB) panels. We analyzed trends in utilization of genetic testing over a two-year period in one NCI-designated Cancer Center, hypothesizing that over time genetic testing usage would trend toward more disease-specific panels. **Methods:** We conducted a retrospective analysis of our program's database for all germline genetic tests ordered from 9/1/2013 to 8/31/2015 (n = 619; 246 in year 1, and 373 in year 2). Tests were categorized into three groups based on specificity: GB (range: 2-12 genes tested), DSE (12-35 genes tested), and C (28-80 genes tested). The Chi-square test was used to analyze test types ordered in year 1 (9/1/2013-8/31/2014) and year 2 (9/1/2014 – 8/31/2015) and the proportions of resulting mutation types. **Results:** A total of 604 germline genetic tests met the inclusion criteria: 39 GB (20 year 1, 19 year 2), 171 DSE (43 year 1, 128 year 2), and 394 C (180 year 1, 214 year 2). Compared to year 1, a larger proportion of DSE tests (35% v. 18%, $p < 0.001$), and a smaller proportion of C tests (59% v. 74%, $p < 0.001$) and GB tests (5% vs. 8%, $p = 0.146$) were ordered. DSE panels revealed a pathogenic variant (PV) at a rate of 16% and a variant of unknown significance (VUS) at a rate of 24%. C tests revealed a PV and VUS at rates of 14% and 29%, respectively. GB tests revealed a PV and VUS at rates of 21% and 18%, respectively. No statistically significant differences in detection rates of mutation types (PV or VUS) were found between GB, DSE, or C tests. **Conclusions:** The rates of PV detection were not significantly different between test types, but the profile of tests ordered changed over time to favor DSE panels. Exploration of factors contributing to changing trends in genetic testing are warranted as counselors and clinicians adapt to the quickly expanding number of genes associated with hereditary cancer risks, many of them moderate-risk, and the evolving landscape of multigene panel testing.

1586 Poster Session (Board #244), Mon, 1:15 PM-4:45 PM

Decision support for family history intake to determine eligibility for *BRCA* testing among multiethnic women. *First Author: Julia E. McGuinness, Columbia University College of Physicians and Surgeons Department of Medicine, New York, NY*

Background: The U.S. Preventive Services Task Force (USPSTF) recommends that women who meet family history criteria for hereditary breast and ovarian cancer (HBOC) be referred for genetic counseling. However, HBOC genetic testing is under-utilized, particularly among racial/ethnic minorities. We evaluated different methods of family history intake, including a validated family history screener, documentation in the electronic health record (EHR), and a web-based decision aid (DA). **Methods:** Among women undergoing screening mammography, we administered a validated family history screener to determine eligibility for *BRCA* genetic testing based upon USPSTF guidelines. We developed a patient-centered DA (*RealRisks*) which includes modules on breast cancer risk, collection of detailed family history, and information on HBOC genetic testing. Women who met high-risk criteria for breast cancer were enrolled in an intervention trial to determine whether exposure to *RealRisks* increases referrals for high-risk consultations. *BRCA* genetic counseling/testing uptake was assessed by self-report and EHR review. **Results:** From November 2014 to June 2016, 3077 women completed the family history screener. Median age was 59 years (range, 29-99), including 76% Hispanic, 4% Ashkenazi Jewish, and 60% with a high school education or less. 12% met family history criteria for *BRCA* genetic testing based upon the family history screener, of which only 5.9% had previously undergone genetic counseling or testing. Sixty high-risk women were enrolled to access *RealRisks*. When family histories based upon the screener, DA, and EHR were compared, 12 (20%) had discrepancies in number of affected relatives, type of cancer, and age at diagnosis which changed eligibility for *BRCA* testing. Follow-up is ongoing to determine whether the DA facilitates appropriate referrals for genetic counseling. **Conclusions:** In a population of predominantly Hispanic and less educated women, a large proportion met USPSTF family history criteria for *BRCA* testing, but uptake of genetic counseling was low. Developing decision support for accurate family history intake is critical to identifying appropriate candidates for genetic referrals.

1587 Poster Session (Board #245), Mon, 1:15 PM-4:45 PM

Remote genomic consultation to support uptake of a multi-gene genomic tumor panel (MGTP) by community oncologists (COs): Results of a pilot study. *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: MGTP use in routine cancer (CA) care is likely to increase w/lower costs for NGS-based testing and growing numbers of actionable targets coupled with targeted therapeutics. Early MGPT uptake has been slow among community oncologists (COs) due to their lower confidence to order, interpret, and act upon results of MGTP. This study evaluated the provision of telephone genomic consultation (GC) via an academic clinician link to an institutional genomic tumor board to support MGTP testing of CA patients (PTs) by COs. **Methods:** 4 practices of COs participated: 9 COs recruited 25 PTs w/metastatic CA. All PTs/COs completed baseline and follow-up (FU) assessments. Tumor blocks were evaluated at Fox Chase Cancer Center (FCCC) and tested w/a 50-gene MGTP. 12% blocks were inadequate. MGTP results were presented when appropriate at FCCC's Genomic Tumor Board. All MGTP yielded > 1 variant (Var) [range 1-6]: 13/22 (59%) pts tested had a clinically relevant V; 6 other Vars were potentially actionable w/ approved therapy, while 3 Vars have novel therapies in Phase I/II studies. MGTP were called out to COs (by MJH) < 2 wks of resulting. A tailored summary was provided to COs. **Results:** At baseline, COs (n = 9) had limited experience w/MGTP (78%, < 5 ordered). Barriers for COs were: poor understanding of MGTPs (67%), cost (89%), uncertain benefit (44%), and poor access to targeted therapies (67%). At FU, 4/8 (50%) COs found GC "very useful", and 63% reported MGPT paired w/GC would "probably/definitely" increase their use of MGTPs. Most (88%) felt MGPTs should be offered to PTs w/incurable CA. Among PTs at baseline (n = 25), awareness of MGTP was moderate (50%), but 79% reported it would help doctors take better care of their PTs. Valuation of MGTP was mixed—30% would pay $0 out of pocket, yet 30% also said they would travel "any distance" for an MGT-targeted experimental therapy. At FU (n = 14), 86% PTs felt MGPT was valuable, yet only 46% would "definitely" retest, and only 31% would pay > $100 to retest, even for 500+ genes. **Conclusions:** GC can be effective to support COs to use MGTPs. PTs w/CA have high expectations of MGTPs to improve their care, and yet attribute modest value to retest or to have a larger MGTP.

1588 Poster Session (Board #246), Mon, 1:15 PM-4:45 PM

VHVT: An ultra-sensitive somatic mutation detection and performance assessment program. *First Author: Jilong Liu, BGI-Shenzhen, Shenzhen, China*

Background: NGS as a high throughput technique is particular valuable for cancer given its ability to detect multiple driver mutations. While reads contain SNVs and short InDels can be mapped to the right position using gatk-like programs, a program designed for germline mutation detection, reads contain long InDels such as EGFR EX19 deletions often wrongly mapped especially when deletions near the ends of the reads. Thus, gatk would not recognize these reads, consequently underestimate the mutation allelic frequency, and even missed out InDels when supporting reads were rare. **Methods:** Here we present a variation hotspot validation toolkit (VHVT), a validation based method to precisely detect the ultra-low frequency somatic mutations. As far as we know, it is the first specialized somatic mutation detection software. First, reference sequences aimed at the hotspot mutations were assembled, then reads were be mapped to the new assembled reference to precisely distinguish the supporting reads. Moreover, log odds (LOD) and Poisson mathematical model were integrated to control sequencing error, as a result, VHVT can achieve a limitation of detection at 0.01% with sensitivity and specificity above 95% and 99% respectively. In addition, we developed a method to quantitatively assess the performance of variation detection program using standard reference data. By mapping to the reconstructed reference, all supporting reads will be detected in sequencing data, and comparing theses with the number of supporting reads delivered by a program we can define recognition ratio of supporting reads. **Results:** Our reference standard data showed that VHVT can recognize average 30% more support reads than gatk for EGFR EX19 deletions. In a total 498 NSCLC clinical samples test, VHVT detected actionable mutations in 289 samples. 243 positive mutations were verified (168 by SANGER sequencing, 75 by ddPCR) with concordance rate at 100%. **Conclusions:** Taken all together, our results demonstrated the robust performance of VHVT for somatic mutation detection and program assessment and thus facilitate the development of personalized cancer therapy.

1589 Poster Session (Board #247), Mon, 1:15 PM-4:45 PM

Assessment of BRCA testing uptake in ovarian cancer patients during the implementation of an oncologist-led genetic counseling model at an urban and suburban teaching hospital. *First Author: Jennifer Jorgensen, Montefiore Medical Center, Bronx, NY*

Background: *BRCA* testing has become an integral component of ovarian cancer management; however, low testing uptake remains an obstacle. This study evaluated the impact of an oncologist-led counseling and testing model on *BRCA* testing uptake. **Methods:** The ENGAGE study (NCT02406235) is a prospective study of an oncologist-led *BRCA* counseling and testing model in patients with epithelial ovarian, primary peritoneal and fallopian tube cancer (EOC). The United States lead accruing gynecologic oncology sites were Montefiore, an urban academic medical center; and Winthrop, a suburban teaching hospital. Oncologists were trained in *BRCA* counseling prior to site activation, and directly submitted patients' samples for *BRCA* testing. Prior to the ENGAGE study, EOC patients were referred to genetics professionals for counseling and testing. We determined the number of *BRCA* tests performed, and simple descriptive statistics were used to summarize the data. **Results:** A combined total of 141 EOC patients underwent BRCA testing during the 20 consecutive months analyzed. In the 10 months pre-ENGAGE, 8 Montefiore patients had *BRCA* testing, all submitted through the genetics division. Nineteen Winthrop patients had *BRCA* testing, 16 from their oncologist's office and 3 from an external genetics office. During the 10-month ENGAGE trial, 64 Montefiore patients and 50 Winthrop patients had *BRCA* testing. This represents a four-fold increase in *BRCA* testing uptake, with 114 patients tested during ENGAGE versus 27 patients tested pre-ENGAGE. Of these 114, 99 had *BRCA* counseling and testing through their oncologist's office. **Conclusions:** Implementation of an oncologist-led genetic counseling and testing model was associated with increased *BRCA* testing among ovarian cancer patients in both the urban and suburban hospitals. Increased *BRCA* testing could be related to increased patient convenience and standardized training of the clinical team. These findings may guide other institutions as they implement streamlined genetic counseling and testing protocols.

1590 Poster Session (Board #248), Mon, 1:15 PM-4:45 PM

Dissemination of universal genetic testing to three unique oncology care settings. *First Author: Erica Bednar, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Efforts are occurring across the United States to improve the rates of identification and standard of care genetic counseling (GC) and genetic testing (GT) of pts with breast and ovarian cancer. Following a successful quality improvement (QI) initiative to increase referrals and utilization of GC/GT among pts with breast and ovarian cancer to >80% at our host site (HS), we sought to disseminate the QI project to three unique oncology care settings (OCS). **Methods:** The OCS described in the Table are certified members of the HS network, were strategically identified, and agreed to participate in the QI project. Genetic counselors at the HS and OCS built teams to plan and initiate the project. A 130-item environmental scan was created by the HS team to assess OCS structure, resources, and GC/GT processes. OCS teams completed the environmental scan and a semi-structured interview with the HS; and from this, barriers to GC/GT were identified, then categorized using Ishikawa diagrams. Clinical interventions were designed to address these barriers. Resulting QI protocols follow the PDSA-cycle QI model. A database was built for retrospective and prospective data collection of eligible pts and rates of GC/GT referral and completion from 2015-2018. **Results:** Although unique barriers were identified at each OCS, all identified: pt referral/scheduling issues, technology and electronic medical record system inefficiencies, and inconsistent physician referral/GT practices. OCS interventions include: implementation of physician-coordinated GT, GC within chemo infusion suites, physician education sessions, GC scheduling improvements, creation of pt education documents, and development of referral tracking processes. **Conclusions:** Genetic counselors collaborated, planned, and initiated dissemination of a QI project to improve GC/GT utilization at three unique OCS. QI interventions were developed to address the unique environment and barriers at each OCS.

TPS1591 Poster Session (Board #249a), Mon, 1:15 PM-4:45 PM

ASAMET: A randomized, 2x2 biomarker prevention trial of low-dose aspirin and metformin in colorectal cancer. *First Author: Marilena Petrera, Division of Medical Oncology, E.O. Galliera Hospital, Genoa, Italy*

Background: Epidemiological studies and cardiovascular prevention trials have shown that low-dose aspirin (ASA) can inhibit colorectal cancer (CRC) incidence and mortality, including inhibition of distant metastases. Metformin (MET) has also been associated with decreased CRC incidence and mortality in meta-analyses of epidemiological studies in diabetics and has been shown to decrease by 40% colorectal adenoma recurrence in a randomized trial. Recent studies have shown that ASA is an inhibitor of mTOR/S6K1 and an activator of AMPK, targeting regulators of intracellular energy homeostasis and metabolism, and that the combination of ASA and MET, another AMPK activator and S6K1 inhibitor, has a striking additive effect on AMPK activation and mTOR inhibition, with increased autophagy and decreased cell growth in CRC cell lines. While both drugs are being tested as single agents, their combination has not been tested in clinical trials. **Methods:** This is a randomized, placebo-controlled, double-blind, 2x2 biomarker trial of ASA and MET to test the activity of either agent alone and the potential synergism of their combination on a set of surrogate biomarkers of colorectal carcinogenesis. After surgery, 160 patients with stage I-III CRC will randomly be assigned in a 4-arm trial to either ASA, 100mg qd, MET 850mg bid, their combination, or placebo for 1 year. The primary endpoint is the change, defined as the difference between pre- and post-treatment expression, of NFκBin the unaffected mucosa of proximal and distal colon obtained by multiple biopsies in paired colonoscopies one year apart. Additional biomarkers will include: 1) the genomic profile of candidate genes, pathways, and overall genomic patterns in tissue biopsies by genome-wide gene expression arrays; 2) the IHC expression of tissue pS6K, p53, beta-catenin, PI3K; 3) the associations of mutations and SNPs with treatment response by NGS of primary tumors; 4) the measurement of circulating IL-6, CRP and VEGF, and 5) plasma and colonic MET concentrations and their correlation with biomarker profiles. A favorable biomarker modulation may provide important clues for a subsequent phase III adjuvant trial. Clinical trial information: EudraCT Number: 2015-004824-77.

TPS1592 Poster Session (Board #249b), Mon, 1:15 PM-4:45 PM

Effect of bariatric surgery on breast tissue and biomarkers in obese women at increased risk for breast cancer. *First Author: Tarah Jean Ballinger, Indiana University, Indianapolis, IN*

Background: Obesity represents a challenging epidemic associated with increased risk of several malignancies, including breast cancer in postmenopausal women. Proposed mechanisms for the association between obesity and breast cancer risk include increased insulin resistance, elevated levels of circulating estrogens, and chronic inflammation. Intentional weight loss from bariatric surgery has been associated with decreased risk of breast cancer. While rapid improvements in serologic markers of metabolism and inflammation are seen following bariatric surgery, short- and long- term changes in breast tissue remain less clear. This study investigates the effect of bariatric surgery on breast density and biomarkers of increased risk in breast tissue. **Methods:** This pilot, single institution, observational study (NCT02681120) is recruiting pre- and post-menopausal women with BMI ≥30 from a University bariatric surgery clinic using the Hughes risk application as a screening tool. Eligible patients must have a lifetime risk for breast cancer of ≥20%. Participants are evaluated by imaging, breast biopsy, and blood samples at baseline, 14 days post-operatively to determine the effects of rapid metabolic changes, and 1 year post-operatively to determine the effects of significant weight loss. The impact of bariatric surgery on known imaging parameters of breast cancer risk is assessed by background parenchymal enhancement on MRI and breast density on mammogram. Breast tissue is evaluated for changes in immune infiltrates, aromatase expression, and the presence of crown-like structures, a marker of inflammation seen in the breast tissue of obese women. Tissue samples at each time point are also compared to samples from lean women in the Susan G. Komen Tissue Bank at the IU Simon Cancer Center. Blood is collected for correlative studies evaluating markers of inflammation, insulin resistance, metabolism, and hormone synthesis. Enrollment is currently ongoing with a planned accrual of 40 patients, and data collection is estimated to complete by the end of 2018. Clinical trial information: NCT02681120.

2000 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Randomized, double-blind, phase III trial of a personalized peptide vaccination for human leukocyte antigen-A24-positive glioblastoma multiforme patients refractory to temozolomide-based therapy. *First Author: Mizuhiko Terasaki, Department of Neurosurgery, Kurume University, Kurume, Japan*

Background: To establish whether personalized peptide vaccination (PPV) is clinically beneficial for human leukocyte antigen (HLA)-A24-positive glioblastoma multiforme (GBM) patients refractory to temozolomide (TMZ)-based therapy. **Methods:** From January 2012 to March 2016, 88 HLA-A24-positive GBM patients refractory to TMZ-based therapy from 20 Japanese hospitals were randomly assigned to receive PPV treatment (n = 58) or best supportive care (BSC) (n = 30) at a 2 to 1 ratio. Four peptides chosen from 12 peptide candidates based on pre-vaccination IgG levels specific to each peptide or 4 corresponding placebos were injected subcutaneously once weekly for 12 times at the first course followed by biweekly vaccinations until disease progression. The primary endpoint was overall survival (OS). **Results:** The primary endpoint was not met in this clinical trial. Unfavorable prognostic factors were performance status (PS) 3, higher plasma levels of pre-vaccination granulocyte macrophage-colony stimulating factor (GM-CFS), and PPV containing SART2-derived peptides. Therefore, 78 patients with PS of 0 to 2 (50 with PPV and 28 with BSC) were provided for the subgroup analysis. Among them, the median OS of 39 PPV patients (10.4 months, 95% CI, 7.8-12.0 months) who had either lower levels of GM-CSF ($<$ 0.9 pg/mL) or 4 peptide vaccinations that did not include SART2-derived peptides was significantly (p = 0.03) longer than that of the corresponding 19 BSC patients (6.8, 4.6-12.7). In contrast, the median OS of 10 PPV patients (4.1, 1.1-8.3) who had both higher levels of GM-CSF ($>$ 0.9 pg/mL) and 4 peptide vaccinations containing SART2-derived peptides was significantly (p = 0.01) shorter than that of the corresponding 9 BSC patients (not reached, 1.6-not reached). A single grade 3 adverse event was the only PPV-related adverse event of grade $>$ 3 in this study. **Conclusions:** PPV monotherapy could be a new treatment modality for HLA-A24-positive GBM patients refractory to TMZ-based therapy, since this approach showed clinical benefit and safety under precision medicine-based pre-vaccination selection of appropriate patients. Clinical trial information: UMIN000006970.

2001 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Histopathologic review of suspected disease progression in patients with recurrent glioblastoma (GBM) receiving nivolumab ± ipilimumab: CheckMate 143. *First Author: Solmaz Sahebjam, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Patients treated with immunotherapies can have a transient increase in lesion size due to immune cell infiltration that is suggestive of disease progression, but undergo subsequent regression with continued treatment. For patients with GBM, distinguishing progression from immune-related treatment effects using neuroimaging is challenging. Histopathologic examination of tumors could show the activity of immunotherapies in GBM and potentially minimize premature discontinuation of therapy and increase clinical benefit. Neuropathologic data from patients with recurrent GBM treated in CheckMate 143 who underwent biopsy/resection after suspected progression are presented. **Methods:** Patients received nivolumab 3 mg/kg (nivo 3) Q2W or nivo 3 + ipilimumab 1 mg/kg (ipi 1) Q3W $\times$ 4 doses then nivo 3 Q2W. Tissue collected from patients with suspected radiologic progression was submitted for blinded central review by 2 neuropathologists. Potentially significant treatment effect was defined as $\geq$30% necrosis/reactive changes and $\leq$50% viable solid tumor by area in posttreatment samples, or significant morphological changes from a prior biopsy if available. Results were compared with those from automated morphometry, pretreatment biopsy, and control pairs from unrelated patients with GBM treated with standard of care. **Results:** Of patients treated with nivo 3 (n = 20) or nivo 3 + ipi 1 (n = 1), 13 had potential treatment-related effects and 8 had no evidence of treatment effects (consistent with disease progression). Results were sent in real time to the treating physician to help inform treatment decisions; 4/13 patients with potential treatment effects continued therapy. Treatment effects were unrelated to age, *MGMT* methylation status, or PD-L1 expression (clone 28-8; archival tissue). Results were similar for automated morphometry analyses and showed differences between patients receiving nivo ± ipi and unrelated controls. **Conclusions:** These results suggest that histopathologic analyses may help better inform decisions on continuing nivo ± ipi in challenging cases, and show that immunotherapies may have intracerebral biological activity. Clinical trial information: NCT02017717.

2002 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Phase 1b open-label randomized study of the oncolytic adenovirus DNX-2401 administered with or without interferon gamma for recurrent glioblastoma. *First Author: Frederick F. Lang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: DNX-2401 is a replication-competent, tumor-selective, oncolytic adenovirus with enhanced infectivity that causes durable tumor control by killing tumor cells and eliciting antitumor immunity. To increase immune activation, a phase 1b randomized study of intratumoral DNX-2401 alone versus DNX-2401 with interferon gamma (IFN) was conducted. **Methods:** A total of 27 patients with biopsy-confirmed glioblastoma at first or second recurrence received a single intratumoral injection of 3e10 vp DNX-2401. Patients were randomized in a 2:1 ratio to receive 50 mcg/m^2 of subcutaneous IFN (Actimmune) Q3W initiated 14 days after DNX-2401 or to be followed without further treatment for safety and survival. **Results:** Twenty-seven (27) patients were enrolled following first (59%) or second (41%) recurrence having previously failed surgery, radiation, and temozolomide (100%). The median longest tumor diameter was 40 mm (range 20-77 mm). Patients were randomized to DNX-2401 followed by IFN (n = 18) or to DNX-2401 alone (n = 9). Due to the poor tolerability of IFN, the median duration of treatment was only 6 weeks (range 0-30 weeks), and two patients did not initiate treatment as scheduled due to early clinical deterioration. The most frequent grade 3-4 AEs across treatment groups were fatigue, headache, and seizures consistent with pre-existing symptoms, underlying disease and/or surgery. Based upon a preliminary intent-to-treat analysis, IFN did not appear to provide additional benefit. However, OS-12 and OS-18 for all patients enrolled was 33% and 22%, respectively regardless of treatment assignment. Three patients remain alive at 19, 21, and 22 months (DNX-2401, n = 1; DNX-2401 + IFN, n = 2). Interestingly, 50% of patients with a baseline tumor diameter of $\leq$ 42 mm survived beyond 12 months, potentially identifying a sub-population of patients that may live longer following intratumoral DNX-2401. **Conclusions:** DNX-2401 was well tolerated as monotherapy. Although the addition of IFN did not improve survival, clinical activity following a single injection of DNX-2401 is encouraging and supports an ongoing Phase II study of DNX-2401 for recurrent glioblastoma. Clinical trial information: NCT02197169.

2003 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Efficacy analysis of ABT-414 with or without temozolomide (TMZ) in patients (pts) with EGFR-amplified, recurrent glioblastoma (rGBM) from a multicenter, international phase I clinical trial. *First Author: Andrew B. Lassman, Columbia University Medical Center, New York, NY*

Background: GBM is the most common malignant primary brain tumor in adults. Pts with rGBM have a poor prognosis. EGFR is amplified (amp) in ~50% of GBMs and is a compelling therapeutic target. ABT-414 is an antibody-drug conjugate composed of an EGFR-directed antibody conjugated to a microtubule toxin, MMAF. ABT-414 binds a unique epitope exposed during EGFR activation, either through ligand stimulation or mutation such as EGFR variant III (EGFRvIII), releasing MMAF into the cancer cell. Here, we report a pooled safety and efficacy analysis of ABT-414 +/- TMZ in EGFR amp, rGBM. **Methods:** M12-356 is a Phase 1, open-label, multi-arm study. Results from the 2 arms accruing rGBM pts were pooled for analysis. Eligible adults had rGBM, centrally confirmed EGFR amp, and KPS $\geq$ 70. Pts received 0.5-1.25 mg/kg ABT-414 on days 1 and 15 +/- 150-200 mg/m^2 TMZ on days 1-5 of 28-day cycles until progression (per RANO). **Results:** As of 11 January 2017, 126 pts were treated. The most common adverse events (AEs, $\geq$ 25% pts) were ocular (90%) and included blurred vision (64%) and photophobia (31%), which were mainly reversible. Common non-ocular AEs were fatigue (36%) and headache (30%). Grade 3/4 AEs ($\geq$ 5% pts) included ocular toxicities (29%) and decreased platelets/thrombocytopenia (10%). Serious AEs included seizure and keratitis (2% each). Of 125 pts evaluable by RANO, 52% had improvement or stabilization as best response (2 CR, 9 PR, 54 SD), and the remaining 60 (48%) had PD. Of 115 pts with measurable disease at baseline, the objective response rate (ORR) was 10% (2 CR + 9 PR). For 5 pts, re-resection for radiographic PD revealed mostly necrotic tissue and pts were classified as SD, suggesting the ORR may be an underestimate. Of all 126 pts, the 6-month PFS rate (PFS6) was 26%; median OS was 8.5 months. **Conclusions:** In this Phase 1 trial of EGFR amp, rGBM, we observed encouraging disease control (52%, CR + PR + SD) and PFS6 (26%) rates. Toxicity was mainly ocular, and reversible. A global, randomized trial of ABT-414 vs. ABT-414 + TMZ vs. TMZ/lomustine in EGFR amp, rGBM has completed accrual with results expected later this year (NCT02343406). Clinical trial information: NCT01800695.

2004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Vemurafenib in patients with *BRAF*^{V600} mutant glioma: A cohort of the histology-independent VE-basket study. *First Author: David Michael Hyman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recurrent malignant gliomas (MG) are a universally fatal disease in desperate need of better therapies. Pleiomorphic xanthoastrocytomas (PXA) and juvenile pilocytic astrocytomas (JPA) typically have better outcomes, although when recurrent, also represent an aggressive disease with no proven effective chemotherapy. *BRAF*^{V600} alterations have been identified in a substantial proportion of gliomas, including glioblastoma (GBM), astrocytoma, PXA, and JPA. The phase 2, open-label, histology-independent VE-BASKET study of vemurafenib, a selective BRAF^{V600} kinase inhibitor, in patients with *BRAF* mutation-positive non-melanoma tumors, included those with gliomas in the 'all-others' cohort. We now report final data for patients with recurrent gliomas. **Methods:** Patients received vemurafenib (960 mg bid) until disease progression or unacceptable toxicity. The primary endpoint was investigator-assessed response rate; secondary endpoints included clinical benefit rate (confirmed complete or partial response or stable disease lasting ≥6 months), progression-free survival (PFS), overall survival (OS), and toxicity. ClinicalTrials.gov NCT01524978. **Results:** 24 patients (median age 32 years; 18 female, 6 male) with glioma were treated, including mg (n = 11; 6 GBM and 5 anaplastic astrocytoma [AA]), PXA (n = 7), anaplastic ganglioglioma (AG, n = 3), JPA (n = 2), and unknown (n = 1). In patients with mg (n = 11), best response included PR (n = 1; AA), SD (n = 5), PD (n = 3), and unknown (n = 2). Two patients with mg had durable SD lasting 12.9 months (GBM) and 14.9 months (AA). In patients with PXA (n = 7), best response included CR (n = 1), PR (n = 2), SD (n = 3), and PD (n = 1). Additionally, 1 patient with JPA and 1 with AG achieved a PR. The most frequent AEs included arthralgia (67%), melanocytic nevus (38%), palmar-plantar erythrodysesthesia (38%), photosensitivity reaction (38%) and alopecia (33%). **Conclusions:** Vemurafenib demonstrated activity in patients with *BRAF*^{V600} mutant glioma. The safety profile was similar to that seen in previous melanoma studies. Survival data will be presented. Clinical trial information: NCT01524978.

2005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase I study of AZD1775 with radiation therapy (RT) and temozolomide (TMZ) in patients with newly diagnosed glioblastoma (GBM) and evaluation of intratumoral drug distribution (IDD) in patients with recurrent GBM. *First Author: Brian Michael Alexander, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: The standard of care treatment for newly diagnosed GBM is maximal safe surgical resection followed by two DNA damaging agents, RT and TMZ. Cellular response to DNA damage involves checkpoints that halt the cell cycle to allow DNA repair. AZD1775 is an oral small molecular inhibitor of a nuclear tyrosine kinase Wee1, a key regulator of the G2/M checkpoint. Abrogation of the G2/M checkpoint prevents repair and pushes cells into mitosis with unrepaired DNA damage. AZD1775 was shown to enhance TMZ and RT effects in preclinical models. **Methods:** The Adult Brain Tumor Consortium 1202 trial (NCT01849146) is a phase I, open label, multicenter dose-finding study of AZD1775 in combination with standard RT and TMZ followed by an IDD study for patients undergoing surgery for recurrent GBM. The dose finding portion is comprised of two arms, one with AZD1775 given Monday through Friday during concurrent RT/TMZ and a second arm given with adjuvant TMZ qd x 5d/28d cycle. Each arm had standard 3+3 design. A combination cohort with both concurrent and adjuvant AZD1775 at MTD and analysis of PK/PD and IDD at MTD in patients undergoing surgery for recurrent GBM followed. **Results:** 51 patients enrolled in the dose finding arms. For the concurrent arm, the MTD was 200 mg. At 275 mg one patient had grade 3 fatigue and another had grade 4 thrombocytopenia and neutropenia. Two of 6 total patients enrolled at 200 mg experienced DLTs (grade 4 neutropenia and grade 3 ALT elevation). The MTD for the adjuvant arm was 425 mg as 1 of 6 patients had DLT (grade 4 decrease in ANC). At 500 mg, 2 of 3 patients experienced intolerable diarrhea despite prophylaxis. Enrollment in the combination cohort is completed and evaluation of safety is underway. The drug concentration in contrast enhancing and non-enhancing brain tumor was 4-8 x and 0.5-2.6 x greater than plasma, respectively for patients on IDD portion. **Conclusions:** The MTD for AZD1775 in combination with RT/TMZ is 200 mg qd M-F with concurrent RT/TMZ and 425 mg qd x 5d/28d cycle in combination with adjuvant TMZ. IDD and PK/PD analysis is ongoing to inform the decision to proceed to phase II testing. Clinical trial information: NCT01849146.

2006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase I study (BLOOM) of AZD3759, a BBB penetrable EGFR inhibitor, in patients with TKI-naïve, EGFRm NSCLC with CNS metastases. *First Author: Myung-Ju Ahn, Division of Hematology and Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: The dose escalation phase is complete forAZD3759, the first EGFR inhibitor primarily designed to cross the blood brain barrier (BBB) to treat patients with EGFRm NSCLC with CNS metastases. AZD3759 is being further evaluated in patients with brain (BM) and leptomeningeal metastases (LM) in TKI-naïve and TKI pre-treated cohorts (data presented separately) (NCT02228369). **Methods:** The primary objective is safety and tolerability, and secondary objectives include anti-tumor efficacy. Dose levels of 200 and 300 mg BID AZD3759 were assessed based on safety and efficacy data in dose escalation cohorts. **Results:** As of24 September, 2016,38 patients with EGFRm NSCLC were recruited into the expansion cohorts of this study: 16 patients with TKI naïve BM and 4 patients with TKI naïve LM. 15 and 5 patients were treated with 200 and 300 mg BID of AZD3759, respectively. No DLTs were observed at either dose, while 200 mg BID AZD3759 was better tolerated than 300 mg BID during > 2 month treatment. The longest duration on treatment was > 9 months. Drug-related adverse events (AEs) seen are typically observed for EGFR TKIs. In BM cohort, 56% and 13% of patients had dose interruptions and reductions respectively due to drug-related AEs. The C_{trough} free plasma and CSF exposure at both doses were above pEGFR IC_{90}. By investigators' assessment, the intracranial objective response rate (ORR) was 63% (12 out of 19 evaluable patients) and achieved confirmed/unconfirmed partial/complete response [PR/CR]), extracranial ORR was 50% (10 out of 20 evaluable patients), and the overall ORR was 60% (12 out of 20 evaluable patients). 4 patients have not reached the 6-week RECIST assessment at the data cut-off. 18 of 20 patients are still ongoing (median 4-month follow up). 2 patients have withdrawn, one due to disease progression (de novo T790M mutation in both plasma and CSF), and another due to a non-drug related SAE. **Conclusions:** AZD3759 was well tolerated at the selected doses, achieved sufficient CNS exposure for target inhibition and demonstrated promising anti-tumor efficacy in both intracranial and extracranial tumors in TKI-naïve patients with CNS metastases. Updated clinical data will be shared at the meeting. Clinical trial information: NCT02228369.

2007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Identification of single nucleotide polymorphism of PI3k-AKT-TOR pathway as a risk factor of central nervous system metastasis in metastatic breast cancer. *First Author: Jacques Bonneterre, Centre Oscar Lambret, Lille, France*

Background: Although new therapeutic options are available, an early diagnosis of central nervous system (CNS) metastasis may be needed to improve the prognosis. The PI3k-Akt-mTor pathway has been shown to be relevant in the development of CNS metastasis. Our aim was to identify risk-associated single nucleotide polymorphisms (SNP) of the PI3K Akt-mTOR pathway in the development of CNS metastasis in patients with metastatic breast cancer. **Methods:** We performed a secondary analysis in a subpopulation of patients from the GENEOM study (NCT00959556). In this previous study, blood samples were collected from 914 breast cancer patients treated by chemotherapy in the neoadjuvant, adjuvant or metastatic setting for genomic analysis. We identified CNS metastatic patients (both leptomeningeal and parenchymal) and non-CNS metastatic patients (no neurological symptoms or normal brain MRI before death or during 5-years metastatic period). Based on the literature, 88 SNPs of the PI3K-Akt-mTOR pathway were analyzed, including AKT1 (17 SNPs), AKT2 (4), FGFR1 (2), mTOR (7), PDK1 (4), PI3KR1 (11), PI3KCA (20), PTEN (17), RPS6KB1 (6). **Results:** Of the 342 patients with metastases in the GENEOM cohort, 100 patients with CNS metastasis (parenchymal lesions only, n = 51; leptomeningeal lesions only, n = 18; both, n = 31) and 107 patients without CNS metastasis were included. Negative hormonal status (p = 0.002) and presence of vascular emboli on breast cancer samples (p = 0.006) were associated with CNS metastasis. In univariate analysis, genotypes CC of AKT1 rs3803304, AA of AKT2 rs3730050, CC of AKT2 rs8100018, TT of PDK1 rs1168690, GG of PDK1 rs11904366 and GG of PI3KR1 rs251408 were associated with CNS metastasis at the $p < 0.05$ threshold. Only genotype TT of PI3KR1-rs706716 was statistically associated with CNS metastasis after Bonferroni correction ($p = 0.0003$, < 0.00085). **Conclusions:** PI3KR1-rs706716 is associated with CNS metastasis in metastatic breast cancer patients, in addition to negative hormonal status and presence of vascular emboli and could be combined in a composite score to predict the risk of and to detect early CNS metastasis in this population.

2008 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Cambridge Brain Mets Trial 1 (CamBMT1): A proof of principle study of afatinib penetration into cerebral metastases (mets) for patients (pts) undergoing neurosurgical resection, combined with low-dose, targeted radiotherapy (RT)—Phase 1b results. *First Author: Richard D. Baird, Cambridge Cancer Trials Centre, Cambridge, United Kingdom*

Background: Failure of drugs to cross the blood brain barrier (BBB) can be a major reason for treatment failure in pts with brain tumours. Preliminary data suggest that low-dose RT may disrupt the BBB, and could facilitate increased drug delivery into brain tumours. CamBMT1 is a phase 1b/2 preoperative window-of-opportunity trial designed to test if the delivery of afatinib into brain mets might be enhanced by targeted, low dose-RT. **Methods:** Pts with operable brain mets from breast or lung origin were treated with afatinib for 11 days prior to surgery on day 12. Pts also received a single fraction of targeted RT on day 10 (pts in either 2Gy or 4Gy arm). In phase 1b, afatinib dose (20, 30, or 40mg QD) was escalated in each arm using an accelerated titration design. Primary endpoint: steady-state afatinib concentration in resected brain mets, compared with plasma. Secondary endpoints: safety and tolerability. **Results:** 10 pts were treated (4 breast, 6 lung), with no dose-limiting toxicities seen, thus completing recruitment to phase 1b. Treatment was generally well tolerated. Median afatinib concentrations on day 12 were: plasma 22.7ng/mL (range 9.94-179); and tumour 405ng/g (range 120-1129). **Conclusions:** It was feasible to conduct a window-of-opportunity study of afatinib plus RT in pts with operable brain mets. The recommended phase 2 dose of afatinib was 40mg QD for both 2Gy and 4Gy arms. Afatinib concentrations in resected tumour were on average >15-fold higher than those in plasma. Phase 2 of CamBMT1 is now underway in multiple UK sites, and randomises patients into 3 treatment arms (n=20 per arm): 1. afatinib 40mg QD; 2. afatinib 40mg QD + 2Gy# RT; 3. afatinib 40mg QD + 4Gy# RT. Clinical trial information: NCT02768337.

Dose escalation, treatments received and pharmacokinetic results.

2009 **Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

Final results of the EORTC Brain Tumor Group randomized phase II TAVAREC trial on temozolomide with or without bevacizumab in 1st recurrence grade II/III glioma without 1p/19q co-deletion. *First Author: Martin J. Van Den Bent, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Although bevacizumab (BEV) is frequently used in recurrent grade II and III glioma without 1p/19q co-deletion, this use is without evidence from randomized trials. **Methods:** The TAVAREC trial (NCT01164189) is a randomized phase II study in locally diagnosed non-1p/19q co-deleted grade II or III glioma, with a first and contrast-enhancing recurrence after initial radiotherapy. Prior chemotherapy was allowed provided patients were at least 6 months off treatment. Patients were treated with either 200mg/m^2 temozolomide (TMZ) day 1-5 every 4 weeks for a maximum of twelve cycles, or with the same TMZ regimen in combination with BEV 10 mg/kg every 2 weeks until progression. Response, Quality of Life (QOL, using the EORTC QOL C30/BCM20 questionnaire) and neurocognitive function (NCF) using a standardized test battery with Hopkins Verbal Learning, Trail Making test A/B and Controlled Oral Word Association were evaluated every 3 months. Primary endpoint is the Overall Survival (OS) rate at 12 months (OS12). Tumor samples were centrally analyzed for *MGMT* status (Illumina methylation arrays) and *IDH1/2* mutations (*IDHmt*). **Results:** Between 8/2/2011 and 31/7/2015, 155 patients were randomized; median age was 44 years, 88 (70%) of 125 tested tumors showed an *IDHmt*, 27% of patients had received prior chemotherapy. OS12 was 61% in the TMZ arm and 55% in the TMZ+BEV arm, with overlapping OS and progression free survival (PFS) Kaplan Meier curves and similar response rates (TMZ: 42%; TMZ + BEV: 49%). Post-progression, 33% of the TMZ and 17% of the TMZ + BEV patients received BEV. OS was longer in *IDHmt* tumors compared to *IDH wild type* tumors (15 mo vs 10.7 mo, p = 0.001) but PFS was clinically similar (6.7 mo vs 5.1 mo, p = 0.056). *IDH* mutational status was not predictive for benefit to BEV. Compliance to NCF testing and QOL was above 60% in the 1st year. At the group level, NCF was similar in the TMZ and in the TMZ+BEV patients. QOL and *MGMT*results will be presented at the meeting. **Conclusions:** The addition of BEV to TMZ does not improve OS, PFS, or cognitive function in recurrent grade II and III 1p/19q intact gliomas; regardless of IDH mutational status. Clinical trial information: NCT01164189.

2010 **Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

A phase I study of convection enhanced delivery (CED) of ^{124}I-8H9 radiolabeled monoclonal antibody in children with diffuse intrinsic pontine glioma (DIPG). *First Author: Mark M. Souweidane, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Diffuse intrinsic pontine glioma (DIPG) represents one of the most deadly central nervous system tumors of childhood with a median survival of less than 12 months. Convection-enhanced delivery (CED) has been recently hypothesized as a means for augmenting distribution of therapeutic agents within the brain stem. We conducted this study to evaluate CED in children with DIPG. **Methods:** We performed a standard 3+3 phase I, open-label, dose escalation study in patients with non-progressive DIPG 4 to 14 weeks post-completion or radiation therapy. Seven dose levels of a single injection of ^{124}I-8H9 (range 0.25 to 4.0 mCi, 250 to 4000 mcl) were studied. **Results:** 25 children were treated. The average age at enrollment 8 years old (range 3-17). There was no dose limiting toxicity (DLT) and adverse events were limited to grade 1 or 2 (CTCAE v4.0). Estimations of distribution volumes were dose dependent and ranged from 1.5 to 20.1 cm^3. The mean volume of distribution/volume of infusion (Vd/Vi) was 3.4 (SD 1.2). The mean lesion absorbed dose was 1527 rad/mCi. The mean tumor coverage on dose level 7 was 107%. **Conclusions:** CED in the brain stem of children with DIPG who were previously irradiated is a safe therapeutic strategy. Up to 4 mCi of ^{124}I-8H9 was well tolerated. An infusion volume of 4000 mcl appears to be a reasonable single dose for good tumor coverage. PET-based dosimetry validates the conceptual basis for direct drug delivery. Based on our finding CED merits further exploration in early phase clinical trials for children with DIPG. Clinical trial information: NCT01502917.

2011 **Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

A phase II of everolimus and octreotide for patients with refractory and documented progressive meningioma (CEVOREM). *First Author: Thomas Graillon, Neurosurgery Department, Hopital La Timone, AP-HM, Marseille, France*

Background: After iterative surgeries and radiotherapy (RT)/radiosurgery (RS) failure, aggressive meningiomas remain an unmet medical need. We have shown in vitro that everolimus (EVE) combined to octreotide (OCT) is active in meningiomas. **Methods:** Prospective multicentric single arm phase II study (NCT02333565) including pts with recurrent meningioma with documented progression (> 10% increase of tumor surface over 6 months) after surgery and RT/RS. EVE was orally administrated at 10mg/day and OCT by IM injection 30 mg/28 days. MRI was performed every 3 months with planned central review of imaging including volumetric progression at inclusion and during treatment. The primary endpoint was PFS6. The criteria for success was defined as a PFS6 > 40%. **Results:** 20 pts were included, aged 30-75 years (median 55) with 37 progressive intra cranial meningiomas (WHO: 2 grade I, 27 grade II, 8 grade III) including 4 NF2 pts. Median KPS was 70%. All pts previously underwent at least one surgery and more than 1 in 18/20 patients. 19/20 pts were treated with radiotherapy or radiosurgery and 5 pts with prior chemotherapy. 1 pt was not evaluable at 3 months. With a median f/u of 12.3 months (2-24 months), PFS6 was 58.2% (95% CI 33.5-76.5%) and PFS12 was 38% (95% CI 16-60%). Volumetric analysis at 3 months demonstrated a decrease in tumor volume superior to 10% in 8 tumors (4 pts). Pre therapeutic growth rate was decreased of more than 50% in 29/35 tumors (18/20 pts) during the first 3 months. Inclusion (I)-to-3 months tumor growth rate (mean at 1.9%/month) was significantly lower than pre inclusion (Pre-I)-to-I growth rate (mean at 18.5%/month) (p = 0.0003). 3 highly aggressive tumors (3 pts) were separately assessed: Pre-I-to-I growth rate superior to 1000%/month was decreased to 3%, 15% and 44%/month in the first 3 months. Toxicity included 7 grade III AE (stomatitis, 3; pneumopathy, 1). AE of special interest included stomatitis (10, 50%), rash (8, 40%), abdominal pain and diarrhea (11, 55%) and nausea and vomiting (4, 20%). **Conclusions:** Everolimus and octreotide combination appears active in refractory aggressive and progressive meningiomas with acceptable and manageable toxicity and should request further evaluation. Clinical trial information: NCT02333565.

Phase II trial of bevacizumab and temozolomide for upfront treatment of elderly patients with newly diagnosed glioblastoma. *First Author: Phioanh Leia Nghiemphu, University of California, Los Angeles, Los Angeles, CA*

Background: Randomized clinical trials in newly diagnosed, elderly GBM patients have shown that treatment with temozolomide chemotherapy is at least equivalent to treatment with radiotherapy. Glioblastoma in elderly patients may also have high angiogenic activities. Bevacizumab is an antiangiogenic agent, a humanized monoclonal antibody directed against the vascular endothelial growth factor. We conduct a clinical trial of temozolomide and bevacizumab to evaluate the safety and efficacy of this combination in the treatment of elderly patients with newly diagnosed GBM, good performance status, and willing to forgo upfront treatment with radiation therapy. **Methods:** This is a phase II trial of newly diagnosed GBM patients age ≥70 with no prior treatments other than surgery and Karnofsky Performance Status (KPS) ≥60. Patients receive treatments 4-6 weeks after surgery with bevacizumab (10mg/kg every 2 weeks) and temozolomide (150-200 mg/m^2 for 5 days out of 28 days, up to 12 cycles) until tumor progression. Primary outcome measures are overall survival and safety evaluations. **Results:** From June 2010 to January 2016, 50 GBM patients enrolled in this study. To date, all patients have tumor progression and 3 are still alive. The median age is 75 (range 70 - 87), and median KPS is 80 (range 60-100). 15 patients have a gross total resection. 26 out of 49 patients with tissues available for evaluation have methylation of the MGMT promoter, and no patient has IDH-1 mutation. Median overall survival is 12.3 months (14.8 months for those with methylation of MGMT, 10.0 months for unmethylated MGMT). Serious adverse events related to treatments include wound healing problems (2), CNS hemorrhage (3), pulmonary embolism (4), and bowel perforation (1). Serious hematological adverse events include thrombocytopenia (3) and neutropenia (5). **Conclusions:** For patients with newly diagnosed GBM age ≥70, KPS ≥60, treatment with temozolomide and bevacizumab may show promising survival benefits and have tolerable side effects. More detailed safety and efficacy analysis will be presented. Clinical trial information: NCT01149850.

Clinical and molecular features associated with long-term survival of elderly patients with glioblastoma. *First Author: Michael Weller, Laboratory of Molecular Neuro-Oncology, Department of Neurology, and Neuroscience Center Zurich, University Hospital and University of Zurich, Zurich, Switzerland*

Background: Glioblastomas in elderly patients are associated with particularly poor outcome, with only few patients demonstrating long-term survival (LTS). **Methods:** To better characterize clinical and molecular correlates of LTS in elderly glioblastoma patients, we searched the German Glioma Network (GGN) database for patients aged 71 years or more with histological confirmation of glioblastoma and survival of at least two years after diagnosis. **Results:** Of 2071 glioblastoma patients enrolled in the GGN from 2004-2012, 425 patients were aged 71 years or more; of these, 27 patients (6.4%) survived for 2 years or more (median survival: 37.1 months, 95% confidence interval: 30.0-44.2 months). A comparison of these 27 patients with the 398 patients who survived shorter than 2 years (median survival: 6.2, 95% confidence interval: 5.2-7.2 months) revealed more intensive upfront treatment and a trend towards higher initial Karnofsky performance score as distinguishing clinical factors. Molecular analyses additionally showed more frequent O^6-methylguanine-DNA methyltransferase (*MGMT)* promoter methylation in the LTS patients. Isocitrate dehydrogenase (IDH) mutation was restricted to single patients and the frequency of telomerase reverse transcriptase (*TERT*) promoter mutation did not differ between groups. Genome-wide DNA copy number and methylation profiling using 450k microarray analysis performed for 16 LTS patients and 40 control patients revealed limited differential DNA methylation and no specific copy number profiles linked to LTS. **Conclusions:** Collectively, our findings confirm that LTS is rare in elderly patients with glioblastoma and that clinical and tumor-associated molecular factors linked to LTS resemble those in standard age patients, except for less common IDH mutation.

Bevacizumab plus hypofractionated radiotherapy versus radiotherapy alone in elderly patients with glioblastoma: Efficacy and imaging analyses of the ARTE trial. *First Author: Hans-Georg Wirsching, Department of Neurology, University Hospital, Zürich, Switzerland*

Background: The addition of bevacizumab (BEV) to first-line temozolomide chemoradiotherapy prolonged progression-free survival (PFS), but not overall survival (OS) in newly diagnosed glioblastoma in two phase III trials. Elderly and frail patients are underrepresented in most clinical trials, but early uncontrolled reports of BEV treatment of glioblastoma suggested preferential benefit in this patient population. **Methods:** ARTE was a 2:1 randomized, multi-center, open-label trial of hypofractionated radiotherapy (RT) in combination with intravenous BEV every 2 weeks (Arm A, N = 50) versus RT alone (Arm B, N = 25) in patients with newly diagnosed glioblastoma aged 65 years or older. Quality of life (QoL) was monitored by the EORTC QLQ-C30/BN20 modules. Response was assessed using Response Assessment in Neuro-Oncology (RANO) criteria. Exploratory imaging studies included apparent diffusion coefficient (ADC) mapping and 18F-fluoro-ethyl-tyrosine (FET) positron emission tomography (PET). **Results:** Established prognostic factors including age, Karnofsky performance score (KPS), O6-methylguanine DNA methyltransferase (MGMT) gene promoter methylation and steroid intake at study entry were balanced between arms. Median PFS was longer in Arm A vs. Arm B (7.6 vs. 4.8 months, p = 0.003), but OS was similar (12.1 vs 12.2 months, p = 0.8). Prior to progression, no differences in QoL were noted, but clinical deterioration was deferred in Arm A vs. Arm B. In a Cox model that controlled for established prognostic factors, an association with prolonged PFS was detected for Arm A versus Arm B (hazard ratio [HR] 0.36, p = 0.001) and for KPS 90-100% versus 60-80% (HR 0.50, p = 0.02). Applying a similar Cox model to OS detected an association with age 65-69 vs 70+ (HR 0.52, p = 0.02) and KPS 90-100% versus 60-80% (HR 0.53, p = 0.03). Exploration of imaging predictors of OS for Arm A identified response by RANO (HR 0.52, p = 0.02), but detected no prognostic role for T2, ADC or FET signal intensity. **Conclusions:** Efficacy outcomes and exploratory imaging analyses of the ARTE trial do not support the notion that benefit from BEV is more pronounced in elderly glioblastoma patients. Clinical trial information: NCT01443676.

2015 Poster Discussion Session; Displayed in Poster Session (Board #257), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Radiomic analysis of pseudo-progression compared to true progression in glioblastoma patients: A large-scale multi-institutional study. *First Author: Srishti Abrol, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment-related imaging changes are often difficult to distinguish from true tumor progression. Treatment-related changes or pseudoprogression (PsP) subsequently subside or stabilize without any further treatment, whereas progressive tumor requires a more aggressive approach in patient management. Pseudoprogression can mimic true progression radiographically and may potentially alter the physician's judgment about the residual disease. Hence, it can predispose a patient to overtreatment or be categorized as a non-responder and exclude him from the clinical trials. This study aims at assessing the potential of radiomics to discriminate PsP from progressive disease (PD) in glioblastoma (GBM) patients. **Methods:** We retrospectively evaluated 304 GBM patients with new or increased enhancement on conventional MRI after treatment, of which it was uncertain for PsP versus PD. 149 patients had the histopathological evidence of PD and 27 of PsP. Remaining 128 patients were categorized into PD and PsP based on RANO criteria performed by a board-certified radiologist. Volumetrics using 3D slicer 4.3.1 and radiomics texture analysis were performed of the enhancing lesion(s) in question. **Results:** Using the MRMR feature selection method, we identified 100 significant features that were used to build a SVM model. Five texture features (E, CS, SA, MP, CP) were found to be most predictive of pseudoprogression. On Leave One Out Cross-Validation (LOOCV), sensitivity, specificity and accuracy were 97%, 72%, and 90%, respectively. **Conclusions:** 3D radiomic texture features of conventional MRI successfully discriminated pseudoprogression from true progression in a large cohort of GBM patients.

2016 Poster Discussion Session; Displayed in Poster Session (Board #258), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Multicenter study to demonstrate radiomic texture features derived from MR perfusion images of pseudoprogression compared to true progression in glioblastoma patients. *First Author: Nabil Elshafeey, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: To differentiate between pseudoprogression and true progression in patients with glioblastoma using MR perfusion radiomic texture analysis (TA). **Methods:** 98 patients with pathologically-proven diagnosis of GBM were retrospectively included in this IRB approved HIPAA compliant study. All patients underwent DSC and DCE Perfusion MRI as part of their routine clinical care. Images were analyzed using Nordic ICE 2.3 (Nordic-NeuroLab) ; rCBV and ktrans maps were obtained. Subsequently, 3D slicer 4.3.1(http://www.slicer.org) was used to segment the entire tumor on the different processed maps to create a volume of interest (VOI) for Radiomic TA. Multiple invariant texture features where then extracted from each VOI. 475 invariant texture features were applied to each map. Leave-one-out cross-validation (LOOCV), receiver operating characteristic (ROC), Kaplan Meier, and multivariate Cox proportional hazards regression analyses were used to assess the relationship between texture feature and pseudoprogression and true progression. **Results:** Variance and sum entropy were the two most significant radiomic features that discriminated between pseudoprogression and true progression. P value, AUC, specificity and sensitivity were 0.03, 89.26%, 81.82%, and 100% respectively. **Conclusions:** Radiomic TA derived from perfusion images can be helpful in determining true versus pseudoprogression in GBM. Further, this study illustrates successful application of radiomic TA as an advanced processing step for different MRI perfusion maps (DCE, DSC).

2017 Poster Discussion Session; Displayed in Poster Session (Board #259), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Low grade glioma patients with IDH mutation and 1p19q codeletion: To treat or not to treat? *First Author: Enrico Franceschi, Department of Medical Oncology, Bellaria Hospital, Azienda USL - IRCCS Institute of Neurological Sciences, Bologna, Italy*

Background: Molecular characterization of low grade gliomas (LGG) is essential for diagnosis and treatment of these diseases. LGG patients (pts) with IDH mutation and 1p19q codeletion (codel) are characterized by a median OS (mOS) longer than 10 years. Thus, the role of treatments and side effects should be carefully evaluated. **Methods:** We evaluated LGG pts from our data warehouse (n=679 pts) who received surgery and had sufficient tissue to assess biomarkers characterization. Pts with gliomatosis were excluded. IDH1/2 assessment was performed on formalin-fixed paraffin-embedded samples by qPCR. In wild type cases we performed NGS. 1p/19 codel analysis was performed by FISH. **Results:** 93 consecutive LGG with IDH mutation and codel were included. The median follow up (FU) was 96.1 months. Mean age was 40 yrs (range: 25-66); 8 pts (8.6%) underwent biopsy, 61 pts (65.6%) partial resection, 24 pts (25.8%) complete resection. 84 pts (90.3%) were considered high risk using RTOG criteria (>40 years and/or incomplete resection). Fifty pts (53.7%) received only FU, 17 pts (18.3%) received chemotherapy (CT), 18 pts (19.4%) received radiotherapy (RT), 8 pts (8.6%) received RT + CT. Median PFS (mPFS) was 59.6 months (95%CI: 41.8-77.4) and was significantly longer in pts who received postsurgical treatments (79.5 months, 95%CI: 66.4-92.7) than pts who received FU (46.3 months, 95%CI: 36.0-56.5; P=0.001). mPFS was 50.8 months (95%CI: 17.4-84.3), 103.6 months (95%CI: 11.7-195.6) and 120.2 months (95%CI: 40.5-199.8) in pts treated with CT alone, RT alone and RT + CT, respectively. Multivariate analysis showed that receiving a post-surgical treatment (P<0.001), and the extent of resection (P=0.043) were significantly correlated with PFS. **Conclusions:** Our study evaluated the role of treatments in LGG pts assessed with NGS and FISH. Post-surgical treatments are crucial to extend PFS in pts with IDH mutation and codel. The choice of post-surgical treatments seems to have a role, being CT alone less effective than RT and RT+CT. Longer FU is needed to provide information about OS.

2018 Poster Discussion Session; Displayed in Poster Session (Board #260), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Identification of novel therapeutic targets in glioblastoma with functional genomic mRNA profiling. *First Author: Cyrillo Gerardo Brahm, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Glioblastoma (GBM), the most common primary brain tumor in adults, universally recurs and has a dismal prognosis. Therefore, there is an unmet need for new and more effective treatment strategies. Here, we aim to discover new therapeutic targets by identifying upregulated genes in GBM with known antineoplastic drug interactions. **Methods:** Publicly available, raw microarray expression data of patient-derived GBM samples and normal brain tissue were collected from the Gene Expression Omnibus (GEO) and The Cancer Genome Atlas (TCGA). Subsequently, we applied functional genomic mRNA profiling (FGmRNA-profiling), a method that is able to correct the gene expression profile of an individual tumor for physiological and experimental factors, which are considered not to be relevant for the observed tumor phenotype. Next, the FGmRNA-profiles of healthy brain tissue and glioblastoma were used to perform a class comparison analysis. Significantly upregulated genes in GBM were prioritized based on: known interaction with antineoplastic agents and the current status of clinical evaluation in humans. **Results:** After FGmRNA-profiling 66 normal brain tissue samples and 1280 patient-derived GBM samples, class comparison identified 712 significantly upregulated genes. Of all significantly upregulated genes, 27 genes interacted with antineoplastic drugs. 17 out of these 27 druggable genes, including EGFR and VEGFA, have already been clinically evaluated in GBM, and had limited efficacy. Out of the 10 remaining druggable genes, we prioritized RRM2, MAPK9 and XIAP, as these genes are associated with biologic pathways involved in the carcinogenesis of GBM and are therefore considered as novel potential therapeutic targets. **Conclusions:** Based on data-driven prioritization, we identified three potential therapeutic druggable targets, which have not yet been explored in the context of glioblastoma. Further preclinical and clinical research on the inhibition of these druggable genes is necessary and may lead to an improvement of treatment outcomes for patients with GBM.

2019 Poster Discussion Session; Displayed in Poster Session (Board #261), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

RNA-Seq analysis of glioma tumors to reveal targetable gene fusions. *First Author: Deepa Suresh Subramaniam, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Fusions involving oncogenes have been reported in gliomas and may serve as novel therapeutic targets. We aim to use RNA-sequencing to interrogate a large cohort of gliomas for targetable genetic fusions. **Methods:** Gliomas were profiled using the ArcherDx FusionPlex Assay at a CLIA-certified lab (Caris Life Sciences) and 52 gene targets were analyzed. Fusions with preserved kinase domains were investigated. **Results:** Among 404 gliomas tested, 39 (9.7%) presented potentially targetable fusions, of which 24/226 (11%) of glioblastoma (GBM), 5/42 (12%) of anaplastic astrocytoma (AA), 2/25 (8%) of grade II astrocytoma and 3 of 7 (43%) of pilocytic astrocytoma (PA) harbored targetable fusions. In GBMs, 1 of 15 (6.7%) IDH-mutated tumors had a fusion while 22 of 175 (12.6%) IDH-wild type tumors had fusions. 46 oligodendroglial tumors were profiled and no fusions were seen, which was lower than frequency of fusions in astrocytic tumors (34/300, p = 0.0236). The most frequent fusions seen involved FGFR3 (N = 12), including 10 FGFR3-TACC3 (1 AA, 6 GBM and 3 glioma NOS); 1 FGFR3-NBR1 (AA) and 1 FGFR3-BRAP (GBM). 11 fusions involving MET were seen, 10 in GBM and 1 in AA. The most common MET fusion was PTPRZ1-MET (1 in AA and 4 in GBM), followed by ST7-MET (N = 3, GBM), CAPZA2-Met (N = 2, GBM) and TPR-MET (N = 1, GBM). 8 NTRK fusions were seen; 1 involving NTRK1 (BCAN-NTRK1, PA), 6 NTRK2 (1 NOS1AP-NTRK2 in AA; GKAP1-NTRK2, KCTD8-NTRK2, TBC1D2-NTRK2 and SOSTM1-NTRK2, 1 each in GBM and 1 VCAN-NTRK2 in grade II astrocytoma) and 1 NTRK3 (EML4-NTRK3 in GBM). EGFR fusions (2 EGFR-SEPT14 and 1 EGFR-VWC2) were seen in 3 GBMs, BRAF in 3 (1 KIAA1549-BRAF, 1 LOC100093631-BRAF in PA and 1 ZSCAN23-BRAF in glioma NOS) and PDGFRA (RAB3IP-PDGFRA, in GBM) in 1. C11orf95-RELA fusions were seen in 2 of 3 grade III ependymomas but not in the 2 grade II ependymomas. **Conclusions:** We report targetable fusion genes involving NTRK, MET, EGFR, FGFR3, BRAF and PDGFRA including novel fusions that haven't been previously described in gliomas (e.g., EGFR-VWC2; FGFR3-NBR1). Fusions were seen in over 10% of astrocytic tumors, while none was seen oligodendrogliomas. Identification of such kinase-associated fusion transcripts may allow us to exploit therapeutic opportunities with targeted therapies in gliomas.

Osimertinib for patients (pts) with leptomeningeal metastases (LM) from EGFR-mutant non-small cell lung cancer (NSCLC): Updated results from the BLOOM study. *First Author: James Chih-Hsin Yang, National Taiwan University Hospital, Taipei, Taiwan*

Background: LM due to NSCLC progression are associated with poor prognosis. Osimertinib is an oral, CNS-active, irreversible EGFR-TKI selective for sensitizing (EGFRm) and T790M resistance mutations. **Methods:** In the BLOOM study (NCT02228369), pts with EGFRm advanced NSCLC who had progressed on prior EGFR-TKI therapy and had LM confirmed by positive cerebrospinal fluid (CSF) cytology received osimertinib 160 mg once daily (qd). Response was assessed (by investigator) in 2 cohorts: T790M unselected and T790M positive (by central test); results are presented as a combined analysis set. Analyses were based on CSF cytology, brain MRI imaging, and neurological examination every 6 weeks (wk; relative to first dose) until progression. Adverse events (AEs) were graded according to CTCAE. EGFR-mutant DNA in CSF was determined by ddPCR. Plasma and CSF samples were collected for PK analyses. **Results:** As of 24 Sep 2016,32 pts had received treatment: 21 T790M unselected; 11 T790M positive. Max treatment duration was 17.5 months (m; median 6.0 m); 21 pts ongoing. 23/32 pts had a 12-wk brain image assessment: 10 had radiological improvement, 13 had stable disease (SD). The same 23 pts had a 12-wk neurological assessment: of 8 symptomatic pts, 7 improved, 1 had SD; of 15 asymptomatic pts, 2 worsened, 13 remained asymptomatic. The geometric mean decrease in EGFR-mutant DNA copy was 57% (95% CI 30, 74) in 22 pts with pre-dose and Cycle 2 Day 1 CSF samples. Most common AEs were skin effects (n = 20), diarrhea (n = 13), nausea (n = 11) and paronychia (n = 9). All were grade (G) 1/2 except 1 case each of diarrhea and nausea (both G3). 9 pts had dose interruptions and 4 had dose reductions to 80 mg qd. Osimertinib mean concentration in CSF was 7.51 nM (range 2.19–21.1 nM) at steady state (N = 16); CSF:free plasma ratio: 16%. Accrual is now complete (n = 41; 21 T790M unselected, 20 T790M positive) and updated data (including overall survival) will be presented. **Conclusions:** Osimertinib penetrates the blood-brain barrier. Encouraging activity and manageable tolerability in pts with LM from EGFRm NSCLC was observed at 160 mg qd, with a median treatment duration of 6.0 m; continued evaluation is ongoing. Clinical trial information: NCT02228369.

2021 Poster Discussion Session; Displayed in Poster Session (Board #263), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Final results from the dose-escalation stage of a phase 1/2 trial of TPI 287, a brain penetrable microtubule inhibitor, plus bevacizumab in patients with recurrent glioblastoma. *First Author: Samuel Aaron Goldlust, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ*

Background: Microtubule inhibitors, including taxanes, are active in preclinical models of glioblastoma (GBM), however, clinical benefit is hampered by poor blood-brain barrier (BBB) accumulation. TPI 287, a third-generation taxane designed to evade P-glycoprotein mediated efflux, readily penetrates the BBB and overcomes this limitation. CB-017 is a multi-center phase 1/2 trial designed to determine the optimal dose of TPI 287 and potential efficacy in patients treated with this drug plus bevacizumab (BEV) for treatment of recurrent GBM. Final results of the dose escalation Phase 1 stage of this trial are reported. **Methods:** GBM patients at first or second relapse after standard therapy and without prior exposure to anti-angiogenic agents were eligible for enrollment. BEV was administered at 10 mg/kg every 2 weeks and TPI 287 every 3 weeks via IV infusion. MRIs were obtained every six weeks with response assessed via RANO criteria. TPI 287 dose escalation was based on a traditional 3+3 design. **Results:** Twenty-four patients were enrolled in 7 TPI 287 dose-escalation cohorts (140-220 mg/m2) from 6 U.S. centers. Twenty and 23 patients were evaluable for response and survival, respectively. Median follow-up was 28 months. Results are shown in the table below. Of the 9 patients from which biomarker data was available, tumors from 8 patients (89%) harbored an unmethylated MGMT promoter, an established negative prognostic indicator for survival. No DLTs were reported and myelosuppression (n=3) was the only drug-related grade 3/4 adverse event. **Conclusions:** TPI 287 in combination with BEV is safe and well tolerated at doses up to 220 mg/m2. Final survival results from the Phase 1 portion of this study compare favorably with historical controls and support further investigation of TPI 287 plus BEV for treatment of recurrent GBM. Clinical trial information: NCT01933815.

# evaluable patients	23
Overall response	60% (12/20*)
CR	15% (3/20*)

Results of the OPARATIC trial: A phase I dose escalation study of olaparib in combination with temozolomide (TMZ) in patients with relapsed glioblastoma (GBM). *First Author: Sarah E. R. Halford, Cancer Research UK Centre for Drug Development, London, United Kingdom*

Background: Olaparib, a small molecule inhibitor of poly (ADP-ribose) polymerase (PARP), may improve GBM outcomes by enhancing cytotoxic effects of ionising radiation and TMZ. Clinical development of PARP inhibitors has been restricted by exacerbation of hematological toxicity. We investigated tumor pharmacokinetics (PK) of olaparib and safety and tolerability of its combination with TMZ. **Methods:** Dose escalation explored different schedules of olaparib (tablet formulation) with 42 day cycles of daily low dose TMZ. A dose expansion cohort evaluated the maximum tolerated schedule. PK analysis was performed on tumor and blood samples from patients undergoing neurosurgical resection, who received 4 olaparib doses pre-operatively. **Results:** 48 patients were recruited (median age 51(18-68); 29 male, 19 female) of whom 27 underwent surgery and 35 received olaparib/TMZ and were evaluable. 13 evaluable patients received expansion dose schedule (median age 54(21-67); 9 male, 4 female). Olaparib was detected in 73 of 74 tumor core specimens from 27 patients; mean conc. 588nM (97-1374nM), and in 27 of 28 tumor margin specimens from 10 patients; mean conc. 500nM (97-1237nM). Margin: core ratios ranged from 0.2–3.9(mean 1.2); tumor: plasma ratios ranged from 0.01 to 0.9 (mean 0.25). Olaparib dosing on days 1-5 was hindered by myelosuppression. Expansion cohort dose was defined as TMZ 75 mg/m^{2}daily plus olaparib 150 mg (OD) days 1-3 weekly. Of 13 evaluable patients receiving expansion dose-schedule, 9 completed cycle 1, 2 completed cycle 2 and 2 completed cycle 3. Currently 45% of the evaluable patients remain progression-free at 6 months, with 2 still on treatment (full data set May2017). Of 35 evaluable patients, 24 experienced AE Grade ≥3 (see Table). **Conclusions:** Olaparib penetrates both core and margins of recurrent GBM despite failing to penetrate the intact brain barrier in pre-clinical heathy rodent models. Combination with extended low dose TMZ is safe and well tolerated, yielding encouraging 6 month progression-free survival rates. Clinical trial information: NCT01390571.

NCCTG N1174: Phase I/comparative randomized phase (Ph) II trial of TRC105 plus bevacizumab versus bevacizumab in recurrent glioblastoma (GBM) (Alliance). *First Author: Evanthia Galanis, Mayo Clinic, Rochester, MN*

Background: TRC105 is a humanized antibody targeting CD105 (endoglin), a member of the TGFβ receptor superfamily. CD105 is expressed in glioma stem cells and circulating endothelial cells (CECs) in GBM patients (pts), increasing following VEGF inhibition. N1174 was conducted in recurrent bevacizumab (bev) naïve GBM pts to investigate the hypothesis that CD105 blockade+bev can delay development of bev resistance. **Methods:** After a ph I cohort (15 pts) established the ph II dose of TRC105 as 10 mg/kg IV over 4 hours every 7 days in combination with standard dose bev, the ph II trial used 1:1 randomization with 90% power and 0.10 type I error to detect a 3 month (mo) difference in progression-free survival (PFS) between the two arms. CECs including CD105 positive subsets were measured by flow cytometry at baseline and multiple time points. **Results:** Based on 101 evaluable ph II pts, there was no significant difference in PFS between TRC105+bev and bev only (2.9 vs 3.2 mo, respectively; HR=1.14, 95% CI 0.73-1.77, p=0.57), or overall survival (10.0 vs 7.4 mo; HR 1.02 95% CI 0.63-1.65, p=0.93). Response rate (complete or partial) was 12.2% (6/49) for TRC105+bev and 11.6% (5/43) for bev only. Overall incidence of grade (gr) 3+ toxicity was higher for TRC105+bev (67.3% vs 32.7%, p<0.001) mainly due to 14 pts with gr 3 anemia in the TRC105+bev arm vs 0 in the bev only pts. Gr 3+ non-heme toxicities were higher in pts receiving TRC105+bev vs bev only (50% vs 30.6%, p=0.07), mainly due to headache (6 vs 1 pts) and hyperglycemia (3 vs 0 pts). CECs remained stable in combination treated pts, suggesting a possible impact of the anti-CD105 blockade, but increased at progression in the bev only arm. There was no association between PFS and initial changes in CEC values, independent of treatment received. **Conclusions:** TRC105 plus bev did not prolong median PFS vs single agent bev in recurrent GBM pts, although it was associated with a non-significant prolongation of OS. These data and associated correlative analysis of CECs from study pts point against endoglin being a clinically significant factor for the development of bev resistance. Support: U10CA180821, U10CA180882. Clinical trial information: NCT01648348.

2024 Poster Session (Board #266), Mon, 1:15 PM-4:45 PM

SHADOW study: Comparison of conventional clinical follow-up with clinician led video follow-up in newly diagnosed patients with intermediate and high grade glioma receiving adjuvant temozolomide therapy. *First Author: Vijay Maruti Patil, Tata Memorial Centre, Mumbai, India*

Background: In patients with gliomas, nurse led telephonic follow-up was associated with high satisfaction rates and was a valid alternative approach to conventional hospital based follow-up. However, other alternative forms of follow-up have not been studied in patients on active treatment. **Methods:** SHADOW was a prospective, randomized trial (CTRI/2017/01/007626). Adult intermediate to high grade glioma patients on adjuvant temozolomide with facilities for live video call were invited. After their consent, patients underwent a video follow-up (VF) 4 days prior to clinical follow-up (CF). The decisions taken during the VF and CF were noted in 5 domains, relating to temozolomide decisions (primary endpoint), concurrent medications, need for imaging, molecular testing and rehabilitation. Clinicians performing VF or CF were randomly assigned and were blinded for the other arm decisions. Patients satisfaction and costs incurred in each type of follow-up was documented. The planned sample size was 65, assuming an alpha of 0.05, a kappa coefficient of 0.9 with a one sided CI for lower limit of 0.6 and assuming a 20% lost to follow up rate. Agreement analysis was performed for calculation of Cohen's kappa coefficient. Results: 112 patients were screened and 65 were accrued. All patients underwent both VF and CCF. The concurrence in decision of administering temozolomide between VF and CCF was 100% (Cohen kappa = 1.0, 95%CI 1.0-1.0, $p < 0.00$). In concurrent medication domain (k = 0.66,95% CI 0.04 -1, $p < 0.00$), imaging domain (k = 1.0, 95%CI 1.0-1.0, $p < 0.00$), rehabilitation domain (k = 1.0, 95%CI 1.0-1.0, $p < 0.00$) and molecular testing domain (k = 0.65, 95% CI 0.20-1, $p < 0.00$), the agreement was substantial. The satisfaction rate was 100% post video follow up and was 98.5 % post clinical follow up. The median cost incurred in VF was 58.15 USD (IQR 43.38-91.69) while that incurred in CCF was 131.23 USD (IQR 68.8-256 ($p < 0.00$)). Conclusions: The decisions taken regarding administration of adjuvant TMZ were similar between VF and CCF. Hence, it's practical and economical to substitute CCF with VF during adjuvant TMZ administration. Clinical trial information: CTRI/2017/01/007626.

2025 Poster Session (Board #267), Mon, 1:15 PM-4:45 PM

Association of aggressive resection with survival and progression-free survival in adult low-grade glioma: A systematic review and meta-analysis with numbers needed to treat. *First Author: Timothy J Brown, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Low-grade gliomas (LGG) account for 17-22% of all primary brain tumors. Optimal surgical management consists of optimum safe resection with the goal of complete resection. We performed a systematic review and meta-analysis to quantify the association of extent of resection with likelihood of survival, expressing our results in numbers needed to treat (NNT). **Methods:** A systematic review and study-level meta-analysis to determine the association of resection with overall survival and progression-free survival in newly diagnosed, supratentorial LGG in adults was performed by querying PubMed. Data were extracted to compare gross total resection (GTR) to subtotal resection (STR) and STR to biopsy (Bx) to determine relative risks (RR) of death and progression at 2, 5, and 10 years. Data were analyzed using a random effects model. NNT were calculated from significant comparisons and rounded up to the nearest whole number. Quality of evidence was determined by American Academy of Neurology criteria. **Results:** The systematic review resulted in 283 potential studies. Ultimately 29 studies were included in at least one comparison. There were no high quality (class I and II) or prospective studies discovered in the review. Comparing GTR to STR, RR with 95% confidence intervals (CI) of death at 2, 5, and 10 years, and NNT to avoid one death at 2, 5, and 10 years (GTR vs. STR) were 0.29 [0.17-0.52, $p < 0.0001$, NNT 17], 0.39 [0.29-0.51, $p < 0.00001$, NNT 6], and 0.50 [0.35-0.70, $p < 0.0001$ NNT 4]. RR and NNT for progression (GTR vs. STR) at 2, 5, and 10 years were 0.37 [0.24-0.57, $p < 0.0001$ NNT 7], 0.50 [0.39-0.64, $p < 0.0001$ NNT 4], and 0.67 [0.53-0.84, $p = 0.0005$ NNT 4]. Comparing STR to Bx, RR of death at 2, 5, and 10 years were 0.55 [0.34-0.88, $p = 0.01$ NNT 10], 0.9 [0.61-1.34], and 0.95 [0.73-1.23]. **Conclusions:** Increasing resection thresholds appear to be associated with improved overall and progression free survival, but the body of literature consists of low quality studies. Prospective studies are required to explore whether extent of resection matters or whether resectable tumors share a favorable biology associated with better outcome.

2026 Poster Session (Board #268), Mon, 1:15 PM-4:45 PM

A phase II trial of temozolomide (TMZ) 1 week on/1 week off as initial treatment for high risk low grade oligodendroglial tumors: An AINO (Italian Association for Neuro-Oncology) study. *First Author: Roberta Ruda, Department of Neuro-Oncology, University of Turin and City of Health and Science, Turin, Italy*

Background: The efficacy of dose-dense temozolomide (TMZ, 1 week on/1 week off) in grade II gliomas is not well known and could depend on the molecular subtype. **Methods:** Between 2006 and 2010 a single arm phase II study on 60 patients with grade II oligodendroglial tumors was performed. Inclusion criteria were as follows: 1) age $\geq$ 18 years; 2) KPS $\geq$ 70; 3) biopsy-proven grade II oligodendroglioma or oligoastrocytoma ; 4) a measurable residual tumor after surgery. The primary endpoint was tumor response on MRI according to RANO criteria, while the secondary endpoints were progression-free survival (PFS), overall survival (OS), and seizure control. Most patients (65%) had seizures. Molecular factors (IDH 1-2 mutations, 1p19q codeletion, MGMT methylation) were available in 49/60 patients (81.7%). The median number of cycles was 11 (2-18). Median follow up was 64 months (7-112). **Results:** Response rate was PR in 21/60 (35%) patients, minor PR (mPR) in 14/60 (23%), SD in 21/60 (35%) and PD in 4/60 (7%). Most patients achieved the best tumor response within 6 months after the start of TMZ. Among patients with mPR and PR, 15/49 (30.6%) were IDH1-2 mutated with a PFS of 71.4% at 36 months and 28.6% at 60 months with a median value of 46 months while 11/49 (22.4%) were IDH 1-2 wild-type with a PFS of 45.8% at 36 months and 25% at 60 months with a median value of 34 months. OS was 90.5% at 36 months and 66.7% at 60 months with a median value of 76 months in the IDH1-2 mutated/1p19q codeleted subgroup, while OS was 66.7% at 36 months and 50% at 60 months with a median value of 60 months in the IDH1-2 wild-type subgroup. Responses were higher in MGMT methylated patients. Seizure improvement was achieved in 29/34 patients (85%): 17/33 (52%) patients at 12 months and 18/29 (62.1%) at 24 months were seizure-free. Time to maximal seizure response was earlier than that observed on MRI (3 vs 6 months). **Conclusions:** Dose-dense TMZ has shown a significant activity in terms of tumor and seizure control, especially in IDH1-2 mutated/1p19q codeleted patients. Seizure reduction could represent an early indicator of response to chemotherapy and maybe predict the duration of response. Clinical trial information: 2007-000386-38.

2027 Poster Session (Board #269), Mon, 1:15 PM-4:45 PM

Use of targeted next generation sequencing (NGS) to assess mutational load in glioblastoma (GBM). *First Author: Stephen Joseph Bagley, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Trials of immune checkpoint inhibitors in GBM are ongoing. Evidence from other tumors suggests that high mutational load predicts response to these agents. We estimated mutational load in adults with newly diagnosed GBM using targeted NGS and assessed its association with other clinicopathologic parameters. **Methods:** NGS was performed for all patients diagnosed with isocitrate dehydrogenase wild-type (IDH-WT) GBM at our institution since September 1, 2016. Our panel performs targeted exome sequencing of 153 cancer-related genes (+/- 10 bp at intron/exon boundaries) and detects insertions, deletions, and single nucleotide variants at an allele frequency of 2%. Polymorphisms present in $>$ 0.1% of the population according to the ExAC database and 1000 Genomes Project were filtered to reduce germline variants in the absence of matched normals. To avoid upward skewing of mutational load due to the panel's preferential detection of genes recurrently mutated in cancer, alterations with known or likely functional disruption per the COSMIC database and/or our internal variant knowledge base were also not counted. The number of mutations counted was divided by the coding region target territory of the NGS panel (~0.5 Mb) to extrapolate mutational load to the whole exome. The Mann-Whitney U test was used to compare mutational load according to sex, age ($\geq$65 vs. $<$ 65), and *MGMT* methylation status (positive vs. negative). **Results:** Of 28 patients, median age was 65, 75% were male, and 37% were *MGMT*-methylated. Mean mutational load was 3.6 mutations/Mb (range 0-8, standard deviation 2.3) and was higher in males (4.3, 95% CI 3.3-5.3) compared to females (1.4, 95% CI 0.03-2.8) ($p = 0.004$). Mutational load did not differ according to age or *MGMT* methylation. **Conclusions:** In newly diagnosed IDH-WT GBM, targeted NGS revealed an estimated mutation rate similar to that reported in whole exome sequencing studies. In addition, we detected a higher mutational load in males compared to females. The latter finding adds to recent evidence suggesting sex-specific differences in the biology of GBM, and implies that future studies should account for sex when assessing mutational load as a predictive marker of immune checkpoint inhibition.

2028 Poster Session (Board #270), Mon, 1:15 PM-4:45 PM

Comparison of high dose methotrexate treatments in CNS lymphoma patients: The Henry Ford experience. *First Author: Ranya Selim, Henry Ford Hospital, Detroit, MI*

Background: The main backbone of therapy for CNS lymphoma involves systemic treatment with high dose methotrexate (HDMTX)-based regimens, with radiotherapy reserved only for cases that fail systemic therapy due to the significant cognitive toxicity of radiation. Over the last decade, rituximab and subsequently temozolomide were added to HDMTX chemotherapy regimens. **Methods:** Patients diagnosed with CNS lymphoma between 2009 and 2015 were identified. A retrospective cohort study was conducted of patients who received HDMTX alone (Cohort A), HDMTX and rituximab (Cohort B) and HDMTX, rituximab and temozolomide (Cohort C). Data collected included treatment related adverse events along with OS and PFS. **Results:** 31 patients were diagnosed with CNS lymphoma. 11, 10 and 6 patients were in cohorts A, B and C respectively. Median PFS and OS for the entire cohort were 14 and 25 months respectively. Cohort results were compared to the respective reference trials published in the literature. Cohort A had a PFS of 11 months and OS of 12 months compared to 12.8 months and 22.8+ months in the reference Phase II trial. Cohort B had a median PFS of 25+ months and OS of 41 months compared to 21 months and 33.5 months in the reference trial. Cohort C had a 2-year PFS of 0.50 compared to 0.57 in the reference trial. 3 (9.6%), 5 (16.1%), and 2 (6.4%) patients developed renal dysfunction in cohorts A, B and C respectively. 4 (12.9), 2 (6.4%), and 0 patients developed leukopenia in cohorts A, B and C respectively. 3 (9.6), 2 (6.4%), and 1 (3.2%) patients developed anemia in cohorts A, B and C respectively. 1 (3.2%), 1 (3.2%) and 1 (3.2%) patient developed thrombocytopenia in cohorts A, B and C respectively. **Conclusions:** The addition of Rituximab to HDMTX treatment for the treatment of CNS lymphoma increased the PFS and OS compared to HDMTX alone and is in concordance with the reference phase II trials reported in the literature if not better. In addition, our data at HFH shows no increased risk of adverse events with combination therapies compared to HDMTX alone. The addition of Temozolomide to Rituximab and High Dose methotrexate treatment showed a median 2 year PFS of 0.50 which is comparable to published reports of a 2-year PFS of 0.59.

2029 Poster Session (Board #271), Mon, 1:15 PM-4:45 PM

Neurocognitive outcome in children with sensorineural hearing loss after treatment of malignant embryonal brain tumors. *First Author: Christine Dahl, Hospital for Sick Children, Toronto, ON, Canada*

Background: Neurological side effects associated with childhood brain tumors and their treatments contribute to long term neurocognitive morbidity. The aims of this study were to identify the incidence of sensorineural hearing loss (SNHL) in a large sample of children treated for malignant brain tumors, and to evaluate the potential relationship between SNHL and intellectual functioning following the completion of treatment. **Methods:** We conducted a prospective follow-up study at a single center with review of 119 patients treated for embryonal brain tumors at the Hospital for Sick Children, between 1996-2015, to analyze the impact of significant SNHL (Chang $>$ 2b) on intellectual function. Hearing was assessed post-treatment (median age: 13.5y (+4.5)) and the median age for neurocognitive testing was 12.8y (+ 4.1). The median interval from time of diagnosis was 5.8y (+ 3.7). **Results:** Severe SNHL was identified in half the patients (50.4%, n = 60/119). We identified a subset of patients (n = 61) who had assessments of intellectual function. In this cohort, intellectual function was significantly poorer in the group with severe SNHL, even after controlling for the effect of craniospinal radiation (severe SNHL 22.4 Gy + 13.3, no or mild hearing loss 20.4 Gy +12.8) and boost dose and volume. Children experiencing severe SNHL had lower overall IQ (severe SNHL 72.4 + 16.6; no/mild hearing loss 92.0 + 20.5) $p < 0.001$ and in significantly lower verbal comprehension (severe SNHL 78.7 + 15.9; no/mild hearing loss 94.7 + 13.8) $p < 0.001$, and working memory (severe SNHL 78.2+ 17.6; no/mild hearing loss 94.8 + 16.4) $p < 0.001$, scores. **Conclusions:** Hearing loss is a much more significant complication in children with embryonal brain tumors than previously estimated. We show the profound impact of hearing loss on intellectual deficit in children. Namely, patients with severe SNHL have difficulty using and understanding verbal language, and they have a reduced ability to concentrate and manipulate information in short-term memory. Our results have implications on future trial designs and follow-up of children treated for embryonal brain tumors.

2031 Poster Session (Board #273), Mon, 1:15 PM-4:45 PM

Is less more? Comparing chemotherapy alone to chemotherapy and radiation for high risk, grade II glioma—An analysis of the National Cancer Data Base. *First Author: Jaymin Jhaveri, Department of Radiation Oncology at Emory University, Atlanta, GA*

Background: Grade II glioma patients with subtotal resection (STR) or age $\geq$ 40 are considered high risk. RTOG 9802 demonstrated that for these high-risk patients, chemotherapy and radiation therapy improved overall survival (OS) compared to radiation alone. The purpose of this study is to compare the OS of high risk, grade II glioma patients treated with adjuvant chemotherapy alone (CA) to chemotherapy and radiation therapy (CRT). **Methods:** Using the National Cancer Data Base (NCDB), high risk (age $\geq$ 40 or STR) grade II glioma patients with oligodendroglioma, astrocytoma, or mixed tumors were identified. Patients receiving CA were compared to patients receiving CRT. Univariate and multivariable analyses (MVA) were performed. Propensity score (PS) matching was utilized to account for difference in patient characteristics. Kaplan Meier statistics were utilized to compare OS. **Results:** 1054 high risk, grade II glioma patients were identified, 47.1% receiving CA and 52.9% receiving CRT. Median follow up time was 55.1 months. Patients treated with CA were statistically more likely (all $p < 0.05$) to be oligodendroglioma histology (65.5% vs. 34.2%), 1p/19 co-deleted (22.8% vs. 7.5%), younger median age (47 vs. 48 years) and treated at an academic program (65.2% vs. 50.3%). MVA demonstrated treatment type was not a significant predictor for OS ($p = 0.125$), while tumor size $>$ 6cm, astrocytoma histology, and older age were predictors for worse survival (all $p < 0.05$). Utilizing 1:1 PS matching, with 662 total patients, OS was statistically similar ($p = 0.919$) for CA and CRT at 5 years (69.1% vs. 68.5%, respectively) and 7 years (55.5% vs. 60.0%, respectively). **Conclusions:** In this retrospective analysis of the NCDB, long term OS for high-risk, grade II glioma patients treated with CA appears similar to CRT. These findings are hypothesis generating, with the standard of care still remaining CRT as established by RTOG 9802. Prospective clinical trials comparing CA and CRT are warranted.

2032 Poster Session (Board #274), Mon, 1:15 PM-4:45 PM

Benefits and costs of bevacizumab in recurrent glioblastoma: A quality adjusted survival and cost analysis (EVALUATE). *First Author: Katrin Lisa Conen, University of Basel and University Hospital Basel, Medical Oncology, Basel, Switzerland*

Background: Routine clinical use of bevacizumab (Bev) in recurrent glioblastoma (rGBM) is controversial, as no large RCT has shown a survival advantage. We describe treatment algorithms, survival (OS), quality-adjusted survival (QAS) as well as costs of patients (pts) with GBM treated at an academic hospital in Switzerland, where Bev is registered and reimbursed for rGBM. **Methods:** Pts' and treatment characteristics from diagnosis until death (including neurological symptoms and toxicities) of all pts over a 5-year period were retrospectively retrieved from our GBM database. For each treatment period (1st-line, recurrence and "best supportive care") time to next treatment (TNT), OS and QAS were calculated and modelled for prognostic factors (Cox regression). QAS was evaluated as previously described (Murray *et al*). In- and out-patient costs were calculated from time of diagnosis until death in respect of Bev treatment (+Bev vs. –Bev). **Results:** 82 newly diagnosed GBM pts with a median age of 66 years (range 39-85), median KPS of 90% (range 50-100%), who were treated with 1 (n = 75), 2 (n = 36) or 3 (n = 14) lines of therapy, respectively, lived for a median OS of 11.9 (SD 9.7) months (mos). QAS was 5.3 (SD 6.9) mos i.e. 44% of the numerical survival time. 40% of patients were treated with Bev at 1st or 2nd recurrence. Pts, who were selected for BEV treatment, had a longer time from diagnosis to 2ndline treatment (median 5.2 (SD 6.3) mos) as compared to pts in the -Bev group (median 2.1 (SD 1.8) mos). Younger age and Bev treatment were associated with longer OS and QAS. QAS to OS ratio was 52% (9.4 out of 18.1 mos) for BEV treated patients and 34% (2.8 out of 8.2 mos) for the –Bev group, respectively. Bev treatment increased the overall treatment costs by 1.7x. The population adjusted incremental cost-effectiveness ratio (ICER) was CHF 75,669 per life year gained. **Conclusions:** QAS in patients with GBM is short (one third to half of OS). In our cohort, pts selected for Bev treatment had longer OS and longer QAS - at costs below the accepted threshold of 100,000 CHF per life year gained. Whether this gain of lifetime is a direct result of Bev treatment or a consequence of a selection bias needs to be addressed prospectively.

2033 Poster Session (Board #275), Mon, 1:15 PM-4:45 PM

Retrospective review of safety and efficacy of checkpoint inhibition in refractory high-grade gliomas. *First Author: Samantha Reiss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Treatment options for refractory high grade gliomas (HGG) are limited. Programmed cell death ligand-1 (PD-L1) expression has been reported in 0-61% of HGGs and therefore might be a suitable target in HGG. The purpose of this study was to describe safety and efficacy of PD-1 inhibition in patients with refractory HGGs. **Methods:** This IRB approved single center retrospective study at Memorial Sloan Kettering Cancer Center included pathologically confirmed HGG with an age ≥18 years who received a PD-1 inhibitor between 9/2014 and 10/2016 outside of a clinical trial. **Results:** Twenty five HGGs were identified. All patients received the PD-1 inhibitor pembrolizumab (pembro) as part of compassionate use. Median age was 49 years (range 30-72); 44% were men; 13 had glioblastoma (52%), 7 anaplastic astrocytoma (28%), 2 anaplastic oligodendroglioma (8%), 2 unspecified HGG (8%), and 1 gliosarcoma (4%). Patients received a median of 4 prior lines of therapy (range 1-9). Nineteen (76%) previously failed bevacizumab. Median baseline KPS was 80 (range 50-100). Concurrent treatment included bevacizumab in 17 (68%) or bevacizumab and temozolomide in 2 (8%) patients. Median number of doses administered was 3 (range 1-14). Treatment toxicity and response was assessed in 24 patients. PD-1 inhibitor related adverse events (AEs) included LFT elevations (33%), hypothyroidism (17%), diarrhea (17%), myalgias/arthralgias (13%), and rash (8%). Other common AEs were hyperglycemia, fatigue, thrombocytopenia, lymphopenia, headache, and nausea in the setting of concomitant therapy and additional supportive care (dexamethasone). Grade 3 AEs included seizure (4%), headache (4%), nausea (4%), and vomiting (4%). Best radiographic response was partial response (n = 2), stable disease (n = 5), and progressive disease (n = 17). Median progression free survival (PFS) was 42 days (range 7-282) and median overall survival was 121 days (range 15-415). Three patients (12%) had a PFS > 90 days; of these, 2 received single agent pembro. **Conclusions:** Patients with HGG had low response rates. However, a small number of patients had prolonged PFS. Pembro was tolerated with few serious AEs, even in patients receiving concomitant therapy.

2034 Poster Session (Board #276), Mon, 1:15 PM-4:45 PM

Phase I/II study of an implantable device delivering low intensity pulsed ultrasound (LIPU) to disrupt the blood-brain barrier (BBB) followed by intravenous carboplatin chemotherapy in patients with recurrent glioblastoma (GBM). *First Author: Ahmed Idbaih, Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06 UMR S 1127, Institut du Cerveau et de la Moelle épinière, ICM, Paris, France*

Background: The BBB prevents the passage of most drugs from the blood to the brain and may be responsible for the limited efficacy of current chemotherapies in GBM patients. Two to four minutes of LIPU in combination with injection of micron-sized microbubbles has been shown to be a safe method for disrupting the BBB for a duration of 6 hours to increase the passage of drugs such as carboplatin by 5 to 7 fold in normal brain. **Methods:** Patients with recurrent GBM were implanted with a 1 MHz, 10-mm diameter pulsed ultrasound device in a burr hole during additional debulking surgery or during a dedicated procedure under local anesthesia. Ultrasound dose was escalated using a 3+3 Simon design. The device was activated monthly in combination with injection of a sulfur hexafluoride microbubble to transiently disrupt the BBB in 5 cm^3 of the tumor field before IV administration of carboplatin chemotherapy (AUC4-6). Patients received 150-270 seconds of pulsed ultrasound < 1 hour prior to chemotherapy. BBB disruption was visualized using contrast-enhanced T1w MRI, and patients were monitored clinically and with T2, FLAIR, DWI and SWI sequences. Tumor progression was evaluated using the RANO criteria. **Results:** Nineteen patients were treated by LIPU until tumor progression. In 65 ultrasound sessions, 52 showed BBB disruption. The median number of monthly sonications per patient was 3 and ranged from 1-10. No significant adverse events related to ultrasound sonications were observed. Six patients (31%) had long PFS (19, 20, 35, 38, 40, 52 weeks). When tumor recurrence occurred, it was predominantly outside of the ultrasound sonication field. **Conclusions:** This trial has demonstrated that LIPU is a safe modality for disrupting the BBB in GBM patients and may increase the effectiveness of drug therapies in the brain. The sonication of larger volumes of brain may further increase the effectiveness of this therapy in patients with GBM. Clinical trial information: NCT02253212.

2035 Poster Session (Board #277), Mon, 1:15 PM-4:45 PM

PD-L1 expression of high grade glial tumors at diagnosis and change of expression status at recurrence. *First Author: Basak Oyan, Acibadem University, Istanbul, Turkey*

Background: PD-L1 expression status is the main predictive factor for response to immune checkpoint inhibitors. PD-L1 status may change over time with the impact of therapies. The aim of this study is to determine if PD-L1 expression status changes in recurrent gliomas after chemoradiotherapy. **Methods:** Thirty eight patients with recurrent high grade gliomas who had surgical excision at least two times were included in this retrospective cross-sectional study. Nine patients were excluded because of the lack of appropriate pathology slides for pathologic evaluation. PD-L1 expression of 29 patients was evaluated by an expert pathologist with immunohistochemical methods. PD-L1 positivity was defined as expression in ≥1% of tumor cells. Change in PD-L1 expression status was defined as an absolute 5% difference between two resections. **Results:** Of the 29 patients, 15 patients (51.7%) had PD-L1 expression in ≥1% of tumor cells and 7 patients (24.1%) had PD-L1 expression in ≥10% of tumor cells. Tumor PD-L1 expression (defined as expression in ≥1% of tumor cells) was positive in 15 (51.7%) of 29 patients at diagnosis and at the time of recurrence. The PD-L1 status did not change in 17 patients (58.6%). 8 patients had PD-L1 negative tumors both at diagnosis and at recurrence, while 9 patients had PD-L1 positive tumors both at diagnosis and at recurrence. In 6 patients (20.7%) a negative-to-positive switch and in 6 patients (20.7%) a positive to negative switch were seen. Tumor PD-L1 expression increased in 7 of 29 patients (24.1%) and decreased in 9 of 29 patients (31.1%). PD-L1 expression remained stable in 13 of 29 patients (34.4%). The change in PD-L1 status over time was not statistically significant. **Conclusions:** More than 50% of high grade glial tumors express PD-L1 at diagnosis, so these tumors are good candidates for immune checkpoint inhibitors. The expression status changes in more than 40% of high grade glial tumors at recurrence, so immune responsiveness of glial tumors can be modified by treatments like chemotherapy and radiotherapy.

2036 Poster Session (Board #278), Mon, 1:15 PM-4:45 PM

Study of the impact of cytomegalovirus-encephalopathy on survival of brain cancer patients undergoing treatment with radio(chemo)therapy. *First Author: Nicole Lydia Goerig, Department of Radiation Oncology, Universitatsklinikum Erlangen, Friedrich-Alexander-Universitat Erlangen-Nürnberg, Erlangen, Germany*

Background: As recently demonstrated (Neurooncology, 2016), neurological decline of patients with brain cancer (high grade glioma, brain metastases) during radio(chemo)therapy (RCT) of the brain is oftentimes caused by CMV-encephalopathy but not disease progression or therapeutic complications. We examined the impact of clinical and serological CMV-status on the survival one year after the onset of radio(chemo)therapy of the brain. **Methods:** 118 patients requiring whole-brain radiotherapy for brain metastases (n = 55) or local RCT of the brain for high-grade gliomas (n = 63) were observed in the prospective GLIO-CMV-01 study. MRIs and blood samples were obtained before, halfway through, and at the end of radiotherapy. MRIs were screened for disease progression or increased intracranial pressure. Blood was tested for anti-CMV immunoglobulin (Ig)M, anti-CMV IgG, and CMV DNA. **Results:** 68 of 118 (58%) patients were positive for anti-CMV IgG before radio(chemo)therapy. 28 of those 68 (41%) developed CMV-viremia during or up to 28 days after the end of irradiation. 21 of those 28 (75%) required treatment for symptomatic CMV-associated encephalopathy. One year after the start of RCT, survival was 72% (34/47) (no encephalopathy, anti-CMV-IgG+) or 68% (34/50) (no encephalopathy, anti-CMV-IgG-) versus 38% (8/21) (encephalopathy) (p = 0.0034). **Conclusions:** Symptomatic CMV-encephalopathy all but doubles the mortality of brain cancer patients within one year of RCT, despite antiviral treatment with ganciclovir. These findings heavily underline the importance to identify patients with increased risk profile for developing CMV-encephalopathy before initiating RCT.

2037 Poster Session (Board #279), Mon, 1:15 PM-4:45 PM

Comparison of 2-hydroxyglutarate (2HG) levels in tissue and serum of isocitrate dehydrogenase (IDH)-mutated (MUT) versus wild-type (WT) gliomas. *First Author: Hao-Wen Sim, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: IDH mutations are common in low-grade gliomas and confer significantly improved prognosis. IDH catalyzes the oxidative decarboxylation of isocitrate to α-ketoglutarate, and subsequently to the oncometabolite 2HG. Mutant IDH leads to preferential accumulation of the R relative to the S enantiomer of 2HG. We analyzed the ratio of R to S enantiomers (rRS) in glioma tissues and matched serum samples, and correlated findings with IDH status, 1p19q codeletion status and survival. **Methods:** Fresh frozen glioma tissues and matched serum samples were obtained from the University of Toronto Brain Tumor Bank. IDH status was determined by immunohistochemistry and confirmed by 450K methylation profile or direct sequencing. 1p19q codeletion status was determined by loss-of-heterozygosity PCR analysis. R-2HG and S-2HG levels were quantified using HPLC tandem mass spectrometry coupled with a CHIROBIOTIC column. **Results:** Glioma tissues from 70 patients were analyzed – 52 with IDH MUT and 18 WT. 30 had matched serum samples. Using glioma tissues, rRS clearly distinguished MUT vs WT (median 574 vs 1.3, $p < 1x10^{-9}$) with only three outliers. In contrast, rRS was not elevated in serum samples (median 1.5 vs 1.2, p = 0.13). Overall survival (OS) was significantly longer for MUT vs WT (median 178 vs 33 months, $p < 1\times10^{-7}$). Stratifying MUT by tissue rRS, median OS was 197, 178, 178 and 122 months for lowest to highest quartiles of rRS respectively. 1p19q codeletion status and tumor latency did not explain this trend, given rRS was similar in codeleted vs non-codeleted MUT, and similar in MUT operated < 3 vs ≥3 months from diagnosis. Progression-free survival results corresponded to OS. **Conclusions:** rRS from glioma tissues effectively differentiated MUT vs WT, whereas serum samples were unreliable. Unlike current methods, tissue rRS enables real-time determination of IDH status, and thus may guide clinical practice such as extent of surgical resection intraoperatively and upfront selection of adjuvant therapy. rRS potentially stratifies survival within MUT patients, providing detailed correlative information.

2038 Poster Session (Board #280), Mon, 1:15 PM-4:45 PM

Clinical and molecular subgroups of ependymoma in adulthood: An analysis of the German Glioma Network. *First Author: Dorothee Gramatzki, Laboratory of Molecular Neuro-Oncology, Department of Neurology, and Neuroscience Center Zurich, University Hospital and University of Zurich, Zurich, Switzerland*

Background: Ependymoma is a subtype of glioma that is rare in adults. Its classification has remained entirely morphological until recently, and surgery and radiotherapy remain the mainstays of treatment. Here we characterized DNA methylation profiles and their clinical correlates in the prospectively assembled cohort of the German Glioma Network. **Methods:** The GGN cohort was screened for patients diagnosed with myxopapillary ependymoma, subependymoma, classic ependymoma and anaplastic ependymoma for whom clinical data and remaining tumor tissue were available. Tumors were subjected to DNA methylation profiling using the Illumina Infinium HumanMethylation450 BeadChip platform. Molecular data were correlated with morphological tumor and clinical patient characteristics. **Results:** One hundred and twenty-two ependymoma patients with available tumor tissue were identified. Each adult tumor could be assigned to one of the previously defined methylation classes of ependymoma. Molecular entities of ependymal brain tumors display distinct copy-number variations. PF-EPN-B and ST-EPN-RELA tumors tend to have a worse prognosis than other ependymal subtypes in adults. **Conclusions:** Molecular classification of adult ependymal methylation subclasses should be implemented in routine diagnostics. Patients with PF-EPN-B and ST-EPN-RELA subtypes might benefit from early treatment beyond surgery.

2039 Poster Session (Board #281), Mon, 1:15 PM-4:45 PM

Overall survival (OS) by line of therapy (LOT) in Medicare-enrolled glioblastoma multiforme (GBM) patients (pts). *First Author: Abdalla Aly, Pharmerit International, Bethesda, MD*

Background: In clinical trials, the median OS of elderly GBM pts on standard treatment (tx) is ~9 months (mos) from diagnosis (dx), but has not been described in the real world (RW). This analysis describes RW OS for US Medicare GBM pts by LOT. **Methods:** GBM pts aged ≥66 years (y) were identified in SEER-Medicare (2007–2011). Pts were followed from dx to death, Medicare disenrollment or 12/31/2013. Systemic tx patterns were characterized as untreated (0L), ≥first line (1L+) and ≥second line (2L+). OS was estimated by the Kaplan-Meier method from dx for 0L, and from LOT start for 1L+ and 2L+. **Results:** Among 2533 eligible GBM pts (median age: 74 y; Charlson comorbidity index [CCI] ≥2: 13%), 49.9% received 1L+ and only 16.3% received 2L+. Median (1-year) OS for all pts was 5.3 mos (26%), range 1.6–10.7 mos (3–45%) depending on LOT, surgical resection (R) or Biopsy alone (B), tumor size, age, and CCI (Table). **Conclusions:** Receipt of tx has a significant impact on OS in Medicare GBM pts. This RW study shows that only 50% of pts receive tx, even though each LOT is associated with additional OS benefit. This suggests an unmet need for more efficacious therapies to allow additional treatment and improve outcomes.

	Median OS, mos (1-year OS, %)

2040 Poster Session (Board #282), Mon, 1:15 PM-4:45 PM

Changes in survival of primary central nervous system lymphoma based on a review of national databases over 40 years. *First Author: Joe Sammy Mendez, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There has been significant improvement in treatment outcomes of Primary Central Nervous System Lymphoma (PCNSL) at specialized centers over past decades, and it is unclear if these changes have translated to benefits in the general population. In this study, we utilized national databases to examine survival trends over time. **Methods:** Incidence rates were obtained from the Central Brain Tumor Registry of the United States (CBTRUS, 2000 – 2013) and 18 Surveillance, Epidemiology and End Results (SEER, 1973 – 2013) registries. Data for survival analysis was obtained from SEER and analyzed using SEER*STAT. To focus on non-HIV-associated PCNSL, patients with "other infectious and parasitic diseases including HIV" as cause of death and follow up were excluded. CBTRUS identified 19,027 patients over 13 years and SEER 6,765 over 40 years. **Results:** The annual incidence of PCNSL in 2013 was 0.4 per 100,000 population (CBTRUS/SEER). Incidence increased from 0.1 per 100,000 in the 1970s to 0.4 per 100,000 in the 1980s, correlating with an increase in the diagnosis of elderly patients, ≥70 (1973:0.2 vs 2013:2.1 – SEER). Incidence rates differed greatly between young and elderly patients (20-29: 0.08 vs 70-79: 4.32 – CBTRUS). The median overall survival (mOS) of all patients is 17 months (m) with no survival benefit based on sex. Survival doubled from 12.5 m in the 1970s to 26 m in the 2010s. There was a significant difference in survival based on age: < 50: 83 m vs 50-69: 25 m vs ≥70: 6 m (p-value < 0.0001). In patients < 50, mOS increased from 35.5 m in the 1970s to 134 m in the 2000s (mOS not achieved in 2010s). In patients 50-69, mOS increased from 8 m in the 1970s to 35 m in the 2010s. However, mOS in the elderly population, ≥70, has not changed in the last 40 years (6 m in the 1970s vs 7 m in the 2010s, p-value = 0.1). **Conclusions:** PCNSL is a disease that more frequently affects the elderly. Although overall survival has increased over the past 4 decades, reflecting current literature in PCNSL, survival in the elderly has not changed since the 1970s. Identification of this vulnerable patient population highlights the need for clinical trials targeting the elderly in hopes of improving treatment strategies and ultimately outcomes.

2042 Poster Session (Board #284), Mon, 1:15 PM-4:45 PM

Phase 2 study to evaluate safety and efficacy of MEDI4736 (durvalumab [DUR]) in glioblastoma (GBM) patients: An update. *First Author: David A. Reardon, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: DUR is a human IgG1 monoclonal Ab against PD-L1. PD-1/PD-L1 blockade has shown benefit in solid tumors. PD-L1 is expressed by many GBM tumors while cytotoxic lymphocytes infiltrating GBM tumors often express PD-1; thus, there is a rationale for exploring PD-1/PD-L1 blockade in GBM. Bevacizumab (BEV) is a VEGF-specific angiogenesis inhibitor approved for recurrent GBM. PD-L1 blockade and angiogenesis inhibition may be synergistic. **Methods:** This ongoing Phase 2, multicenter, open-label study (NCT02336165) evaluates safety/efficacy of DUR (10 mg/kg every 2 wks) in 5 GBM cohorts. Secondary endpoints are safety/tolerability, median PFS/OS, overall response rate and quality of life measures. Exploratory endpoints: neurologic function and immunocorrelative biomarkers. **Results:** Enrollment as of 16 Dec 2016: Cohort A = 35, B = 31, B2 = 34, B3 = 34, and C = 20 pts. Enrollment is ongoing for Cohorts A and C. This is an update to the interim analysis that was reported for Cohort B (male: 83.9%; mean age: 54.0 [24-77] years; baseline ECOG PS0: 51.6%, PS1: 48.4%; baseline measurable lesions: 77.4%). Incidences of treatment-related adverse events (TRAEs) by max CTCAE grade (Gr) were Gr1: 35.5%; Gr2: 41.9%; Gr3: 9.7%; and Gr4/5: 0%. Most common TRAEs (≥3 pts): fatigue, headache, hemiparesis, gait disturbance, increased AST, and decreased platelets/WBCs/lymphs. Six of 30 evaluable pts were progression free at 6 months (Kaplan-Meier, 20.0% [90% CI: 9.7, 33.0]); best overall response: partial response, 4 (13.3%) pts and stable disease, 14 (46.7%). At 1 year, 4 pts remained progression free (longest PFS ongoing at 80 wks, n=2). OS-6 and OS-12 are 59.0 and 44.4%, respectively. As of 16 Dec 2016, 7 pts remain alive (longest OS ongoing at 86 wks). **Conclusions:** DUR monotherapy appears to be well tolerated and shows durable activity in a subset of BEV-naïve recurrent GBM pts. Study is ongoing. Clinical trial information: NCT02336165.

GBM Population	Cohort (planned n)	Concomitant Therapy	Primary Endpoint
Newly diagnosed + unmethylated MGMT	A (37)	Radiotherapy	12-month overall survival (OS-12)
BEV naïve recurrent	B (30)	none	6-month progression-free survival (PFS-6)
	B2 (32)	BEV 10 mg/kg	
	B3 (32)	BEV 3 mg/kg	
BEV refractory recurrent	C (17)	BEV 10 mg/kg	OS-6

2043 Poster Session (Board #285), Mon, 1:15 PM-4:45 PM

Radiomics method to predict loss of heterozygosity on chromosome 1p/19q of oligodendroglial tumor. *First Author: Jingwei Wei, Chinese Academy of Sciences, Beijing, China*

Background: Oligodendroglial tumor (OT) is one of the main types of gliomas, which is incurable in current situation. As a tumor-specific genetic alteration of OTs, loss of heterozygosity (LOH) on chromosome 1p/19q indicates a preferable response to chemo/radiotherapy and a better survial, which could be used as a key molecular signature for personalized treatment decision making. However, 1p/19q LOH status is now commonly obtained by fluorescence in situ hybridization after the tumor resection, which is highly likely to lead functin deficit with tumor locating on eloquent area. Thus, a non-invasive predicition on 1p/19q LOH is required. Here, we used a "Radiomics" method to achieve the prediction based on magnetic resonance imaging in this study. **Methods:** A cohort of 113 OT patients was collected from Beijing Tiantan Hospital. 593 three-dimensional imaging features were extracted on T2-weighted images including textural and non-textural features. We used "minimum redundancy maximum relevance" and "iterative backward elemination and forward inclusion" algorithms to pick up the most effective features with a p-value < 0.05. With the selected features as the input, support vector machine algorithm was adopted to predict the 1p/19q LOH status with 10-fold cross validation. Comparisons were made between the traditional clinical predictors and the established model. **Results:** The prediction accuracy for 1p/19q LOH turned out to be 86.6%. The top three features contributing most to the prediction were respectively: GlobalUniformity, GaborBankD4GLRLMLGRE and GaborBankD4GLRLMSRLGE. The predictive performance of the radiomics model was proved to be far more valid than the clinical predictors (indistict tumor border and heterogeneous signal intensity) with the higher area under curve (AUC). Compared with the best single feature (GlobalUniformity, AUC: 0.749), this combined-feature model has the best diagnostic performance with an AUC of 0.898. **Conclusions:** This study reveals the intrinsic association between the imaging features and 1p/19q LOH status, meanwhile, realizes the high precision prediction, providing reliable basis for the pre-operative treatment regime.

2044 Poster Session (Board #286), Mon, 1:15 PM-4:45 PM

Expanded phase I study of intratumoral Ad-RTS-hIL-12 plus oral veledimex: Tolerability and survival in recurrent glioblastoma. *First Author: E. Antonio Chiocca, Brigham and Women's Hospital, Boston, MA*

Background: Glioblastoma (GBM) is an aggressive brain tumor affecting ~74,000 people worldwide annually. Recurrent GBM patients have a median OS (mOS) of 6-7 months. OS in patients who have failed temozolomide, bevacizumab or equivalent salvage chemotherapy, is ~3-5 months. New therapies are urgently needed. Ad-RTS-hIL-12 (Ad) is a novel gene therapy expressing IL-12 under the control of an oral activator ligand, veledimex (V), through the RheoSwitch Therapeutic System. Intratumoral administration of Ad results in targeted tumor cytotoxicity and induction of systemic T cell memory. Ad + V is a treatment strategy to extend the IL-12 therapeutic window. **Methods:** In a multicenter Phase I dose escalation trial and expansion cohort, subjects with recurrent or progressive Grade III or IV glioma undergoing resection were injected intratumorally with Ad 2 x 10^{11} viral particles and daily oral V for 15 doses, beginning prior to surgery. The primary endpoint is safety and tolerability of Ad + V; secondary endpoints include OS. **Results:** 25 subjects were dosed in 3 dose escalation cohorts: 20 mg (n = 7), 30 mg (n = 4), and 40 mg (n = 6) and an expansion cohort of 20 mg (n = 8). Results show V crossed the blood brain-barrier with 35±5% of plasma levels detected in the brain tumor. The 20 mg dose (n = 15) had better drug compliance (86%) than the 30 mg (63%) or 40 mg (52%) cohorts and the 20 mg cohort shows better survival (mOS 12.7 months) compared to other cohorts. The frequency of related ≥Grade (G)3 AEs in the 20 mg cohort was significantly lower: 20% in 20mg, 50% in 30mg and 40 mg. In the 20 mg cohort, the most frequent AEs were transient mild flu-like symptoms seen in 12/15, G3 cytokine release syndrome in 2/15, G3 elevated ALT/AST in 1/15 and G3 lymphopenia in 3/15. All AEs reversed promptly upon discontinuing V. **Conclusions:** Overall, Ad + 20 mg V is well tolerated; toxicities were predictable and reversible upon discontinuing V. There is a correlation between V dose, BBB penetration and drug related AEs. The tolerability and encouraging survival observed to date warrant further investigation in a pivotal trial. A stereotactic arm and a pediatric trial in diffuse intrinsic pontine glioma patients are planned. Clinical trial information: NCT02026271.

2045 Poster Session (Board #287), Mon, 1:15 PM-4:45 PM

Assessment of tumor hypoxia in BEV resistant GBM using FMISO ^{18}F-PET and MRI. *First Author: Yichu Liu, The University of Texas at San Antonio, San Antonio, TX*

Background: Glioblastoma (GBM) is the most common malignant brain tumor in adults, and is characterized by poor survival and marked resistance to treatment. Hypoxic volume is directly correlated with poor outcome in GBM, with structural and functional tumor vasculature changes regarded as a primary driver of tumor hypoxia. As part of an ongoing clinical trial with a hypoxia activated prodrug, we sought to explore the correlation between abnormal tumor vasculature and hypoxia in bevacizumab (BEV) resistant GBM. **Methods:** MRI and ^{18}F-FMISO PET scans were acquired at study entry. The MRI protocols include standard anatomical sequences as well as Dynamic Susceptibility Contrast (DSC/perfusion) imaging. Enhancing tumor ROIs were determined from Delta T1 maps, non-enhancing tumor ROIs were obtained from FLAIR images, ratio between enhancing and non-enhancing volumes were calculated, values from standardized rCBV maps were extracted from corresponding enhancing ROIs. Decay correction was applied to ^{18}F-FMISO images and converted to SUV units. After registration to MR images, cerebellar regions were used as surrogates for blood activity. The FMISO images were then normalized to generate tissue to blood ratio (TB). A threshold of TB > 1.2 was used in discriminating the hypoxia volume (HV). Correlation between parameters was assessed using Pearson correlation. **Results:** 7 patients from University of Texas Health Science center and 7 patients from Dana-Farber Cancer Institute had evaluable MR and PET imaging. We compared MRI parameters (enhancing and non-enhancing tumor volumes, srCBV) with hypoxia (HV and maxSUV). There was a positive correlation between HV and enhancing volume ($R = 0.732$, $p = 0.0029$) as well as between HV and ratio ($R = 0.644$, $p = 0.013$. The correlation between other pairs were not statistically significant (HV vs srCBV: $p = 0.862$, T1 vs maxSUV $p = 0.492$, srCBV vs maxSUV: $p = 0.393$, ratio vs maxSUV = 0.178). **Conclusions:** The hypoxic volume following bevacizumab failure correlates with both the volume of enhancement and the fraction of enhancement within the mass. The clinical implications of this is being assessed in an ongoing phase 2 study. Clinical trial information: NCT02342379.

2046 Poster Session (Board #288), Mon, 1:15 PM-4:45 PM

A two-part safety and exploratory efficacy randomized double-blind, placebo-controlled study of a 1:1 ratio of the cannabinoids cannabidiol and delta-9-tetrahydrocannabinol (CBD:THC) plus dose-intense temozolomide in patients with recurrent glioblastoma multiforme (GBM). *First Author: Chris Twelves, University of Leeds and St. James's Institute of Oncology, Leeds, United Kingdom*

Background: Several plant-derived cannabinoids have shown efficacy in animal models of GBM, particularly when co-administered with temozolomide, a commonly-used treatment in both primary and recurrent disease. **Methods:** We conducted a two-part study in patients with recurrent GBM following standard chemo-radiotherapy treatment as described by Stupp et al. In Part 1 of the study, 6 patients were treated to an MTD of 1:1 CBD:THC oro-mucosal spray, as an adjunct to dose-intense temozolomide (DIT), to assess the safety of the combination. Part 2 was a double blind, randomized, placebo-controlled study in a planned 20 patients receiving either their individualized dose of 1:1 CBD: THC or placebo plus DIT. The primary endpoint was tolerability of 1:1 CBD: THC plus temozolomide. **Results:** There were no Grade 3 or 4 toxicities in Part 1 of the study. In Part 2, 12 patients were randomized to CBD:THC and 9 to placebo. Mean age was 58 years in both treatment groups, but there were more males in the placebo group (5 of 12 and 8 of 9, respectively). Baseline median Karnofsky score was 90 in both groups and median time from diagnosis of recurrence to start of treatment (day 1) was similar (3.6 and 3.0 weeks in the CBD:THC and placebo group, respectively). The median number of days of dosing with CBD:THC or placebo was similar (155 days [range: 50-356] and 134 days [range: 13-359]). Median survival in the placebo group was 369 days, and $>$ 550 days in the CBD:THC treatment group (NS) and 1 year survival was 83% and 56% in the CBD:THC and placebo groups, respectively ($p = 0.042$). PFS6 was 42% in the CBD:THC group and 33% in the placebo group (NS). Overall, the commonest treatment related toxicities were dizziness (in 11/18 patients) and nausea (in 7/18 patients). Results of biomarker analyses are awaited. **Conclusions:** This randomized study provides preliminary evidence that 1:1 CBD:THC offers some efficacy in patients with recurrent GBM when used as an adjunct to dose-intense temozolomide and confirms the safety and feasibility of individualized dosing. Clinical trial information: NCT01812603.

2047 Poster Session (Board #289), Mon, 1:15 PM-4:45 PM

***TERT* promoter mutations in progressive treatment-resistant meningiomas.** *First Author: Tareq A. Juratli, University Hospital Dresden, Dresden, Germany*

Background: Recurrent meningiomas often undergo a grade-progression to become atypical or malignant upon recurrence. Detailed study of progressive meningioma has been hampered by the lack of available paired specimens. Here, we sequenced the *TERT* promoter (*TERT*p) in a large series of patients with treatment-resistant meningiomas at initial diagnosis as well as their sequential recurrences. **Methods:** We scored 77 meningiomas from 36 patients for *TERT*p mutations. All patients in this study developed recurrences during the median follow-up of 13.3 years (range 6.4 - 25.5 years) and underwent three surgeries on average (range 2-8). Additionally, we screened geographically distinct sites of all *TERT*p-mutant meningiomas to interrogate intratumoral heterogeneity. **Results:** *TERT*p mutations were detected in 18 tumor samples (18/77 = 23.3%) from 12 patients, but not in any of the matched blood sample DNAs, excluding germline mutations. Notably, the *TERT*p mutations were absent in the initial lower-grade tumor and were present in the subsequent recurrent tumors. Moreover, we observe emergent spatial heterogeneity in the form of mixed populations of recurrent tumor cells containing different mutation status of the *TERT* promoter gene in three cases. Patients with emergence of *TERT*p-mutant meningiomas had a significantly shorter overall survival than their *TERT*p wild-type counterparts, when measured from the time of initial diagnosis (2.4 vs 11.1 years, 95% CI 0.25-4.54 vs 9.3- 16.8 years $p = 0.007$). **Conclusions:** Our data confirm the high frequency of *TERT*p mutations and the emergence of *TERT* promoter mutation in recurrent progressive meningiomas, strongly indicating the presence of ongoing evolution impacting the natural history of these tumors. *TERT*p mutations are mostly associated with poor outcome. Finally, our study provides important insight into the complexity of tumor heterogeneity and has important implications for targeted therapy in treatment-resistant meningiomas.

2048 Poster Session (Board #290), Mon, 1:15 PM-4:45 PM

A novel MGMT methylation-based prognostic score in patients with glioblastoma. *First Author: Lorenzo Gerratana, Department of Medicine, University of Udine and Department of Oncology, University Hospital of Udine, Udine, Italy*

Background: The methylation status of the O6-methylguanine-DNA methyltransferase (MGMT) promoter has been associated with improved outcome in glioblastoma (GBM) patients (pts). Pyrosequencing (PSQ) has been reported to be an accurate method for quantitative detection of CpG islands (CpGs) methylation, but the role of methylation heterogeneity among different CpGs sites is still unclear. Aim of this study was to evaluate on a large multicentric cohort a novel prognostic score based on the evaluation of the MGMT promoter methylation at 10 different CpGs sites. **Methods:** We retrospectively analyzed a series of 185 pts with GBM treated at the University Hospital of Udine and Istituto Oncologico Veneto in Padua between 2006 and 2015. The methylation level of 10 CpGs (74 – 83) was determined by PSQ. The cut-off point of 9% was used to define a CpG as methylated. One point was assigned to each methylated CpG, with a total score from 0 (all CpGs $<$ 9%) to 10 (all CpGs $\geq$ 9%). A threshold capable to detect a favorable outcome (Overall Survival, OS $>$ 24 months) has been identified through ROC analysis as 6 by a previous study conducted at our center. The prognostic impact was explored through Cox regression. **Results:** After a median follow-up of 59 months, the median OS and Progression Free Survival (PFS) in the whole population were 16.41 and 9.67 months, respectively. A score $\geq$ 6 identified pts with a considerably better median OS (24.85 vs 12.99 months, $p < .0001$) and PFS (11.44 vs 8.22 months, $p < .0001$). On multivariate analysis, it remained independently associated with a favorable prognosis (HR 0.38, 95% CI 0.27-0.55, $p < 0.0001$) after adjustment for IDH1 mutational status (HR 0.42, 95% CI 0.20-0.87, $p = .02$), age ($>$ 70 vs $\leq$ 70 years HR 2.20, 95% CI 1.48-3.28, $p = .0001$) and ECOG performance status (2-3 vs 0-1 HR 2.35, 95% CI 1.59-3.49, $p < .0001$). The score's prognostic value was maintained in all the explored subgroups. **Conclusions:** Combining methylation data from multiple CpGs increases the prognostic value of the MGMT promoter methylation assessment. The study confirmed the independent prognostic value of a novel score system based on the evaluation of the MGMT promoter methylation at 10 different CpGi sites.

2049 Poster Session (Board #291), Mon, 1:15 PM-4:45 PM

Number of tumor-infiltrating lymphocytes in breast cancer brain metastases compared to matched breast primaries. *First Author: Jessie Narloch, Clinical Research Training Program, Duke University Medical Center, Durham, NC*

Background: Breast cancer brain metastasis (BCBM) is frequent in advanced disease, has limited therapies, and is associated with poor prognosis. Increased stromal tumor infiltrating lymphocytes (sTILs) are prognostic in triple-negative breast cancer (TNBC) and predictive of therapeutic response in early breast cancer (BC). However, little is known about sTILs in the metastatic setting. We compared %sTILs between the largest known cohort of matched primary tumors and BCBM and correlated the results with clinical endpoints. **Methods:** We retrospectively investigated 37 matched primary tumors and BCBM tissue from three institutions. In addition, we identified 29 primary tumors from patients later diagnosed with BCBM. H&E-stained sections were manually measured for %sTILs using standard criteria. Wilcoxon signed rank tests assessed for changes in %sTILs between primary and metastatic lesions. A Cox proportional hazards model was used to determine if %sTILs in the breast tissue predicts time from primary tumor biopsy to diagnosis of brain metastasis (TTDBM) while adjusting for clinicopathologic features. **Results:** Average age at time of BCBM diagnosis was 53.6 (SD 12.3). 52% (34/66) of primary tumors were hormone receptor (HR) positive. Of 60 patients with known HER2 status, 28% (17) were HER2 positive and 40% (24) TNBC. Median %sTILS was significantly different between all primary tumors (15, IQR 5-20) and brain metastases (10, IQR 5-10), $p = 0.001$. The TNBC subtype ($n = 11$) showed the largest decrease in % sTILs between primary tumors (20, IQR 10-20) and brain metastases (5, IQR 5-10), $p = 0.022$. Comparing primary tumors and brain metastases, there was a 5% decrease in %sTILs in HR-/HER2+ ($n = 5$, $p = 0.13$) and HR +/HER2- ($n = 7$, $p = 0.13$), and a 5% increase in %sTILs in the HR+/Her2+ subtype ($n = 9$, $p = 0.69$). Percent sTILs in the primary tumors was not a significant predictor of TTDBM, when adjusting for race, age, HR status, and HER2 status, $p = 0.87$. **Conclusions:** BCBM have a significantly decreased %sTILs compared to their primary tumors, most prominent in TNBC. These results suggest altered tumor immunogenicity in the metastatic setting which has broad implications for the development of immunotherapy.

2050 Poster Session (Board #292), Mon, 1:15 PM-4:45 PM

Characterizing glioma microenvironment with ultra-high gradient diffusion MRI. *First Author: Ina Ly, Massachusetts General Hospital, Boston, MA*

Background: The infiltrating nature of gliomas, particularly into the peritumoral area, is a major barrier to improving clinical outcome as microscopic disease remains even after apparent gross total resection. Conventional T1 post-contrast and T2/FLAIR MRI do not capture full tumor extent. A better imaging biomarker is needed to improve differentiation between tumor, peritumoral area and normal brain. **Methods:** 4 pre-surgical patients with non-enhancing, FLAIR-hyperintense lesions suspicious for glioma underwent ultra-high gradient diffusion MRI on the Connectome MRI scanner, a unique scanner with maximum gradient strength of 300 mT/m enabling mapping of cellular microstructures on a micron-level scale. The FLAIR area was defined as the tumor region of interest (ROI). Radiographically normal appearing brain up to 1 cm around the FLAIR area was defined as the peritumoral ROI. Using a novel 3 compartment diffusion model (Linear Multiscale Model), the volume fraction of water (VFW) was calculated within restricted (intracellular), hindered (extracellular) and free (CSF) spaces. VFW in the tumor, peritumoral ROI, contralateral normal white matter (WM) and cortex were compared. **Results:** Within the tumor ROI, the median VFW in the restricted compartment was decreased vs. the peritumoral ROI (↓ 34%), WM (↓ 46%) and cortex (↓ 18%) while median VFW in the hindered compartment was increased vs. the peritumoral ROI (↑ 26%), WM (↑ 54%) and cortex (↑ 25%). Within the peritumoral ROI, median VFW in the hindered compartment was increased compared to WM (↑ 23%). 3 patients had available histopathology revealing isocitrate dehydrogenase-mutant gliomas. **Conclusions:** Using ultra-high gradient diffusion MRI and a novel diffusion model, we detected distinct diffusion patterns in the tumor and peritumoral area not seen on conventional MRI. Lower VFW in the restricted compartment within the tumor may reflect decreased intracellular water mobility due to enlarged nuclei. Higher VFW in the hindered compartment in the tumor and peritumoral area may reflect higher degree of tissue permeability and edema. MRI-pathology and larger cohort validation studies are underway to elucidate microenvironment changes in response to treatment.

2051 Poster Session (Board #293), Mon, 1:15 PM-4:45 PM

Whole exome sequencing and copy-number variation analysis of 20 NF2-associated spinal and cranial meningiomas. *First Author: Ramita Dewan, University of Maryland School of Medicine, Baltimore, MD*

Background: Neurofibromatosis type 2 is a heritable tumor predisposition syndrome characterized by the growth of multiple tumor types in the nervous system, including bilateral vestibular schwannomas, meningiomas and ependymomas. Recent genomic sequencing studies have revealed that *NF2* inactivation is the most frequent genetic event in sporadic meningiomas. In line with Knudson's hypothesis, it is accepted that somatic inactivation of the wildtype *NF2* allele initiates tumor growth in NF2 patients, but little is known of what other genes or pathways influence meningioma tumorigenesis. **Methods:** To investigate this question, we performed whole exome sequencing (WES) (Illumina Hi-Seq 2500 platform, 96 Mb SeqCap EZ Exome + UTR Library, NimbleGen) and SNP-array analysis (HumanOmniExpressExome-8, v1.2 arrays, Illumina) of twenty spinal and cranial meningioma samples from seven NF2 patients. Mutation validation was completed via orthogonal sequencing (IonTorrent, ThermoFisher). **Results:** We identified *NF2* germline mutations in all patients, including five nonsense, one splice site and one likely pathogenic intronic mutation. We found that the predominant mechanism of somatic *NF2* inactivation in the tumors was loss of heterozygosity (LOH): we identified large chromosome 22 deletions containing *NF2* in nineteen out of twenty meningiomas. The second most frequent chromosomal aberration was a deletion within chromosome 1p, followed by entire chromosome X deletion and rearrangements in chromosome 17q. The remaining samples exhibited normal diploid genomic architecture. Somatic mutations included about twenty point substitutions and small indels. **Conclusions:** Our study revealed that somatic inactivation of *NF2* is the most frequent and only recurrent genetic event in NF2-associated meningiomas. Large LOH events are the most prevalent second hit mechanism and may also represent a common path of meningioma progression. Somatic single nucleotide substitutions and small indels are rare in these tumors. Interestingly, we did not identify mutations in *TRAF7*, *KLF4*, *AKT1*, or *SMO,* which have been found to be critical for non-NF2 meningioma growth.

2052 Poster Session (Board #294), Mon, 1:15 PM-4:45 PM

Bevacizumab (Bev) to reduce the negative impact of glioblastoma (GBM) tumor size on survival from first recurrence. *First Author: Huy Tram N. Nguyen, University of California Los Angeles Neurology, Los Angeles, CA*

Background: Bev was FDA approved for recurrent GBM in 2009. However, the survival benefit from Bev in GBM remains to be demonstrated. **Methods:** We retrospectively identified 168 primary GBM patients diagnosed between 2001-2015 at UCLA and Kaiser Permanente LA, who received upfront radio-chemotherapy, followed with Bev and/or Lomustine (CCNU) at 1st recurrence. We measured tumor size at 1st recurrent treatment initiation, using bi-dimensional (2D) and volumetric (3D) techniques. We analyzed overall survival (OS) from 1st recurrence by Kaplan-Meier analysis. **Results:** Three groups of patients diagnosed from 2009-2015 were identified: patients treated with Bev alone (n = 49), CCNU alone (n = 36), and concurrent Bev/CCNU (n = 53). Patients were statistically different in performance status at 1st recurrence and tumor size; the CCNU alone group had smaller tumor sizes at diagnosis compared to the Bev groups. The CCNU group showed substantially greater survival (median OS (mOS) = 14.1 mo) compared to the Bev and Bev/CCNU groups (mOS = 6.9 and 7.1 mo, respectively), which may be explained by the imbalance in tumor sizes among the groups, and high rate of crossover (69%) to Bev in subsequent recurrences. To minimize selection bias, we identified another control group (n = 30) diagnosed from 2001-2004 who received CCNU only (CCNU 01-04). These patients had tumor size and KPS more comparable to both Bev groups, and a low rate of crossover (7%). OS for CCNU 01-04 (mOS = 5.7 mo) was similar to the Bev groups. Across all patients, we observed poor OS associated with larger 2D size vs. those with small tumors (mOS = 6.7 vs. 8.8 mo; p = 0.003). In separate stratification of each treatment group by tumor size, this association was retained in the CCNU 01-04 group (mOS = 4.0 vs. 8.4 mo, $p < 0.001$), but not in either Bev (mOS = 6.7 vs. 7.3 mo) or BEV/CCNU (mOS = 7.0 vs. 8.8 mo). Analysis of effect of tumor size by 3D measurement yielded similar results. **Conclusions:** Bev appears to reduce the negative impact of large tumor size on GBM patient survival from 1st recurrence. 2D and 3D measurements were correlated, suggesting the adequacy of use of conventional tumor bi-dimensional measurement to predict benefit of Bev in patients based on tumor size.

2053 Poster Session (Board #295), Mon, 1:15 PM-4:45 PM

A cellular platform to enable targeted brain delivery of T cells to glioblastoma. *First Author: Heba Samaha, Texas Children's Hospital, Houston, TX*

Background: Poor T cell homing hinders the development of effective cell therapy for central nervous system (CNS) malignancies. Lessons learnt from inflammatory brain diseases can give insight into how to overcome the blood brain barrier (BBB) blockade created by cancer. Activated Leukocyte Cell Adhesion Molecule (ALCAM; CD166) is a pathological adhesion molecule upregulated in the endothelium of a number of inflammatory/infiltrative CNS diseases, such as multiple sclerosis. Antibodies blocking ALCAM decrease leukocyte access to the brain and are currently being tested in a clinical trial for MS. **Methods:** We studied the difference in the dynamic signature of adhesion molecules in the "anergic" brain tumor endothelium and that of infiltrative brain conditions. Consequently, we mapped the ALCAM minimal binding region to domain 3 (D3) of CD6 and created an artificial molecule with the intent of creating a novel cellular platform to reverse endothelial anergy, through ALCAM specific binding. **Results:** GBM endothelium fails to launch the second wave of adhesion molecules necessary for firm T leukocyte capture and effective BBB transmigration. Engineered D3 on the T cell crosslinked to ALCAM on endothelial cells in proximity ligation assays (PLA; < 40nm) during TEM. Under shear stress, D3 T cells showed a global improved ALCAM specific trafficking kinetics: higher capture on ALCAM+ endothelium, rolling with slower velocity, and better TEM. In an ex vivo model of BBB, D3 T cells exhibited higher transmigratory ability. We discovered that signaling through the D3 endodomain phosphorylated pZAp70 recruiting Talin that enables LFA-1 (ICAM-ligand) open confirmation, mediating effective TEM. Lastly, in an orthotopic model of GBM, D3 T cells homed more and accumulated at the tumor site compared to NT controls. And, testing Her2 CAR T cells on D3 platform showed an advantageous homing after IV administration which was reflected in tumor control and better survival. **Conclusions:** We created a cellular platform that enables targeted brain delivery of T cells. This platform serves as a gateway to the effective cellular therapeutics for brain malignancies but potentially as a delivery system for complex biologics for other pathological conditions.

2055 Poster Session (Board #297), Mon, 1:15 PM-4:45 PM

Treatment through progression with ofranogene obadenovec (VB-111), an anti-cancer viral therapy, significantly attenuates tumor growth in recurrent GBM: Individual phase 2 patient data. *First Author: Andrew Jacob Brenner, The University of Texas Health Science Center, San Antonio, TX*

Background: Ofranergene obadenovec (VB-111) is a viral cancer-therapy with a dual mechanism: vascular disruption and induction of a tumor directed immune response. Prolongation of overall survival (OS) has been shown in recurrent glioblastoma (rGBM) patients treated through progression with VB-111 in combination with bevacizumab (BEV) compared to historical controls and to patients with limited exposure (LE) to VB-111. Here we present individual patient tumor growth data. **Methods:** VB-111 was administered at $1x10^{13}$viral particles bimonthly until progression, followed by BEV standard of care (LE cohort). The protocol was amended to allow treatment through progression (TThP) with VB-111 bimonthly, with the addition of BEV 10mg/Kg biweekly, until further progression (TThP cohort). Tumor dimensions were assessed q2 months by MRI locally and by an independent central lab. The slope of the log tumor measurement over time was calculated for each patient, average slopes were compared across therapy groups using the Wilcoxon Rank Sum test. **Results:** 46 patients received up to 13 doses of VB-111. All started with VB-111 monotherapy. 22 were included in the LE cohort; 24 in the TThP cohort. Cohorts were comparable by measures of age, performance status, prior lines of therapy, baseline tumor dimensions and progression-free-survival. Spider diagrams demonstrate similar rapid tumor growth in both LE and TThP cohorts during the VB-111 monotherapy period (local site data; median % increase (MPI) per 30d: 14.8 vs 14.1, p = 0.98). In the TThP cohort, growth was attenuated after the 1stprogression, compared to the preceding VB-111 monotherapy period (MPI: 0.6 vs 14.1, p = 0.0032); responses were seen, including 2 complete responses (CR), one patient remaining in CR over 3 years. A similar attenuation was seen in central lab tumor measurements. **Conclusions:** Treatment through progression with VB-111 in combination with BEV induced durable tumor growth attenuation, which was associated with prolonged OS of 15 months in patients with rGBM. The GLOBE phase 3 randomized controlled trial of VB-111 in rGBM is currently underway. Clinical trial information: NCT01260506.

2056 Poster Session (Board #298), Mon, 1:15 PM-4:45 PM

Activity of cabazitaxel in temozolomide refractory glioblastoma: Final results of a phase 2 study (C-GBM study; EudraCT 2013-001550-98 NCT 01866449). *First Author: Bernhard Heinrich, Hematological-Oncological Practice, Augsburg, Germany*

Background: Following progression on Temozolomide (TMZ) glioblastoma (GBM) is a therapeutic challenge with a 6 month survival rate of only ~20-30% and no well-established 2nd line treatments. **Methods:** We designed a phase II study to assess the efficacy of cabazitaxel, a second generation taxoid, in TMZ-refractory GBM pts (pts). Primary enpoint was response at 12 weeks of treatment. Secondary endpoints were overall survival (OS), quality of life, and pharmacokinetics. The study population were pts with progressive GBM during or within 6 months after TMZ treatment, in whom radiotherapy and surgery was no treatment options. Exclusion criteria were signs of inflammation, an ECOG performance score (PS) $>$ 2, as well as impaired organ function. Patient characteristics: In total, between 2014 and 2016 8 female and 16 male pts were included with a median age of 55 years (range 32-76 years) and a median of 3 previous therapies (range 1-9). Treatment: Cabazitaxel was given at 25mg/m^2 q3w with G-CSF prophylaxis. Every two cycles response assessment was performed (MRI). Treatment was discontinued in case of i) progressive disease (RANO criteria), ii) PS$\geq$3, or iii) persistent toxicity. **Results:** Five pts went off study prior to the first MRI assessment due to progressive disease, while 19 of 24 of pts could be evaluated for response after 2 cycles. We did not observe any objective response (i.e. complete or partial remission). In 7 pts a stable disease (SD) was obtained; 12 pts had progressive disease. Of the 7 SD pts, 4 progressed after 4 cycles of treatment and the remaining pts remained in SD for 6, 10 and 12 cycles, respectively. The median OS was 155 days. Toxicity was manageable by G-CSF application in pts with CTC grade 3/4 neutropenia/leukopenia in 12 pts. Non-hematological toxicity CTC grade 3/4 comprised infection (n = 2), diarrhea (n = 2), vaginal bleeding (n = 1) and hypokalemia (n = 1). **Conclusions:** Cabazitaxel shows only marginal activity in TMZ refractory GBM with a disease stabilization rate following 4 cycles of only 12.5% in heavily pretreated GBM pts and median OS of 155 days. Clinical trial information: NCT 01866449.

2057 Poster Session (Board #299), Mon, 1:15 PM-4:45 PM

Quantifying the benefit of chemotherapy and radiation in low-grade glioma: A systematic review and meta-analysis of numbers needed to treat. *First Author: Timothy J Brown, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: The optimal role of chemotherapy and radiation (RT) in adult low-grade glioma (LGG, WHO grade 1 & 2) is unclear. We conducted a systematic review and study-level meta-analysis of the literature on overall survival (OS) and progression free survival (PFS) in patients with LGG. **Methods:** Pubmed was queried with MeSH terms. All comparative studies of adults with newly diagnosed, supratentorial LGG were included. Comparisons of interest were OS and PFS at 2, 5, and 10 years in chemotherapy versus no chemotherapy and early RT versus delayed or no RT. Data were extracted from studies and synthesized with a random effects model. Quality of evidence was determined by American Academy of Neurology criteria and further analysis was performed, separating high quality (class I and II) from low quality (class III and IV) evidence. Numbers needed to treat (NNT) were determined from the risk difference. **Results:** 1531 articles were screened; 18 studies were included. Chemotherapy was not associated with a significant survival advantage compared to control. However, an analysis of high quality data revealed a survival advantage at 10 years associated with chemotherapy compared to control with NNT 5 (relative risk death chemo vs control 0.69 [0.56-0.86] p = 0.0006). Furthermore, NNT to prevent one progression with chemotherapy at 5 and 10 years was 6 and 3, respectively. Early RT was not associated with an OS advantage compared to control. However, early RT had progression benefit at all time points, with NNT of 10, 6, and 5 at 2, 5, and 10 years. **Conclusions:** Further study will be needed to confirm the optimal role of chemotherapy and RT. Caution must be used in interpretation as much of the literature consists of low-quality studies.

2058 Poster Session (Board #300), Mon, 1:15 PM-4:45 PM

Association of SDF1 inhibition with local control and relative cerebral blood volume of glioblastoma. *First Author: Reena Parada Thomas, Stanford University Hospital, Palo Alto, CA*

Background: Glioblastoma is the most common and aggressive primary brain tumor, with 75-85% of patients historically having recurrence within the original tumor site. We have shown in preclinical studies that inhibition of the SDF1/CXCR4 pathway by the CXCR4 inhibitor Plerixafor increases tumor response to irradiation by inhibition of the recovery of tumor blood vessels. **Methods:** Newly diagnosed glioblastoma patients were enrolled to the clinical trial using the investigational agent Plerixafor after standard radiation therapy and temozolomide (NCT01977677). To date, 28 patients out of the planned accrual of 29 have been enrolled to this study. Normalized relative cerebral blood volume (rCBV) ratios were calculated by the mean rCBV within the 95% isodose radiation field one month post-radiation as compared to contralateral white matter outside of the radiation field. Our imaging analysis compares patients treated with Plerixafor compared to a control group receiving standard therapy (chemo-RT). **Results:** There was a significant reduction in rCBV measured by DSC-MRI within the 95% isodose field one month after radiation therapy in patients receiving Plerixafor compared to control ($p < 0.02$). The rCBV out of the radiation field was similar between patients receiving Plerixafor compared to control patients one-month post radiation therapy. As of February 7, 2017, only 2 of the total of 9 recurrences occurred within the irradiated field. The rate of out of field recurrence (77%) was therefore much higher than expected (20%), with statistical significance ($p < 0.03$, Fisher's exact test). **Conclusions:** We show that Plerixafor has a meaningful impact on local control of glioblastoma. Furthermore, DSC-MRI could be a useful biomarker of its efficacy.

2059 Poster Session (Board #301), Mon, 1:15 PM-4:45 PM

Immunological targeting of CD133 in recurrent glioblastoma: A multi-center phase I translational and clinical study of autologous CD133 dendritic cell immunotherapy. *First Author: Jeremy David Rudnick, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: A hallmark of glioblastoma is the high incidence of tumor recurrence, thought to be triggered by cancer stem cells. These tumorigenic cells are resistant to irradiation and chemotherapeutic agents. The target antigen, CD-133, was chosen because it has been reported as a cancer stem cell antigen overexpressed in glioblastoma tumors and associated with shorter survival. Recent clinical trials suggest that the mean overall survival for these patients is roughly 5-9 months, emphasizing the important unmet medical need in this disease requiring additional strategic approaches. Dendritic cell immunotherapies such as ICT-121 could provide benefit to patients by educating their immune systems to induce the formation of cytotoxic T cells that attack tumor cells bearing the target antigen. In addition to immediate attack on tumor cells present at dosing, a long-term memory response effective against tumor recurrence might be induced. Immunotherapy, such as ICT-121, that targets cancer stem cells could be an important treatment for this disease. **Methods:** This Phase I multi-center trial of ICT-121 targeting CD133 was designed to assess safety and tolerability (primary endpoint) and to monitor overall survival and progression-free survival (secondary endpoints). ICT-121 is comprised of autologous dendritic cells that are loaded with two HLA-A2 restricted epitopes of the CD133 antigen. CD133 is overexpressed on glioblastoma cancer stem cells. The HLA-A2 patients that had undergone resection for recurrence of glioblastoma were treated with ICT-121 once a week for 4 weeks during the induction phase and then once every 2 months during the maintenance phase until disease progression, death, ICT-121 depletion or discontinuation. **Results:** A total of 20 patients were treated and eight of these patients are still alive. Immune response data with cytokine mRNA expression demonstrated a response to the CD133 epitopes. A total of 20 patients were treated and eight of these patients are still alive. **Conclusions:** The results from this Phase I trial suggest that ICT-121 is both safe and well-tolerated with an immune response seen in a subset of patients. Clinical trial information: NCT02049489.

2060 Poster Session (Board #302), Mon, 1:15 PM-4:45 PM

Phase I trial of dimethyl fumarate, temozolomide, and radiation therapy in glioblastoma multiforme. *First Author: Danielle A. Shafer, Virginia Commonwealth University, Richmond, VA*

Background: Evidence is increasing for altered immune responses in malignant gliomas. Tumor-associated microglia/macrophages infiltrate human glioma tissue and produce cytokines that promote glioma growth, invasion and angiogenesis. Dimethyl fumarate (DMF), approved for relapsing-remitting multiple sclerosis, is toxic to in vitro activated microglial cells. Based on pre-clinical data demonstrating synergism with radiation (RT) and temozolomide (TMZ), we conducted a phase I study of DMF in patients with newly-diagnosed glioblastoma (GBM) in combination with RT and TMZ. **Methods:** Using a standard 3+3 dose escalation design (3 dose levels: 120 mg bid, 240 mg bid and 240 mg tid), newly-diagnosed GBM patients received daily DMF with RT (60 Gy) and concurrent TMZ 75 mg/m2 daily, followed by adjuvant DMF (continuously) and TMZ for up 6 maintenance cycles (150-200 mg/m2 on days 1-5 of each 28 day cycle). The maximum tolerated dose (MTD) was defined as the dose with $\leq$ 1/6 dose-limiting toxicities (DLT). The MTD was determined by evaluation of DLTs during the first 6 weeks of therapy. **Results:** Twelve patients were treated at the three dose levels, and no DLT was identified. There were no unexpected toxicities. The most common toxicities were lymphopenia (11 grade 3/4 events) and thrombocytopenia (2 grade 3/4 events). The only grade 3/4 non-heme toxicity was a grade 3 hemorrhoid event. Of the 12 evaluable patients, one remains on active treatment in maintenance phase. Three patients completed all treatment (concurrent and maintenance) with stable disease. Two patients had a partial response (RANO criteria) but then experienced disease progression during maintenance. Five patients had disease progression during study treatment and one patient chose to withdraw from the study during maintenance. **Conclusions:** These data suggest that DMF may be safely combined with RT and TMZ in GBM patients. A phase II study is under consideration. Clinical trial information: NCT02337426.

2061 Poster Session (Board #303), Mon, 1:15 PM-4:45 PM

VXM01 phase I study in patients with resectable progression of a glioblastoma. *First Author: Wolfgang Wick, Neurology Clinic, DKFZ, DKTK, Heidelberg, Germany*

Background: VXM01 consists of an attenuated *Salmonella typhi* Ty21a carrying a plasmid encoding for VEGFR-2. The bacterium is serving as a vector *via* the oral route of administration carrying the plasmid into the Peyer's plaques. The vaccine construct elicits a systemic T-cell response targeting VEGFR-2. This trial was set up to examine safety and tolerability, clinical and immunogenic response to VXM01 after treatment with at least four vaccinations [10^6 or 10^7colony-forming units (CFU)] in patients with recurrent glioblastoma who have failed at least radiochemotherapy with temozolomide. **Methods:** Patients with progressive resctable glioblastoma were subjected to single oral administration of VXM01 each on day 1, 3, 5, and 7. In addition, VXM01 was allowed to be administered in 4-weekly single doses every 4 weeks during the tumor follow-up period after reoperation. Follow-up was done by weekly safety laboratories and physical examinations in the treatment period and 4-weekly thereafter, MRI including perfusion maps (days 15 and 30 and six-weekly thereafter), 12-weekly T-cell immunomonitoring in the peripheral blood, and brain tumor immunohistochemistry. **Results:** Eight patients have been treated according to the schedule and surgery has been performed in seven of them. Under VXM01 treatment 47 adverse events, mostly unrelated to VXM01, were observed after a median of 7 doses per patient. Four out of eight patients (50%) showed a VEGFR-2 specific T cell response. In four patients there was a relevant increase in cerebral blood volume and apparent diffusion coefficient on post-vaccination MRI. In one patient there was an objective and durable T1 response, whereas three further patients remained stable prior to surgery and thereafter. Evaluation of infiltrating T cells in the tissue from re-operation revealed an increase in CD8+ T-cells in 5 out of 7 patients relative to the primary tumor tissue. **Conclusions:** VXM01 was safe and produces specific peripheral immune responses as well as enumeration of tumor-infiltrating T-cells in post-vaccine tumor tissue. Post treatment MRI imply vascular normalization and there was one patient with an objective response. As a consequence of this data, an expansion cohort of this trial has been launched. Clinical trial information: NCT02718443.

2062 Poster Session (Board #304), Mon, 1:15 PM-4:45 PM

Effect of treating glioblastoma with a cytokine inhibitor, ibudilast, in combination with temozolomide on survival in a patient-derived xenograft model. *First Author: Kerrie Leanne McDonald, University of NSW, Kensington, Australia*

Background: Recurrence in patients with glioblastoma (GBM) is inevitable, even in patients with *O-6-Methylguanine-DNA Methyl Transferase* (*MGMT*) methylation. We identified increased expression of the inflammatory cytokine, Macrophage Inhibitory Factor (MIF) and its receptor CD74 in patients with recurrent tumors. High levels of MIF and CD74 were associated with poor overall survival in GBM patients. This study aims to determine efficacy of Ibudliast (MN-166; 3-isobutyryl-2-isopropylpyrazolo-[1,5-a]pyridine) to block MIF expression and decrease tumor burden. Ibudilast is an anti-inflammatory drug that was developed for the treatment of bronchial asthma. **Methods:** The patient derived cell lines (PDCLs) RN1 (*MGMT* unmethylated), BAH1 (*MGMT* methylated), and HW1 (*MGMT* methylated) were treated *in vitro*with different concentrations of ibudilast in combination with temozolomide (TMZ). Patient derived xenograft (PDX) models of GBM were developed and treated with the combination of ibudilast and TMZ. Overall survival was calculated. **Results:** Regardless of MGMT status, significant synergism between ibudilast and TMZ was observed in the PDCLs. Efficacy was associated with significantly decreased expression of its targets, MIF and CD74. Downstream proteins such as Src and Akt were also significantly inhibited. The combination induced apoptosis. RN1 tumors were established intracranially in Balb/c nude mice. Significant increases in survival times of the mice were recorded when treated with the combination. **Conclusions:** Ibudilast in combination with TMZ resulted in significant blockage of MIF expression, increased apoptosis and longer survival *in vivo*. A human pilot study for recurrent GBM patients is underway.

2063 Poster Session (Board #305), Mon, 1:15 PM-4:45 PM

Heterogeneous spectrum of childhood and adult SHH medulloblastoma: Clinical, radiogenomic features, patterns of failure and survival. *First Author: Rakesh Jalali, Tata Memorial Hospital, Mumbai, India*

Background: To present SHH pathway driven medulloblastoma (MB) diversities in pediatric and adult patient populations. **Methods:** 60 patients with SHH-MB seen at our institute during 2009-2015. We assigned 22 predefined radiological features for all MB subgroups including SHH. Outcome data was retrieved from a prospectively maintained database. **Results:** Median age of entire cohort was 14 years (1-48 years). 29 were adults (a-SHH) and 31 were pediatric SHH (p-SHH). Radiological data available for 39 patients showed a-SHH having lateralised location in 72% cases. Distinct MRI features to predict SHH include mild/moderate contrast enhancement (90%), cystic changes (82%), edema (92%); identical in two age groups. We could predict SHH accurately 95% times. p-SHH were seen to have higher frequency of p53 mutations (70% vs 45%). At median follow-up of 37 months, 25 patients failed [isolated tumor bed (TB) in 10, TB and supratentorially in 2, cranium outside TB in 1, craniospinal in 5 (along with TB), extraneuraxial (ENM) in 5, second primary in 2 (lymphomas)]. 1 and 3 year DFS was 74% (p-SHH) vs 96% (a-SHH) and 58% vs 73% respectively (p-0.19). The failures seen in a-SHH were typically late (10/11 failed $>$ 22 months) as compared to p-SHH (12/14 failing $<$ 24 months). Also location of recurrences was different, with 7 of a-SHH failing at TB and rest 3 developed ENM. Ten of 13 in p-SHH failed beyond TB. Post- recurrence salvage was better in a-SHH compared to p-SHH, 1-year survival of 50% vs 19% (p-0.08). Overall survival at 1 and 3 year 84% and 55% for p-SHH and 100% and 88% for a-SHH respectively ($p = 0.04$). Histology and tumor location significantly correlated with OS. No significant correlation was seen with CSI dose or chemotherapy. **Conclusions:** SHH medulloblastoma have unique MRI features and can be predicted up to 95% times pre-operatively. Adult and pediatric SHH MB form extreme diverse groups with different patterns of failure reflecting different tumor kinetics. Adults fail primarily over TB after initial 2 years. Paediatric SHH follow aggressive course with early disseminated recurrences in 1st year. Different treatment modalities may be needed for pediatric and adult SHH MB.

2064 Poster Session (Board #306), Mon, 1:15 PM-4:45 PM

Comprehensive assessment of *ATRX* mutation, protein expression, and alternative lengthening of telomeres (ALT) phenotype in grade II and III gliomas. *First Author: Aline P. Becker, The Ohio State University, Columbus, OH*

Background: *ATRX* mutations are key molecular markers for classification of gliomas. We aimed to evaluate *ATRX*mutations and protein expression and the ALT phenotype as potential biomarkers for grade II and III gliomas. **Methods:** Retrospective analysis of 156 adult gliomas, with long-term follow up. Gene sequencing (*IDH1/2* and *ATRX*), Oncoscan array (1p19q co-deletion), FISH assays (1p19q co-deletion and ALT phenotype) and immunohistochemistry (IDH1 R132H and ATRX) were performed and the results were correlated with OS and PFS. **Results:** Twenty-six out of 94 samples (27.7%) had *ATRX* mutations, commonly related to *IDH1/2* mutant-1p/19q intact tumors (22/26 cases – $p < 0.0001$), however, 3 (11.5%) mutant tumors had concurrent 1p/19q co-deletions. ATRX loss of expression occurred in 66/150 cases (44%), consistently related to *ATRX* mutations ($p < 0.0001$). Intriguingly, 4/25 *ATRX* mutant tumors (2 frameshift and 2 point mutations with low/medium functional impact) showed weak/heterogeneous expression, while 18/65 (27.7%) *ATRX* wild type tumors had loss of protein expression. ALT phenotype was detected in 50/150 cases (33.3%), strongly related to *ATRX* mutations (23/32 cases), loss of protein expression (45/50 cases), and to *IDH1/2* mutant-1p/19q intact tumors (35/41 cases). Two *ATRX* mutant tumors were ALT negative, while nine *ATRX* wild type tumors with loss of expression had ALT phenotype. *ATRX*mutations, loss of protein expression, and ALT phenotype were strongly related to longer OS in grade III gliomas ($p = 0.006$, 0.023 and 0.003, respectively). Further subset analyses were not completed due to small sample sizes. **Conclusions:** *ATRX* mutations and loss of protein expression as well as ALT phenotype are potential prognostic factors for grade III gliomas. Importantly, this study highlights possible discrepancies (although infrequent) between *ATRX* sequencing, immunohistochemistry, and FISH (ALT). In addition, other mechanisms of *ATRX* gene silencing should be further investigated in grade II and III gliomas. FUNDING: R01CA108633, R01CA169368, RC2CA148190, U10CA180850-01 (NCI), Brain Tumor Funders Collaborative Grant, and The Ohio State University CCC (all to AC).

2065 Poster Session (Board #307), Mon, 1:15 PM-4:45 PM

Apparent diffusion coefficient (ADC) decrease to predict longer survival in glioblastoma patients treated by dendritic cell immunotherapy plus standard of care. *First Author: Marica Eoli, Molecular Neuroncology Unit, Carlo Besta Institute - IRCCS, Milano, Italy*

Background: The MRI follow –up of patients affected by glioblastoma (GBM) and treated with immunotherapy may be difficult, as immune responses may mimic tumor progression. To explore the potential contribution of quantitative MRI to the identification of patients with clinical benefit benefit, we used advanced MRI to study GBM patients treated with dendritic cell (DC) immunotherapy added to standard treatment (surgery, radiotherapy with concomitant temozolomide (TMZ) followed by adjuvant TMZ; DENDR1 trial, EUDRACT N° 2008-005035-15). **Methods:** A retrospective analysis was performed on longitudinal MRIs obtained soon after radiotherapy, within two days before the first vaccination (basal MRI) and every two months, in 22 patients enrolled in DENDR1. The following parameters were collected: tumor volume of contrast–enhanced lesions, mean rCBV, maximal rCBV, mean ADC, minimal ADC, ADC skewness. Receiver Operating Characteristic (ROC) curves were used to determine optimal sensitivity and specificity in differentiating patients as responder or not responder. Association with PFS (as per RANO criteria) and OS was analyzed using log-rank test and Cox regression. **Results:** Ten patients with PFS $>$ 12 months were defined as responders Their basal mean ADC was significantly higher than in non responders (1.34 ± 0.17 vs 1.14 ± 0.34, $p = 0.03$). After four DC vaccinations mean ADC significantly decreased in responders only from 1.34 ± 0.17 to 1.23 ± 0.23 ($p = 0.028$); the decrease persisted during immunotherapy. A basal mean ADC value $\geq$ 1.07 and a decrease in mean ADC value $\geq$ 0.13 were significant predictors of longer PFS (15.4 vs 9 m $p = 0.0006$; 17.2 vs 10.2 $p = 0.04$) and OS (29 vs 12.5 mo $p = 0.002$; 33 vs 19.9 $p = 0.04$ No significant correlations between the other parameters and the outcome were observed. **Conclusions:** Association with prolonged survival may suggest that in DENDR1responders decreased ADC is partly contributed by immune cells infiltrating the tumor.

2066 Poster Session (Board #308), Mon, 1:15 PM-4:45 PM

Initial phase 1 study of WT2725 dosing emulsion in patients with advanced malignancies. *First Author: Siqing Fu, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: WT2725 is a Wilms' tumor (WT1)-derived-oligopeptide vaccine intended to induce WT1 specific cytotoxic T-lymphocytes against WT1 positive tumors in HLA-A*0201+ or HLA-A*0206+. This first in human study of WT2725 was conducted to evaluate the safety, tolerability, and efficacy. **Methods:** Subjects with progressive or recurrent glioblastoma (GBM), acute myeloid leukemia (AML) (patients in morphologic remission with minimal residual disease determined by WT1 RT-PCR were allowed), non-small cell lung cancer (NSCLC), or ovarian cancer despite standard therapy were treated with 0.3, 0.9, 3, and 9 mg of WT2725 subcutaneously (s.c.) every week for 4 weeks, then every other week for 6 weeks, and every 4 weeks thereafter until progression or other discontinuation event (part 1); and with 18 mg and 27 mg of WT2725 s.c. every week for 8 weeks, then every other week for 10 weeks, and every 4 weeks thereafter until progression or other discontinuation event (part 2). Responses were evaluated by Immune-related Response Criteria (irRC) for solid tumors and modified International Working Group (IWG) for AML. **Results:** 62 subjects were dosed, the most frequent adverse events were grade 1 injection site reactions (no grade 3 injection site reactions or dose limiting toxicities observed). Of the 21 GBM subjects who were dosed, seven survived for $\geq$ 1 year (33%). Of these seven subjects, three survived for $\geq$18 months (14%), and two for $\geq$2 years (both in complete radiologic remission, 9.5%). One of the seven subjects with $\geq$1 year survival had previous treatment with bevacizumab. Two subjects continue dosing (1 complete response with no measurable disease $>$3 years and 1 partial response $>$ 13 months on study). Results in subjects with non-GBM tumors (12 subjects with AML, 21 with ovarian CA, 7 with NSCLC, and 1 other cancer) are not presented here. WT1-specific CTLs and tumor burden was monitored. WT1 specific CTLs were associated with decrease of tumor burden in two patients with low tumor burden. Some patients with high disease burden did not respond. **Conclusions:** Preliminary data suggests WT2725 is well tolerated with potential antitumor activity in GBM patients, supporting future development of WT2725 for treatment of GBM in selected subjects. Clinical trial information: NCT01621542.

2067 Poster Session (Board #309), Mon, 1:15 PM-4:45 PM

Epidemiologic study of risk factors for meningioma in the Mayo Clinic Study of Aging. *First Author: Alissa Butts, Mayo Clinic, Rochester, MN*

Background: An estimated 2% of the general population has a meningioma (Vernooij et al. 2007), which accounts for about 36% of all primary intracranial tumors (Ostrom et al. 2015). The most established risk factors are older age and female gender. One small study identified gender but no other risk factors with meningioma (Krampla et al 2004). A larger study using the Iowa Women's Health study data found lower levels of physical activity, greater body mass index (BMI), greater height and uterine fibroids were associated with meningioma (Johnson et al. 2011). We sought to replicate these findings and to identify additional risk factors related to meningioma in a large population-based sample. **Methods:** Study participants were enrolled in the Mayo Clinic Study of Aging (MCSA), a population-based sample of Olmsted County, Minnesota residents used to study prevalence, incidence, and risk-factors for Mild Cognitive Impairment and dementia and includes a variety of medical factors. Using a text search of radiologists' notes of 2,402 MCSA individuals, mean age 77±8 years and scanned between 2004-2014.We identified 52 subjects who had at least one meningioma. We estimated the association of selected potential risk factors with presence of meningioma using odds ratios and 95% confidence intervals from logistic regression models adjusted for age and gender, which informed the multivariable models. **Results:** In the initial models, significant risk factors identified included BMI (as a continuous variable) (OR = 1.06 95%CI 1.01 to 1.12), taking NSAIDS (OR = 2.11, 95%CI 1.13 to 3.95), aspirin (OR = 1.90, 95%CI 1.04 to 3.46), and blood pressure lowering medication (OR = 2.06, 95%CI 1.07 to 3.99). Protective factors included male gender (OR = 0.51, 95%CI 0.29 to 0.90), coronary artery disease (CAD; OR = 0.46, 95%CI 0.22 to 0.97) and higher Beck Anxiety Inventory (BAI) total score (OR = 0.88, 95%CI 0.78 to 0.98). Simultaneous adjustment for these factors in a multivariable model did not attenuate these associations. **Conclusions:** Findings reveal gender and BMI as risk factors for meningioma. Additionally, certain medications such as NSAIDS and BP lowering medications warrant follow up as potential factors related to development of meningioma.

2068 Poster Session (Board #310), Mon, 1:15 PM-4:45 PM

Pituitary carcinoma: The University of Texas MD Anderson Cancer Center experience. *First Author: Fernando Santos Pinheiro, MD Anderson Cancer Center, Houston, TX*

Background: Pituitary carcinoma (PC) is a rare and aggressive neuroendocrine tumor diagnosed once a pituitary adenoma (PA) becomes metastatic. Although no standard treatment currently exists, surgery, radiation (XRT) and/or chemotherapy are most commonly used. Recently, treatment with temozolomide (TMZ) has shown promising results, although the lack of prospective trials limits accurate outcome assessment. **Methods:** We describe a single-center multidisciplinary team experience in managing PC patients over a 13-year period (Oct, 2003 to Jan, 2017). **Results:** A total of 17 patients (9 males) were seen. Median age at diagnosis of PC was 44 years (range 16-82 years) and the median time from PA to PC conversion was 6 years (range 1-29 years). Median follow-up time: 28 months (range 8-158 months) with 7 reported deaths. The majority of PC was hormone-secreting (HS) subtype (n = 12): ACTH (n = 5), PRL (n = 4), FSH/LH (n = 2), GH (n = 1). After PC diagnosis, all pituitary tumors were locally invasive, all underwent at least one resection (mean 2.3) and all received at least one course of XRT alone (IMRT = 76%, SRS = 29%, IMPT = 12%) or concurrent with chemotherapy (18%). Immunohistochemistry showed high Ki-67 labeling index ($>$ 3%) in 9 (53%) cases. Most cases (n = 14) had metastases to the CNS, 35% of those had combined CNS and systemic foci. Ten (59%) cases underwent focal treatment of metastases, 90% of which underwent XRT. The most common chemotherapy used was TMZ [n = 14 (82%): single agent (n = 10); TMZ+capecitabine (n = 5); concurrent TMZ+XRT (n = 3); concurrent TMZ+XRT with adjuvant TMZ (n = 1)]. The median longest progression-free survival (LPFS) was 18 months (range 4-45 months). TMZ was associated with the chemotherapy-related LPFS in 9 (75%) cases. The 2, 3 and 5 year survival rate was 65%, 53% and 35%, respectively. All patients surviving $>$ 5 years were treated with TMZ (n = 5, 2 survived $>$ 10 years). Two refractory cases are currently on PD-1 inhibitor agent. Eighty percent of non-functioning PC were alive at last follow-up (HS-PC, 58%). Recurrence occurred in 11 (65%) cases. **Conclusions:** Treatment of PC requires a multidisciplinary approach. Multimodality therapy with surgery, radiation and TMZ was associated with higher survival rates and longer PFS.

2069 Poster Session (Board #311), Mon, 1:15 PM-4:45 PM

Phase I study (BLOOM) of AZD3759, a BBB penetrable EGFR inhibitor, in EGFRm NSCLC patients with leptomeningeal metastasis (LM) who progressed after other anti-cancer therapy. *First Author: Byoung Chul Cho, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea*

Background: AZD3759 is the first EGFR inhibitor primarily designed to effectively cross the blood brain barrier (BBB) to treat central nervous system (CNS) metastases. A phase I study is ongoing to assess AZD3759 in EGFRm NSCLC patients with leptomeningeal metastasis (LM) who progressed after other treatment (NCT02228369). **Methods:** The primary objective is safety and tolerability, and secondary objectives include anti-tumor efficacy. Two dose levels of AZD3759, 200 mg and 300 mg BID, were assessed. **Results:** As of24 September, 2016,38 patients were recruited into the expansion cohorts of this phase I study. Of those, 18 were TKI pre-treated EGFRm NSCLC patients with LM. 10 and 8 patients were in the 300 and 200 mg BID cohorts, respectively. No DLTs were observed at either dose, while AZD3759 was better-tolerated at 200 than 300 mg BID during $>$ 2 month treatment. The longest duration on treatment was $>$ 9 months. Most common AEs included skin rash and diarrhea. 67% (12 out of 18) patients had drug-related dose interruption and/or reduction, however, there were no drug-related discontinuations.The C_{trough} free plasma and CSF exposure were above pEGFR IC_{90}at the two doses. 40% of patients (4 out of 10) had $>$ 50% inhibition of pEGFR in CSF tumor cells at C1D8, and 70% of patients (7 out of 10) had reduced EGFR copy numbers in CSF at C3D1. 53% of evaluable patients (9 out of 17) had confirmed improved/stable LM MRI imaging. 2 out of 3 patients with concomitant measurable BM lesions achieved confirmed/unconfirmed partial CNS response. Among 18 patients with measurable extracranial lesions, 6 (33%) had confirmed stable extracranial disease as best response. 3 patients achieved clearance of tumor cells in CSF by two consecutive assessments. After 6 months follow-up, 29% patients (5 out of 17 evaluable) were still surviving, plus 5 surviving patients with less than 6 months follow-up. **Conclusions:** AZD3759 was well-tolerated, achieved sufficient CNS exposure for target inhibition and demonstrated promising anti-tumor activity in patients with LM who progressed after multiple lines of treatment. Updated clinical data will be shared at the meeting. Clinical trial information: NCT02228369.

2070 Poster Session (Board #312), Mon, 1:15 PM-4:45 PM

Detection of tumor-derived DNA mutations in cerebrospinal fluid of patients with primary or metastatic brain tumors. *First Author: Jianfei Wang, Genecast Precision Medicine Technology Institute, Beijing, China*

Background: Because detecting tumor-derived cell free DNA (cfDNA) in the blood of patients with primary or metastatic brain tumors is challenging, here we studied whether cerebrospinal fluid (CSF) could be serve as an alternative "liquid biopsy" by enabling measurement of circulating DNA within CSF to characterize tumor specific mutations. **Methods:** The paired cfDNA in CSF and plasma were collected from 20 patients with brain tumors and was subjected to enrichment for a 1.15M size panel cover exon regions from 1,086 genes. Followed by next generation sequencing on an Illumina X10 platform, the captured sequencing data was further processed using bioinformatics analysis to identify somatic mutations, including single nucleotide variants (SNV) and short insertions/deletions (indels). **Results:** The mutation profiles of 48 tumor associated genes in cfDNA were compared between the CSF and plasma. Our results showed that both average somatic mutation number and frequency identified in the cerebrospinal fluid was much higher than that in the corresponding plasma samples (25 vs. 18 & 1.39% vs. 0.55%). Among the twenty cases, one more potential actionable mutation, EGFR exon 19 deletion mutation with a 25.38% allele frequency variation, was only detected in the CSF cfDNA of a patient with brain metastasis lung cancer. **Conclusions:** Tumor mutations were detectable in CSF cfDNA of patients with different primary and metastatic brain tumors. Thus cerebrospinal fluid cell free DNA analysis could be a potential alternative analysis for patients with primary or metastatic brain tumors.

2071 Poster Session (Board #313), Mon, 1:15 PM-4:45 PM

What drives patient outcomes in brain metastases: Number, volume, or biology? *First Author: Rupesh Kotecha, Department of Radiation Oncology, Cleveland Clinic Foundation, Cleveland, OH*

Background: To delineate the prognostic importance of number of brain metastases (BM), lesion volume, and biology on overall survival. **Methods:** Patients treated for BM with whole-brain radiation therapy (WBRT), surgery, and/or stereotactic radiosurgery (SRS) at a single tertiary care institution from 1997-2015 were reviewed. The primary outcome was overall survival. Multivariable proportional hazards regression was used to adjust for confounding factors. **Results:** 3,955 patients with 16,189 BM were included in the analysis. There was a reduction in median survival with increasing number of lesions [1 lesion, 10.2 months; 2-4 lesions, 7.2 months, Hazard Ratio (HR) 1.36; 5-10 lesions, 5.6 months, HR: 1.69; > 10 lesions, 5.5 months, HR: 1.57, $p< 0.001$]. Among 1,651 patients (35%) who underwent SRS, there was a similar reduction in median survival with increasing lesion number [1 lesion, 12.2 months; 2-4 lesions, 10.1 months, HR 1.20; 5-10 lesions, 8.4 months, HR 1.41; > 10 lesions, 6.9 months, HR 1.19], $p< 0.001$). Among patients who underwent upfront SRS, increasing number of BM did not adversely affect survival in those with the smallest intracranial disease volume (≤0.4 cc, 10th percentile, $p= 0.39$), but was associated with inferior survival in patients with larger disease volumes (≤1.1 cc, 25th percentile, $p= 0.05$; ≤2.6 cc, 50th percentile, $p= 0.005$; ≤6.3 cc, 75th percentile, $p= 0.006$, and ≤12.2 cc, and 90th percentile, $p =0.004$). After partitioning the cohort into molecular subsets, patients with *ALK+* disease had no difference in survival based on either lesion number or volume. Patients with *EGFR+*, *HER2+*, and luminal B disease had no difference in survival based on number of metastases, while patients with *BRAF V600+*and luminal A disease had no difference in survival based on intracranial disease volume. **Conclusions:** Number of BM closely correlates with survival in the majority of patients and intracranial disease volume impacts survival independent of number of metastases. For patients with certain tumor subtypes (*ALK+*), intracranial disease burden appears to have no correlation with survival. Molecular profile characterization is important to identify patients with favorable subtypes given available treatment options.

2072 Poster Session (Board #314), Mon, 1:15 PM-4:45 PM

Examination and prognostic implications of the unique microenvironment of breast cancer brain metastases. *First Author: Grace Prince, University of North Carolina, Chapel Hill, NC*

Background: Brain metastases (BM) are an increasingly common consequence of breast cancer (BC). Knowledge of the microenvironment in primary BC and its impact on prognosis is evolving. A similar understanding of the microenvironment of BC metastases is lacking, particularly for the brain, where unique immune regulation governs stroma composition. Such features of the peri-tumoral landscape, i.e. high immune infiltrate and low hemorrhage, offer prognostic value in BM from melanoma. This study reports on 4 biomarkers, gliosis (glio), immune infiltrate (immune), hemorrhage (hem) and necrosis (nec), and their prognostic significance in BCBM. **Methods:** A biobank of 203 patients (pts) who underwent craniotomy between 1989-2013 was created across 4 sites. Glio, immune, and hem (grouped 0 v 1-3) and nec (0-2 v 3) were scored via H&E stain (0-3). Overall survival (OS (years)) from craniotomy was estimated using the Kaplan-Meier method; log-rank tests compared OS. Cox proportional hazards regression was used to evaluate prognostic value of the 4 biomarkers. **Results:** Mean age at primary BC diagnosis was 48 years (range 26-77). BCBM subtype (n = 158) was 36% HER2+, 26% HR+/HER2-, 38% HR-/HER2- (TN). Across all samples, expression was 82% glio, 45% immune, 82% hem, and 13% nec. Subtype differences were seen for nec (higher in TN, $p < 0.01$). Across all pts, expression of glio, immune, and hem was associated with improved OS (years): 1.08 v 0.62 (p = 0.03), 1.31 v 0.93 (p = 0.03), 1.07 v 0.92 (p = 0.1), respectively. Nec was associated with inferior OS: 0.38 v 1.12 (p = 0.01). The association with improved OS was maintained for glio in TN (p = 0.02), and immune (p = 0.001) and hem (p = 0.07) in HER2+. In a multivariable model for OS, adding the 4 biomarkers to traditional clinical variables (age, race, subtype) significantly improved the model fit ($p < 0.001$). **Conclusions:** Nec is a poor prognostic finding in BCBM across all subtypes. Glio confers superior prognosis in TN, while immune and hem correlate with superior prognosis in HER2+. A deeper understanding of the rich BCBM microenvironment both refines prognostic considerations for this pt population and may lead to future investigations of targeted immunotherapies in select subtypes of BCBM.

2073 Poster Session (Board #315), Mon, 1:15 PM-4:45 PM

Neurocognitive function testing and health related quality of life in stage IV lung cancer patients with and without brain metastases. *First Author: Grainne M. O'Kane, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Survival in stage IV lung cancer (S4LC) patients (pts) continues to improve, highlighting the importance of assessing health related quality of life (HRQoL). Lung cancer, involvement with brain metastases (BM), and systemic or brain-specific treatment can all impact neurocognitive function (NCF) and HRQoL. We evaluated the relationship between NCF and HRQoL in S4LC pts by BM status. **Methods:** S4LC pts with BM (BM+) were frequency distributionally-matched to pts without BM (NBM). NCF was measured using the Hopkins Verbal Learning Test – Revised (HVLT-R), the Controlled Oral Word Association Test (COWAT) and Trail Making Tests (TMT-A/B); scores were correlated with health utility score (HUS) data from EQ5D-3L surveys (Pearson Coefficient, R). **Results:** BM+ (n = 54) and matched NBM (n = 40) pts had similar demographics. The overall median age was 61years; 59% were female; of 89% that were adenocarcinomas, half had *EGFR/ALK* alterations; mean time since diagnosis was 2.6 years; mean time since BM were diagnosed in BM+ pts was 0.5 years. Mean HUS (mHUS) were similar between groups: 0.77 for BM+ vs. 0.78 for NBM; p = 0.86. However, pts with stable BM had higher HUS than those with progressive BM (mHUS: 0.80 *vs* 0.69; p = 0.045). Of BM+ pts, 44% had received whole brain radiation (WBRT). Correlations of NCF and HUS specific for BM+ pts were observed for several HLVT scores, including Total Recall (TR), which was correlated with HUS in BM+ (R = 0.35, p = 0.01) but not in NBM (R = 0.04, p = 0.84) and Recognition Discrimination Index (BM+: R = 0.32, p = 0.03 *vs* NBM: R = 0.13, p = 0.51). In contrast, TMT-A/B NCF test results had slightly stronger associations with HUS in NBM pts. COWAT was least associated with HUS in BM+ or NBM pts. In BM+ pts treated *vs* untreated with WBRT, HLVT scores were better in untreated patients (TR, p < 0.0001; delayed recall, p = 0.006; retention, p = 0.089), associations not seen with either TMT-A/B or COWAT. Mutation status had no bearing on these associations. **Conclusions:** NCF impacts HUS in S4LC pts and should be considered in treatment planning. HVLT scores are useful to assess specifically the impact of BM and WBRT in S4LC pts, and is reflected in associations with HRQoL.

2074 Poster Session (Board #316), Mon, 1:15 PM-4:45 PM

Planned interim analysis of PATRICIA: An open-label, single-arm, phase II study of pertuzumab (P) with high-dose trastuzumab (H) for the treatment of central nervous system (CNS) progression post radiotherapy (RT) in patients (pts) with HER2-positive metastatic breast cancer (MBC). *First Author: Nancy U. Lin, Dana-Farber Cancer Institute, Boston, MA*

Background: There is currently no clear standard of care to address the management of recurring/multiple intracranial metastases post RT in HER2-positive MBC. The ongoing PATRICIA study (NCT02536339) is evaluating the safety and efficacy of P in combination with high-dose h for patients with HER2-positive MBC with CNS metastases who have CNS progression following RT. Reported herein are results from the protocol-specified interim analysis of PATRICIA. **Methods:** All eligible patients must have measurable (≥10 mm) CNS progression post RT, and stable non-CNS disease. Patients receive P (840-mg loading dose, then 420 mg every 3 weeks) and high-dose h (6 mg/kg weekly). The primary efficacy endpoint is objective response rate (ORR) in the CNS per Response Assessment in Neuro-Oncology Brain Metastases (RANO-BM) criteria. The interim analysis was planned after 15 patients were enrolled and had ≥2 left ventricular ejection fraction (LVEF) measurements, 2 cycles of study drugs, and 2 response measurements. The study would proceed to full enrollment (n=40) if objective response or stable disease in the CNS was observed in ≥1 of 15 patients and <2 of 15 patients develop congestive heart failure (CHF) related to P or H. **Results:** As of Sept 6, 2016, 15 patients had been enrolled across 9 sites. Median treatment duration was 4.4 (range 1.2−8.3) months. Six patients discontinued treatment (5 for disease progression; 1 for symptomatic deterioration). Range for duration of response was 1.4−3.3 months. There were no new safety signals for P combined with high-dose h treatment. No patients had CHF or a clinically significant drop in LVEF. **Conclusions:** Based on early evidence of clinical benefit (ORR 20%) and a lack of new safety signals, the safety and futility boundaries for PATRICIA have been passed and study enrollment continues. Clinical trial information: NCT02536339.

Efficacy within CNS per RANO-BM criteria	n (%)
Complete response (CR)	0
Partial response (PR)	3 (20)
Stable disease (SD)	9 (60)
Disease progression	3 (20)
ORR[a]	3 (20)
95% CI	4.3−48.1
CR + PR + SD ≥4 months	6 (40)
95% CI	16.3−67.7

2076 Poster Session (Board #318), Mon, 1:15 PM-4:45 PM

The value of ^{18}F-fluordesoxyglucose positron emission tomography (FDG-PET/CT) in the detection of the primary lesion and for staging in brain metastasis (BM) patients with cancer of unknown primary site (CUPS). *First Author: Emilie Le Rhun, Lille University Hospital, Lille, France*

Background: Brain metastasis (BM) are the first clinical presentation of cancer in around 30% of patients. They are then referred as BM from cancer of unknown primary site (BM-CUPS). The value of ^{18}F-fluordesoxyglucose positron emission tomography (FDG-PET)/CT has not yet be determined for the management of these patients. **Methods:** A total of 566 patients were operated for BM at the University Hospital Zurich between 2004 and 2014, of whom 127 were identified as BM-CUPS patients. Two cohorts from other independent centers (n = 100 and 120) were used for the validation of data. **Results:** No difference in determining the localization of the primary lesion was observed between FDG-PET/CT and CT (FDG-PET/CT: 73/78, 93.6%; CT: n = 70/78, 89.7%; p = 0.25, McNemar's test). The same pattern of primary lesion and other extracranial lesions was observed in 36 of 64 patients (56.3%). Additional suspicious extracranial metastases were identified by FDG-PET/CT in 28 patients (43.7%). The median graded prognostic assessment (GPA) scores were 2.5 determined according to FDG-PET/CT and 3 according to CT alone ($p = 3.8x10^{-5}$), resulting in predicted survival times of 3.8 versus 5.3 months ($p = 6.1x10^{-5}$; Wilcoxon's test). **Conclusions:** A similar sensitivity of FDG-PET/CT and chest CT was observed for the detection of the primary tumor in BM-CUPS, however, FDG-PET/CT significantly improved the accuracy of staging. FDG-PET/CT should be preferred for the management of BM-CUPS and may help to avoid redundant CT imaging.

2077 Poster Session (Board #319), Mon, 1:15 PM-4:45 PM

Linac-based radiosurgery for multiple brain metastases: A quality assurance and feasibility study. *First Author: Raphael M. Pfeffer, Assuta Medical Center, Tel Aviv, Israel*

Background: The classical treatment for multiple brain metastases is whole brain radiotherapy (WBRT). For patients with 1-3 brain metastases stereotactic radiosurgery (SRS) results in better response, similar survival and less short and long term toxicity such as neurocognitive dysfunction than WBRT. For patients with $>$ 3 metastases there is little prospective data of SRS partly due to the technical and logistic difficulties of delivering SRS to multiple metastases. We present a new SRS planning program (MMM) that allows the planning and delivery of linac-based SRS to up to 10 brain metastases simultaneously in less overall time than for WBRT. **Methods:** Between August 2014 and August 2016, patients referred for RT with 2 or more brain metastases were offered treatment with MMM. System QA included ArcCheck diode array and film dosimetry and gel dosimetry based on a patient derived phantom. Individual QA included replanting treatment arcs on an independent system. **Results:** 94 patients with 2-10 (median 5) metastases and a combined volume of 0.01-8.64 cc were treated. Planning time including image fusion, target delineation and RT plan generation required on average 20 minutes minutes. SRS was delivered using 4-5 (is more 7-10 since return arcs do not address the same targets) non-coplanar arcs and a single isocenter at the center of mass of the metastases. Treatment time to deliver 18-24 Gy to all metastases was 25 mins (beam on time ~6 minutes) for a total time of 45 minutes. This is the same as the time for each individual metastasis on earlier planning systems and compares to 20 minutes planning time and 12 mins delivery time for each of 10 fractions for a conventional 2 field WBRT plan WBRT (total 140 minutes). At 6 months follow up, 88% of treated metastases had decreased in size, 10% were stable and 2% grew. Acute toxicity was mild except for one patient with intractable seizures. **Conclusions:** Linac based SRS for multiple brain metastases is efficient, requiring the same resources as for treatment of a single metastasis and less resources than for WBRT, with a high rate of local control. Appropriate equipment is available in most radiotherapy departments which will allow more prospective studies of SRS for multiple metastases.

2078 Poster Session (Board #320), Mon, 1:15 PM-4:45 PM

Outcomes from 735 patients with breast cancer brain metastases (BM) according to biological subtype, number of BMs, and systemic treatment after local therapy. *First Author: Anna Niwinska, Department of Breast Cancer and Reconstructive Surgery, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

Background: To assess survival when BM is detected according to the biological subtype of breast cancer, number of BMs and systemic treatment after local therapy. **Methods:** Subjects were 735 consecutive breast cancer patients with BM treated during 2003-2015. Whole brain radiotherapy was undertaken in 97%, neurosurgery -19% and systemic therapy was performed in 74% cases. The biological subtypes: triple-negative (TNBC), HER2+ER/PR-, HER2+/ER/PR+ and ER/PR+HER2- (Luminal) were determined in 714 subjects. Survival after BM detection was assessed in the entire group, in patients with a single BM (1 brain lesion regardless of metastases in other organs) and those with a solitary brain metastasis (1 brain lesion but no metastases in other organs). Factors influencing survival upon detecting BM were assessed by Cox multivariate analysis. **Results:** The median survivals for all patients with TNBC, HER2+ER/PR-, HER2+/ER/PR+ and Luminal breast cancer BM were respectively 4, 8, 10 and 9 months ($p < 0.001$). In those both treated and untreated systemically within the TNBC, HER2+ER/PR-, HER2+/ER/PR+ and Luminal subtypes survivals were correspondingly 6, 10, 14, 11 and 2, 3, 2, 2 months ($p < 0.001$). Median survivals of 171 patients with a single BM treated and untreated systemically were respectively 15 and 5 months ($p < 0.001$). Median survivals of 70 patients with solitary BM treated and untreated systemically were respectively 28 and 6 months ($p < 0.001$). In patients with solitary brain metastasis, median survival within the TNBC, HER2+ER/PR-, HER2+/ER/PR+ and Luminal subtypes, with systemic treatment was respectively 16, 28, 28, 28 months and without systemic treatment 6, 7, 7 and 7 months ($p < 0.001$). **Conclusions:** Patients with TNBC and BM had the worst prognosis. Systemic treatment performed after local therapy is an important factor prolonging survival of patients with breast cancer BM, even in those with solitary brain metastasis. Based on the present evidence and our recent publication, systemic treatment should be performed in all patients with BM after local treatment, even those with brain metastases as an isolated recurrence.

TPS2079 Poster Session (Board #321a), Mon, 1:15 PM-4:45 PM

Individualized screening trial of innovative glioblastoma therapy (INSIGhT). *First Author: Brian Michael Alexander, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: Patient with glioblastoma (GBM) with unmethylated *MGMT* promoters derive limited benefit from temozolomide (TMZ) and have dismal outcome. Prioritizing the numerous available therapies and biomarkers for late stage testing requires an efficient clinical testing platform. INSIGhT (NCT02977780) is a biomarker-based, Bayesian adaptively randomized, multi-arm phase II platform screening trial for patients with newly diagnosed GBM and unmethylated MGMT promoters. **Methods:** INSIGhT compares experimental arms to a common control of standard concurrent TMZ and radiation therapy (RT) followed by adjuvant TMZ. The primary endpoint is overall survival (OS). Patients with newly diagnosed, unmethylated GBM that are IDH R132H mutation negative, and with genomic data available or who consent to whole exome sequencing through the ALLELE companion study for biomarker grouping are eligible. Two experimental arms consist of concurrent RT/TMZ followed by adjuvant neratinib (EGFR, HER2, and HER4 inhibitor) or abemaciclib CDK 4/6 inhibitor), respectively, in place of TMZ. The other experimental arm is CC-115 (TORC1/2 and DNA PK inhibitor), which replaces TMZ in both the concurrent and adjuvant phases. Biomarker groups include: EGFR + patients with EGFR amplification/mutation; PI3K + patients with PIK3CA mutation/amplification, PIK3R1 mutation, AKT3amplification, PIK3C2B $>$ 1 copy gain, or PTEN dual loss; CDK: + patients with wild-type RB1 and CDK4 amplification, CDK6 amplification, or CDKN2A $>$ 1 copy loss. Given the lack of pretrial biomarker data and the anticipated overlap of the groups, randomization will initially be equal. As the trial progresses, randomization probabilities will be adapted based on the Bayesian estimation of the probability of treatment impact on progression-free survival (PFS). These randomization probabilities can vary among the biomarker groups so predictive biomarkers will be identified and utilized if present. Treatment arms may drop due to low probability of treatment impact on OS, and new arms may be added. Experimental arms are compared only with control and should be thought of as discrete experimental questions, with INSIGhT being open to new investigators with proposed therapeutic hypotheses. Clinical trial information: NCT02977780.

TPS2080 Poster Session (Board #321b), Mon, 1:15 PM-4:45 PM

A phase 2 study to determine the efficacy and safety of TVB-2640 in combination with bevacizumab in patients with first relapse of high grade astrocytoma. *First Author: Adolfo Enrique Diaz Duque, University of Texas Health San Antonio - MD Anderson Cancer Center, San Antonio, TX*

Background: The mainstay of treatment for Glioblastoma Multiforme (GBM) remains surgical removal followed by combined chemotherapy with temozolomide and radiation therapy. Second line Bevacizumab (Bev) is indicated upon progression, but unfortunately the responses are not very long lasting, and there are no therapeutic options available at that point. We have learned that antiangiogenic resistance in GBM is promoted by hypoxia; moreover, metabolomic profile of GBM under such conditions reveals an increased presence of long chain fatty acids. On second hand, tumor cells compared to normal cells depend more on palmitate, and is Fatty Acid Synthase (FASN) the enzyme capable of catalyzing its biosynthesis. Further studies have shown how GBM overexpress FASN and how its inhibition selectively inhibits growth and viability of tumor cells by inducing tumor cell apoptosis. TVB-2640 emerges as a novel agent that selectively inhibits FASN. This study represents a phase 2 clinical investigation of TVB-2640, which is to be conducted in patients with Recurrent High Grade Astrocytoma. **Methods:** This is a prospective, randomized, phase 2 study of TVB-2640 in combination with Bev or Bev alone in patients with GBM in first relapse. Primary end point is progression free survival (PFS). Patients 18 years or older, with ECOG 0 to 2 and GBM progression following standard combined modality treatment will qualify for the study. Patients will be randomized into 2 separate arms. Patients in arm number one will receive Bev every 2 weeks in combination with TVB-2640 while patients in arm number two will receive Bev alone every 2 weeks. MR-Spectroscopy will be obtained on all patients at day 1 and 28 of first cycle. Starting on cycle 2 day 1, all patients will converge to a single arm and will continue to receive Bev in combination with TVB-2640. A total sample size of 24 patients will provide 90% power to detect a 4 months difference in PFS (3 months for Bev alone (historic controls) versus 7 months for TVB-2640 in combination with Bev, i.e., a hazard ratio of 0.43) using a one-sided log-rank test with alpha = 0.1. The trial is open and enrollment will begin in Feb 2017. Clinical trial information: NCT03032484.

TPS2081 Poster Session (Board #322a), Mon, 1:15 PM-4:45 PM

STELLAR: A phase 3, randomized, open-label study of eflornithine with lomustine vs lomustine for patients with first recurrence of anaplastic astrocytoma after RT and adjuvant temozolomide. *First Author: Victor A. Levin, Orbus Therapeutics, Inc, Greenbrae, CA*

Background: Eflornithine irreversibly inhibits ornithine decarboxylase an enzyme that catalyzes the biosynthesis of putrescine, one of 3 polyamines in mammalian cells. Over 390 patients with anaplastic gliomas (AG) received eflornithine alone, with a nitrosourea, or the PCV combination in past clinical trials. A phase 3 randomized study of adjuvant chemotherapy with PCV vs eflornithine-PCV in 228 patients with AG found a median overall survival (mOS) increase from 61.1 to 75.8 months in the eflornithine-PCV arm. **Methods:** Patients must have histologically proven diagnosis of WHO grade 3 anaplastic astrocytoma (AA) with unequivocal evidence of first AA tumor progression or recurrence $\leq$ 3 months prior to randomization following surgical resection or biopsy, RT and temozolomide chemotherapy. Patients must have RT $\geq$ 6 months prior to randomization and have a KPS of $\geq$ 70. Randomization of 280 patients will be 1:1 with stratification to: Age ($\leq$ 45 yrs, $>$ 45 yrs), region (US, Ex-US), IDH1 status (wild, mutant), and prior surgeries (biopsy, 1-2 resections). Patients will receive eflornithine 2.8 g/m^2 orally every 8 h on a 2 week on, 1 week off schedule, and lomustine 110 mg/m^2 orally once every 6 weeks, or lomustine alone dosed at 110 mg/m^2 orally once every 6 weeks. Lomustine will be limited to 6 cycles or 12 months of therapy. Eflornithine can be given up to 24 months in the combination arm. The primary endpoint will be OS. Secondary objectives include PFS and objective response rate (ORR) based on MRI. The study sample size was calculated by assuming true mOS of 12 months for lomustine monotherapy and true mOS of $>$ 18 months for the eflornithine plus lomustine arm. Such an improvement represents a true hazard ratio of 0.667 (investigational arm/control arm). Inferential comparisons of OS will be performed using a stratified log-rank test with 137 patients per arm and total information of 194 deaths with 80% power to detect a 33% reduction in the OS failure hazard rate. The study is open at 55 sites in the USA, Germany and Italy with an additional 10-15 sites being evaluated in 3 additional countries. Study enrollment is expected through 2018. Clinical trial information: NCT02796261.

TPS2082 Poster Session (Board #322b), Mon, 1:15 PM-4:45 PM

Clinical trials of VAL-083 in patients with chemo-resistant glioblastoma. *First Author: Jeffrey A. Bacha, DelMar Pharmaceuticals, Vancouver, BC, Canada*

Background: Glioblastoma (GBM) is the most common and aggressive primary brain cancer. Current standard of care includes surgery, radiation and treatment with temozolomide (TMZ), however nearly all tumors recur and the prognosis for recurrent GBM is dismal. Most GBM tumors have unmethylated promoter status for O6-methylguanine-DNA-methyltransferase (MGMT); a validated biomarker for TMZ-resistance. Second-line treatment with anti-angiogenic agent bevacizumab has not improved overall survival (OS) and 5-year survival is less than 3%. Dianhydrogalactitol (VAL-083) is a bi-functional alkylating agent targeting N7-Guanine and inducing interstrand DNA cross-links, double-strand breaks and cell death in GBM cell lines and GBM cancer stem cells, independent of MGMT status *in vitro*. VAL-083 readily crosses the blood-brain barrier and accumulates in brain tumor tissue. Our recent phase I/II clinical trial in recurrent GBM patients failing both TMZ and bevacizumab, suggested that VAL-083 offers clinically meaningful survival benefits for patients with recurrent GBM and pinpointed a new dosing regimen (40 mg/m^2/d on days 1,2,3 of a 21-day cycle) which was well-tolerated and was selected for study in subsequent GBM trials. **Methods:** These trials include i) an ongoing single-arm, biomarker driven, Phase 2 study to determine if VAL-083 treatment of *MGMT*-unmethylated adult GBM patients at first recurrence/progression, prior to bevacizumab improves overall survival at 9 months, compared to historical control with lomustine (clinicaltrials.gov identifier: NCT02717962). ii) A pivotal Phase 3 study in recurrent GBM after failing both TMZ and bevacizumab. The control arm will consist of a limited number of salvage chemotherapies currently used in bevacizumab-failed GBM. If successful, this study will serve as the basis for a New Drug Application (NDA) submission for VAL-083. iii) A single arm, biomarker driven, Phase 2 study to confirm the tolerability and efficacy of VAL-083 in combination with radiotherapy in newly diagnosed *MGMT*-unmethylated GBM patients whose tumors are known to express high MGMT levels. The results of these studies may support a new treatment paradigm in chemotherapeutic regimens for the treatment of GBM. Clinical trial information: NCT02717962.

TPS2083 Poster Session (Board #323a), Mon, 1:15 PM-4:45 PM

A phase 0/II study for ribicoclib in patients with recurrent glioblastoma. *First Author: Nader Sanai, Barrow Neurological Institute, Phoenix, AZ*

Background: Disruption of CDK4/6-dependent G1-S cell cycle regulation is a hallmark of glioblastoma (GBM) progression in 78% of cases. Newly-developed CDK4/6 inhibitors have shown promise in non-CNS cancer trials and glioma animal models. To explore the utility of Ribociclib, a specific CDK4/6 inhibitor, in treating recurrent GBM patient, we designed a phase 0/II clinical trial to examine the pharmacokinetic (PK) and pharmacodynamics (PD) of Ribociclib. **Methods:** 24 adult patients are allocated to 3 time-escalation arms and receive 5 days of daily Ribociclib prior to planned GBM resection. Eligible patients are selected based on intact Rb expression and loss of Ink4a/Arf locus. Intensive PK sampling of blood, CSF, and tumor is performed intraoperatively and Ribociclib concentrations are determined by a validated LC-MS/MS method. PD endpoints, including RB phosphorylation and FoxM1 expression, are compared to matched archival tissue. Patients exhibiting positive PK and PD outcomes will graduate to a therapeutic regime of Ribociclib as part of the Phase II component of the study with a primary endpoint of progression-free survival, as determined by Response Assessment in Neuro-Oncology (RANO) criteria. Clinical trial information: NCT02933736.

TPS2084 Poster Session (Board #323b), Mon, 1:15 PM-4:45 PM

Nivolumab combined with hypofractionated stereotactic irradiation (HFSRT) for patients with recurrent high grade gliomas: A phase I trial (NCT02829931). *First Author: Solmaz Sahebjam, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Nivolumab is an IgG4 monoclonal antibody that targets the PD-1 immune checkpoint pathway and prevents binding of PD-1 with PD-L1 and PD-L2. Expression of PD-1 and PD-L1 is found in the microenvironment of high grade gliomas and correlates with worse outcome providing a rationale for investigating nivolumab in this group of patients (pts) with very limited treatment options. Nivolumab monotherapy is well tolerated in recurrent glioblastoma pts. Preclinical studies have demonstrated that radiotherapy synergizes with anti PD-1/PD-L1 blockade and produces tumor regression and long-term survival in orthotopic murine models of glioma. This report describes an ongoing phase I trial of nivolumab in combination with HFSRT in pts with recurrent WHO grade III or IV gliomas. **Methods:** This phase I study includes a safety cohort of 6 pts followed by dose expansion cohort of 20 pts (NCT02829931). Pts with bevacizumab naïve recurrent WHO grade III or IV gliomas (maximum diameter of enhancing brain lesion $\leq$ 4 cm) are eligible. An interval of at least 6 months after the end of prior radiation therapy is required unless there is a new recurrence outside of the previous radiotherapy treatment field. Eligible patients will be treated with HFSRT to the recurrent tumor (30 Gy delivered in 5 fractions). Nivolumab will be started 5 days after HFSRT. It will be administered intravenously every 2 weeks (at 240 mg flat dose) for 4 months. After 4 months, nivolumab will be administered every 4 weeks at 480 mg flat dose. The primary study objectives are to determine safety and tolerability of nivolumab administered in combination with HFSRT to recurrent high grade gliomas. Secondary endpoints include determination of the preliminary antitumor activity (response rate, 6-months survival and 9-months survival rates), and exploring tissue and imaging biomarkers. Study Progress: At deadline for abstract submission, 5 patients have been treated on this study. Clinical trial information: NCT02829931.

TPS2085 Poster Session (Board #324a), Mon, 1:15 PM-4:45 PM

REGOMA: A randomized, multicenter, controlled open-label phase II clinical trial evaluating regorafenib (REG) activity in relapsed glioblastoma (GBM) patients (PTS). *First Author: Giuseppe Lombardi, Department of Clinical and Experimental Oncology, Medical Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: GBM is the most common and malignant form of primary brain tumor with a high recurrence rate after surgery, radiation therapy and temozolomide. Currently, there is no established regimen for the treatment of recurrent GBM. GBMs are highly vascularized tumors with high expression of pro-angiogenic factors and activation of multiple signaling pathways in the tumor microenvironment, including the receptor tyrosine kinases, VEGFR, FGFR, and PDGFR, which control the tumor vasculature. REG, an oral multikinase inhibitor, inhibits these angiogenic kinases and the mutant oncogenic kinases KIT, RET and B-RAF. REG was demonstrated to be safe and effective in metastatic colon-rectal cancer, hepatocellular carcinoma and GIST PTS. It was shown that REG inhibits tumor angiogenesis and tumor cell proliferation in rat GBM tumor xenografts (Wilhelm S.M, et al. Regorafenib: a new oral multikinase inhibitor of angiogenic, stromal and oncogenic receptor tyrosine kinases with potent preclinical antitumor activity. Int. J. Cancer:129,245-255.2011). **Methods:** Primary aim of the study is to assess the role of REG activity in prolonging the overall survival in relapsed GBM PTS after surgery and Stupp regimen; secondary aims are to analyze progression free survival, objective response rate, disease control rate and quality of life. Eligible PTS with ECOG PS 0-1, documented progression of disease (after Stupp treatment) as defined by RANO criteria, adequate bone marrow, liver and renal function are randomized in a 1:1 ratio to REG 160 mg/die (3 weeks on, 1 week off) or lomustine 110 mg/m2 (every 6 weeks). A total of 112 PTS will be randomized ($\alpha = 0.20$, $\beta = 0.20$) and stratified based on surgery at recurrence. Disease evaluation is performed with gadolinium brain MRI every 8 weeks according to RANO criteria. Additional exploratory objectives include analysis of specific angiogenic and metabolic biomarkers in tissue as possible predictors of response to REG. The trial started in Nov 2015; as of Jan 2017, 105 PTS have been enrolled. Final analysis is planned in Dec 2017. Clinical trial information: NCT02926222.

TPS2086 Poster Session (Board #324b), Mon, 1:15 PM-4:45 PM

Cognitive support program for patients with brain metastases. *First Author: Nadine M. Richard, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Brain metastases occur in ~30% of cancer patients. While treatment options continue to evolve, prognosis remains poor in both morbidity and survival, and quality of life (QOL) is increasingly emphasized. Most patients will experience cognitive dysfunction. Deficits in executive and self-regulatory functions, memory, and communication interfere with patients' functional independence, participation in valued activities, relationships and QOL; they also affect families and caregivers. There are currently no established interventions for oncology and supportive care teams to address cognitive dysfunction and its impact on patient and family QOL. This study targets this gap in knowledge and clinical practice through development and piloting of a novel cognitive support program (CSP) for brain metastasis patients and their primary caregivers. **Methods:** Building on relevant neuroscience and behavioral research in other cognitively-impaired populations, we designed the CSP as a brief, structured, client-centered program. Using a prospective longitudinal design, 24 cognitively-impaired patients are being recruited from an outpatient multidisciplinary brain metastasis clinic. Each patient, together with their primary caregiver, attends 3 weekly individual sessions to learn strategies for memory, communication and executive functions. At-home practice between sessions applies the strategies in daily activities. Feasibility will be assessed through retention and adherence. Preliminary efficacy will be assessed by reliable change on cognitive, functional and QOL measures completed by patients pre-, post-, and 3 months following the CSP intervention. Caregivers will complete ratings of patient functioning and their own QOL at the same intervals. Analyses of variance will examine CSP intervention effects, with regression analyses to explore moderating effects of participant demographics, baseline levels of cognitive impairment, disease and treatment factors (e.g., volume and location of brain lesions, CNS-directed treatments received). Results of this pilot trial will lay the groundwork for a future randomized trial and further development of cognitive supports for brain metastasis patients and their families.

2500 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Debio 1347, an oral FGFR inhibitor: Results from a first-in-human, phase I dose-escalation study in patients with FGFR genomically activated advanced solid tumors. *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Oncogenic alterations in fibroblast growth factor receptors (FGFR) are seen across multiple solid tumor malignancies. Debio 1347 is an orally available, highly selective panFGFR inhibitor with potent antitumor effect in preclinical models bearing FGFR1-3 genetic alterations. **Methods:** Patients harboring defined FGFR 1, 2 or 3 alterations received escalating doses of Debio 1347 starting from 10 mg once daily. Dose escalation followed a 3+3+3 algorithm based on a modified Fibonacci sequence. The MTD was defined as the level where ≥ 3/9 patients suffer a DLT. Pharmacokinetics (PK) and pharmacodynamic were serially evaluated in blood, skin and/or tumor tissue. **Results:** Fifty-six patients were enrolled, including patients with mutations (n = 17), amplifications (n = 28) and fusions (n = 11). The dose was escalated up to 150 mg over 8 cohorts. DLTs were experienced by 4/56 patients, including G2 intolerable dry mouth + eyes at 60 mg, G3 hypercalcemia + hyperamylasemia at 80 mg, and G3 bilirubin increase at 110 mg. At data cut-off, the most common treatment-emergent adverse events (TEAE) were hyperphosphatemia (73%), fatigue (41%), diarrhea (39%), nausea (37%), and inappetence (32%). Fifteen patients (27%) experienced a grade ≥ 3 related TEAE. Twenty-five patients (47%) required dose modification, primarily due to hyperphosphatemia and cutaneous toxicity. An MTD has not been reached. PK appeared overall linear, with a half-life of 14 hours; hyperphosphatemia was dose-dependent. Among the 54 response-evaluable patients, 4 confirmed and 1 unconfirmed partial responses were observed in patients with cholangiocarcinoma (FGFR2 mutant), uterine (FGFR2 and FGFR1 amplified), colon (FGFR2 fusion), and urothelial cancer (FGFR3 fusion); an additional 10 patients had target regression < 30%. **Conclusions:** Debio 1347 had a tolerable and manageable safety profile. Encouraging antitumor activity was seen in several tumor types, mainly in patients with FGFR2 or 3 gene alterations, including fusion events, treated at 80 mg and 110 mg daily. Efficacy will be further explored in disease-specific and molecularly defined expansion cohorts. Clinical trial information: NCT1948297.

LBA2501 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

The efficacy of larotrectinib (LOXO-101), a selective tropomyosin receptor kinase (TRK) inhibitor, in adult and pediatric TRK fusion cancers. *First Author: David Michael Hyman, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, June 3, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

2502 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Ceritinib plus nivolumab (NIVO) in patients (pts) with anaplastic lymphoma kinase positive (ALK+) advanced non-small cell lung cancer (NSCLC). *First Author: Enriqueta Felip, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Induction of PD-L1 expression due to constitutive oncogenic signaling has been reported in NSCLC models harboring EML4–ALK rearrangements. Here we explore whether the combination of ALKi (ceritinib) and PD1-inhibitor (NIVO) will provide sustained clinical benefit to pts with ALK+ NSCLC. **Methods:** This phase 1 dose escalation study enrolled previously treated (ALK inhibitor [ALKi] or chemotherapy) or tx-naive pts with stage IIIB/IV ALK+ NSCLC; who received NIVO 3 mg/kg IV Q2W + ceritinib with low-fat meal, at 450 mg/day (group 1) or 300 mg/day (group 2) until progression/unacceptable toxicity. Primary objective: MTD/recommended dose for expansion. Dose escalation was guided by Bayesian logistic regression model with overdose control. **Results:** Median follow-up: group 1 (n = 14) 13 mos (10-15); group 2 (n = 22) 6 mos (2-10). As of 9 Sep 2016, 16/36 (44%) pts discontinued tx: disease progression (11 [31%] pts), AE's (3 [8%] pts), and death (2 [6%] pts). In group 1, 4 pts experienced DLT: pancreatitis (n = 2), lipase and transaminase increase (n = 1), and autoimmune hepatitis (n = 1). In group 2, 2 pts experienced DLT: G3 ALT increase. Both dose levels met Bayesian criteria for dose expansion. Overall most frequent (≥40%) AEs (n = 36), were diarrhea (64%), ALT increase (56%), AST increase (44%) and vomiting (42%). Most frequent (> 10%) grade ≥3 AEs were increases in ALT (22%), GGT (17%), amylase (11%), and lipase (11%), and maculopapular rash (11%). Incidence of rash (grouped term) was 61%; similar in both groups. Grade 3 rash was reported in 29% pts in group 1 and 14% pts in group 2. Preliminary ceritinib steady state PK ($AUC_{0\text{-}24}$ and C_{max}) suggested that 300 mg/day exposure was ~ 70-75% of 450 mg/day. Confirmed (c)/unconfirmed (u) ORR: ALKi-pretreated pts (group 1 [n = 8], group 2 [n = 12]) was 63% (4 cPR,1 uPR; 95% CI: 25%, 92%), and 33% (4 uPR) 95% CI: 10%, 65%) respectively; ALKi-naïve pts, (group 1 [n = 6], group 2 [n = 10]) was 83% (5 cPR; 95% CI: 36%, 100%), and 70% (1 cCR, 3 cPR 3uPR; 95% CI: 35%, 93%) respectively. **Conclusions:** Ceritinib + NIVO is an active combination in ALK+ NSCLC. However, the protocol will be amended to address observed toxicities. Data will be updated for presentation. Clinical trial information: NCT02393625.

2503 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

An investigator-initiated phase I study of ONX-0801, a first-in-class alpha folate receptor targeted, small molecule thymidylate synthase inhibitor in solid tumors. *First Author: Udai Banerji, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: ONX-0801 is a first-in-class alpha folate receptor (AFR) targeted thymidylate synthase inhibitor, engineered to differentially accumulate 6000-fold in AFR overexpressing cancer cells. **Methods:** A 3+3 dose escalation design was used and two IV schedules were explored. Schedule A, weekly dosing (QW) and schedule B, once every 2 weeks dosing (Q2W). A cycle consisted of 4 weeks and treatment was stopped after 6 cycles in both schedules. An expansion cohort to evaluate clinical activity in patients with AFR overexpressing high grade serous ovarian cancer (HGSOC) was planned. **Results:** 21 patients each were treated in schedule A and B exploring doses ranging from 1-6 mg/m^2 and 2-12 mg/m^2, respectively. The dose limiting toxicity on schedule A was G3 cellulitis; no dose limiting toxicity was seen on schedule B. The most common toxicities were fatigue 15/42 (36%), nausea 9/42 (21%) and dysgeusia 5/42 (12%). Within schedule A at 4 mg/m^2, 2 patients developed suspected drug-related changes on pulmonary function tests (drop in Dlco > 15%) at cycles 5 and 6, respectively. No cases of suspected drug-related drop in Dlco were noted in patients treated in schedule B. No grade 3-4 diarrhea, mucositis or neutropenia were seen in either cohort. The Cmax, AUC and half-life at 12 mg/m^2 were 4952 ng/mL, 85170 h*ng/mL and 26 h, respectively. Pre-clinical PK-PD modelling aimed to achieve concentrations between 0.05-1 μM and this was achieved for periods of 48 h at doses of 4 mg/m^{2}and above. Based on safety and PK, the recommended phase II dose (RP2D) of ONX-0801 was 12 mg/m^2 Q2W and an expansion in patients with HGSOC is ongoing. 5 patients with HGSOC had partial responses (PRs) in the dose escalation cohort. In the current expansion cohort in patients with HGSOC, 5/11 patients had PRs. Archival samples have been analyzed from 8/11 patients in the expansion cohort. 4/4 AFR+ve and 4/4 AFR-ve patients did and did not have a PR following treatment with ONX-0801, respectively. **Conclusions:** The RP2D of ONX-0801 is 12 mg/m^2 Q2W. At the RP2D, multiple patients with AFR overexpressing HGSOC have had PRs and further randomized biomarker prespecified phase II trials are warranted. Clinical trial information: NCT02360345.

2504 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Phase I first-in-man trial of a novel bromodomain and extra-terminal domain (BET) inhibitor (BI 894999) in patients (Pts) with advanced solid tumors. *First Author: Philippe Georges Aftimos, Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

Background: The BET family (BRD2, BRD3, BRD4) regulates transcription, epigenetic memory and cell growth, emerging as a novel therapeutic strategy. BI 894999 is a highly potent and selective orally available BET inhibitor. **Methods:** BI 894999 was given once a day, continuously (1 cycle = 3 weeks; Arm A). An intermittent schedule was explored: once a day, D1-14 Q21 days (1 cycle = 3 weeks; Arm B). Bayesian Logistic Regression Model was used to guide dose escalation. HEXIM1, HIST2H2BF and CCR2 gene expressions were used as pharmacodynamic (PD) markers. **Results:** 28 pts were treated: 21 in Arm A, 7 in Arm B. Median number of cycles was 2 (range: 1-12). Pts were treated at 6 dose levels in Arm A (0.2-5 mg) and 2 dose levels in Arm B (1.5 and 2 mg). The maximum tolerated dose (MTD) was exceeded at 2 mg in Arm A. In Arm B, dose escalation was halted due to the observation of ECG changes in 3 pts and raised serum troponin in 8 pts, pending cardiology review. MTD in Arm A was defined as 1.5 mg. The most frequent (≥10%) treatment-related adverse events were: fatigue (50%), thrombocytopenia (29%), decreased appetite (21%), diarrhea (18%), increased troponin T (18%), dysgeusia (14%), nausea (14%), stomatitis (14%), increased CK (11%), neutropenia (11%) and vomiting (11%). DLTs included: thrombocytopenia grade (G) 4 (n=3), increased troponin G3 (n=1), hypophosphatemia G3 (n=1), multiple G2 events in 1 pt preventing adequate dose intensity in cycle 1. Of 27 evaluable pts, 3 had partial response (PR; one was confirmed) and 1 had stable disease (SD) lasting >4 cycles. C_{max} and AUC increased with dose in a greater than linear fashion particularly at higher dose levels. Mean terminal $T_{1/2}$ was ~1 day with high interpatient variability. PD analyses showed target engagement in all 3 genes at doses ≥1 mg in both schedules. **Conclusions:** BI 894999 showed target engagement at doses ≥ 1 mg and demonstrated clinical activity (3 PRs and 1 SD lasting >4 cycles). Thrombocytopenia prevented continuous dosing and 1.5 mg was defined the MTD for Arm A, whilst dose escalation was halted in Arm B due to cardiac findings. Mitigating hematological toxicity of BI 894999 via synergistic drug combinations should be explored. Clinical trial information: NCT02516553.

2505 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Phase I trial of a novel stapled peptide ALRN-6924 disrupting MDMX- and MDM2-mediated inhibition of *WT p53* in patients with solid tumors and lymphomas. *First Author: Funda Meric-Bernstam, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ALRN-6924 is a cell-penetrating stapled alpha-helical peptide designed to equipotently disrupt the interaction between the p53 tumor suppressor protein and its endogenous inhibitors, murine double minute X (MDMX) and 2 (MDM2). For TP53 wild-type (WT) tumors, pharmacological disruption of this interaction offers a means to restore p53-dependent cell cycle arrest and apoptosis, resulting in antitumor efficacy via a novel mechanism. **Methods:** The study evaluated safety, PK, PD and anti-tumor effects of ALRN-6924 in patients (pts) with advanced solid tumors or lymphomas in a standard 3+3 design. Pts received ALRN-6924 IV once weekly for 3 consecutive wks on a 28-day cycle (arm A), or 2/wk for 2 consecutive wks on a 21-day cycle (arm B). **Results:** As of Dec 2016, 69 pts were enrolled with median age 61 yrs (25-78). Pts received a median of 2 (1-19) cycles in arm A [0.16-4.4 mg/kg] and 3 (1-19) cycles in arm B [0.32-2.7 mg/kg]. ALRN-6924 showed a $t_{1/2}$ of 5.5 hours, dose-dependent PK, and an increase in serum macrophage inhibitory cytokine-1. Treatment-related AEs seen in 96% of pts were primarily grade 1 and 2; most frequent were GI side effects, fatigue, anemia, and headache. DLTs were G3 fatigue at 3.1 mg/kg, and G3 hypotension, G3 alkaline phosphatase elevation, G3 anemia and G4 neutropenia at 4.4 mg/kg all in 5 pts in arm A. No G3/4 thrombocytopenia was observed. All DLTs resolved with dose hold. Infusion-related reactions were seen in 7 pts, with 3 treatment discontinuations. The RP2D was determined to be at MTD: 3.1 mg/kg QW for 3 wks every 28 days. In 55 pts evaluable for efficacy, disease control rate (DCR) was 45%, including 2 CR (Peripheral T-cell Lymphoma [PTCL], Merkel Cell Carcinoma), 2 PRs (Colorectal Cancer, Liposarcoma) and 21 pts with SD. In WT TP53 pts who initiated ALRN-6924 at ≥0.8 mg/kg, DCR was 57%. 9 pts remain on treatment post data cutoff including 3 pts exceeding 1 year of treatment. **Conclusions:** ALRN-6924 was well tolerated and demonstrated intriguing anti-tumor activity in this first-in-human phase I trial. An expansion phase IIa cohort in PTCL opened in August 2016 using 3.1 mg/kg (arm A) and is currently enrolling. Clinical trial information: NCT02264613.

2506 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Results from the biomarker-driven basket trial of RO5126766 (CH5127566), a potent RAF/MEK inhibitor, in RAS- or RAF-mutated malignancies including multiple myeloma. *First Author: Maxime Chenard-Poirier, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: RO5126766 is a potent RAF and MEK inhibitor with activity in xenografts models of RAS and RAF-mutated cancers. We present data from the RAS/RAF-mutated advanced solid tumor cohort and the initial results for the multiple myeloma (MM) cohort. **Methods:** Patients with *KRAS*, *NRAS* or *BRAF*-mutant tumours were treated with RO5127566 using a novel schedule: 4mg twice weekly in 4-week cycles. For MM patients, it was given 3 weeks out of 4 and co-administration of weekly dexamethasone was authorised. Response assessment was completed using RECIST 1.1 criteria for solid tumours and the International Myeloma Working Group (IMWG) criteria were used for MM. **Results:** A total of 20 patients with solid tumours (10 NSCLC, 5 gynaecological cancers and 5 miscellaneous cancers) and 1 MM patients were evaluable. Among the 10 *KRAS*-mutant NSCLC patients, tumour regression was seen in 6/10 (60 %), of which 3/10 (30 %) were partial responses. Two of these patients had maintained response for over 1 year and one patient is still on study after 30 cycles. Of the gynaecological cancers, 3/5 patients (60%) achieved a partial response (*KRAS*-mutant endometrial and ovarian cancer and *BRAF*-mutant ovarian). Of these patients, 1 of the *KRAS* mutants had received 2 previous lines of MEK inhibitors and the *BRAF* mutant had previously received a BRAF inhibitor. In the miscellaneous group, 4 patients with colorectal cancer (2 BRAF and 2 NRAS) and 1 patient with *NRAS*-mutant melanoma were treated and none responded. Two patients with MM have been treated so far (1 *KRAS*, 1 *KRAS+NRAS*). The one evaluable patient has had an IMWG partial response (PR) after 1 cycle (FLC-λ from 324 mg/L to 161mg/L, ratio 0.03 to 0.08) without concomittant dexamethasone. This patient was previously treated with an immunomodulatory drug, a proteasome inhibitor and two ASCTs. **Conclusions:** RO5126766 has shown exciting preliminary activity across a wide range of *RAS*- and *RAF*-mutated malignancies, with significant response rates in lung and gynaecological cancers. To our knowledge, the PR seen in our MM patient represents one of the first responses to a single-agent RAF/MEK inhibitor in multiple myeloma in a trial context. Clinical trial information: NCT02407509.

2507 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

A first-in-human dose phase 1 study of LY3009120 in advanced cancer patients. *First Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LY3009120, a pan-Raf and dimer inhibitor, demonstrates inhibition of phospho-Mek/Erk and tumor growth inhibition in several non-clinical cancer models with BRAF, NRAS, or KRAS mutations. This is the first-in-human phase 1 study of LY3009120 in patients (pts) with advanced cancer. **Methods:** The safety and tolerability of LY3009120 was evaluated in pts with cancer aged 18 years or older who had an ECOG performance status ≤1, at least 1 unidimensionally measurable lesion (RECIST 1.1), and adequate organ function (NCT02014116; I6X-MC-JBDA; Eli Lilly & Co.). The study sought to determine a recommended phase 2 dose using the toxicity band method and the safety, pharmacokinetic, and preliminary efficacy of LY3009120. Pharmacodynamic (PD) biomarkers, including pERK, p27 and Ki67, were evaluated in tumor tissue. The dose escalation phase evaluated dosages from 50 mg to 500 mg by mouth twice daily in pts with advanced cancers. **Results:** 34 pts (3 at 50 mg, 4 at 100 mg, 3 at 200 mg, 15 at 300 mg, 7 at 400 mg, and 2 at 500 mg) in dose escalation and 1 pt in dose expansion (1 at 300 mg) received at least one dose of LY3009120 by January 2, 2016 (median age = 47.4 yrs, range: 26-82). Most pts had a gene mutation (BRAF, n = 7; N/KRAS, n = 18); the most common cancer types included colon (n = 9), non–small cell lung cancer (n = 8), and pancreatic (n = 5). There were 6 dose-limiting toxicities in the dose escalation phase: 2 pts at 300 mg (G3 dermatitis acneiform [n = 1] and G2 blurred vision [n = 1]); 2 pts at 400 mg (G2 increased ALT with G3 hyperbilirubinemia [n = 1] and G3 increased ALT [n = 1]); 2 pts at 500 mg: (G3 arthralgia/myalgia [n = 1] and G3 stomatitis/pain [n = 1]). Based on these data, the maximum tolerated dose for LY3009120 was determined to be 300 mg twice daily. Treatment-emergent adverse events related to LY3009120 occurring in ≥10% of pts included fatigue (34%), nausea (31%), decreased appetite (20%), and dermatitis acneiform (20%) (Grade 1,2). A dose proportional increase in exposure was observed, but not at the 400 mg dose. The best response was stable disease in 5 pts. PD effect by rtPCR was not observed in tested paired tumor samples. **Conclusions:** LY3009120 is well tolerated at doses of 300 mg twice daily. Updated data from dose expansion will be presented in the meeting. Clinical trial information: NCT02014116.

2508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

First-in-class oral ERK1/2 inhibitor Ulixertinib (BVD-523) in patients with advanced solid tumors: Final results of a phase I dose escalation and expansion study. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Aberrant MAPK pathway activation is known to be an oncogenic driver in many solid tumors, making ERK inhibition an attractive therapeutic strategy. Ulixertinib is an oral ERK1/2 inhibitor that demonstrated potent activity in vitro and tumor regression in *BRAF* and *RAS* mutant xenograft models. **Methods:** This multi-center phase I trial enrolled patients (pts) with advanced solid tumors. Dose escalation utilized an accelerated 3+3 design; expansion cohorts included *BRAF or NRAS* mutant melanoma and other *BRAF* or *MEK* mutant cancers. Study objectives were to characterize dose limiting toxicities (DLTs), maximum tolerated dose (MTD), toxicity profile, pharmacokinetics, pharmacodynamics and preliminary anti-tumor activity by RECIST 1.1. **Results:** A total of 135 pts were enrolled. Dose escalation enrolled 27 pts (10-900 mg BID) and established the MTD and recommended phase 2 dose (RP2D) of 600 mg BID. DLTs included rash, diarrhea, elevated AST, and elevated creatinine. Drug exposure was dose proportional up to the RP2D, which provided near-complete inhibition of ERK activity in whole blood. In the 108 pt expansion cohort, there were no drug related deaths; however, 32% of pts required a dose reduction. The most common adverse events were rash (49%), diarrhea (47%), fatigue (41%), and nausea (37%). In addition to 3 pts with partial responses during escalation (11%), an additional 9 of 83 (11%) evaluable pts at expansion had a partial response: 1 melanoma pt refractory to prior BRAFi/MEKi treatment, 3 *NRAS* mutant melanoma pts, 2 pts with *BRAF* V600E mutant lung cancers including response in brain metastases, 1 with *BRAF* V600E mutant glioblastoma multiforme, 1 with *BRAF* G469A head & neck cancer, and 1 with *BRAF*L485W gallbladder cancer. The duration of response ranged from 2 to 24+ months. **Conclusions:** Ulixertinib at 600 mg twice a day has an acceptable safety profile and has produced durable responses in pts with *NRAS* mutant melanoma, *BRAF* V600 and non-V600 mutant solid tumors including melanoma, glioblastoma multiforme, lung cancers with brain metastases, gallbladder and head & neck cancers. These data support further clinical development of ulixertinib. Clinical trial information: NCT01781429.

2509 Poster Discussion Session; Displayed in Poster Session (Board #1), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Phase I study of ABBV-399, a c-Met antibody-drug conjugate (ADC), as monotherapy and in combination with erlotinib in patients (pts) with non-small cell lung cancer (NSCLC). *First Author: Eric Angevin, Institut Gustave Roussy, Villejuif, France*

Background: The c-Met receptor is overexpressed in ~50% of pts with NSCLC. ABBV-399 is a first-in-class ADC composed of ABT-700, an anti–c-Met antibody, conjugated to monomethyl auristatin E (a microtubule inhibitor). Preclinical data demonstrate that ABBV-399 can deliver a potent cytotoxin directly to c-Met+ tumor cells. **Methods:** ABBV-399 was administered at doses ranging from 2.4 to 3.0 mg/kg (dose expansion and combination cohorts at 2.7 mg/kg) once every 21 days to 29 pts with advanced c-Met+ (immunohistochemistry [IHC] H-score ≥150) NSCLC both as monotherapy (ABBV-399/monoT; 16 pts) and in combination with oral erlotinib 150 mg daily (ABBV-399/ERL; 13 pts) (NCT02099058). c-Met overexpression was assessed by IHC utilizing the SP44 antibody (Ventana; Tucson, AZ, USA). **Results:** As of January 9, 2017, 16 pts with c-Met+ NSCLC received ≥1 dose of ABBV-399/monoT. Monotherapy treatment-related adverse events (TRAEs) occurring in ≥10% of pts (all dose levels and all grades) were fatigue (43.8%), nausea (37.5%), neuropathy (25.0%), vomiting (18.8%), and anemia, constipation, and diarrhea (12.5% each). Three of 16 (19%) ABBV-399–treated c-Met+ NSCLC pts had a confirmed partial response (PR) with duration of response (DOR) 3, 4.5, and 10+ months. At week 12, 6 of 16 pts (37.5%) had disease control. TRAEs in ABBV-399/ERL occurring in ≥10% of pts (all grades) were neuropathy (30.8%), and acneiform rash, diarrhea, fatigue, nausea, and dry skin (15.4% each). Four of 13 (31%) evaluable ABBV-399/ERL–treated c-Met+ pts had a PR (3 confirmed, 1 unconfirmed) with DOR 1+, 2.7, 5.3+, and 11+ months. Three of the 4 pts with PR had EGFR-mutated tumor and recently progressed on TKI. At week 12, 8 of 13 pts (61.5%) had disease control. There were no treatment-related deaths as monotherapy or in combination with erlotinib. Responses were seen in both squamous and non-squamous histology. **Conclusions:** ABBV-399 is well tolerated at 2.7 mg/kg once every 21 days and has demonstrated antitumor activity in pts with c-Met+ NSCLC both as monotherapy and in combination with erlotinib. Updated efficacy/safety data and *MET* gene status will be presented. Clinical trial information: NCT02099058.

Preliminary results from a phase 1 study of the antibody-drug conjugate ABBV-221 in patients with solid tumors likely to express EGFR. *First Author: Emiliano Calvo, START Madrid, Centro Integral Oncológico Clara Campal, Madrid, Spain*

Background: ABBV-221 is a 2nd-generation antibody-drug conjugate (ADC) targeting EGFR based on the 1st-generation ADC ABT-414. ABT-414 shows efficacy in glioblastoma (GBM) patients (pts) with EGFR amplification in ongoing studies. ABBV-221 is an affinity matured monoclonal antibody against EGFR linked to the toxin MMAE. ABBV-221 has higher affinity for overexpressed EGFR than ABT-414, potentially allowing it to target a broader range of tumor types. **Methods:** This is a Phase 1, multicenter study to determine maximum tolerated dose (MTD) and recommended Phase 2 dose (RPTD) of ABBV-221. Pts are required to have an EGFR-dependent cancer to be eligible. Starting dose of ABBV-221: 0.3 mg/kg IV infused over 3 hrs for each 21-day cycle, with alternate dosing schedules utilized (2 wks on, 1 wk off or weekly) to mitigate infusion reactions. **Results:** As of 11 January 2017, 42 pts were treated (13 colon, 5 head & neck (H&N) cancer, 5 non-small cell lung cancer, 5 GBM, 2 breast, 12 other). Ten dose escalation cohorts have been completed with the last cleared dose 4.5 mg/kg per cycle. Tumor tissue samples were evaluated for EGFR protein expression by IHC, EGFR and EGFR ligand mRNA expression by RNAseq, and the results compared to outcome. The most common adverse event (AE) was infusion reaction in 18/42 pts (43%); 3 pts experienced severe infusion reactions. Several mitigation strategies were used to permit continued dose escalation. The other most common AE was fatigue in 17/42 pts (41%). Only 1 pt had keratitis (Grade 4). Sixteen pts (38%) had stable disease (SD), including 4 pts who remained on study longer than 6 months. One H&N pt who has received 2 cycles of ABBV-221 had an unconfirmed partial response and continues to be treated. This pt had high levels of both EGFR and EGFR ligand. Preliminary pharmacokinetics (PK) analysis suggests ABBV-221 exposures are approximately dose-proportional. **Conclusions:** Safety, PK, pharmacodynamics, and preliminary efficacy data of ABBV-221 warrant further study in this population. Infusion reactions have been manageable and primarily a first dose phenomenon. The duration of SD in pts with refractory solid tumors is encouraging. Clinical trial information: NCT02365662.

A phase I study of PF-06647263, a novel EFNA4-ADC, in patients with metastatic triple negative breast cancer. *First Author: Ignacio Garrido-Laguna, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: PF-06647263 is an anti-Ephrin-A4 (EFNA4) antibody drug conjugate (ADC) composed of a humanized mAb, a hydrazone cleavable linker, and calicheamicin, a potent DNA damaging agent. Higher levels of EFNA4 expression have been shown in tumor versus normal tissue, including in two thirds of triple negative breast cancers (TNBC). In vivo preclinical studies demonstrate PF-06647263 induced tumor regression in TNBC models. **Methods:** In Part 1 of a dose escalation, cohorts of 2-12 patient (pts) with solid tumors that were unselected for EFNA4 expression received escalating doses of PF-06647263 once every 3 weeks (Q3W, Cohort A) or weekly (QW, Cohort B). Escalations were based on mTPI design. An expansion cohort enrolled TNBC patients (n=12) unselected for EFNA4 expression. Efficacy, safety, EFNA4 RNA expression, pharmacokinetic (PK) and anti-drug antibody development were assessed. **Results:** Part 1 (dose escalation):A total of 48 pts (25 in A and 23 in B) wereenrolled. The most common treatment related adverse events (AE) were fatigue (65%), and nausea (60%), thrombocytopenia (40%), and decreased appetite (38%). DLTs were observed in 6 and 2 pts in the Q3W and QW regimens, respectively. One confirmed VOD and one suspected VOD were observed in two patients in the Q3W schedule. The maximum tolerated dose (and RP2D) was determined to be 0.015 mg/kg QW. Confirmed partial responses (PR) were observed in 5 pts (3 Ovarian Ca and 2 TNBC). Part 2 (TNBC dose expansion at RP2D)data are available on 10 of 12 pts treated (2 ongoing). The most common adverse events (AE) were nausea (40%), asthenia (30%), vomiting (30%) and mucosal inflammation (30%). No objective RECIST response was observed; there was no dependency with duration of treatment relative to EFNA4 expression. **Conclusions:** In Part 1 of this study, PF-06647263 was generally well-tolerated in the QW schedule and some antitumor activity was observed in heavily pretreated pts with EFNA4 unselected advanced malignancies. However, in the expansion cohort (Part 2) at RP2D in TNBC no objective responses were observed regardless of EFNA4 expression. Final safety, efficacy, expression and PK data will be reported at the meeting. Clinical trial information: NCT02078752.

Personalized, molecularly matched combination therapies for treatment-na. *First Author: Jason K. Sicklick, Department of Surgery, University of California San Diego, San Diego, CA*

Background: Precision medicine has been studied in patients (pts) with advanced, heavily-treated cancers by administering molecularly matched monotherapies. With increasing availability of large gene assays and cognate agents, we hypothesized that offering customized combination therapies to treatment-naïve tumors would be feasible and improve response rates. **Methods:** Investigation of Profile-Related Evidence Determining Individualized Cancer Therapy (I-PREDICT, NCT02534675) targeted metastatic and/or unresectable, untreated lethal cancers (> 50% 2-yr mortality). Comprehensive genomic profiling (CGP, Foundation Medicine; 315 genes), and, if possible, PD-(L)1 IHC, tumor mutational burden (TMB) and circulating tumor DNA were performed. A molecular tumor board discussed results immediately upon receipt, and emphasized customized combinations. Final decisions were the treating physician's choice. **Results:** CGP was evaluable in 40/47 treatment-naïve pts (85.1%); 22 (46.8%) were treated [17 matched (36.2%); 5 unmatched (10.6%); 11 different diagnoses). The other 25 pts (53.2%) are awaiting therapy (8, 17%) or could not be treated (17, 36.2%), mainly due to patient deterioration or payor limitations. Each tumor had a unique genomic portfolio. The median (range) of genomic alterations/patient was 5 (1-12). TMB was available in 17 pts (12 low; 4 intermediate; 1 high). The median (range) Matching Score [(matches (#)/characterized genomic alterations (#)] was 33% (14-100%; 100% designated immunotherapy match or all alterations matched to targeted agents) [Reference PMID 2719717]. Nine/17 matched pts (53%) achieved SD > 6 months (N = 2) or CR (1)/PR (6). The median progression-free survival (PFS) for matched vs. unmatched pts was 4.7 vs. 1.0 months (P= 0.0019). There were no drug-related deaths. **Conclusions:** With the use of broad-based DNA sequencing assays, inclusion of pts earlier in their disease course, timely mandated molecular tumor board discussions, and increasing availability of cognate drugs for customized combinations, we report: 1) high molecular matching rates (~36%); 2) high rates of SD > 6 months/CR/PR (~53%); and 3) improved PFS. Study expansion is ongoing. Clinical trial information: NCT0253467.

Initiative for Molecular Profiling and Advanced Cancer Therapy (IMPACT): An MD Anderson precision medicine study. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We present outcomes for 637 patients who were referred for phase I trials and were treated under IMPACT. **Methods:** Patients with advanced, refractory cancer who had tumor genomic analyses were treated with matched targeted therapy (MTT) when available. **Results:** Overall, 1,179 (82.1%) of 1,436 patients had ≥1 alteration (median age, 59.7 yrs; men, 41.2%); 637 had ≥1 actionable aberration and were treated with MTT (n=390) or non-MTT (n=247). Patients treated with MTT had higher rates of CR and PR (11% vs. 5%; p=.0099) (Table), longer failure-free survival (FFS) (3.4 vs. 2.9 months; p=.0015), and longer overall survival (OS) (8.4 vs. 7.3 months; p = .041) than unmatched patients. Two-month landmark analyses showed that, for MTT patients, FFS for responders vs. non-responders was 7.6 vs. 4.3 months (p<.0001) and OS was 23.4 vs. 8.5 months (p<.0001); for non-MTT patients (responders vs. non-responders), FFS was 6.6 vs. 4.1 months (p=.0005) and OS was 15.2 vs. 7.5 months (p = .43). Patients with both PI3K and MAPK pathway alterations matched to PI3K/Akt/mTor axis inhibitors alone showed outcomes comparable to unmatched patients. **Conclusions:** Matched versus unmatched patients had significantly better outcomes. For matched responders, median survival reached almost two years. However, matching patients who harbor both a PI3K and a MAPK pathway alteration to only a PI3K pathway inhibitor did not improve outcome. Clinical trial information: NCT00851032.

Response by matching (N=637).

	Treatment Group	Evaluable for response	CR+PR (%)	Odds Ratio (95% CI)	P-value	SD≥6 months + CR+PR+v(%)	Odds Ratio (95% CI)	P-value

Development and validation of a real-world clinicogenomic database. *First Author: Gaurav Singal, Foudation Medicine, Inc., Cambridge, MA*

Background: Genomic findings have diagnostic, prognostic, and predictive utility in clinical oncology. Population studies have been limited by reliance on trials, registries, or institutional chart review, which are costly and represent narrow populations. Integrating electronic health record (EHR) and genomic data collected as part of routine clinical practice may overcome these hurdles. **Methods:** Patients in the Flatiron Health Database with non-small cell lung cancer (NSCLC) who underwent comprehensive genomic profiling (CGP) by Foundation Medicine were included. EHR processing included structured data harmonization and abstraction of variables from unstructured documents. EHR and CGP data were de-identified and linked in a HIPAA-compliant process. Data included clinical characteristics, alterations across > 300 genes, tumor mutation burden (TMB), therapies and associated real-world responses, progression, and overall survival (OS). **Results:** The cohort (n = 1619) had expected clinical (mean age 66; 75% with smoking hx; 80% non-squamous) and genomic (18% EGFR; 4% ALK; 1% ROS1) properties of NSCLC. Presence of a driver mutation (EGFR, ALK, ROS1, MET, BRAF, RET, or ERBB2; n = 576) was associated with younger age, female gender, non-smoking, improved OS (35 vs 19 mo, LR p < 0.0001), and prolonged survival when treated with NCCN-recommended therapy (42 vs 28 mo, LR p = 0.001). CGP identified false negative results in up to 30% of single-biomarker tests for EGFR, ALK, and ROS1. CGP accuracy was supported by clinical outcomes. For example, 5 patients with prior negative ALK-fusion testing began ALK-directed therapy after positive CGP results. All 5 exhibited at least a partial response as recorded in the EHR by treating clinicians. Immunotherapy was used in 22% of patients (n = 353). TMB predicted response to nivolumab, including in PD-L1 negative populations. We recapitulated known associations with smoking, histology, and driver mutations. **Conclusions:** We present and validate a new paradigm for rapidly generating large, research-grade, longitudinal clinico-genomic databases by linking genomic data with EHR clinical annotation. This method offers a powerful tool for understanding cancer genomics and advancing precision medicine.

Pharmacokinetic-driven phase I study of DCC-2618 a pan-KIT and PDGFR inhibitor in patients (pts) with gastrointestinal stromal tumor (GIST) and other solid tumors. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: DCC-2618 is a potent switch control inhibitor of KIT and PDGFR kinases active in a broad range of mutations. GIST is an important disease to achieve a proof-of-concept due to the heterogeneity of KIT resistance mutations, which emerge on treatment with approved KIT inhibitors. **Methods:** This was a PK-guided dose escalation study of oral DCC-2618 (QD or BID q28 days) in advanced solid tumors. FDG-PET scans were used to assess changes in FDG uptake in GIST pts after 3 wks of therapy. Next generation sequencing (NGS) of plasma cell-free (cf) DNA was performed throughout the study to assess and quantify KIT and other molecular alterations in drug targets and potential mechanisms of resistance. **Results:** 38 pts were enrolled (30 GIST; 4 glioma; 1 mastocytosis, 3 other carcinoma) to 8 dose levels: BID doses: 20 (4 pts), 30 (4), 50 (5), 100 (6), 150 (6) and 200 mg (3); QD doses: 100 (5) and 150 mg (4). Safety of evaluable pts is as follows: G3 or G4 adverse effects (regardless of attribution and occurring in > 1 pt) included anemia (5), lipase increase (4), hypertension (2). Two of the G3/4 lipase increase at 100 mg BID and 200 mg BID were DLTs. All G3/4 lipase increase were asymptomatic. G1/2 AEs (considered at least possibly related to DCC-2618) and occurring in ≥15% (n > 5) of pts include fatigue (12), alopecia & lipase increase (7), weight decrease (6). Starting with 50 mg BID dose level, trough concentrations of total drug exceeded the IC90 of the least sentivitive KIT mutations. Plasma concentrations > 5μM were achieved starting at 100 mg BID and the selection of the expansion phase dose is being finalized. Of 18 pts with KIT mutant GIST assessed by FDG PET, 14 (78%) had partial metabolic response per EORTC criteria. RANO/RECIST partial responses (PRs) were reported in 3 patients (1 GBM with PDGFRA/KIT amplifications and 2 GIST with Ex 11 & 17 / Ex 11 & 18 mutations, respectively). NGS of plasma cfDNA revealed 44 KIT mutations in baseline samples from 19 of 21 pts with GIST. **Conclusions:** DCC-2618 is well tolerated with encouraging preliminary activity in GIST pts with a broad spectrum of mutations and prior therapies. PR was also seen in a pt with GBM with PDGFRA/KIT amplifications. Clinical trial information: NCT02571036.

2516 Poster Discussion Session; Displayed in Poster Session (Board #8), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

A first-in-human first-in-class (FIC) trial of the monocarboxylate transporter 1 (MCT1) inhibitor AZD3965 in patients with advanced solid tumours. *First Author: Sarah E. R. Halford, Cancer Research UK Centre for Drug Development, London, United Kingdom*

Background: A key metabolic alteration in tumour cells is an increased dependency on the glycolysis, resulting in the production of lactate, which is transported out of cells by MCTs. Inhibition of MCT-1 leads to a profound inhibition of cancer cell growth in preclinical models. AZD3965 is a FIC inhibitor of MCT-1, and we report results from the phase I study of this agent. **Methods:** Patients with advanced solid tumours were treated with oral (po) AZD3965 at total daily doses of 5-30mg given once (od) and twice daily (bd). Exclusion criteria included a history of retinal or cardiac disease due to preclinical toxicology findings in the eye and heart (which express MCT-1). The primary objectives were to determine the safety, dose limiting toxicities (DLT) and maximum tolerated dose (MTD) of AZD3965. Intensive pharmacokinetic (PK) profiling was performed with subsequent modelling for receptor occupancy. Pharmacodynamic profiling included imaging to detect pH changes and tumour glucose uptake; plasma/urine metabolomics and MCT-1 and MCT-4 tumour expression by immunohistochemistry. **Results:** 35 patients (20M:15F median age 65) were treated at dose levels 5, 10, 20, and 30mg od and 15 and 10mg bd. AZD3965 was generally well tolerated with nausea and fatigue (CTCAE Gr1-2) the most commonly reported side effects. A single DLT of cardiac troponin rise was observed at 20mg od. Asymptomatic, reversible retinal ERG changes were observed in all but the lowest dose levels, with DLTs observed at doses above 20mg od. PK data indicate exposures in the preclinical efficacy range. Metabolomic changes in urinary lactate and urinary ketones correlate with on-target activity. The increase in urinary ketones is likely to be attributable to the role of MCT1 in physiological ketone transport. **Conclusions:** The MCT1 inhibitor AZD3965 can be administered to patients at doses which engage the drug target, with a MTD of 20mg od po. DLTs seen were primarily dose dependent, asymptomatic and reversible changes in retinal function, which were an expected on-target effect. Investigation of the activity of AZD3965 is ongoing in tumours known to express MCT1. Clinical trial information: NCT01791595.

2517 Poster Discussion Session; Displayed in Poster Session (Board #9), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Phase 1 study of ARQ 761, a β-lapachone analog that promotes NQO1-mediated programmed cancer cell necrosis. *First Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: NAD(P)H:quinone oxidoreductase 1 (NQO1) is a two-electron oxidoreductase expressed in multiple tumor types at levels 5- to 200-fold above normal tissue. ARQ761 is a β-lapachone hydroquinone analog that exploits the unique elevation of NQO1 found in solid tumors to cause tumor-specific cell death by eliciting a futile redox cycle generating high levels of reactive oxygen species and ultimately PARP1 hyperactivation-dependent cell death. **Methods:** 3+3 dose escalation study of 3 schedules (weekly, every other week, 2/3 weeks) of ARQ 761 as a 1-hr or 2-hr infusion. Eligible patients had refractory advanced solid tumors, ECOG 0-1, adequate organ function, and central venous access. Blood samples were analyzed for ARQ761 levels and NQO1 polymorphisms. Archival tumor tissue was analyzed for NQO1 staining intensity and prevalence. After 18 patients were analyzed, enrollment was restricted to patients with NQO1-positive tumors (defined as Histo-score ≥200). **Results:** A total of 42 patients were treated. Median number of prior lines of therapy was 4. For all schedules, the maximum tolerated dose (MTD) was 390 mg/m^2 as a 2-hr infusion. DLT was hemolytic anemia. The most common treatment-related adverse events were anemia (79%), fatigue (45%), hypoxia (33%), hemolysis (17%), nausea (17%) and vomiting (17%). Transient grade 3 hypoxia, due to methemoglobinemia, occurred in 26% of patients. Among 31 evaluable patients, the best response was stable disease (n = 11) and progressive disease (n = 19). For the 18 analyzed cases analyzed prior to NQO1 enrollment biomarker, clinical benefit appeared associated with tissue NQO1 expression: disease control rate was 65% in NQO1-positive tumors and 18% in NQO1-negative tumors (P=0.06). Analysis of all 31 evaluable patients did not show a significant difference in progression-free survival (PFS) according to NQO1 status (P=0.26), but 3-mo PFS rate was numerically greater among NQO1-positive cases (40% versus 20%). **Conclusions:** ARQ 761 has clinical activity in NQO1-positive tumors. Principal toxicities include hemolytic anemia and methemoglobinemia. Combination studies are underway.

2518 Poster Discussion Session; Displayed in Poster Session (Board #10), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

A phase I trial of TRC102 (methoxyamine HCl) with temozolomide (TMZ) in patients with solid tumors and lymphomas. *First Author: Robert S. Meehan, Early Clinical Trials Development Program, DCTD, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: TRC102 inhibits BER by binding to abasic sites and acting as a topo II poison to cause DNA strand breaks; it potentiates the activity of alkylating agents including TMZ in murine models. In xenograft studies, TRC102 efficiently enhanced the antitumor effect of TMZ regardless of cell line genetic characteristics, e.g., O^6-methylguanine DNA-methyltransferase, mismatch repair (MMR), or p53 status. This is the first report for the expansion phase (the escalation phase was reported previously (ASCO2016)). **Methods:** We conducted a phase 1 trial of TRC102with TMZ in patients (pts) with refractory solid tumors. Eligibility criteria included adults that had progressed on standard therapy, ECOG PS of 0-2, and adequate organ function. TRC102 and TMZ were given orally days 1-5, in 28-day cycles. The pharmacokinetic and pharmacodynamic profile of TRC102 with TMZ was evaluated. Antitumor responses were determined using RECIST 1.1 criteria. The DNA damage response (DDR) markers γH2Ax, pNbs1, and Rad51 were evaluated in the expansion cohort at DL6, tested by previously described methods on paired tumor biopsies prior to and after the first course of therapy. **Results:** After the recommended Phase 2 Dose was defined as DL6 (TRC102 125mg, TMZ 150mg/m^2 D1-5), 15 pts were accrued to the expansion cohort between 9/2015 to 11/2016. A total of 52 pts were enrolled (37 escalation, 15 expansion). Grade 3/4 adverse events included neutropenia (13%), anemia (the DLT;10%), thrombocytopenia (7%), hemolysis (5%) or hypophosphatemia (3%). 4 pts had a partial response (PR) (NSCLC, ovarian (2), and colon); 13 pts had stable disease (SD), 29 progressive disease (PD), and 6 were not evaluable; three pts remain on study. 11/14 paired biopsies were suitable for analysis. Rad51 signal was induced in 6/11pts. One patient showed γH2Ax and 2 showed pNbs1 induction. 4/5 colon cancer specimens had evidence of DDR marker induction. **Conclusions:** The combination of TRC 102/TMZ is active with 4 PRs and 13 SDs, and the side effect profile is manageable. DDR markers were induced in 4 of 5 paired colon biopsies indicating DNA damage following treatment. A phase 2 trial of patients with colon cancer, NSCLC, and granulosa cell ovarian cancer is accruing. Clinical trial information: NCT01851369.

2519 Poster Discussion Session; Displayed in Poster Session (Board #11), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

A phase I study of PT-112 in advanced solid tumors. *First Author: Daniel D. Karp, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PT-112 is a novel platinum-pyrophosphate agent designed to avoid the toxicity and drug resistance mechanisms of conventional chemotherapy. Pre-clinical models show effects on multiple cell signaling components: p16 mediated G1/S cell cycle arrest; modulation of MDM2/p53 expression; extrinsic apoptosis initiation; and immunogenic cell death (ICD) induction. This Phase I first-in-human, multicenter, open label study assesses PT-112's safety and pharmacokinetic (PK) profile in advanced solid tumor patients (pts), to determine the RP2D and signals of activity. **Methods:** Pts with advanced solid tumors and acceptable marrow / organ function received PT-112 IV over 1-hr on days 1, 8, and 15 every 4 wks in a 3+3 dose escalation design. Intra-subject escalation was allowed. PK samples from cycles 1-2 were analyzed by ICP-MS and LC-MS/MS. **Results:** 44 pts have been treated across dose levels (DL) from 12-300mg/m^2. Cumulative dosing ranged from 1 to 60 infusions, and cumulative exposure from 96 to 5,244 mg/m^2. PK parameters were dose proportional. Target C_{max} and AUC levels were achieved, with constant V_D. DLTs were observed at 150mg/m^2 (G3 pancytopenia); 250mg/m^2 (G2 renal injury in a cervical ca pt with hydronephrosis); and 300mg/m^2 (G3 rash). The most common treatment-related AEs were G1-2 fatigue (26% pts), nausea (23%), vomiting (14%), constipation (12%), and diarrhea (12%). Numerous signals of activity were observed at DLs ≥ 125mg/m^2. These include a confirmed PR in a NSCLC pt with 6 prior lines of therapy and no response to TKI inhibition or PD-1 blockade; PFS > 6 months (7-18 months) in 3 pts; metabolic response via PET scan in bone and liver mets (basal cell and pancreatic ca.); biomarker responses in ovarian and prostate ca.; and nodal/metastatic volumetric reduction in 3 pts. **Conclusions:** PT-112 is a well-tolerated novel agent with a pleiotropic mode of action and feasibility for long-term and combination treatment. Numerous signals of anti-cancer efficacy in heavily pre-treated pts suggest lack of cross-resistance with conventional agents. MTD has not yet been reached. PT-112's profile makes it an attractive candidate for further development, including in combination with immunotherapy. Clinical trial information: NCT02266745.

GMI-1271, a novel E-selectin antagonist, in combination with chemotherapy in relapsed/refractory AML. *First Author: Daniel J. DeAngelo, Dana-Farber Cancer Institute, Boston, MA*

Background: GMI-1271 is a novel antagonist of E-selectin (E-sel) that down-regulates cell survival pathways and enhances chemotherapy response. We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC) for the treatment of patients (pts) with relapsed/refractory (R/R) AML. **Methods:** A phase (Ph) 1trial in pts with R/R AML escalated GMI-1271 across pharmacologically active doses from 5-20 mg/kg combined with MEC. Safety, tolerability and anti-leukemia activity were assessed. GMI-1271 was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction/consolidation. Eligible pts had an ECOG score 0-2, received ≤2 prior inductions, WBC < 20K (< 40K after 2 dose levels), no active CNS disease, and adequate renal/hepatic function. E-sel expression was assessed. After confirming safety and tolerability, a Ph 2 study of GMI-1271 at 10 mg/kg plus MEC was initiated. **Results:** To date, 47 pts have enrolled (Ph 1 = 19; Ph 2 = 28 of planned 47). The recommended Ph 2 dose is 10 mg/kg based on drug exposure, time over IC50 for E-sel binding, lack of DLT, and clinical outcomes. Ph1/Ph2 combined median age was 55yrs (range 26-84) with 70% male pts. Prior AML history included 26% primary refractory, 36% CR1 < 6 mos; 17% prior SCT; 55% unfavorable cytogenetics (by SWOG). Common Gr 3/4 AEs were febrile neutropenia (36%), sepsis (26%), bacteremia (13%), hypoxia (13%). 30 and 60 d mortality were 0 and 7%, respectively. ORR (CR/CRi/MLFS/PR) was 21/42 evaluable (50%). Remission rate (CR/CRi) was 45%. Observed/expected remission (CR/CRi) ratio was > 2.75 (Estey, Blood 1996). With a median follow-up of 11 mos, the Ph 1 median Leukemia Free Survival was not reached and Overall Survival was 7.6 mos. The median E-sel ligand binding at baseline was 35% of blasts (range, 1-75%) and was higher in those achieving remission. **Conclusions:** The addition of GMI-1271, a novel E-sel antagonist, to MEC chemotherapy is well tolerated with a high ORR, low induction mortality, and promising initial survival outcomes in pts with R/R AML. Furthermore, the baseline expression of E-sel ligand is predictive of response. Clinical trial information: NCT02306291.

2521 Poster Session (Board #13), Mon, 8:00 AM-11:30 AM

Dose escalation results from a first-in-human, phase 1 study of the glucocorticoid-induced TNF receptor-related protein (GITR) agonist AMG 228 in patients (Pts) with advanced solid tumors. *First Author: Ben Tran, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: AMG 228 is an agonistic human IgG1 monoclonal antibody that binds to GITR (CD357), a TNFSFR costimulatory molecule expressed by effector/regulatory T cells. Dose escalation of this open label, first in human, phase 1 study evaluated the safety, pharmacokinetics (PK), pharmacodynamics, and maximum tolerated dose (MTD) and recommended phase 2 dose of AMG 228 in pts with advanced solid tumors. **Methods:** Pts with refractory advanced colorectal cancer (n = 13), squamous cell carcinoma of head and neck (n = 10), non–small cell lung cancer (n = 2), urothelial transitional cell carcinoma (n = 4), and melanoma (n = 1) received AMG 228 IV Q3W. Dose escalation was in two stages: single-pt cohorts until AMG 228-related grade > 2 adverse events (AEs), efficacy, or 90 mg dose reached (4 cohorts: 3, 9, 30, and 90 mg), followed by rolling six design (n = 2 to 6) until MTD or highest planned dose of 1200 mg reached (5 cohorts: 180, 360, 600, 900, and 1200 mg). Primary endpoints included incidence of dose-limiting toxicities (DLTs) and AEs and PK. Additional endpoints were objective response (RECIST 1.1) and evidence of biological activity. **Results:** In total, 30 pts (median age 63 y) were treated (3, 9, 30, and 90 mg, n = 1; 180 mg, n = 6; 360 mg, n = 4; 600 mg, n = 6; 900 mg, n = 4; 1200 mg, n = 6). Twenty-seven (90%) pts had treatment-emergent AEs; the most common were hypophosphatemia (23%), fatigue (23%), anemia (23%), nausea (20%), and pyrexia (20%). No DLTs occurred; the MTD was not reached. AMG 228 exposure was dose-related, with PK profiles at low doses (3 to 90 mg) consistent with target mediated drug disposition; doses > 360 mg achieved serum levels needed for 95% receptor occupancy on activated PBMCs. No evidence of T cell activation was observed despite complete target coverage in both tumor and peripheral blood. Among 29 evaluable pts, none had an objective response. **Conclusions:** In this population of pts with advanced solid tumors, AMG 228 Q3W was tolerable up to the highest tested dose (1200 mg), showing favorable PK. However, no clinical or immunological activity was observed in this limited number of pts. Clinical trial information: NCT02437916.

2522 Poster Session (Board #14), Mon, 8:00 AM-11:30 AM

First-in-human phase 1/2 study of MCLA-128, a full length IgG1 bispecific antibody targeting HER2 and HER3: Final phase 1 data and preliminary activity in HER2+ metastatic breast cancer (MBC). *First Author: Maria Alsina, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: MCLA-128 is a novel IgG1 bispecific antibody with enhanced antibody-dependent cell-mediated cytotoxicity (ADCC) activity targeting HER2 and HER3 receptors. We report final phase 1 single agent escalation data, and safety and preliminary activity at the recommended phase 2 dose (RP2D). **Methods:** In the phase 1 part, patients (pts) with advanced solid tumors received MCLA-128 every 3 weeks (q3w) IV over 1-2 hr from 40 to 900 mg. In the phase 2 part, pts with selected metastatic indications were treated at the RP2D. Antitumor activity was assessed as per RECIST 1.1. Clinical benefit rate (CBR) was defined as CR + PR + SD ≥12 weeks. **Results:** As of January 2017, 28 advanced solid tumor pts were treated in the escalation part. No dose limiting toxicities were seen. The RP2D was established as 750 mg q3w (flat dose, corticosteroid premedication) based on safety and PK data. Fifteen pts with HER2 amplified tumors were treated at the RP2D (8 MBC, 4 gastric, 2 ovarian, 1 colorectal). Median age was 52 years (range 33-71), ECOG PS 0/1: 3/12, all ≥2 metastatic sites. The safety profile at the RP2D confirmed dose escalation data; the most common AEs were infusion related reactions in 6 pts (40%; G1-2 in 5 pts, G4 in 1 pt), and G1-2 diarrhea, rash, fatigue in 2 pts each (13%). No congestive heart failure or significant LVEF decreases occurred. The 8 MBC pts had a median 5.5 prior lines of metastatic therapy (range 4-14), all had progressed on 3 prior Her2 inhibitor therapies and received a median of 4.5 MCLA-128 cycles (range 2-12); 1 had a confirmed PR, 5 had SD (including 2 sustained, 11 and 12 cycles). SD was also seen in 2 evaluable MBC pts treated at 480 mg in the phase 1 part (7 and 4 cycles). Overall, CBR in these 10 MBC pts was 70%. Evaluation of other indications is ongoing. **Conclusions:** MCLA-128 showed a well tolerated safety profile. Consistent antitumor activity was seen in heavily pretreated MBC patients progressing on HER2 therapies. Further exploration of MCLA-128 based combinations with chemotherapy or trastuzumab in less pretreated MBC patients progressing after ≥2 prior Her2 inhibitors including TDM-1 is planned. Clinical trial information: NCT02912949.

2523 Poster Session (Board #15), Mon, 8:00 AM-11:30 AM

A phase I study of LY3022855, a colony-stimulating factor-1 receptor (CSF-1R) inhibitor, in patients (pts) with advanced solid tumors. *First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Binding of CSF-1 to the CSF-1 receptor (CSF-1R) results in proliferation, differentiation, and migration of monocytes/macrophages. Intratumoral infiltration with macrophages correlates with increased invasiveness, growth, and immunosuppression. LY3022855 (LY) is a human IgG1 antibody (mAb) targeting CSF-1R. **Methods:** Eligible pts (ECOG 0-2) with advanced solid tumors were enrolled. Mandatory pre and post-treatment biopsies were obtained. LY was given on a 6-week cycle. Two escalation regimens (Part A: weight-based dosing; Part B: flat dosing) were investigated in a 3+3 design. Primary objective was to establish the safety and characterize the pharmacokinetics (PK) of LY. Secondary objectives were to establish recommended phase 2 dose (RP2D) and to characterize pharmacodynamics (PD). **Results:** As of Sept 6, 2016, 35 cancer pts (colorectal 14; lung 4; pancreas 3; others 14) were treated (29 in Part A; 6 in Part B) with median treatment duration 4 weeks (range 1-21). Common treatment-emergent adverse events (TEAEs) were fatigue (54%), hypoalbuminemia (40%), nausea (37%), AST increase (37%), anemia (34%), anorexia (34%), creatine kinase elevation (29%), and constipation (23%). Most common grade (G) 3/4 TEAEs were anemia (11%), fatigue (11%), ascites (9%), and lymphocyte count decrease (9%). 3/28 evaluable pts had DLTs: G3 left ventricular systolic dysfunction (1), G4 rhabdomyolysis and G4 acute renal failure (1), and G3 pancreatitis (1). Eight treatment unrelated deaths were reported. One pt (adenoid cystic carcinoma) had stable disease (~3 mo as of last visit), 19 pts had progressive disease, and 15 pts were non-evaluable for response assessment. PK profile of LY was consistent with IgG1 mAbs. An interim analysis following completion of Part A demonstrated a lack of relationship between weight and clearance, prompting evaluation of non-weight based dosing. PD analyses revealed dose-dependent increases in serum CSF-1 levels as well as suppression of circulating non-classical monocytes ($CD14^{dim}$ $CD16^{bright}$), indicating biologic activity at studied doses. **Conclusions:** RP2D for LY monotherapy has been determined. Detailed PK and PD data will be presented. Clinical trial information: NCT01346358.

2524 Poster Session (Board #16), Mon, 8:00 AM-11:30 AM

Results of a phase Ib study of ARQ 092 in combination with carboplatin (C) plus paclitaxel (P), or with P in patients (pts) with solid tumors. *First Author: Nehal Lakhani, START Midwest, Grand Rapids, MI*

Background: ARQ 092 is an oral, potent AKT inhibitor with single agent antitumor activity. P or P+C is the standard therapy or the therapy of choice for pts with various solid tumors. ARQ 092 potentiated antitumor activity of P in in vivo xenograft models, providing the rationale for this study. **Methods:** This is an open-label, phase Ib study of ARQ 092+C+P (CP Arm) or ARQ 092+P (P Arm) in pts with advanced solid tumors to determine safety and tolerability of these 2 combinations. Blood samples are collected for PK. **Results:** Enrollment into CP Arm has been completed with 13 pts (15% male; median age 62 years, 4 ovarian, 9 others) being treated in 2 dose cohorts (see table and results below). Enrollment into P Arm is ongoing. Data from P Arm (80 mg/m2 weekly) will be presented during the meeting. In CP Arm, 3 DLTs were observed in 2 pts (both received ARQ 092 at 200 mg BID, 1 day/week) including grade (G) 4 neutrophil count decreased, G 4 thrombocytopenia and G 3 diarrhea. ARQ 092-related adverse events (AEs) in ≥10% pts included diarrhea 69%, fatigue 54%, hyperglycemia 31%, maculopapular rash 31%, nausea 23%, mucosal inflammation 23%, anemia 15%, platelet count decreased 15% and hypokalemia 15%. Paclitaxel- and/or carboplatin-related AEs in ≥10% pts included fatigue 77%, alopecia 62%, thrombocytopenia 39%, platelet count decreased 39%, nausea 31%, lymphocyte count decreased 31%, neutrophil count decreased 31%, white blood cell count decreased 31%, anemia 23%, mucosal inflammation 23%, hypomagnesaemia 23%, peripheral sensory neuropathy 23%, neutropenia 15%, vomiting 15% and hypokalemia 15%. Two ovarian pts previously treated with CP achieved complete response (mutant AKT) and partial response (AKT mutation unknown) respectively and 3 pts (Gastroesophageal, pancreatic, ovarian mixed mullerian) experienced stable diseases for >12 weeks. PK data will be presented during the meeting. **Conclusions:** Encouraging anticancer activity was demonstrated in heavily pretreated ovarian cancer pts, but full dose CP was not tolerated by most patients. Clinical trial information: NCT02476955.

Arm	ARQ 092	Carboplatin	paclitaxel	N
CP	200 mg BID, 1 day/week	AUC 6 Q3W	175 mg/m2, Q3W	10
CP	100 mg QD, 5 days on/5-6 days off	AUC 6 Q3W	175 mg/m2, Q3W	3

2525 Poster Session (Board #17), Mon, 8:00 AM-11:30 AM

Development of a population pharmacokinetic (PPK) model of intravenous (IV) trastuzumab in patients with a variety of solid tumors to support dosing and treatment recommendations. *First Author: Whitney Paige Kirschbrown, Genentech, Inc., San Francisco, CA*

Background: The aim of this analysis was to develop a PPK model for IV trastuzumab (Herceptin), to assess the impact of patient covariates on PK, and perform simulations to support dosing recommendations. **Methods:** Serum trastuzumab concentration data (26,040 samples) from 1582 patients with metastatic breast cancer (MBC), early breast cancer (EBC), advanced gastric cancer (AGC) or other tumor types, and 6 healthy volunteers in 18 Phase I, II, and III trials were analyzed using nonlinear mixed-effects modeling (NONMEM). Monte Carlo simulations were performed using the NONMEM PK parameter estimates (with variability) to inform dosing recommendations. **Results:** A two-compartment model with parallel linear and nonlinear elimination best described the data. Significant covariates ($P < 0.001$) influencing linear CL were baseline weight, SGOT, albumin, primary tumor type, and presence of liver metastases. MBC had similar PK parameters as EBC, with lower distributions of $C_{min,ss}$ in MBC explained by covariates. The higher linear CL in AGC patients resulted in a 30.5% lower $C_{min,ss}$. Simulations for drug washout indicated that 95% of patients with breast cancer (BC) reach trastuzumab concentrations < 1 μg/mL (~97% washout) at ≤7 months. Simulations also indicated that a missed dose of trastuzumab in BC or AGC patients of ≤1 week did not result in a long PK under-exposure (i.e. the trastuzumab concentration is within 15% of $C_{min,ss}$ by 3 weeks) but a missed dose of > 1 week took approximately 6 weeks to get back within the steady-state exposure range. **Conclusions:** Trastuzumab PK was well described by a two-compartment model with parallel linear and nonlinear eliminationacross cancer types, disease status, and regimens. No dose adjustment is required based on any of the identified patient covariates (e.g. weight, tumor type). Simulations using the PPK model informed the prescribing information for Herceptin; trastuzumab has a 7-month serum washout period during which patients should avoid an anthracycline-based therapy, pregnancy, or breastfeeding. A re-loading dose is required if a maintenance dose is missed by > 1 week to maintain serum concentrations.

2526 Poster Session (Board #18), Mon, 8:00 AM-11:30 AM

Phase I study of nab-paclitaxel, gemcitabine, and bevacizumab in advanced cancers. *First Author: Shiraj Sen, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Gemcitabine (gem) with nab-paclitaxel (nab-p) is known to have antitumor activity and a favorable toxicity profile. The addition of bevacizumab (bev) to nab-paclitaxel has also been found to enhance nab-paclitaxel cytotoxicity. **Methods:** We therefore performed a modified 3+3 dose escalation study with 15 dose levels of fixed dose gem 1000 mg/m^{2}IV (day 1, 8, 15) and escalating doses of nab-p IV (day 1,8, 15) and bev IV (day 1,15) every 28 days. The study design allowed for the possibility of multiple MTDs. Correlative studies on VEGF polymorphism and response were planned. (NCT01113476). **Results:** 103 patients (45 male) with advanced cancers were enrolled (19 ovarian, 18 pancreatic, and 18 gastroesophageal (GE) cancers among the most common). All patients were ECOG PS 0-2, median age was 60 years (range 17-85), and 51 patients (50%) were gem refractory with a median of 3 prior lines of therapy. 3 DLTs were observed during dose escalation - one with nab-p 50 mg/m^2 and bev 10 mg/m^2 (grade 3 dysphagia, dehydration), one with nab-p 75 mg/m^2 and bev 10 mg/m^2 (grade 3 cellulitis) and one with nab-p 150 mg/m^2 and bev 5 mg/m^2 (grade 3 bacteremia, hypotension). 2 DLTs were observed among the 13 patients in the nab-p 100 mg/m^2 and bev 5 mg/m^2 expansion cohort (one grade 3 diarrhea, one grade 3 fatigue) and 1 DLT among the 12 patients in the nab-p 75 mg/m^2 and bev 10 mg/m^2 expansion cohort (grade 3 rectal bleed). Dose escalation up to nab-p 125 mg/m^2 and bev 15 mg/m^{2}was well tolerated with no MTD. One patient with gem refractory peritoneal papillary carcinoma achieved a complete response, 13 patients (13%) had partial responses (PR), and 54 patients (52%) had prolonged stable disease (pSD) ≥ 12 weeks. 4 patients achieving PR and 26 patients with pSD were previously gem refractory. 3/6 (50%) small cell cancers achieved PR and all 6 of these patients had tumor shrinkage of at least 25%. 4/19 (21%) ovarian cancers achieved PR, 3/18 (17%) GE cancers achieved PR, and 1/18 (6%) pancreatic cancers achieved PR. **Conclusions:** The combination of gem 1000 mg/m^2, nab-p 125 mg/m^2 and bev 15 mg/m^2 is safe, well-tolerated, and has activity even at lower doses in advanced malignancies, including gem refractory tumors. Correlative VEGF polymorphism studies are ongoing. Clinical trial information: NCT01113476.

2527 Poster Session (Board #19), Mon, 8:00 AM-11:30 AM

A phase I study of carboplatin and talazoparib in patients with and without DNA repair mutations. *First Author: Mallika Sachdev Dhawan, University of California, San Francisco, San Francisco, CA*

Background: Talazoparib is a novel PARP inhibitor (PARPi) in clinical development. Synergistic anti-tumor effects of PARPi and chemotherapy have been observed in preclinical models. Overlapping toxicity may limit tolerability in patients with germline DNA repair defects. **Methods:** In a dose escalation Phase 1 trial, we tested the safety, tolerability, pharmacokinetics (PK), and efficacy of talazoparib and carboplatin in patients with and without germ line mutations. **Results:** 24 patients with solid tumors were enrolled in 4 cohorts evaluating talazoparib 0.75 or 1 mg daily and carboplatin AUC 1 or 1.5 mg/mL/min 2 or 3 weeks of a 3-week cycle. Dose-limiting toxicities included grade 3 fatigue and grade 4 thrombocytopenia. Other grade 3/4 toxicities included fatigue (13%), neutropenia (63%), thrombocytopenia (29%), and anemia (38%). Post cycle 2 hematologic toxicities required dose delays/reductions in all patients. One complete and two partial responses occurred in germline BRCA1/2 (gBRCA1/2) patients. Of the 4 patients with stable disease beyond 4 months, 3 had somatic BRCA mutations and 1 had a BRIP1 germline mutation suggesting greater benefit in tumors with DNA repair mutations. PK-toxicity modeling suggests that after 3 cycles of carboplatin AUC 1.5 weekly and talazoparib 1 mg daily, the percent decrease in neutrophil counts from baseline was significantly more pronounced in gBRCA carriers; -78% (95% CI: -87 to -68%) vs. non-carriers; -63% (95% CI: -72 to -55%), p-value < 0.001. This modeling also showed that 2-4 fold dose reductions for each drug are needed to improve tolerability of this combination. Pulse dosing of talazoparib may be more tolerable in gBRCA carriers. **Conclusions:** The combination of carboplatin and talazoparib showed responses in gBRCA carriers but also had increased hematologic toxicity in gBRCA carriers. PK toxicity modeling was used to determine alternate dosing strategies based on carrier status. Clinical trial information: NCT02317874.

2528 Poster Session (Board #20), Mon, 8:00 AM-11:30 AM

Effect of target lesions selection on between-reader variability of response assessment according to RECIST 1.1. *First Author: Christiane K. Kuhl, University of Aachen, RWTH, Aachen, Germany*

Background: Response-classification-systems, e.g. RECIST1.1, and dedicated oncology software-tools (DOST) are used to standardize response assessment. Expectation is that different readers should yield the same response-classification for any given patient. We investigated real-life variability between readers who, as in clinical practice, were free to select target-lesions (TL). **Methods:** Prospective study on 316 patients with metastatic disease who underwent 932 CT-studies, yielding a total 616 follow-up occasions (baseline vs. follow-up) for analysis. All CT-studies were independently evaluated by 3 radiologists who used state-of-the-art DOST (MintLesion). Readers were free to select TL in the respective baseline study, and did so independently. Kappa-statistics were used to analyse agreement for RECIST1.1 response-class-assignment depending on whether readers had selected the same or different TL.To investigate possible impact on treatment decisions, agreement was also determined after aggregating response classes into progressive (PD) vs. non-progressive (CR/PR/SD). **Results:** Readers used the same TL in 38.6 (238/616), different in 61.4% (378/616). Where readers happened to select the same TL, agreement was "almost perfect" (κ = 0.966 [96%-CI: 0.912–1.00] for assignment of individual response-classes, and 0.977 [0.898–1.0] for the distinction progressive-vs-non-progressive). Where readers had selected different TL, agreement was only "moderate" (0.583 [0.541–0.624] for individual response-class-assignment, and 0.644 [0.587 to 0.701] for distinction progressive-vs.-non-progressive). Choice of the same TL was associated with agreement for distinction between progressive-vs.-non-progressive-disease in 97.7 % [95.4%–100.0%] of patients; choice of different TL was associated with disagreement in 44.7% [37.6%–51.8%]. **Conclusions:** If different radiologists use RECIST1.1 and DOST for response assessment, they will select different TL more often than not. Just depending on whether TL selection was concordant or not, radiologists will exhibit perfect agreement, or substantial disagreement, even for distinguishing progressive vs non-progressive disease.

2529 Poster Session (Board #21), Mon, 8:00 AM-11:30 AM

Deflexifol (a novel formulation of 5FU): Phase 1 dose escalation study of infusional and bolus schedules after failure of standard treatment. *First Author: Philip R. Clingan, Southern Medical Day Care Centre, Wollongong, Australia*

Background: 5-Fluorouracil (5FU) is administered in combination with leucovorin (LV) to enhance clinical activity. However, simultaneous administration is not feasible as 5FU and LV are chemically incompatible, so the maximum possible interaction for benefit is not achieved Deflexifol, an all in one formulation of 5FU/LV with cyclodextrin (HP-β-CD 100mg/ml, 5-FU 15mg/ml & LV 1mg/ml) at physiological pH, was developed to improve efficacy and tolerance. **Methods:** A phase I dose-escalation trial to assess the safety, tolerability, MTD and DLT of Deflexifol given in two schedules has been completed. Secondary objectives included the pharmacokinetic (PK) profile and efficacy outcomes. Cohorts of patients with advanced malignancy after failure of standard treatment received Deflexifol as 46-h infusion Q2W or bolus weekly x6 in a standard 3+3 phase I design with no intra-patient dose escalation from dose level 1: 375mg/m² bolus or 1200mg/m² infusional up to dose level 5: 575mg/m² bolus or 3600mg/m² infusional. PK sampling of 5FU and dihydroFU was conducted on all patients to assess PK variability and adequacy of dosing. **Results:** 40 patients (21 infusional, 19 bolus) with breast (7), colorectal (24), other GI (6) & NSCLC (3) received a total 293 courses of treatment. No > grade 1 toxicity was noted at 375-475 mg/m^2 bolus, or at 1200-2400 mg/m^2 infusion. The DLT in bolus schedule was grade 3 diarrhea and myelosuppression at 575 mg/m^2, with no DLT in the infusion schedule at the maximum dose 3600 mg/m^2. The MTD have been established for both treatment arms: bolus 525mg/m²; 46-h infusion 3,600mg/m², with no grade IV toxicity observed. Other grade 3 toxicities were nausea, vomiting, and raised liver function tests. 5FU PK in this mixture is similar to 5FU alone. Encouraging efficacy results were seen with partial response in 1 patient and stable disease in 23 patients. Median PFS was (12.3 wks) and OS was (24.8 wks). **Conclusions:** Deflexifol has little toxicity and is effective in bolus and infusion schedules at doses equal to or greater than those feasible with 5FU and LV infused separately. A first-line phase II study in combination with oxaliplatin is planned. Clinical trial information: 044867.

2530 Poster Session (Board #22), Mon, 8:00 AM-11:30 AM

Deflexifol (a novel formulation of 5FU): Pharmacokinetics in a phase 1 trial in comparison to 5FU. *First Author: Stephen P. Ackland, University of Newcastle, Callaghan, Australia*

Background: Simultaneous administration of 5-fluorouracil (5FU) and leucovorin (LV) is generally not feasible as 5FU and LV are chemically incompatible (CaPO4 crystals), so the maximum possible interaction for benefit is not achieved. Deflexifol, an all in one formulation of 5FU/LV with cyclodextrin (HP-β-CD 100mg/ml, 5-FU 15mg/ml & LV 1mg/ml) at pH 7, was developed to overcome this problem. **Methods:** Limited sampling PK was done with dose 1 and 6 in a standard 3+3 phase I trial of Deflexifol given in two schedules (46-h infusion Q2W or bolus weekly x6) with no intrapatient dose escalation, at doses shown in Table. Sample times were infusion: 0, 2, 46h; bolus: 0, 0.2, 0.4, 1, 24h. 5FU and dihydroFU were measured as per Ackland et al, Anal Biochem 1997. 5FU AUC, clearance (CLR) and t1/2 were estimated for each patient to assess PK variability and adequacy of dosing compared to previous reports. **Results:** 40 patients were treated (21 infusion, 19 bolus, median age 67, 19 M, 21 F). The MTD(bolus) was 575 mg/m^2, with no DLT in infusion schedule to 3600 mg/m^2. PK showed substantial inter-patient variability – CLR(bolus) 21-900 L/h, t1/2 0.11-0.52 h, with intra-patient dose 6 CLR = 54-117% of dose 1, and a trend to increased AUC (mg/L.h) with dose (Table). Infusion CLR and AUC estimates were highly variable (CLR range 2-1200), with many cases with insufficient data. Compared to historical data with 5FU alone, AUC was likely subtherapeutic until 475mg/m^2 bolus and for many patients with infusion <3000mg/m^2. **Conclusions:** 5FU PK with Deflexifol is similar to 5FU alone. No evidence of saturation of kinetics over this dose range was seen, or induction of metabolism with repeated dosing. In each schedule AUC data supports the clinical impression of reduced toxicity at the same dose of 5FU. Accurate estimation of infusion PK requires more than 2 timepoints. PK in a phase II study is planned. Clinical trial information: 044867.

2531 Poster Session (Board #23), Mon, 8:00 AM-11:30 AM

A phase I dose escalation study of SCB01A, a micro-tubular inhibitor with vascular disrupting activity, in patients with advanced solid tumors refractory to standard therapy. *First Author: Nai-Jung Chiang, National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan*

Background: SCB01A is a novel anti-microtubular agent with vascular disrupting activity. The Phase I study aimed to determine the dose-limiting toxicity (DLT), maximum tolerated dose (MTD), safety, and pharmacokinetic (PK) profiles of SCB01A in patients with advanced solid tumor. **Methods:** This was an open-label, phase I clinical trial with a rapid titration followed by a 3 x 3 study design. Eligible patients would receive a 3-hr intravenous infusion of SCB01A, every 21 days as one cycle. All adverse events were classified according to the CTCAE V4.0. DLT was defined as the occurrence of grade 3 with complications and grade 4 hematoloigcal, or ≥grade 3 non-hematological toxicities. **Results:** From June 2011 to November 2015, a total of 33 eligible patients were enrolled to eight dose levels: 2 mg/m^2 (n = 1), 3 mg/m^2 (n = 1), 4 mg/m^2 (n = 6), 6.5 mg/m^2 (n = 9, with 3 additional subjects were recruited for safety concern), 10 mg/m^2 (n = 3), 16 mg/m^2 (n = 3), 24 mg/m^2 (n = 6) and 32 mg/m^2 (n = 4). Six episodes of DLTs were observed in 5 patients (each one in dose levels of 4/6.5/24 mg/m^2 and two in dose level of 32 mg/m^2), including grade 4 blood creatine phosphokinase elevation (4 mg/m^2), grade 3 gastric hemorrhage (6.5 mg/m^2), grade 2 venous thrombosis (24 mg/m^2), grade 3 peripheral neuropathy manifested as weakness of lower limbs, grade 3 aspartate aminotransferase elevation, and grade 3 hypertension (32 mg/m^2). The MTD was determined to be 24 mg/m^2. Pharmacokinetic profiles revealed a linear AUC-dose response with an average elimination half-life ($t_{1/2}$) of 2.5 hours. Partial response was observed in one subject with buccal cancer. A total of 57.6% (19/33) subjects had stable disease for at least 2 cycles. **Conclusions:** SCB01A is safe and tolerable in patients with solid tumor. The MTD of SCB01A is 24 mg/m^2 every 21 days, which deserves further development. Clinical trial information: NCT011159522.

2532 Poster Session (Board #24), Mon, 8:00 AM-11:30 AM

Phase 1/2a trial of daily oral BAL101553, a novel tumor checkpoint controller (TCC), in advanced solid tumors. *First Author: Rebecca Sophie Kristeleit, University College London, London, United Kingdom*

Background: BAL101553 (prodrug of BAL27862) is a small molecule TCC that binds microtubules and promotes tumor cell death by activation of the spindle assembly checkpoint. In a previous study (NCT01397929, Lopez et al. JCO 34, 2016; abstr 2525), 2-h IV infusion on Days 1, 8, 15 (q28d) of BAL101553 up to 80 mg/m^2 (maximum administered dose, MAD) showed vascular toxicities, including transient hypertension, which appeared to be C_{max} related. The recommended Phase 2 dose (RP2D) was 30 mg/m^2 weekly IV. Based on nonclinical models, antiproliferative effects of BAL27862 are driven by AUC. This trial explores whether once daily oral administration of BAL101553 reduces C_{max}-related toxicity and improves the therapeutic window (NCT02490800). **Methods:** Patients (pts) with advanced solid tumors who failed standard therapy, received QD oral BAL101553 (28-d cycles) in a 3+3 dose-escalation design to determine the MTD. Adverse events were assessed by CTCAEv4 grade (G); tumor response by RECIST 1.1; serial PK on Day 1 of Cycles 1 and 2. **Results:** In the ongoing study, 19 pts (9M/10F; median age 67 y) received doses of 2, 4, 8, 16 or 30 mg oral BAL101553 QD. The MAD was 30 mg with DLTs of reversible G2 hallucination and asymptomatic, reversible G3 electrolyte imbalances. No DLTs were observed at ≤ 16 mg. Dosing is ongoing between 16 and 30 mg QD to determine the MTD. BAL27862 exposures after oral QD dosing of BAL101553 compared to weekly 2-h infusions suggested high relative oral bioavailability. The BAL27862 weekly AUC at the oral MAD (30 mg QD) compared to the RP2D of 30 mg/m^2 for 2-h IV was more than 5-fold higher (19,656 vs 3,584 ng*h/mL) and C_{max} was 1.5-fold lower (171 vs 266 ng/mL). Both $C_{max}$and AUC were dose-proportional, with low/moderate variability. Oral BAL101553 had no effects on blood pressure and showed no vascular toxicity. 5 pts had stable disease (2 pts [cholangiocarcinoma, neuroendocrine pancreatic cancer] > 4 cycles). **Conclusions:** Daily oral BAL101553 enables higher weekly exposures of BAL27862 with lower C_{max} levels compared with a 2-h weekly infusion, due to the absence of C_{max} related vascular toxicity. Doses up to 16 mg QD are well tolerated. The MAD has been identified as 30 mg QD; definition of the MTD is ongoing. Clinical trial information: NCT02490800.

2533 Poster Session (Board #25), Mon, 8:00 AM-11:30 AM

Representation of minorities in oncology clinical trials: Review of the past 14 years. *First Author: Narjust Duma, Mayo Clinic, Rochester, MN*

Background: Many cancer clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained. Therefore, we determined the representation of ethnic minorities in oncology CT. **Methods:** Enrollment data from all therapeutic trials reported as completed in clinicaltrial.gov from 2003 to 2016 were analyzed. CT in rare cancers (< 1% incidence) or with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 SEER database cancer prevalence. Chi-square test was used to estimate differences in categorical data. **Results:** Out of 1,012 CT, 310 (31%) reported ethnicity with a total of 55689 enrollees. Distribution by race and comparison with data from 1996-2002, US cancer prevalence and US census are described in the Table. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 1.2%) than African Americans (EF of 0.7%, $p < 0.001$) and Hispanics (EF of 0.4%, $p<0.001$). A decrease in African Americans (AA) and Hispanics (H) enrollment was observed when compared with historical data from 1996 to 2002. Hispanics were less represented in breast and prostate cancer CT contributing only to 3% and 1.5% of the study population; African Americans were less represented in lung (5.4%) and renal cell carcinoma (3%) trials. Asians were well represented and their recruitment doubled over the past 14 years (2% vs 5.3%). **Conclusions:** African Americans and Hispanics were less likely to be enrolled in CT. Comparing with historical data; we observed a decrease in minorities' recruitment in the past 14 years. This change could be attributed to the increased complexity of CT and mandatory molecular testing as many minorities lack access to institutions with genetic testing capacity. Future trials should take extra measures to recruit participants that adequately represent the U.S. cancer population.

Race/ethnicity	Trials participants No. (%)	1996-2002 trial participants %	2013 cancer prevalence %	2010 U.S. Census %
NHW	46431 (83)	85.5	79	66
AA	3270 (6)	9.2	10	12.6
H	1484 (2.6)	3.1	7	16
Asian	2982 (5.3)	2	3.3	4.8
Native American	190 (0.3)	0.2	0.3	0.6
Other	1332 (2.4)			

2534 Poster Session (Board #26), Mon, 8:00 AM-11:30 AM

Validation of RECIST 1.1 for use with cytotoxic agents and targeted cancer agents (TCA): Results of a RECIST Working Group analysis of a 50 clinical trials pooled individual patient database. *First Author: Saskia Litière, European Organisation for Research and Treatment of Cancer, Brussels, Belgium*

Background: The Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 were derived from an international collaborative effort supported by data from clinical trials (16 studies, 9147 patients) on cytotoxic chemotherapy (CT), providing a standard tool for response assessment. RECIST's role has been questioned for TCA. Using a pooled individual patient database (IPD) from clinical trials performed by industry and cooperative groups, we assessed whether modifications to RECIST are required to evaluate antitumor activity of TCA. **Methods:** Data were collected from phase 2 and 3 clinical trials testing TCA in solid tumors. To study the occurrence of mixed responses, the variability of response of lesions within patients was studied. Furthermore, response was correlated with survival through landmark analyses and time dependent Cox models. **Results:** Clinical data were obtained from 23,259 patients, mainly with lung (36%), colorectal (28%) or breast cancer (11%). 15,620 patients (67%) received a TCA, mainly transduction or angiogenesis inhibitors, either as single agent (37%) or combined with other TCAs (7%) or CT (56%); 28% received CT only and 5% best supportive care or placebo. Within-patient variability reduced as the number of lesions used for response assessment increased, and did so similarly for TCAs (+/- CT) and CT. Mixed responses seemed to occur similarly across these treatment categories as well. Landmark analyses showed improving overall survival by % tumor shrinkage and a clear distinction between the effect of tumor shrinkage and progressive disease (PD) according to RECIST 1.1. This was confirmed by time dependent analysis. In addition target lesion growth showed no marked improvement in overall survival prediction over and above the other components of RECIST 1.1 PD (new lesions, non-target PD), regardless of treatment (TCA, CT or both) received. Similar results were seen focusing on major tumor types and classes of TCA. **Conclusions:** Using a large IPD dataset we demonstrated that RECIST 1.1 performs equally well for response assessment of TCA as for CT. No modifications are required.

2535 Poster Session (Board #27), Mon, 8:00 AM-11:30 AM

Food effect studies and drug label recommendations: A review of recently approved oncology products. *First Author: Mark Farha, AstraZeneca, Waltham, MA*

Background: Evaluation of the effect of food on the pharmacokinetics of orally administered oncology drugs is a critical aspect of drug development, as food can mitigate or exacerbate toxicities and can change and influence variability in systemic exposure. Our aim in this review of approved oncology products is to describe the approaches used by sponsors to assess food effect and decide on the final dosing recommendations. **Methods:** Data for small molecule oncology drugs approved between 2003-2016 was extracted from the clinical pharmacology review in the sponsor's FDA submission package. Information on food-effect study design, outcomes, intersubject variability, exposure-response relationships for safety, and the label dosing recommendation regarding food was analyzed. **Results:** Of the 29 drugs analyzed, 19 food effect studies were conducted in healthy volunteers, and 10 were conducted in cancer patients. The ratio of population geometric means between fed and fasted treatments fell outside the 80-125 percent equivalence limit in 55% of compounds for AUC and in 69% of compounds for Cmax. 6 drugs (21%) are recommended to be given with food, 11 drugs (38%) in the fasted state, and 12 drugs (41%) can be dosed regardless of food. Label recommendations appeared to be driven by the exposure-response analysis. 80% of drugs with a fasted label recommendation despite an increase in bioavailability with food had an exposure-response relationship for safety. **Conclusions:** Optimizing study design by conducting early food effect studies designed to estimate food effect rather than confirming no food effect, and learning the impact of food early may eliminate unnecessary study arms and save sponsors money and time. Furthermore, understanding the potential of food to mitigate or exacerbate toxicities may improve patients' experience with treatments and has been shown here to be a major driver of the final dosing recommendation regarding food.

2536 Poster Session (Board #28), Mon, 8:00 AM-11:30 AM

A call for global harmonization of phase I oncology trials: Results from two parallel, first-in-human phase I studies of DS-7423, an oral PI3K/mTOR dual inhibitor in advanced solid tumors conducted in the United States and Japan. *First Author: Tomoya Yokota, Shizuoka Cancer Center, Shizuoka, Japan*

Background: The aim of this study was to determine the safety, maximum-tolerated dose (MTD), pharmacokinetics (PK), pharmacodynamics (PD) and efficacy of DS-7423, a novel inhibitor of PI3K/mTOR, in US and Japanese population. We further compared toxicities and recommended phase 2 dose (RP2D) of DS-7423 and approved oncology drugs in the two populations. **Methods:** We conductedparallel, first-in-human studies in US and Japan in patients with advanced solid tumors. We conducted a Pubmed search of pivotal and corresponding phase I studies to compare the RP2D and final approval doses of molecularly targeted agents (MTA) between US and Japan. **Results:** 69 patients were enrolled (n = 42 from US and n = 27 from Japan). Between populations, the only difference at baseline was body weight (BW) and body mass index (BMI). Dose-limiting toxicities included grade 3 rash (48 mg), grade 3 stomatitis (240 mg), grade 3 lung infection (240 mg), grade 4 hyperglycemia (240mg), grade 3 fatigue (320 mg), and grade 3 dehydration (320mg). The MTD and RP2D was 240 mg/d in both populations. Frequent treatment-related adverse events included diarrhea, fatigue, decreased appetite, rash, and stomatitis. No remarkable difference in AUC and Cmax were observed between populations. Prolonged stable disease was seen in cholangiocarcinoma, thymic cancer, non-small cell lung cancer, squamous cell carcinomas, carcinoid, and sarcoma. DS-7423 demonstrated PD effects on serum glucose, C-peptide and Akt phosphorylation and 18F-FDG uptake in tumors. The final RP2D of 17 MTA approved in US and Japan from 2001 to 2015 was near identical. The approved doses in both regions were identical. **Conclusions:** Despite differences in BW, BMI, and ethnicity, DS-7423 showed no difference in PK, PD, toxicity or efficacy between populations. We found near identical RP2D in phase I oncology studies and approved doses in pivotal studies. This supports increased international collaboration in the conduct of phase I oncology trials. Clinical trial information: NCT01364844, Japic CTI, 12766.

2537 Poster Session (Board #29), Mon, 8:00 AM-11:30 AM

Hormone receptor (AR/ER/PR) expression as a prognostic marker and novel candidate for drug development across multiple tumor types. *First Author: Shiraj Sen, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hormone receptor (HR) [androgen receptor (AR), estrogen receptor (ER), progesterone receptor (PR)] expression is ubiquitous across tumor types and central to breast and prostate cancer treatment. While implicated in tumorigenesis, its role as a prognostic biomarker and therapeutic target in other tumor types has yet to be elucidated. **Methods:** We performed bioinformatic analyses of HR expression [reported as median transcripts per million (TPM)] using RNAseq from the Cancer Genome Atlas and completed Kaplan-Meier analyses to identify associations between HR expression and median overall survival (OS). **Results:** 9,743 samples from 9,674 patients across 33 tumor types were analyzed. AR was highly expressed in GBM (2 TPM), low grade glioma (2 TPM), breast (15 TPM), prostate (14 TPM), ovarian (6 TPM), renal clear cell carcinoma (4 TPM) and HCC (2 TPM) . Tumors with the highest quartile of expression had improved OS in renal clear cell [53 months (mo) vs not reached (NR), $p = 4x10^{-11}$] and adrenocortical carcinoma (45 mo vs NR, p = .03) and worse OS in low grade glioma (119 vs 64 mo, $p = 6x10^{-4}$). PR was highly expressed in uterine (12 TPM), breast (5 TPM), and renal chromophobe (2 TPM) carcinoma. PR expression was associated with improved OS in sarcoma (49 mo vs NR, p = .03), endometrial (NR, p = .02) and renal clear cell carcinoma (58 mo vs NR, p = .003) and worse OS in low grade glioma (53 vs 97 mo, p = .01), gastric adenocarcinoma (7 vs 17 mo, p = .04), and possibly pancreatic adenocarcinoma (21 vs 44 mo, p = .07). ER was highly expressed in breast (116 TPM), endometrial (87 TPM), ovarian (32 TPM), cervical (4 TPM), thyroid (4 TPM), prostate (3 TPM), and lung adenocarcinoma (2 TPM). ER expression was associated with improved OS in mesothelioma (15 vs 28 mo, p = .03) and endometrial cancer (NR, p = .001) and worse OS in squamous lung cancer (80 vs 48 mo, p = .02). **Conclusions:** HR expression may represent a novel prognostic marker in multiple tumor types and a candidate for drug development in low grade glioma, gastric adenocarcinomas, squamous cell lung cancer, and pancreatic adenocarcinomas. Protein-based IHC testing and early phase clinical trials targeting HR signaling in these tumor types is warranted.

2538 Poster Session (Board #30), Mon, 8:00 AM-11:30 AM

Large scale adverse event data mining for targeted therapies development. *First Author: Mayur Sarangdhar, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Targeted anti-cancer small molecule drugs & immune therapies have had a dramatic impact in improving outcomes & the approach to clinical trials. Increasingly, regulatory approvals are expedited with small studies designed to identify strong efficacy signals. However, this may limit the extent of safety profiling. The use of large scale/big data meta-analyses can identify novel safety & efficacy signals in "real-world" medical settings. **Methods:** We used AERSMine, an open-source data mining platform to identify drug toxicity signatures in the FDA's Adverse Event Reporting System of 8.6 million patients. We identified patients (n = 732,198) who received either traditional and targeted cancer therapy & identified therapy-specific toxicity patterns. Patients were classified based on exposures: anthracyclines (n = 83,179), platinum (117,993), antimetabolites (93,062), alkylators (81,507), antimicrotubule agents (97,726), HER2 inhibitors (40,040), VEGFis (79,144), VEGF-TKis (90,734), multi TKis (34,457), anaplastic lymphoma Kis (7,635), PI3K-AKT-mTOR inhibitors (33,864), Bruton TKis (9,247), MEKis (4,018), immunomodulatory agents (174,810), proteasome inhibitors (44,681), immune checkpoint inhibitors (20,287). Pharmacovigilance metrics [Relative Risks & safety signals] were used to establish statistical correlation & toxicity signatures were differentiated using the Kolmogorov–Smirnov test. **Results:** To validate the use of the AERSMine to detect AEs, we focused on cardiotoxicity. It identified classic drug associated AEs (e.g. ventricular dysfunction with anthracyclines, HER2is & VEGFis; VEGFi hypertension & vascular toxicity; multi TKIs vascular events). AERSMine also identified recently reported uncommon toxicities of myositis/myocarditis with immune checkpoint inhibitors. It indicated a higher frequency of myositis/myocarditis with combination immune checkpoint therapy, paralleling industry corporate safety databases. These toxicities were reported at higher frequencies in patients > 65 yrs. **Conclusions:** AERSMine "big data" analyses provide a sensitive tool to detect potential new patterns of AEs simultaneously across multiple clinical trials & in the real-world setting.

2539 Poster Session (Board #31), Mon, 8:00 AM-11:30 AM

FDA analysis of patient enrollment by region in clinical trials for approved oncological indications. *First Author: Bindu Kanapuru, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Clinical trials are increasingly conducted on a global scale in an effort to accelerate accrual. This analysis attempts to quantify and characterize participants in trials submitted to support approval of drugs for oncology indications by the region of enrollment. **Methods:** Demographic information was extracted for patients enrolled in clinical trials submitted to the FDA from 2005-2015. Only trials submitted to support approval for malignant solid tumor or hematology indications were included. Countries were grouped into regions for further analysis. A total of 178,024 patients with information regarding age and country were included in this analysis. **Results:** Forty five percent (80,460) of clinical trial participants were enrolled from Europe, 36% (63,958) from North America (includes U.S.A and Canada) and 8.4% (14,975) from Asia. Countries in Latin America, Middle East/Africa and the Baltic States/Russia enrolled the remainder 10.5% of the patients. Among 99,556 participants < 65 years of age; 38.7% (38,538) were enrolled from North America, 40.5% (40,362) from Europe, 9.7 % (9674) from Asia and 11% from the rest of the regions. Europe enrolled the highest number of cancer patients aged 65 years or older; 51.1% (40,098) compared to 32.4% (25,420) from North America and 6.8 % (5301) from Asia. **Conclusions:** Majority of patients enrolled into clinical trials submitted for oncology drug approvals were from regions other than North America, with highest number enrolled from Europe particularly in the older age group. While it is interesting to speculate, the reasons for differential enrollment of patients between Europe and North America and the impact of these findings on interpretation of clinical trial results need additional exploration. Analysis of trends over time may be useful to address this issue.

	North America	Europe	Latin America	Middle East and Africa	Asia	Baltic states and Russia
Total N (%)	63,958 (36.0)	80,460 (45.0)	7788 (4.4)	3237 (1.8)	14,975 (8.4)	7606 (4.3)
Age < 65 yrs. N (%)	38,538 (38.7)	40,362 (40.5)	3761 (3.8)	1940 (1.9)	9674 (9.7)	5281 (5.3)
Age ≥65 yrs. N (%)	25,420 (32.4)	40,098 (51.2)	4027 (5.1)	1297 (1.7)	5301 (6.8)	2325 (3.0)

2540 Poster Session (Board #32), Mon, 8:00 AM-11:30 AM

Suitability factors of core needle biopsies for pharmacodynamic (PD) studies. *First Author: Ralph E. Parchment, Laboratory of Human Toxicology and Pharmacology, Applied/Developmental Research Directorate, Leidos Biomedical Research, Inc., Frederick National Laboratories, Frederick, MD*

Background: There are different requirements of biopsies for diagnosis vs. pharmacologic evaluation of drug mechanism biomarkers. Evaluation of core needle biopsy pairs collected pre-dose and at a defined timepoint post-dose provides insight into the pharmacodynamics of agents in early development. Adequate biopsies are key for quantifying response of the tumor cell population to molecular drug action. Tumor heterogeneity and variable tumor content make many biopsy pairs unsuitable for biomarker evaluation with any assay platform (microscopy, immunoassay, etc.). We analyzed biopsies obtained from the Developmental Therapeutics Clinic (DTC) for suitability for PD assays. **Methods:** Specimens obtained from 2010-2016 across 4 trials were analyzed. For microscopy measurements, biopsy pairs collected using image guidance are snap-frozen, thawed under fixative, and embedded in paraffin with control tissues. The likelihood of finding optimal regions for analysis is maximized by preparing a series of sections with H&E stained flanking slides, and annotation by an anatomic pathologist. **Results:** Of 112 biopsies evaluated, 26% were found to contain $<$ 5% tumor, making them inadequate for quantitative microscopy due to a mixture of factors, with the primary factor being predominantly non-neoplastic tissue, followed by extensive mucin content, necrosis, fibrosis, inadequate size and tissue artifact post-collection. Another 20% contained $\leq$25% tumor, and in this group, tumor segmentation methodology during image analysis increased the rate of evaluable biopsies. 56% of tissues had $>$ 25% tumor and were suitable for analysis. **Conclusions:** Improved communication between oncologists, radiologists and pathologists is key to a better understanding of factors that affect suitability of biopsies for robust PD biomarker analyses. NCI's DTC has implemented protocol modifications including increased tissue collection and frequent case reviews by the Phase 1 team, interventional radiologists and PD team aimed at understanding features during image guidance that relate to suitability. Implementation of a scoring system has allowed the assessment of suitability of biopsies for analysis. Funded by NCI Contract No HHSN261200800001E.

2541 Poster Session (Board #33), Mon, 8:00 AM-11:30 AM

FDA analysis of MRD data in hematologic malignancy applications. *First Author: Nicole Gormley, U.S. Food and Drug Administration, Silver Spring, MD*

Background: There is considerable interest in the use of minimal residual disease (MRD) in clinical trials of hematologic malignancies, especially as a potential surrogate endpoint to expedite drug approval. Although surrogacy has not yet been established in most hematologic malignancies (except CML), MRD data has been submitted in applications to the agency to allow for further characterization of the product's activity. Here we describe the new drug applications (NDA) or biologics licensing applications (BLA) that included MRD data and provide an analysis of the MRD data and the Agency's decisions. **Methods:** The authors reviewed internal databases for all original and supplemental NDA and BLA applications submitted to the Division of Hematology Products (DHP) between 2014 and 2016 that pertained to malignant hematologic conditions. The applications were reviewed for inclusion of MRD data. The clinical reviews and prescribing information (PI) of the identified applications were reviewed for assessment of MRD data and FDA's findings. **Results:** There were 34 NDAs or BLAs submitted between 2014-2016. Of these, 13 (38%) included MRD data, in the following diseases: CML, CLL, ALL, and MM. MRD data was added to the PI in 6 cases (46%), not included in 4 (31%), and was not proposed for inclusion in 3 (23%). Among the 6 cases in which MRD data was included in the PI, 5 used PCR testing and 1 used flow cytometry. Among the 4 in which MRD data was not included in the PI, the identified issues included: missing data among those in CR, incomplete test performance characteristics data (e.g.-limit of detection), disparate sample sources (blood, bone marrow), high amount of test failure rates (i.e.-inability to identify a clonal rearrangement), lack of test validation in the proposed disease setting, and inappropriate planned statistical analyses. **Conclusions:** Nearly 40% of applications submitted to DHP between 2014 and 2016 included MRD data. While the data submitted was deemed adequate for inclusion in the PI in 46% of cases, 31% of applications contained MRD data that the Agency deemed un-interpretable. Data collection and assay performance characteristics should be of significant rigor and completeness to allow for comprehensive review.

2542 Poster Session (Board #34), Mon, 8:00 AM-11:30 AM

Adherence to novel oral anticancer therapies in the phase I setting: The Royal Marsden experience. *First Author: Maxime Chenard-Poirier, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: The use of oral anticancer therapies has increased substantially in recent years. Nonadherence can impair the efficacy of such therapies as well as confound the interpretation of toxicity and pharmacokinetic data in phase I trials. However, there is a paucity of data regarding adherence patterns and barriers in this specific setting. **Methods:** We included patients treated in Phase I trials involving oral investigational medicinal products (IMPs) in the Drug Development Unit, Royal Marsden Hospital, UK, between 2012 and 2014. Patient, disease and treatment characteristics as well as compliance data from prospectively collected trial diary cards and drug accountability were recorded. Relationships between adherence rate and other variables were explored using logistic regression. **Results:** We collected data for 2819 patient-weeks, pertaining to 169 patients treated on 18 different phase I trials. Median age was 61 years (range 18-79), females predominated (60%), median number of previous systemic therapy was 3 (0-12) and median time on trial was 9 weeks (0.3-212.4). Hundred-percent adherence rate was 88% in the first cycle and 79% overall. Nonadherence occurred in 83 of 2819 patient-weeks (3.0%); including 75 (2.7 %) missed doses and 8 (0.3 %) overdoses. In univariate analysis, longer time on trial and a continuous treatment schedule were associated with poorer adherence, whereas fasting requirements pre- or post-dosing was associated with improved adherence. Known intracranial metastases, number of concomitant medications and opiates or anti-emetics use were not significantly associated to adherence. In multivariate analysis, fasting requirements (OR 5.347, 95%CI : 1.443-20.019, p = 0.012) and longer time on trial (OR 0.98, 95%IC : 0.961-0.996, p = 0.017) were statistically significant. **Conclusions:** This is the first report on adherence rates to oral anticancer IMPs in a large phase I trial population. Our observed adherence rates are at the higher end of published data in the general cancer population. Factors influencing adherence in phase I trials appear to be distinct, with fasting requirements being a unique finding. These findings may impact future early-phase trial design and conduct.

2543 Poster Session (Board #35), Mon, 8:00 AM-11:30 AM

Changes in numbers of randomized (RCT) versus non-randomized (NRCT) clinical trials from 2004-2016: Evidence of shifting cancer drug development pathway. *First Author: Laura Vidal Boixader, INC Research, Barcelona, Spain*

Background: Trials using randomized designs have been conducted for decades to demonstrate efficacy of novel anti-cancer drugs (NACD). Recently, several NACD have shown high antitumor activity in early phase studies, prompting suggestions that NRCT could expedite drug development. We sought to determine what changes have occurred in numbers of NACD RCT vs NRCT conducted from 2004-2016. **Methods:** We reviewed a database of NACD clinical trials conducted by INC (excluding phase I and I/II trials) and classified them by RCT vs NRCT, grouped by year ($\leq$ 2010 or $>$ 2010). We queried Citeline Trialtrove database for industry sponsored, phase 2 trials (P2T) initiated from 2006-2016 and examined numbers of RCT vs NRCT by year.A more detailed analysis of non-small cell lung cancer (NSCLC) clinical trials based on drug type category - Immunooncology (IO) vs. all other mechanims of action (NIO) was performed. **Results:** 190 INC-conducted trials were reviewed. 58 trials (31%) were performed $\leq$ 2010 and 132 trials (69%) $>$ 2010. Over this period, NRCT (n = 107, 56%) outnumbered RCT (n = 83, 44%). Whereas RCT outnumbered NRCT from 2004-2010 (74% vs 52%), after 2010, NRCT outnumbered RCT (58% vs 42%). Citeline Trialtrove search revealed 4776 industry sponsored P2T initiated from 2006-2016. The total number of P2T started annually was highest in 2007 (n = 621), decreasing to a low of 375 in 2016. The proportion of phase 2 RCT demonstrated an increase from 27% (n = 166) in 2006 to a peak plateau of 37-39% from 2011-2014, followed by a drop to 33% in 2015 and 29% in 2016. Among IO studies, RCT declined in 2015-6 vs. previous years, and a decreased for all NACD in 2016 vs. previous years also was noted. For studies in NSCLC, declines in RCT were evident from 2015-6 vs. previous years (45% in 2007-14 vs. 25% in 2015-6). **Conclusions:** Our data indicate a trend toward fewer trials of NACD using randomized designs and more studies using non-randomized designs, with overall fewer P2T initiated in the past year. This change reflects shifts in NACD development pathways, related to a better understanding of cancer biology, drive to develop personalized treatment and a more flexible regulatory drug approval process.

2544 Poster Session (Board #36), Mon, 8:00 AM-11:30 AM

FDA analysis of grade 3-4 safety events. *First Author: Marie-Anne Damiette Smit, U.S. Food and Drug Administration, Silver Spring, MD*

Background: In new drug/biologics applications, safety data provided to FDA include serious adverse events (SAEs), defined as adverse events (AEs) resulting in death, life-threatening AE, inpatient hospitalization or prolongation of hospitalization, persistent or significant incapacity or substantial disruption of the ability to conduct normal life functions, or congenital anomaly/birth defect. One limitation of the SAE definition is that hospitalization practices differ across localities and among medical practitioners. Therefore, a safety signal may not be adequately reflected when analyzing SAEs. We hypothesize that evaluating CTCAE Grade 3 (severe) and Grade 4 (life-threatening) AEs, independent of whether or not these were classified as serious, provides a more complete assessment of patient safety. **Methods:** We reviewed SAEs from all nine registrational trials for new molecular entities approved for the treatment of cancer by the FDA in 2014. **Results:** A total of 25,548 AEs were reported in 1,781 patients treated with an investigational agent. There were 2,943 Grade 3-4 AEs and 912 Grade 3-4 SAEs. Information regarding hospitalization was available in 62% of Grade 3-4 AEs. Fifty-five percent of Grade 3-4 SAEs vs. 5.5% of Grade 3-4 non-serious AEs resulted in hospitalization. Several clinically serious Grade 3-4 AEs, including sepsis and respiratory failure, were not classified as SAE. **Conclusions:** There is significant overlap in most common Grade 3-4 AEs and most common Grade 3-4 SAEs. Most AEs that are clinically serious were appropriately classified as SAE. However, some clinically serious AEs and some AEs resulting in hospitalization were not classified as SAE. With the exception of information regarding hospitalization, characterization of the reason why certain AEs were classified as SAEs was not possible. In this pooled analysis, data from the analysis of AEs by severity was more informative than the analyses by SAEs.

Grade 3-4 AEs	% of patients	Grade 3-4 SAEs	% of patients
Anemia	6.6	Pneumonia	2.1
ALT increase	4.8	Anemia	1.5
Neutropenia	4	Febrile neutropenia	1.4
Fatigue	3.5	Abdominal pain	1.3
Febrile neutropenia	3.5	Dyspnea	1.2
Dyspnea	3.1	Sepsis	1
Pneumonia	2.6	Neutropenia	0.7

AST increase	2.3	Pneumonitis	0.6

2545 Poster Session (Board #37), Mon, 8:00 AM-11:30 AM

Effect of a novel IL-2 cytokine immune agonist (NKTR-214) on proliferating CD8+T cells and PD-1 expression on immune cells in the tumor microenvironment in patients with prior checkpoint therapy. *First Author: Chantale Bernatchez, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NKTR-214 is a CD122-biased agonist designed to provide sustained signaling through the heterodimeric IL-2 receptor pathway (IL-2Rβγ) to preferentially activate and expand effector CD8+ T and NK cells over T regulatory cells in the tumor microenvironment. Immune changes in the tumor microenvironment after NKTR-214 treatment was assessed in patients with locally advanced or metastatic solid tumors. **Methods:** NKTR-214 was administered IV in an outpatient setting q2w or q3w. Serial blood and tumor tissue samples were collected to measure immune activation using immunophenotyping including flow cytometry, immunohistochemistry (IHC), T cell clonality and gene expression analyses. **Results:** 26 patients (pts) have been treated with NKTR-214 at q3w, 4@0.003, 9@0.006, 6@0.009 and 1@0.012 mg/kg. Six pts received 0.006 mg/kg q2w. 58% of pts had prior immunotherapy. The most common Gr1-2 TRAEs were fatigue (73%) and pruritus (65%), and decreased appetite (46%). One pt experienced Gr3 syncope and hypotension at the highest dose tested and continued treatment at a lower dose. No drug-related AEs led to study discontinuation. No immune-related AEs or capillary leak syndrome were observed. 6 pts (23%) experienced tumor shrinkage from 10-30%. Three immunotherapy naïve pts receiving sequential anti-PD1 therapy, after ending treatment with NKTR-214, experienced significant tumor regression at first scan. In all pts evaluated, blood samples showed increases in newly proliferating (Ki67+) T and NK cells 8 days post dose. Flow cytometry and/or IHC revealed an up to 10-fold increase from baseline in tumor CD8+T and NK cells in the tumor microenvironment, with minimal changes to Tregs. PD-1 expression increased 2-fold in TILs. Gene expression analysis of tumor tissue showed increases in several immune checkpoint genes, cytotoxic markers (IFNg, PRF1, and GZMB), as well as a dynamic change in T cell clonality. **Conclusions:** Based on a favorable safety profile and strong correlative biomarker data, a phase 1/2 trial combining NKTR-214 and nivolumab is currently enrolling. Clinical trial information: NCT02869295.

2546 Poster Session (Board #38), Mon, 8:00 AM-11:30 AM

First-in-human phase I study of an oral HSP90 inhibitor, TAS-116, in advanced solid tumors. *First Author: Noriko Yanagitani, Department of Thoracic Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: TAS-116 is an oral non-ansamycin, non-purine, and non-resorcinol highly selective inhibitor of HSP90α/β. The objective of this FIH study was to determine the MTD and investigate the safety, tolerability, PK, PD (HSP70 protein levels in PBMCs), and antitumor activity of TAS-116. **Methods:** The study is being conducted in Japan and the UK. Patients with advanced solid tumors received escalating doses of TAS-116 once daily (QD) with an accelerated titration design. After the MTD was determined, safety and tolerability of 5 days on / 2 days off per week administration (QDx5) at the MTD in QD was explored. In parallel, the MTD with every other day administration (QOD) was evaluated by using a 3 + 3 design. **Results:** As of 20 September 2016, 52 patients were enrolled. TAS-116 was evaluated at doses of 4.8 to 150.5 mg/m^2/day in the QD schedule and doses of 107.5 to 295.0 mg/m^2/day in the QOD schedule. The MTD was 107.5 mg/m^2/day with QD and 210.7 mg/m^2/day with QOD. QDx5 at the MTD in QD using a flat dose of 160 mg was evaluated. The most common adverse events in all regimens were gastrointestinal disorders and increased creatinine. DLTs were observed in 4 patients in QD (night blindness, visual disorder, AST/ ALT/ gamma-GTP elevations, and anorexia) and in 2 patients in QOD (platelet count decreased, febrile neutropenia, pneumonia, respiratory failure, and septic shock). Reversible eye disorders were observed in all schedules, but those observed in QDx5 were limited to grade 1. The PK level demonstrated dose proportionality without unexpected accumulation under repeated administration. Dose-related HSP70 induction of PBMCs was observed. As of 20 September 2016, three confirmed durable PRs by RECIST were observed (239 days in GIST and 173 days in NSCLC with QD; 293 + days in NSCLC with QOD). PR and SD ≥ 12 weeks were observed in 15 out of 47 patients. **Conclusions:** TAS-116 had an acceptable safety profile under all schedules, especially QDx5. Preliminary antitumor activity was demonstrated with evidence of target engagement. Dose expansion at the MTD in this phase 1 study and the phase 2 study in patients with GIST are ongoing. Parts of this study will be expanded to the US with an amended study protocol. Clinical trial information: NCT02965885.

2547 Poster Session (Board #39), Mon, 8:00 AM-11:30 AM

The Drug Rediscovery Protocol (DRUP). *First Author: Daphne Liselotte Van Der Velden, Netherlands Cancer Institute, Division of Molecular Oncology, Amsterdam, Netherlands*

Background: Bringing precision medicine to cancer patients remains a challenge. For many cancers, the relative contribution of tumor type, mutations or CNV to drug sensitivity remains unknown. In addition, drug access is generally limited to the labeled indication, bypassing rarer disease subgroups for which large trials are not feasible. An innovative trial that facilitates drug access, whilst systematically analyzing treatment outcomes and biomarkers, could help overcome these challenges. **Methods:** We designed a prospective, non randomized clinical trial in which patients with advanced cancer are treated with targeted or immunotherapy matched to their tumor profile, defined by genetic aberration, microsatellite instability (MSI) or high mutational load (HML). Upon a mandatory pre-treatment tumor biopsy for biomarker research, patients are enrolled in multiple parallel cohorts, each defined by study drug, histologic tumor type and molecular tumor profile. Efficacy is analyzed per cohort, enrolling 8 patients in stage I and 16 more in stage II if ≥1 response is observed in stage I. Study endpoints include objective tumor response (CR or PR), stable disease (SD) at 16 weeks and grade≥3 adverse events. The DRUP is registered at ClinicalTrials.gov (NCT02925234). **Results:** Since start of recruitment in Sep 2016, 76 patients have been submitted for review (mean per month 15, range 8-17) and 16 (21%) have started treatment in 10 different cohorts, directed at either ATM (n = 1; breast cancer), BRAF (n = 2; salivary duct carcinoma and ACUP), BRCA (n = 1; breast cancer), ERBB2 (n = 2; CRC), HML (n = 2; prostate and CRC), MSI (n = 5; CRC, GBM and urothelial carcinoma), RET (n = 1; NSCLC) or RAS-RAF$_{wt}$ (n = 2; SCC and sarcoma). Out of the 7 patients for whom response evaluation is available, PR (n = 2) or SD at 16 weeks (n = 1) was observed in 3 (43%). Thirteen study drugs (supplied by 6 pharmaceutical companies) are currently available, 6 more are expected soon. **Conclusions:** Execution of a nationwide multidrug precision oncology trial is feasible. It contributes to oncologists' education on molecularly targeted therapies and to identification of early signs of activity in rare cancer subsets. Data sharing with similar studies such as TAPUR and CAPTUR will help to enlarge cohorts and affirm conclusions. Clinical trial information: NCT02925234.

2548 Poster Session (Board #40), Mon, 8:00 AM-11:30 AM

A study of vistusertib in combination with selumetinib in patients with advanced cancers: TORCMEK phase Ib results. *First Author: Peter Schmid, Barts Health NHS Trust, London, United Kingdom*

Background: PI3K/mTOR and MAPK pathways are aberrantly activated in many tumours and interact to promote tumour growth and therapeutic resistance. Activity of single pathway inhibition is limited due to compensatory activation of alternative signalling pathways. Dual pathway inhibition has demonstrated synergistic activity in preclinical models, with broad activity across a range of molecular backgrounds. This study was designed to evaluate the optimal doses and schedule of vistusertib (dual mTOR1/2 inhibitor) and selumetinib (MEK1/2 inhibitor) when given in combination. **Methods:** Thisphase Ib/IIa trial with a dose escalation part (Ib) in treatment refractory advanced solid tumours and expansion cohorts in TNBC, squamous and non-squamous NSCLC (KRASmt & WT) (IIa). Both, continuous daily (CC) (25, 35, 50mg BD) and intermittent (IC) schedules (50, 100, 125mg BD 2ds on, 5 ds off) of vistusertib were investigated. Selumetinib dose was given at a dose of 75mg BD daily. Treatment was given until PD (RECIST 1.1) or intolerable toxicity. The primary endpoint was DLTs. Secondary endpoints included response, clinical benefit, PFS and PK. **Results:** 23 evaluable patients were enrolled in the PhaseIb part. For the intermittent schedule, no DLTs were reported at any of the dose levels IC1-3. For the continuous schedule, 2 out of 9 patients treated at dose level C2C developed DLTs (G3 mucositis, dizziness and rash). Dose level C3C was not tolerated with DLTs observed in 2 out of 3 patients (G3 mucositis and G3 LFTs). Separate MDTs were determined for intermittent (I3C) and continuous schedules (C2C). Adverse events were in keeping with established single agent safety profiles. Anti-tumour efficacy was demonstrated at various dose levels and across tumour types including uveal melanoma, breast, cervical, uterine, skin or colorectal cancers. There were no objective responses but confirmed stable disease for $>$ 16 weeks were observed in 7 patients with a duration of response ranging up to 55+ weeks. **Conclusions:** Based on DLTs, dose intensity and cumulative toxicity, the intermittent schedule I3C was selected as RP2D for expansion cohorts. Preliminary anti-tumour activity was observed. Clinical trial information: NCT02583542.

2549 Poster Session (Board #41), Mon, 8:00 AM-11:30 AM

Pharmacokinetics (PK) and pharmacodynamics (PD) of a novel carcinoembryonic antigen (CEA) T-cell bispecific antibody (CEA CD3 TCB) for the treatment of CEA-expressing solid tumors. *First Author: Ignacio Melero, CIMA, CUN, University Navarra, Centro de Investigación Biomédica en Red de Oncología (CIBERONC), Pamplona, Spain*

Background: CEA CD3 TCB (RO6958688) targets CEA on tumor cells and is agonistic for CD3e on T cells. In mouse models, CEA CD3 TCB displays potent anti-tumor activity, leads to increased intra-tumoral T cell infiltration and activation and up-regulates the PD-1/PD-L1 pathway. **Methods:** Biodistribution was assessed in mice using SPECT/CT. Patient (pts) samples correspond to 2 dose-escalation studies in CEA+ solid tumors. Study 1 (S1): single agent weekly (qW) (0.052 to 600 mg, iv, n = 80), and Study 2 (S2): combination of RO6958688 qW (5 to 160 mg, iv) with 1200mg atezolizumab q3W (n = 38). Analytical methods: PK - population modeling approach; anti-drug antibodies (ADA) - ELISA; immunophenotyping in peripheral blood (PB) by flow cytometry (FCM), in pre- (BSL) and on-treatment (OT) biopsies by immunohistochemistry (IHC) and FCM; plasma cytokines - multiplex assays; PD-L1 - SP142 assay. **Results:** In mice, RO6958688 preferentially accumulated in CEA+ tumors. In pts with no ADAs tested thus far in both studies (S1 29; S2 21), RO6958688 showed near linear PK and exposure. In S1, OT biopsies demonstrated a statistically significant increase in density and activation profile of T cells (CD3: 2.6-fold, n = 21; CD3/CD8: 3.7 fold, n = 17; CD3/Ki67: 4-fold, n = 20; CD8/PD1: 1.7-fold, n = 15) without dose-dependence. In S2, preliminary data of T cell density (5-80mg) were similar to S1 (2-fold). In S1, a significant correlation was observed between treatment-induced tumor lesion reduction and increases of OT CD8/CD25 fluorescence intensity from BSL (p = 0.028). PD-L1 expression increased in OT biopsies in both studies. In S1, from week 4, a moderate expansion of activated CD8 T cells (HLA-DR/Ki67) but not of CD4, was detected in PB at doses $>$ 60mg ($>$ 3.3 fold). Transient increases of several cytokines were seen in both studies with levels peaking within 24hrs. **Conclusions:** PK and PD results consistent with tumor inflammation and mechanism of action support that RO6958688 is the first tumor-targeted T cell bispecific to show intra-tumoral biological activity in pts with CEA+ solid tumors. Updated data will be presented. Clinical data are reported separately.

2550 Poster Session (Board #42), Mon, 8:00 AM-11:30 AM

Whole exome sequencing (WES) of multiple spatially distinct biopsies from single metastatic lesions to evaluate tumour heterogeneity and identify actionable truncal mutations (ATMs) in patients (pts) with advanced solid malignancies using a radiologically-guided single-pass percutaneous technique. *First Author: Valerie Heong, National University Hospital, Singapore, Singapore*

Background: Genomic profiling of single core biopsies (bx) are confounded intratumoral heterogeneity, resulting in sampling bias. We explored the use of a novel technique to obtain multiple bx from single metastatic lesion in pts to evaluate heterogeneity and identify therapeutic ATM. **Methods:** 15 pts (5 NSCLC; 3 ovarian; 2 colon, 2 uterine and 1 breast, cervix and HCC) with biopsiable lesions were identified. Using a single pass radiologically guided percutaneous bx technique, we obtained multiple spatially distinct core bx samples from a single metastatic lesion. Each bx underwent DNA extraction and WES using the NextSeq500. **Results:** Median of 4 core bx were obtained from each lesion. Complication rate utilizing this technique was 0%. 2 pts were omitted from analysis due to poor quality DNA with 13 pts successfully sequenced. In 1 pt, only 2 of 4 cores were successfully sequenced. The median amounts of total and non-synonymous variants were 137 (27-1286) and 66 (10-649) respectively. The median (range) filtered variants detected in 1/4, 2/4, 3/4, and 4/4 bx cores was 63(16-91)%, 5(1-65)%, 4(0-30)% and 26(0-63)% respectively, suggesting significant subclonal diversity within a single lesion. ATMs were identitified in 8/13 pts. 4/13 pts (31%) had no ATM across all 4 cores. 3 pts received therapy with inhibitors targeting ATMs. A pt with AKT1_E17K ATM received an AKT inhibitor with 21% tumour shrinkage and PFS 6.1 mths. 2 NSCLC pts harbouring an EGFR_T790M ATM were treated with an EGFRT790M specific TKI. 1 withdrew due to toxicity after 2mths and another had PFS $>$ 16.5 mths. Tumour mutational burden (TMB) was consistent across multiple bx from each lesion. A NSCLC pt with the highest TMB received a checkpoint inhibitor with ongoing $>$ 4 mths stable disease. **Conclusions:** Utilizing a single pass radiologically guided techniqueto obtainmultiple bx is feasible, safe and informative. This allows reconstruction of a tumour's subclonal genomic architecture, providing insights into mutational heterogeneity and help guide therapy.

2551 Poster Session (Board #43), Mon, 8:00 AM-11:30 AM

Axitinib plus crizotinib in patients with advanced solid tumors and metastatic renal cell carcinoma (mRCC): Preliminary phase 1b results. *First Author: M Dror Michaelson, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Axitinib (AX) is a tyrosine kinase inhibitor (TKI) of vascular endothelial growth factor receptor (VEGFR) and a standard treatment for mRCC. Upregulation of mesenchymal-epithelial transition factor (c-MET) is implicated in resistance to VEGFR-directed therapy. An ongoing ph Ib study (NCT01999972) evaluated the safety and efficacy of AX + crizotinib (CZ), a TKI of c-MET, anaplastic lymphoma kinase (ALK), and *ROS1*. **Methods:** mRCC patients (pts) with advanced solid tumors were treated with AX + CZ in a dose escalation phase (DESC). After determining maximum tolerated dose (MTD) (modified toxicity probability interval), mRCC pts were enrolled into 2 cohorts in a dose expansion phase (DEXP). Cohort 1 (C1) was treatment-naïve and C2 had 1–2 prior therapies. The primary objectives were to assess the tolerability of AX + CZ, to obtain the MTD, and to select the recommended phase II dose. **Results:** As of Aug 5, 2016, 24 pts were screened and 22 pts treated in the DESC. Pts received AX 3 mg twice daily (BID) + CZ 200 mg BID (n = 5); AX 3 mg BID + CZ 250 mg BID (n = 3); AX 5 mg BID + CZ 200 mg BID (n = 4); or AX 5 mg BID + CZ 250 mg BID (n = 10) in a median 4 (range 1–23) cycles. There were no cycle 1 dose-limiting toxicities. One pt discontinued due to an AX-related alanine aminotransferase increase. Fifteen (68.2%) pts experienced Grade 3–4 adverse events (AEs), none in $\geq$2 pts; 1 pt had a Grade 5 AE (disease progression). AX 5 mg BID + CZ 250 mg BID was established as the MTD. Most frequent AEs in the MTD group were fatigue (70.0%), nausea (70.0%) and diarrhea (60.0%). In the ongoing DEXP, 15 pts have been treated at the MTD (n = 11 in C1, and 4 C2). Response evaluation (RECIST) is ongoing, with 1 complete response (CR), 3 partial responses (PR) and 4 stable disease (SD) in 10 pts in C1, and 1 PR and 2 SD in 4 pts in C2. Overall, 10 (66.7%) pts experienced Grade 3–4 AEs and 1 pt had a Grade 5 AE (disease progression). Most frequent AEs ($\geq$60% pts) were nausea and diarrhea. **Conclusions:** We have identified AX 5 mg BID + CZ 250 mg BID as the MTD for combination therapy. This regimen has manageable toxicities and exhibits antitumor activity in treatment-naïve and pretreated mRCC. Further studies in VEGFR, c-MET, ALK and *ROS1* tumor types are warranted. Clinical trial information: NCT01999972.

2552 Poster Session (Board #44), Mon, 8:00 AM-11:30 AM

Safety and pharmacokinetics of crizotinib in patients (pts) with hepatic impairment (HI) and advanced cancer. *First Author: Anthony B. El-Khoueiry, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Crizotinib is a kinase inhibitor approved for treating ALK+ and ROS1+ advanced non-small cell lung cancer. Since crizotinib undergoes hepatic metabolism, this phase 1 study evaluated the pharmacokinetics (PK) and safety of crizotinib in pts with liver dysfunction. **Methods:** Crizotinib-naïve pts with different types of advanced cancer (ALK and ROS1 status unknown), ≥ 18 yr old, and ECOG PS 0–2 were enrolled. Pts were assigned to groups A1 – D based on liver function: normal (A1/A2) = both AST and TB ≤ the upper limit of normal (ULN); mild impairment (B) = AST > ULN and TB ≤ ULN, or TB > 1.0 – 1.5 × ULN; moderate (C1/C2) = TB > 1.5 – 3 × ULN; severe (D) = TB > 3 × ULN. Starting dose was based on HI. Pts in A1 and A2 were matched for weight, age, gender, race and ECOG PS to pts in B and C2, respectively. Study objectives included PK, safety and antitumor activity. **Results:** 88 pts were enrolled in A1 (n=11), A2 (n=15), B (n=20), C1 (n=10), C2 (n=16) and D (n=16). The geometric means of PK parameters at steady-state (Cycle 2 Day 1) are shown below. 75% of pts experienced treatment-related AEs (TRAEs), 9 (81.8%), 14 (93.3%), 15 (75.0%), 6 (60.0%), 11 (68.8%) and 11 (68.8%) in groups A1, A2, B, C1, C2 and D, respectively. 25% of pts experienced Grade 3/4 TRAEs, 3 (27.3%), 3 (20.0%), 3 (15.0%), 1 (10%), 7 (43.8%), 5 (31.3%) in groups A1, A2, B, C1, C2 and D, respectively. Three (3.4%) pts, all in A2, experienced treatment-related SAEs. Two pts (10%) in B and 1 (6.3%) in C2 required dose reductions for TRAEs. TRAEs associated with permanent discontinuation of treatment occurred in 1 pt in A1, A2, C2 and D. Overall, 3 pts had partial responses with durations of 96, 17 and 17 wks; 25 pts had stable disease. **Conclusions:** Systemic exposures of crizotinib in pts with mild HI receiving 250 BID and in pts with moderate HI receiving 200 mg BID are comparable with that of pts with normal hepatic function at 250 mg BID. All TRAEs were manageable across the various levels of hepatic function. Clinical trial information: NCT01576406.

Group	A1 (n=8)	A2 (n=9)	B (n=10)	C1 (n=7)	C2 (n=8)	D (n=6)

2553 Poster Session (Board #45), Mon, 8:00 AM-11:30 AM

Phase I study combining MLN8237 with nab-paclitaxel in patients with advanced solid malignancies. *First Author: Kian-Huat Lim, Division of Oncology, Department of Medicine, Washington University School of Medicine, St. Louis, MO*

Background: MLN8237 is a potent Aurora A kinase inhibitor which synergizes with paclitaxel in preclinical studies for various solid malignancies. **Methods:** We conducted a two-part, phase 1 study combining MLN8237 with nab-paclitaxel in patient with advanced, refractory solid malignancies (NCT01677559). The part 1, dose-escalation phase utilizes a standard a 3+3 design for determination of maximum tolerated dose (MTD) and dose limiting toxicities (DLTs), starting from nab-Paclitaxel 100mg/m2/week 3 out of a 4-week cycle, and MLN8237 20mg BID D1-3/week (denoted nP/M 100/20). In the part 2, dose-expansion cohort, patients with advanced pancreatic ductal adenocarcinoma (PDAC) or high grade neuroendocrine tumor (pNET) who progressed on standard chemotherapy were enrolled. **Results:** Totally 33 patients (17 in part 1 and 16 in part 2) with a median age of 61 were enrolled. In part 1, the most frequent treatment-related toxicities (all Grade/Grade 3-4) were: nausea (65%/6%), neutropenia (61%/18%), fatigue (47%/6%), anorexia (47%/0%), oral mucositis (53%/6%) and anemia (35%/18%). Two of 3 patients experienced a DLT at dose nP/M 100/50 (Grade 4 neutropenia; febrile neutropenia). No treatment-related mortality occurred. MTD was set at nP/M 100/40 for part 2. At data cutoff, totally 20 patients from the entire study were evaluable for treatment response. One patient with small cell lung cancer achieved partial response and is in cycle 29. Nine other patients (9/20, 45%) with the following tumor histology achieved stable disease after two cycles: 1 small cell lung cancer, 1 lung neuroendocrine carcinoma, 1 lung squamous cell carcinoma, 1 PDAC and 5 high grade pNET (range: 3 and ongoing ~ 18 cycles). **Conclusions:** MLN8237 plus nab-paclitaxel has manageable side effect profile with very promising activity in tumors with high grade neuroendocrine features, warranting further testing. Exploratory studies on pharmacodynamic markers are ongoing. Clinical trial information: NCT01677559.

2554 Poster Session (Board #46), Mon, 8:00 AM-11:30 AM

Final report of a phase I study of 2-hydroxyoleic acid (2OHOA) a novel sphingomyelin synthase activator in patients (pt) with advanced solid tumors (AST) including recurrent high grade gliomas (rHGG). *First Author: Analia Azaro, Medical Oncology Department Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background: 2OHOA is an orally bioavailable, first-in-class synthetic hydroxylated fatty acid, that activates SGMS1 and modulates the lipid content of cancer cell membranes. This regulates the localization of key signaling proteins, including Ras and PKC at the plasma membrane, leading to inactivation of Ras/MAPK, PI3K/Akt and PKC/cyclin/CDK signaling pathways. A dose escalation (DE) and partial expansion cohorts (EC) results of the phase 1 study have previously been reported. We now present the final results of the study. **Methods:** 2OHOA was evaluated in a 3+3 DE design (7 cohorts from 500mg/d to 16000mg/d) and 2 EC at 4000mg TID in 21 days cycles. PK profiles were determined after single dose (fasted [D-7] or fed [D1]) and multiple doses (fed [D21]) during DE phase and only on D1 throughout EC.Safety assessments were based on CTCAEv4.Tumor response was measured by RECIST and RANO every 6 weeks. **Results:** Overall 54 pt (DE: 32 pt; 21AST/11rHGG; EC: 22 pt; 12 AST/10 rHGG) were treated (median age 60, range 19-78 years). During the EC the most common treatment related G1-G2 toxicities were diarrhea (n = 13;11pt),nausea (n = 7;6pt), ALT increase (n = 6;4pt), pruritus in throat (4pt), fatigue (4pt) and vomiting (3pt). No G3-G4 toxicities or DLTs were reported confirming the MTD from the DE at 4g TID. Food intake did not alter oral 2OHOA bioavailability. Steady state was already achieved at D8. Power model showed dose proportionality in terms of AUC and Cmax, after single and multiple BID dosing. Average t1/2 ranged from1-2h to 8-12h with delayed Tmax and longer half-lives at higher doses. One glioblastoma (GBM) pt had sustained partial response (> 2,5 years) and 4rHGG pt (3 GBM) achieved stable disease for at least 6 months. They had previously received 2 lines of treatment without bevacizumab. Tumor markers were measured and will be presented. **Conclusions:** 2OHOA is well tolerated at the P2RD of 4000mg TID PO daily. The preliminary antitumor activity including a sustained PR in heavy pretreated rHGG pt warrants further investigation in a Ph2 study Clinical trial information: NCT01792310.

2555 Poster Session (Board #47), Mon, 8:00 AM-11:30 AM

Phase I study of the combination of balixafortide (CXCR4 inhibitor) and eribulin in HER2-negative metastatic breast cancer (MBC) patients (pts). *First Author: Marta Gil-Martin, Institut Català D'Oncologia, L'Hospitalet de Llobregat, Barcelona, Spain*

Background: Balixafortide (POL6326) is a cyclic peptide and a potent, selective antagonist of the chemokine receptor CXCR4. Evidence suggests that CXCR4 inhibition interferes with the tumor-protective microenvironment and sensitizes tumor cells to chemotherapy. The combination of balixafortide (B) and eribulin (E) was safe with early signs of efficacy in the dose escalation part of this study. **Methods:** The expanded cohort of thisopen label phase I study was designed to assess the anti-tumor activity, safety and pharmacokinetics of the addition of the recommended phase 2 dose (RP2D) of B to E in pts with MBC and with any CXCR4 expression level at the tumor site. Patients received E (1.4 mg/m^2) on days 2 and 9, flanked by B (5.5 mg/kg) on days 1-3, and 8-10 of 21-day cycles. **Results:** 24 pts with relapsed MBC (median age 59 [33-82]) were enrolled in the expanded cohort. Median number of prior chemotherapies for MBC was 2 (range 1-3). 20/24 (83%) pts were ER and/or PR positive; 3/24 (13%) pts had TNBC. Objective response rate (ORR) was 33%. 8/24 (33%) pts achieved a partial response and 4/24 (17%) pts had meaningful (≥ 6 months) stable disease for a Clinical Benefit Ratio of 50%. Median duration of treatment was 15.3 weeks (range 5-40) with 11 pts still on treatment. The most common Gr 3-4 adverse events were neutropenia (9/24, 38%) and leucopenia (3/24, 13%); 2 pts had febrile neutropenia and 1 patient died from sepsis. 15/24 (63%) pts experienced histamine-like infusion reactions related to B that were manageable with anti-histamines. **Conclusions:** The therapeutic activity of this treatment regimen appears promising with an ORR of 33% in patients with advanced MBC. B (5.5 mg/kg) can be combined safely with E (1.4 mg/m^2) and the safety profile resembles E monotherapy as previously reported. This is the first study of the treatment combination of E with B in relapsed MBC pts. Further confirmatory studies are being considered. Clinical trial information: NCT01837095.

2556 Poster Session (Board #48), Mon, 8:00 AM-11:30 AM

A multicenter phase I trial of the DNA-dependent protein kinase (DNA-PK) inhibitor M3814 in patients with solid tumors. *First Author: Mark van Bussel, The Netherlands Cancer Institute (NKI), Amsterdam, Netherlands*

Background: Agents that generate breaks in DNA are frequently used as cancer therapeutics. These agents induce different forms of DNA damage including double-strand breaks (DSBs), which are the most lethal if left unrepaired. M3814 targets tumor cell growth and survival by inhibiting DNA-PK, which is part of a critical DSB DNA damage repair mechanism. The purpose of the phase I, first in man trial was to evaluate the dose-limiting toxicity (DLT), establish a recommended phase II dose (RP2D), and assess the pharmacokinetic (PK) profile and single-agent clinical activity of M3814. **Methods:** Patients (pts) with potential aberrations in the DNA-damage and repair systemwere included. A standard 3+3 design was implemented with a starting dose of M3814 of 100 mg once daily, determined based on non-clinical safety. M3814 was given continuously and DLT was evaluated after 3 weeks. Throughout the trial rich PK sampling was taken. Tumor evaluation was performed every second cycle and treatment continued until progression, unacceptable toxicity, pt wish, or physician decision. **Results:** A total of 25 pts were enrolled at 6 dose levels (DL). Three pts were enrolled per DL, except at 300 and 400 mg BID where 9 and 4 pts were enrolled, respectively. At 300 mg BID one DLT (several low grade adverse events [AEs] lasting $>$ 1 week) was seen. No DLTs were observed at 400 mg BID, which was declared as the RP2D; further dose escalation was not possible due to an impurity in the drug. An additional 6 pts were included at the RP2D. The most frequent AEs were nausea, vomiting, decreased appetite, constipation, diarrhea, pyrexia, fatigue, and rash, all seen in $>$ 20% of pts. No pts discontinued due to AE and no grade 4 AEs were reported. Six pts (20%) had stable disease for at least 18 weeks; no pt had a partial remission. PK analysis demonstrated high variability of exposure with a tendency for skin rash in pts with the highest exposure. **Conclusions:** M3814 was found to be safe and tolerable at doses up to 400 mg BID, with limited single-agent activity in the studied population. Clinical evaluation of M3814 is ongoing in combination with radiotherapy as well as chemo-radiotherapy and planned in combination with chemotherapy. Clinical trial information: NCT02316197.

2557 Poster Session (Board #49), Mon, 8:00 AM-11:30 AM

A phase II study of copper-depletion using tetrathiomolybdate (TM) in patients (pts) with breast cancer (BC) at high risk for recurrence: Updated results. *First Author: Sheena Sahota, New York Presbyterian Hospital, Weill Cornell Medical College, New York, NY*

Background: The tumor microenvironment (TME) plays a critical role in the spread of tumors. Bone marrow derived VEGFR2$^+$endothelial progenitor cells (EPCs) and copper-dependent lysyl oxidase (LOX) are key in tumor progression. We hypothesized TM-associated copper depletion inhibits tumor metastases by reducing the number of EPCs and other copper dependent (CD) processes in the pre-metastatic niche. These results are an update with longer follow-up. **Methods:** Phase II study of BC pts at high risk for recurrence, defined as node+ triple negative (TNBC), stage 3 and 4 with no evidence of disease (NED) were enrolled on a trial of CD with TM. Ceruloplasmin (Cp) levels were maintained between 8-16 mg/dl for two years with an extension phase or until relapse. The primary endpoint was change in EPCs measured by flow cytometry before and during treatment. Secondary endpoints included tolerability, safety, PFS and LOXL-2 levels. **Results:** 75 pts received 2650 cycles of TM on primary and extension study. The median age is 51 years (range 29-66). Forty-five pts have stage 2/3 BC and 30 with stage 4 NED. TNBC pts were 48% and 40% of pts are stage 4 NED. Median Cp level decreased from 28 to 16 ($p < 0.0001$) after one cycle. Copper depletion was most efficient in TNBC where Cp levels dropped from 23.5 to 13 after one cycle. TM was well tolerated with grade 3/4 toxicities including: reversible neutropenia (2.3%), febrile neutropenia (0.04%), fatigue (0.2%). Five-year analysis showed a decrease in EPC's ($p = 0.004$) and LOXL-2 ($p < 0.001$). At a median follow-up of 6.9 years, the EFS for 75 pts is 75.6%. PFS for 36 pts with TNBC is 79.2%. EFS for stage 2/3 TNBC is 90% and for stage IV TNBC is 66.7%. **Conclusions:** TM is safe, well tolerated and appears to affect multiple components of the TME creating an inhospitable environment for tumor progression especially in high risk patients such as TNBC. Randomized trials are warranted, especially in patients at high risk for relapse. Clinical trial information: UL1TR000457.

2558 Poster Session (Board #50), Mon, 8:00 AM-11:30 AM

Phase I study of indenoisoquinolines LMP776 in adults with relapsed solid tumors and lymphomas. *First Author: Geraldine Helen O'Sullivan Coyne, Early Clinical Trials Development Program, DCTD, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Indenoisoquinolines (ID) are non-camptothecin inhibitors of topoisomerase (TOP1) identified following a COMPARE analysis of the National Cancer Institute's (NCI) in vitro anticancer drug discovery screen. IDs have improved characteristics over camptothecin top1 inhibitors, with better chemical stability (lacking the labile hydroxylactone E-ring) producing stable DNA breaks that are resistant to reversal of the trapped DNA-TOP1 cleavage complex and at different DNA sequence sites to camptothecins (Kohlhagen *et al*. Mol Pharmacol. 2005). IDs have shown more activity against camptothecin-resistant cell lines and mouse models, as well as in cells overexpressing the ATP-binding cassette (ABC) transporters, and multidrug resistance (MDR-1/ABCB1) genes. A parallel first-in-human Phase I study conducted at the NCI of LMP400 in patients with refractory solid tumors and lymphomas showed this molecule to be well tolerated (Kummar *et al*, Cancer Chemother Pharmacol. 2016). A trial of LMP776 (NSC725776), has completed accrual. Primary Objectives: define the maximum tolerated dose (MTD) of LMP776 and the dose-limiting toxicities (DLTs). **Methods:** Phase I trial using Design 4 of the Simon accelerated titration designs (Simon et al. JNCI, 1997), with doses escalated based on toxicity during cycle 1. LMP776 was administered via central line QD over 1 hour on days 1–5 q 28-days. Response is defined by RECIST 1.1 on CT. **Results:** 32 of 34 patients (pts) were evaluable for toxicity and response. Enrollment was expanded at dose level (DL) 2 to 6 pts due to a hypocalcemia DLT, with subsequent enrollment on a 3+3 design. MTD was established at DL7 (12mg/m^2, DLT myelosuppression). Common Grade 3/4 adverse events by CTCAE v.4 included anemia (5 pts, 15%), thrombocytopenia (5), lymphopenia (5) and neutropenia (3 pts, 9%). 12 (37%) pts experienced stable disease (SD), with a median of 4 cycles of treatment (range 2-9). 10 (30%) pts with SD remained on study for $\geq$4 months, with 4 pts on study $\geq$6 months. **Conclusions:** LMP776 is overall well tolerated. Explorative correlatives and additional trials are being considered. Clinical trial information: NCT01051635.

2559 Poster Session (Board #51), Mon, 8:00 AM-11:30 AM

An open-label expanded-access study to evaluate the safety, tolerability, and pharmacokinetics of trifluridine/tipiracil in patients with advanced solid tumors and hepatic impairment. *First Author: Wasif M. Saif, Tufts University School of Medicine, Tufts Cancer Center, Boston, MA*

Background: The Phase 3 RECOURSE study showed that trifluridine/tipiracil (FTD/TPI) was effective in the treatment of refractory metastatic colorectal cancer (Mayer et al. N Engl J Med 2015;372:1909-19). A Phase 1 open-label study evaluated the safety and pharmacokinetics of FTD/TPI in patients with advanced solid tumors and varying degrees of hepatic impairment to inform dosing recommendations for these patients. **Methods:** Patients aged $\geq$18 years with advanced solid tumors, an Eastern Cooperative Oncology Group performance status $\leq$2, normal hepatic function, and mild, moderate, or severe impaired hepatic function according to the National Cancer Institute criteria were enrolled. Patients received FTD/TPI 35 mg/m^2 orally twice daily on days 1-5 and days 8-12 of each 28-day cycle, except for those with severe impaired hepatic function (dose was to be determined). **Results:** 24 patients were enrolled to normal (n=8), mild (n=10), and moderate (n=6) groups. Study enrollment was stopped as 5/6 patients in the moderate group experienced elevated bilirubin levels (grade $\geq$3). The other baseline characteristics were similar across groups. Overall, 12 patients (50%) had at least 1 adverse event leading to study discontinuation: 2 in normal, 5 in mild, and 5 in the moderate hepatic impairment groups. Pharmacokinetic results are summarized in the table. **Conclusions:** The exposure to FTD or TPI was not increased by hepatic impairment and the patients who experienced grade 3 and 4 increased total bilirubin were not overexposed to FTD or TPI. Clinical trial information: NCT02301104.

FTD/TPI pharmacokinetic parameters (mean ± SD)		FTD			TPI		
		Normal	Mild	Moderate	Normal	Mild	Moderate
Day 1	$AUC_{0\text{-}inf}$, ng·hr/mL	6873 ± 2407	6324 ± 2208	4594 ± 1586	421 ± 208	272 ± 120	591 ± 419
Day 12	AUC_{tau}, ng·hr/mL	20392 ± 5609	17489 ± 7379	15406 ± 1244	335 ± 230	305 ± 112	495 ± 288

$AUC_{0\text{-}inf}$, area under the plasma concentration–time curve from time 0 to infinity; AUC_{tau}, area under the plasma concentration–time curve from time 0 to the end of dosing interval for Day 12 only; SD, standard deviation.

2560 Poster Session (Board #52), Mon, 8:00 AM-11:30 AM

GMI-1271, a novel E-selectin antagonist, combined with induction chemotherapy in elderly patients with untreated AML. *First Author: Daniel J. DeAngelo, Dana-Farber Cancer Institute, Boston, MA*

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor, therefore newer and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotherapy resistance. GMI-1271, a novel E-sel antagonist, enhances chemotherapy responses and protects from common toxicities in preclinical models (Becker ASH 2013; Winkler ASH 2013 and 2014). We report interim Phase 2 data for GMI-1271 plus chemotherapy in elderly untreated pts with AML. **Methods:** Pts ≥ 60 yrs with untreated AML, ECOG 0-2, and adequate renal and hepatic function were eligible. Prior treatment of MDS was allowed. GMI-1271 (10 mg/kg) was given 24 hrs prior, during and 48 hrs post induction with infusional cytarabine and idarubicin (7 +3). Safety, tolerability, and anti-leukemia activity were assessed. Two cycles of induction were allowed and responders could receive consolidation with GMI-1271 plus intermediate dose cytarabine. Dose-limiting toxicity (DLT), defined as myelosuppression in the absence of disease or related Grade 3 (Gr) non-hematologic toxicity beyond day 42, was assessed in the first 3 pts. **Results:** 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 68 years (range, 60-79) with 58% male pts, 50% secondary AML (sAML) pts and 25% with high-risk cytogenetics (by SWOG). The first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (47%), pneumonia (20%), pulmonary edema (13%) and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CRi rate was 75% for pts with *de novo*disease and 67% for pts with sAML. E-sel ligand was expressed at high levels on blasts in the majority of pts. **Conclusions:** The addition of GMI-1271 to anthracycline-based induction chemotherapy in untreated elderly pts with AML demonstrates a high remission rate with acceptable side effect profile and low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). A randomized trial is being planned. Clinical trial information: NCT02306291.

2561 Poster Session (Board #53), Mon, 8:00 AM-11:30 AM

A phase Ib/II clinical trial of a novel oxygen therapeutic in chemoradiation of glioblastoma. *First Author: Evan C. Unger, NuvOx Pharma, Tucson, AZ*

Background: Tumor hypoxia limits the response of glioblastoma multiforme (GBM) to radiotherapy (RT) and chemotherapy (temozolomide[TMZ]). Additionally, patient biomarkers are strong predictors of responsiveness to TMZ. The purpose of this study is to evaluate the use of a novel oxygen therapeutic, dodecafluoropentane emulsion (DDFPe), in chemoradiation treatment of GBM and stratify the results based on predicted TMZ response. **Methods:** 11 adult GBM patients have been enrolled. Patients were administered DDFPe via IV infusion (2% w/vol at doses of 0.05, 0.1 or 0.17 mL/kg) an hour prior to each 2 Gy fraction of RT (30 fractions over 6-weeks) with supplemental oxygen. Patients also received standard concurrent and adjuvant TMZ. To confirm tumor re-oxygenation, patients underwent TOLD MRI before and after DDFPe administration. Archived tumor specimens were studied with GliomaSTRAT assay for methylated genes predictive of response. Patients were also studied with serial MRI scans per standard of care and followed for survival. **Results:** There were minimal acute adverse events related to DDFPe administration. One patient at each of dose levels 0.1 and 0.17 mL/kg developed symptomatic radiation necrosis, which was judged to be related to DDFPe. Enrollment has continued at the 0.1 mL/kg dose without additional significant DDFPe-related toxicity. TOLD MRI showed significant decrease in $T_1$of tumor tissue consistent with tumor re-oxygenation (p=0.015) with no significant change in oxygenation of normal brain tissue. Historically, the average overall survival for GBM patients, for both TMZ responders and non-responders, is about 14.6 months. The progress chart for patient overall survival is listed below, 4 patients have died. All other patients are alive. **Conclusions:** DDFPe is a promising oxygen therapeutic for reversing tumor hypoxia. A Phase II study is being planned to assess its effectiveness. Clinical trial information: NCT02189109.

Progress chart: Phase Ib GBM trial.

Patient Number	Age/Sex	DDFPe (mL/kg)	TMZ responder	Overall Survival (months)
1	48-M	0.05	no	21*
2	65-F	0.1	no	19*
3	48-F	0.17	yes	21.5
4	68-M	0.1	yes	15
5	47-M	0.1	no	14
6	30-M	0.1	no	12
7	58-F	0.1	no	8.5*

2562 Poster Session (Board #54), Mon, 8:00 AM-11:30 AM

Patterns of failure on Ga PSMA (GaPSMA) and F18 FDG (FDG) PET CT in a prospective phase 2 trial of ^{177}Lu DKFZ PSMA 617 (LuPSMA) in men with castrate resistant metastatic prostate cancer (mCRPC). *First Author: Anthony M. Joshua, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: LuPSMA is emerging as an effective therapy in mCRPC, with retrospective series reporting high PSA response rates in men undergoing treatment (tx). However, not all men have prolonged tx responses. We report the prospective imaging (GaPSMA/FDG) and PSA response of men who progress biochemically during LuPSMA tx to gain information on characteristics of failure patterns, to determine optimal future tx strategies. **Methods:** Men with mCRPC, who had failed androgen blockade, failed/ineligible/refused chemotherapy, with GaPSMA positive disease were enrolled in a prospective phase 2 trial. All men underwent LuPSMA therapy 6-8Gbq, 4 doses at 6 weekly intervals. Imaging with FDG, GaPSMA, bone scan and CT scans was at screening, at subsequent PSA rise, or 3 months post completion of 4 cycles of therapy. **Results:** 14 men met eligibility criteria and enrolled. 4/14 (28%) men had progressive disease (no PSA response). 10/14 (72%) PSA reduced by a mean 56% .Overall 9/14 (64%) men had >30% decline in PSA, and 5/15(36%) >50% reduction in PSA. 7/15 men were reimaged with GaPSMA, FDG at biochemical failure or 3/12 post tx completion. Imaging revealed 4 distinct patterns (P) of progression. **Conclusions:** PSMA acts as both target for radionuclide therapy and biomarker for effective tx response. PSMA and FDG imaging at PSA failure following or during LU PSMA therapy identifies phenotypic patterns of failure that have implications for determining next best tx options in men with mCRPC.

	Finding	Significance for management
P 1	Progression with diffuse, widespread low PSMA avid disease (SUV max 2-7 all sites)	Progressive non PSMA avid phenotype. change tx
P 2	Marked tx response at all initial sites. Solitary PSMA -/FDG+ lesion	Treat solitary site of PSMA – disease with focal tx. Continue treating with Lu PSMA
P 3	Marked reduction in PSMA + sites, but persistent PSMA activity (SUV max >10)	Disease amenable to tx with LuPSMA. Consider continuing beyond 4 doses of Lu PSMA.
P4	Marked reduction in PSMA /FDG at all sites (>75%). Low volume residual activity only	Cease tx with Lu PSMA until PSA rise / repeat PSMA shows progression, then retreat with Lu PSMA.

2563 Poster Session (Board #55), Mon, 8:00 AM-11:30 AM

Pharmaco-kinetics/dynamics (PK/PD) evaluation and individual patient cross-over studies with growth trajectory assessment to adaptively develop ilorasertib. *First Author: Michael L. Maitland, Inova Schar Cancer Institute, Falls Church, VA*

Background: We evaluated PK/PD of the AURK B/VEGFR2 inhibitor ilorasertib. To detect activity in CDKN2A-deficient tumors, we measured changes-in-tumor-burden by CT-volume before, during, and after discontinuation of therapy. **Methods:** Study 1: open-label, dose-escalation, phase 1 in 58 patients (pts) with advanced solid tumors. Arms I, II, and III assigned: 23 pts (10–180 mg oral QD), 28 pts (40–340 mg oral BID), and 7 pts (8–32 mg i.v. QD), to ilorasertib monotherapy Days 1, 8, and 15 every 28 days. We evaluated PK/PD for validated biomarkers: change-in-diastolic blood pressure (ΔDBP), change-in-plasma [PlGF] (ΔPlGF), and change-in phosphorylated histone H3 (Δ%pHH3) in skin biopsies. Study 2: open-label trial, of 10 solid tumor pts with CLIA-lab-detected *CDKN2A* disruption. Pts received ilorasertib 250 mg oral BID on same schedule. On CT images collected prior to screening, and ~ study days -7, 49, and 98 individual lesion volumes were determined by central lab semi-automated segmentation algorithms on DICOM files. Pts who tolerated ilorasertib with RECIST-stable disease at day 98 discontinued ilorasertib for 42 days and underwent re-imaging before restarting ilorasertib. **Results:** Study 1: the DLTs and frequent adverse events reflected VEGFR2 inhibition. PK/PD analysis showed peak VEGFR2 inhibition on ΔDBP and ΔPlGF at lower systemic concentrations than for peak AURKB-inhibition detected with Δ%pHH3. Two pts in Arm II had partial response; one had homozygous deletion of *CDKN2A*by FISH. Pre-clinically the CDKN2A-deficient cell lines (OVCAR5, MDA MB 231, A549) were among the most ilorasertib-sensitive. At time of submission, Study II enrolled 10 pts, with 5 evaluable for longitudinal tumor burden assessments. Three pts had sustained negative growth trajectories after ilorasertib therapy; one of these had positive growth after cessation of treatment but restabilization of disease after restarting ilorasertib. **Conclusions:** The development plan adapted to the in-human PK/PD assessment. We prospectively conducted individual change-in-tumor burden cross-over studies to assess clinically the sensitivity of CDKN2A-deficient tumors. Clinical trial information: NCT02540876 and NCT01110486.

2564 Poster Session (Board #56), Mon, 8:00 AM-11:30 AM

The utility of genomics and functional imaging to predict irinotecan pharmacokinetics and pharmacodynamics: The PREDICT IR study. *First Author: Michael Michael, Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: BSA-based dosing of Irinotecan (IR), does not account for its pharmacokinetic (PK) and pharmacodynamic (PD) variability. Given IR's unique metabolism, functional hepatic nuclear imaging (HNI) with probes for hepatic transporters correlated with its PK. This study further evaluated the utility of HNI combined with extensive excretory/metabolic/PD pharmacogenomics (PG) to predict IR PK and PD in patients (pts) treated with FOLFIRI to enable dose individualization. **Methods:** Eligible pts had advanced colorectal cancer, suitable for $1^{st}/2^{nd}$-line FOLFIRI± Bevacizumab. Pts had blood analyzed by Affymetrix DMET™ Plus Array and additional SNPs were genotyped. For HNI, pts were given IV 250MBq ^{99m}Tc-IDA and imaging data analyzed for hepatic extraction/excretion parameters (clearance [CL], 1hour retention [1hRET], deconvulutional CL [DeCL], hepatic extraction fraction [HEF]). Pts treated with chemotherapy, q2-weekly, and restaged after 4 cycles. Blood taken for IR and metabolite (SN38, SN38G) analysis on day 1 cycle 1, PK parameters derived by non-compartmental analysis. Statistical correlations were evaluated between (i) IDA HNI and (2) PGs, with IR PK, toxicity, objective response (ORR) and progression-free survival (PFS). **Results:** 32 pts analysed, 31 pts completed 4 cycles. (1) PK correlates: (a) HNI CL and 1hRET with SN38 Metabolic CL, ($P = 0.04$) and (b) HNI DeCL with IR $AUC_{(0-\infty)}$ ($P = 0.04$). (2) Grade 3+ diarrhea ($N = 4$, 13%) predicted by SN38 $AUC_{(0-\infty)}$ and Metabolic CL ($P = 0.04$), and gene variants for SCL22A2 and -28A3, ABCC2, UGT2B17, CYP2C18 and DPYD ($P < 0.05$). (3) Grade 3+ neutropenia ($N = 9$, 28%) predicted by SN38 PK exposure ($P < 0.02$), HNI CL and 1hRET ($P < 0.0001$) and variants for SLC7A7-, SLC22A2-, CHST1-, UGT1A1-, -2B7, ABCB1. (4) ORR ($N = 6$, 20%) predicted by Methylene tetrahydrofolate reductase (MTHFR) 677C > T ($P = 0.002$), SN38 exposure ($P < 0.003$), and variants in metabolic/transporter genes ($P < 0.05$). (5) PFS by SN38 PK exposure, MTHFR 677C > T, HNI CL, HNI HEF and variants in PK genes ($P < 0.05$). **Conclusions:** Hepatic functional imaging with extensive pharmacogenomics correlate with Irinotecan PK and PD enabling the development of nomograms to individualize dosing. Clinical trial information: ACTRN12610000898055.

2565 Poster Session (Board #57), Mon, 8:00 AM-11:30 AM

A phase I study of the tolerability, safety, pharmacokinetics and preliminary antitumor effects of KBP-5209, a novel pan-HER inhibitor, in patients with advanced solid tumors. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: KBP-5209 is a novel potent and irreversible inhibitor of tyrosine kinases of the human epidermal growth factor receptor (EGFR) family that preclinically has demonstrated potent antitumor activities in esophageal and gastric cancers and NSCLC. **Methods:** This first-in-human study (NCT02442414) was conducted to determine tolerability, safety, pharmacokinetics and antitumor activity of KBP-5209 administered QD or BID in patients (pts) with advanced solid tumors. Dose escalation (DE) initially was based on a modified accelerated titration plan and then shifted to a standard 3+3 design. The starting dose was 20 mg QD. Eligible patients were adults with advanced, refractory solid tumors with ECOG PS < 1. A cycle was 28 days. DLTs were evaluated for during the first cycle. DE enriched for patients with tumors having molecular alterations in EGFR or HER2/3. Dose escalation continues so dose expansion has not initiated. **Results:** As of 26 Nov, 2016, 23 pts (15 females, 8 males) are a part of the evaluable population with a median age 57 (37-79) treated at doses of 20mg (1), 40mg (3), 60mg (7), 70mg (4), 80mg (6) QD and 20mg BID (2).Tumor types included breast (6), CRC (4), ovarian (3), H&N (2), sarcoma (2), and NSCLC, sinus, gastric, gallbladder, pancreas, CUP tumor (1 each). Tumor genetic profiles were available for 20 pts. DLTs were G3 diarrhea, nausea, and vomiting, which occurred in 1 pt at 80mg QD and G3 Diarrhea, occurring in 1pt at 80mg QD. The most common adverse events related to study drug were diarrhea (60.9%), nausea (47.8%), vomiting (43.5%), fatigue (21.7%), decreased appetite (17.4%) and lipase increased (17.4%). Serious adverse events (SAEs**)** related to study drug were reported in 4pts: diarrhea (1 pt, 70mg QD; 1pt, 80mg QD), nausea and vomiting (1pt, 70mg QD), and diarrhea, nausea and vomiting (1 pt, 80mg QD). Stable disease has been observed in 7pts up to 24 weeks, in which 2/28 pts (7%) achieved tumor shrinkage. **Conclusions:** Based on the present data, KBP-5209 has been well tolerated with a safety profile similar to other pan-HER inhibitors. For QD dosing, maximum tolerated dose has been identified as 70mg QD. The BID dose escalation continues. Clinical trial information: NCT02442414.

2566 Poster Session (Board #58), Mon, 8:00 AM-11:30 AM

Population pharmacokinetics of durvalumab and fixed dosing regimens in patients with advanced solid tumors. *First Author: Paul Baverel, MedImmune, Cambridge, United Kingdom*

Background: Durvalumab is a human monoclonal antibody that binds to PD-L1 and blocks its interaction with PD-1 and CD80. The objectives of this analysis were to develop a population pharmacokinetics (PK) model of durvalumab, to quantitate the effect of patient/disease characteristics on PK, and to compare weight (WT)-based versus fixed dosing regimens. **Methods:** Data were pooled from two studies: Study 1108 (Phase 1/2; various tumor types) and ATLANTIC (Phase 2; NSCLC). A total of 1324 patients provided data following 0.1 to 20 mg/kg IV durvalumab. The population PK was performed using a non-linear mixed effects modeling approach in NONMEM software. The impact of demographics, clinical indices, and biomarkers on PK was explored. **Results:** Durvalumab PK was best described using a 2-compartment model with both linear and non-linear clearances. The mean (between-patient variability) linear clearance (CL) and central volume of distribution (V_1) were 226 mL/day (~29%) and 3.51 L (~21%), respectively. Although population PK analysis identified a few statistically significant covariates (WT, sex, CrCL, post-baseline ADA, ECOG performance status, LDH, sPDL1 levels, tumor type, and albumin), none were found to be clinically relevant (effect on PK parameters < 30%), indicating no need for dose adjustment. Simulations indicated similar overall PK exposures following WT-based (10 mg/kg Q2W) and fixed dosing regimens (1500 mg Q4W or 750 mg Q2W); with all regimens expected to maintain target trough exposure of ~50 μg/mL in ≥95% patients. In a post-hoc analysis, durvalumab clearance was found to decrease slightly over time, with a mean maximal reduction from baseline value of 15.5%. The decrease in CL was associated with tumor shrinkage, decreased LDH, increased albumin and decreased neutrophil to lymphocyte ratio. The small decrease in CL was not considered relevant to PK exposure or dosing. **Conclusions:** A population PK model of durvalumab was developed and validated. No dose adjustments were needed based on any patient or disease characteristics. The analysis demonstrated the feasibility of switching to a fixed dose regimen. Clinical trial information: NCT02087423 and NCT01693562.

2567 Poster Session (Board #59), Mon, 8:00 AM-11:30 AM

The potential clinical impact of pre-emptive screening of multiple polymorphisms in gene-encoding DPD on patients candidate for fluoropyrimidine based-chemotherapy: An experience of the Northern Italy Cancer Centre. *First Author: Francesco Iachetta, Medical Oncology Unit, Clinical Cancer Centre, Arcispedale Santa Maria Nuova – IRCCS, Reggio Emilia, Italy*

Background: Dihydropyrimidine dehydrogenase (DPD) is a key enzyme in the metabolism of fluorouracil. Deleterious polymorphisms in gene-encoding DPD (*DPYD*) results in a DPD deficiency that causes life-threatening toxicities when the standard dose of fluorouracil is used. DPYD*2A (IVS14+1G > A) is the most common single-nucleotide polymorphism (SNP) associated with critical DPD deficiency. At present, most of the evidence supports screening for at least 3 SNPs (DPYD*2A, c.2846 A > T, c.1679T > G). The aim of this study is to confirm that the detection of additional polymorphisms of DPYD could enhance prevention of fluoropyrimidine toxicity. **Methods:** In 2011, we began to screen DPYD*2A in patients candidate for fluoropyrimidine based-chemotherapy. As the first step of the evaluation, we selected all cases of DPYD*2A wild type, from 2011 to 2012, who developed CTC-NCI-V.3 toxicity ≥ G3. In these patients, we researched the other 3 SNPs (c.2846 A > T, c.1679T > G, c.2194C > A). Mutational status was analyzed with real Time PCR. **Results:** From 2011 to 2016 we pre-emptively screened DPD deficiency in 1,863 patients and 32 subjects (1.6%), with results mutated for DPYD*2A. As the first step of the evaluation, 548 subjects were assessed from 2011 to 2012. We found 7 patients who were carriers of the DPYD*2A mutation (1.27%). Of the 541 wild type cases, 114 presented toxicities ≥ G3. In this subgroup, 22 patients (19%) proved to be mutated for the other SNPs of DPYP, as reported in the table below. **Conclusions:** Preliminary data show that in 22 (19%) of 114 patients who presented severe toxicity which was not correlated with DPYD*2A, we found other polymorphisms of gene encoding DPD. Out of the 3 SNPs evaluated, c.2194 C > A proved to be the most frequent, although it is the polymorphism that is least known and least studied. Such results suggest that the evaluation of additional polymorphisms could enhance the prevention of fluoropyrimidine toxicity. The results are expected to be clarified further in the second step, which is ongoing.

SNPs	No. of pts	%
c.2846 A > T	1	0.88
c.1679T > G	2	1.75
c.2194C > A	19	16.6
Total	22	19.3

2568 Poster Session (Board #60), Mon, 8:00 AM-11:30 AM

Exposure-efficacy and safety analysis of durvalumab in patients with urothelial carcinoma (UC) and other solid tumors. *First Author: Chaoyu Jin, MedImmune, Mountain View, CA*

Background: Durvalumab is a human monoclonal antibody that binds to PD-L1 and blocks its interaction with PD-1 and CD-80. The objective of this analysis was to evaluate the relationship between durvalumab PK exposure with efficacy and safety following 10 mg/kg Q2W durvalumab. **Methods:** Data from Study 1108 (Phase 1/2; all tumor types) and ATLANTIC (Phase 2; NSCLC) were used for exposure-safety analysis for Study 1108 UC cohort, Study 1108 all patients and ATLANTIC patients, respectively, whereas the exposure-efficacy analysis was performed using data from Study 1108 UC cohort. The observed PK exposure metrics included PK concentrations after the first, second or steady state doses. Efficacy endpoints used were objective response rate (ORR) and best percentage change in target lesion from baseline per BICR assessment. Safety endpoints included Grade 3+ AE (any AE, drug-related AE, AESI, and drug-related AESI) and AE leading to treatment discontinuation. **Results:** Overall, no association of PK exposure with efficacy or safety was observed. Distribution of PK metrics were similar between responders and non-responders. The probability of objective response was similar in all quartiles of exposure (p-value ranged from 0.37 to 0.67; n = 96) with no obvious trends between PK exposures and change in tumor size. For Grade 3+ AE (all types) and AE leading to treatment discontinuation, higher PK exposure was not associated with an increased risk of AE (p-value ranged from < 0.00005 to 0.88; n = 158, 929 and 434 for 1108 UC cohort, 1108 all patients and ATLANTIC all patients, respectively). A few inverse trends were observed, likely due to confounding effect of ECOG or albumin since covariate analysis demonstrated that both variables correlated with PK and AEs. In addition, the association of ECOG and albumin versus PK exposure were also observed in the population PK modeling. **Conclusions:** The exposure-efficacy and exposure-safety analyses suggested that 10 mg/kg IV Q2W regimen was an appropriate dose for durvalumab as single agent in UC patients. Overall, no relationship of PK exposure with either the efficacy or safety was observed following 10 mg/kg IV Q2W regimen. Clinical trial information: NCT02087423 and NCT01693562.

2569 Poster Session (Board #61), Mon, 8:00 AM-11:30 AM

Vitamin K epoxide reductase complex subunit 1 (VKORC1): A pharmacogenomic predictor of response and survival in patients (pts) on triplet hepatic artery infusion (HAI) and intravenous cetuximab (IV-Cet) for initially unresectable liver metastases from colorectal cancer (uLM-CRC) (EU trial OPTILIV). *First Author: Francis Levi, Cancer Chronotherapy Unit, Warwick Medical School, Coventry, United Kingdom*

Background: The HAI of Irinotecan-Oxaliplatin-5-Fluorouracil (IFO) with IV-Cet achieved 29.7% complete uLM-CRC resections (R0+R1) and an overall median survival (OS) of 25.7 months in previously treated pts *(Lévi, Ann Oncol 2016)*. **Methods:** To identify pharmacogenomic predictors of outcomes, 207 single nucleotide polymorphisms (SNPs) from 34 pharmacology genes were analysed in blood mononuclear cells (ADME PGx, MassArray platform, Sequenom, USA). Relations between SNPs and tumor response, R0+R1, survival, and toxicities were tested using adjusted Mann Whitney, Fisher Exact, Log Rank tests and Hardy-Weinberg Equilibrium. **Results:** Pts (16F;36M; 33-76 yo; WHO performance status 0-1) received protocol treatment as 2nd (21 pts) or 3-4thline (31 pts). VKORC1 SNPs in promoter (rs9923231) and intron (rs9934438) were consistently associated with early and objective responses, and overall survival. For rs9923231, T/T (N = 8) as compared to C/T (N = 21) had greatest chance of achieving early response (50% vs 5%, p = 0.029) or 4-y survival (46% vs 0%, p = 0.006). VKORC1 SNPs also related to HA thrombosis (rs992331, T/T, 77% vs C/C, 30%, p = 0.04). In contrast, NAT2 SNPs (rs1041983 and rs1801280) were associated with up to 5-fold differences in R0-R1 resection rate. Statistically significant associations ($p < 0.05$) of SNPs with clinical outcomes were found for oxydo-reduction (CYP2E1 and HA thrombosis; CYP2C9 and diarrhea; CYP2C19 and diarrhea, fatigue, and early response), conjugation (UGT1A1 and diarrhea; NAT2 and fatigue); and transport (ABCB1 or SLCOB3 and neutropenia; SLC22A1 and diarrhea; SLC 15A2 and early response). **Conclusions:** VKORC1 was highlighted for the first time, as a pharmacogenomic predictor of HAI efficacy for LM-CRC. Conversion-to-resection was associated with NAT2 polymorphism. VKORC1 γ-carboxylates vitamin K-dependent proteins. Its polymorphism guides personalized warfarin dosing. VKORC1 SNPs determination could help identify the uLM-CRC pts who best benefit from intensive HAI therapy. Clinical trial information: NCT00852228.

2570 Poster Session (Board #62), Mon, 8:00 AM-11:30 AM

A first in human phase I study of AZD8186, a potent and selective inhibitor of PI3K in patients with advanced solid tumours as monotherapy and in combination with the dual mTORC1/2 inhibitor vistusertib (AZD2014) or abiraterone acetate. *First Author: Aaron Richard Hansen, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Loss of PTEN function leads to increased PI3Kβ signalling. AZD8186 (AZD) exhibits significant anti-tumour activity in PTEN-deficient preclinical models, particularly when combined with anti-androgens or the dual mTORC1/2 inhibitor vistusertib (AZD2014). Here we report on the dose-finding part of this Phase 1 study. **Methods:** AZD single agent was administered twice daily (BD) in 3 different schedules (5 days on/ 2 days off, 2 days on/ 5 days off and continuous). Escalating doses of AZD were evaluated in cohorts of 3-6 patients treated until progression, unacceptable toxicity, or consent withdrawal. Accrual is ongoing in the combination arms with vistusertib or abiraterone acetate. **Results:** As of 16 Jan 2017, 87 patients have received AZD at doses of 30–360 mg BD, with 28 confirmed as PTEN deficient (IHC). The selected RP2D for the 5 days on/2 days off monotherapy schedule is 60 mg BD. PK parameters show that systemic exposures to AZD and its major active metabolite increase in a dose proportional manner. 69 serious adverse events (SAEs) were reported in 31 patients on AZD monotherapy with 23 SAEs considered possibly related to AZD. In the 5/2 schedule: 5 dose limiting toxicities (G3 rash with ≥G2 fever and/or chills) were observed in 5 patients at doses of 120-360mg. Adverse events ≥G1 in $>$ 20% included diarrhoea, nausea, fatigue, LFT elevations and decreased appetite. 20 patients remained on study for $>$ 100 days. Dose-dependent target inhibition has been demonstrated in surrogate tissue (platelets). Evaluation of direct tumour target engagement in paired biopsies is currently ongoing. Preliminary efficacy: Confirmed PRs seen in a CRPC patient (BRCA2 and androgen receptor mutant) treated in combination with vistusertib (on study for 411 days) and in one ongoing monotherapy PTEN-deficient colorectal cancer patient (on study $>$ 329 days). Updated data will be presented. **Conclusions:** AZD has potential for treatment of PTEN-deficient tumours. Investigation of the safety/tolerability and preliminary efficacy in combination with vistusertib or abiraterone acetate is continuing. Clinical trial information: NCT01884285.

2571 Poster Session (Board #63), Mon, 8:00 AM-11:30 AM

TAX-TORC: A phase I trial of vistusertib (AZD2014) in combination with weekly paclitaxel with integrated pharmacodynamic (PD) and molecular characterization (MC) studies. *First Author: Raghav Sundar, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: In ovarian cells isolated from ascites, p-S6K levels were found to correlate with resistance to chemotherapy. We hypothesised that inhibiting p-S6K signalling with dual m-TORC1/2 inhibitor vistusertib (V) in addition to paclitaxel (P) would improve outcomes of patients with high-grade serous ovarian cancer (HGSOC). **Methods:** In the dose escalation part, weekly P 80mg/m^{2}IV (6/7 weeks) was evaluated in combination with two schedules of V; Schedule A: V (25, 50 or 75mg) BID PO on day(D) 1-3/week and Schedule B: V (75 or 100mg) BID PO D1-2/week. This was followed by an expansion cohort in 25 HGSOC patients. **Results:** Dose limiting toxicities in Schedule A were fatigue and mucositis and in Schedule B were diarrhoea, rash and fatigue. The AUC, Cmax and half-life of V in the 50mg-cohort were 2821ng.hr/ml, 926ng/ml and 3hrs, comparable to single agent studies. PD analysis (from six 50mg-cohort patients) in platelet-rich plasma showed increased phosphorylation of Ser473 AKT following P induction (1.4 fold, p = 0.1378). Following addition of V to P, phosphorylation levels 4hrs post-treatment with V fell significantly to 53% of pre-dose levels (p = 0.0495). This was 61% lower than the corresponding time point following P alone. Based on toxicity, pharmacokinetic and PD evaluation, recommended phase 2 dose was established as P 80mg/m^2 D1 and V 50mg BID D1-3 for 6/7 weeks. In the HGSOC expansion, 96% of patients had relapsed within 12 months of last platinum therapy and 100% had received previous paclitaxel, with a median of 3 previous lines of treatments. RECIST and GCIG CA125 response rates were 13/25 (52%) and 15/25 (60%) respectively, with median progression free survival of 5.5 months. MC was performed on archival tumor tissue of 24/25 HGSOC expansion cohort patients, with the most common mutations occurring in *p53* (100%), *BRCA* (17%), and *MUC16* (17%). *ATM* mutations occurred in 17% (n = 4), 3 of whom had a response. **Conclusions:** We report a highly active combination of paclitaxel with an intermittent schedule of vistusertib in patients with HGSOC. This combination is now being evaluated in a randomised controlled trial for this indication. Clinical trial information: NCT02193633.

2572 Poster Session (Board #64), Mon, 8:00 AM-11:30 AM

Investigating novel resistance mechanisms to third generation EGFR TKI osimertinib in non-small cell lung cancer patients using next generation sequencing. *First Author: Qiuxiang Ou, Geneseeq Technology Inc., Toronto, ON, Canada*

Background: Third generation epithelial growth factor receptor (*EGFR*) tyrosine kinase inhibitor (TKI) osimertinib (AZD9291) has proven effective in Non-small cell lung cancer (NSCLC) patients who have developed *EGFR* T790M-mediated resistance to other EGFR TKIs. Unfortunately, a majority of patients still undergo progressed disease after receiving osimertinib treatment. Acquired *EGFR* C797S mutation has been identified as one major mechanism; however, resistance mechanisms of remaining cases are still largely unknown. **Methods:** Using next generation sequencing (NGS) targeting 416 cancer-relevant genes, we analyzed the mutation profiles of 99 NSCLC patients that were clinically resistant to osimertinib. **Results:** In addition to the notable *EGFR* C797 variants (22%), L792 mutations were identified in 10% of patients, and a further 7% cases carry L718 mutations. Further analysis of 14 patients with paired pre-treatment samples confirmed that these *EGFR* mutations were acquired during treatment. Interestingly, all L792 mutations are *in cis* with T790M and *in trans* with C797 mutations (when present in the same patient). 2 out of 10 L792-positive patients and 6 out of 7 L718-positive patients did not have co-existing C797 mutations, suggesting C797-, L792- and L718-mutated cells may represent different resistant clones. *In vitro* experiments demonstrated that L792 and L718 mutants also increase osimertinib IC50, and therefore confer their resistance. Besides secondary *EGFR* mutations, alterations in other key genes such as *MET*, *KRAS*, *ERBB2 and PIK3CA* may also contribute to osimertinib resistance. Notably, *MET* and *KRAS* amplifications are present only in patients without above *EGFR* secondary mutations. **Conclusions:** In this study, we identified secondary mutations on C797, L792 or L718 residues of *EGFR* in 29% of osimertinib-resistant patients. Combined with *in vitro* study, our data strongly suggest that L792 and L718 mutations are likely to alternatively cause osimertinib resistance. Furthermore, *MET* and *KRAS* amplification may serve as bypass resistance mechanisms in patients who are EGFR C797-, L792- and L718-wild type.

2573 Poster Session (Board #65), Mon, 8:00 AM-11:30 AM

A phase I trial of selective PI3K inhibitor taselisib (tas) plus palbociclib (palb) with and without endocrine therapy incorporating pharmacodynamic (PD) studies in patients (pts) with advanced cancers. *First Author: Joline Si Jing Lim, Royal Marsden Hospital, Sutton, United Kingdom*

Background: The phosphatidylinositol 3-kinase (PI3K) pathway is commonly mutated in cancer. Tas is a selective β-isoform-sparing PI3K inhibitor with improved therapeutic index compared to pan-PI3K inhibitors. Palb is a CDK4/6 inhibitor now standard of care in combination with endocrine therapy (ET) in hormone receptor positive breast cancer. Combination of Tas, Palb and ET is synergistic in preclinical models. **Methods:** This investigator-initiated study investigated safety and tolerability, pharmacokinetics (PK), PD and antitumor activity of Tas+Palb, with addition of ET in dose expansion. Pts were enrolled in 3+3 dose escalation design. Tas was given continuously or 3-weeks-on, 1-week-off (3/1), Palb was given on 3/1 schedule. PD studies included analyses of platelet-rich plasma (PRP) (n = 20) and paired tumor biopsies (n = 5). Serial circulating tumor DNA was monitored in pts with *PIK3CA* mutations. **Results:** 24 pts were treated, 22 with Tas+Palb, 2 with Tas+Palb+fulvestrant(ful); M/F 11/13, median lines prior therapy 4. Treatment was well tolerated with mainly G1-2 toxicities. Most frequent G3 toxicities were neutropenia (5/24), thrombocytopenia (5/24) and rash (5/24), with no G4/5 toxicities. Two pts had dose-limiting toxicities (DLT) at DL2. No DLTs were observed at DL4, although pts experienced delayed neutrophil recovery. PK was linear and comparable with monotherapy. At 125mg Palb, significant decreases in pAKT and pGSK3β in PRP confirmed PI3K target inhibition. Two pts with *PI3KCA* H1047R mutant breast cancers have ongoing RECIST partial response; 1 pt with *PIK3CA* E542K colorectal cancer had stable disease for 20 weeks. **Conclusions:** Tas+Palb is well tolerated with evidence of PD and antitumor activity. Dose expansion including recruitment to triplet Tas+Palb+ful and Tas+Palb+letrozole is ongoing with continuous Tas 2mg QD, and Palb 100mg QD on 3/1 schedule, increasing to 125mg after cycle 1 in absence of myelosuppression. Clinical trial information: NCT02389842.

Dose level (DL)	Palb dose (mg)	Tas dose (mg)	Tas schedule	N	DLT
1	100	2	3/1	4	-
2	100	4	3/1	3	G3 mucositis G3 hyperglycemia G3 fatigue
3	125	2	3/1	7	-
4	125	2	continuous	6	-

2574 Poster Session (Board #66), Mon, 8:00 AM-11:30 AM

Phase 1 results of PTC596, a novel small molecule targeting cancer stem cells (CSCs) by reducing levels of BMI1 protein. *First Author: Jeffrey R. Infante, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: PTC596 is an oral investigational new drug that reduces levels of BMI1, a protein required for CSC survival. PTC596 reduced the number of CSCs in preclinical models and slowed growth rates of tumor xenografts in rodent models. The primary objectives of this first-in-human trial of PTC596 were to determine safety, dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), and pharmacokinetics (PK). Secondary objectives included exploratory assessments of biological efficacy, pharmacodynamic changes and anti-tumor activity. **Methods:** A Phase I multi-center, open-label study was conducted in patients with advanced solid tumors using a modified 3+3 design, followed by a dose-confirmatory 10-patient expansion. PTC596 was administered using bodyweight-adjusted twice-per-week (biw) oral dosing in 4 week cycles. Dose escalation and MTD were based on observed cycle 1 DLTs. Anti-tumor activity was assessed by RECIST 1.1. **Results:** A total of 31 patients with a broad range of tumor types were enrolled at dose levels of 0.65 (N = 3), 1.3 (N = 3), 2.6 (N = 3), 5.2 (N = 11), 7 (N = 8) and 10 mg/kg (N = 3). Nausea, vomiting, and diarrhea were the most common all grade adverse events, though usually mild and manageable. At 10 mg/kg one patient experienced DLTs of neutropenia, mucositis, and thrombocytopenia. The other two patients at this dose level also experienced poor tolerability with Grade 2 nausea, vomiting, and diarrhea that may be partially due to the overall pill burden and excipients. The recommended dose for the expansion and further study was 7 mg/kg. Over the dosing range, plasma concentrations of PTC596 increased in an approximately dose-proportional manner and at doses of 2.6 mg/kg and above exceeded those associated with activity in vitro and in vivo models. Best response was stable disease in 5 patients including two with minor radiographic reductions in tumor volume. **Conclusions:** PTC596 is tolerable with manageable gastrointestinal side effects. At 7 mg/kg biw exposures exceeded those associated with preclinical activity and future clinical studies are planned for this first-in class molecule that targets CSCs. Clinical trial information: NCT02404480.

2575 Poster Session (Board #67), Mon, 8:00 AM-11:30 AM

Phase 1 study of the p53-MDM2 inhibitor AMG 232 combined with trametinib plus dabrafenib or trametinib in patients (Pts) with *TP53* wild type (TP53WT) metastatic cutaneous melanoma (MCM). *First Author: Stergios J. Moschos, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Large sequencing studies in MCM have shown a TP53WT incidence of approximately 80%. In preclinical TP53WT melanoma models, the oral p53-MDM2 inhibitor AMG 232 exhibited synergistic, cytotoxic-type antitumor activity when combined with MAPK inhibitors. This phase 1 study assessed the toxicity (CTCAE 4.03), maximum tolerated dose (MTD), pharmacokinetics (PK), and preliminary antitumor activity (RECIST 1.1) of AMG 232 plus trametinib (T) and dabrafenib (D) ($BRAF^{V600\text{-}mutant}$) or T ($BRAF^{V600\text{-}WT}$) in pts with TP53WT MCM. **Methods:** Using 3+3 dose escalation design, pts with advanced TP53WT (using a CLIA-approved assay) MCM received AMG 232 PO QD for seven days of each 3-week cycle (7/21) at 120, 240, or 480 mg plus either T 2 mg PO QD and D 150 mg PO BID (Arm 1; $BRAF^{V600\text{-}mutant}$) or T 2 mg QD (Arm 2; $BRAF^{nonV600\text{-}mutant}$). **Results:** At the time of this analysis, 21 pts (median age, 58 y [range 24–76]; male, n = 11; at least 2 systemic treatments, n = 15) were treated. Arm 2 enrolled first: AMG 232 120 mg (n = 6), then 240 mg (n = 6). Due to chronic grade (G) 2 gastrointestinal toxicity, an intermediate dose (180 mg; n = 3) was determined as the preliminary MTD. Arm 1 enrolled at AMG 232 120 mg (n = 4), then 180 mg (n = 2). The most common reasons for AMG 232 withdrawal were disease progression (n = 8) and AEs (n = 4); 6 pts remain on AMG 232. All 21 pts had treatment-related AEs (TRAEs); the most common TRAEs were nausea (n = 18), fatigue (n = 17), diarrhea (n = 14), and vomiting (n = 13). The only DLT (Arm 2; 240 mg) was G 3 pulmonary embolism. Preliminary PK analysis suggests that AMG 232 exposure (area under the curve) is similar to that as monotherapy at the same dose, with no apparent drug-drug interaction between AMG 232 and T; analysis of D and T PK is ongoing. Of 21 pts, 6 had partial response (Arm 1/2, n = 4 [67%]/2 [13%]), 13 had stable disease (Arm 1/2, n = 2 [33%]/11 [73%]), and 2 progressed (Arm 1/2, n = 0/2 [13%]) as best response; 17 had tumor reduction (Arm 1/2, n = 6 [100%]/11 [73%]). **Conclusions:** In this population of pts with MCM, AMG 232 combined with D and/or T during DE was tolerable up to 180 mg QD 7/21 days, showing an acceptable PK profile and early antitumor activity. Clinical trial information: NCT02110355.

2576 Poster Session (Board #68), Mon, 8:00 AM-11:30 AM

Phase 1 dose escalation study of the folate receptor-targeted small molecule drug conjugate EC1456. *First Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

Background: The folate receptor (FR) is highly expressed in a variety of cancers including adenocarcinoma of the lung, but is expressed at low levels in most normal tissues, making it a potential target for therapeutic intervention. EC1456 is an FR-targeted small molecule drug conjugate (SMDC) consisting of folic acid chemically attached through a bio-releasable linker system to a potent microtubule inhibitor, tubulysin B hydrazide (TubBH). EC1456 binds to, and is endocytosed by the FR-expressing cancer cell to deliver TubBH. Following endocytosis, the FR recycles back to the membrane surface every 18-24 hours. Therefore alternative EC1456 schedules will be evaluated for safety, pharmacokinetics, and therapeutic benefit. **Methods:** Part A (dose escalation) is being evaluated in unselected patients (pts) with advanced solid tumors. 4 schedules (3-week cycle) are being evaluated: BIW (twice weekly); QW (once weekly); CWD (continuously weekly); QIW (four times a week). The primary objective of Part A is to determine the RP2 dose and schedule of EC1456. Part B (expansion) will confirm the MTD and RP2 dose and evaluate efficacy of EC1456 in ^{99m}Tc-etarfolatide-selected NSCLC patients in up to three schedules. **Results:** 74 Part A pts are evaluable for toxicity. Median age is 68 (range: 26-88); 53 pts are female. Toxicities are primarily Grade (Gr) 1 and 2. Common treatment-related adverse events (TRAE) are gastrointestinal, fatigue, metabolic changes, alopecia, and headache. 5 Gr 3 DLTs have been observed: infusion reaction (4.5 mg/m^2 QW), headache (10.0 mg/m^2 QW), and abdominal pain (7.5 mg/m^2 BIW, 12.5 mg/m^2 QW and 10.0 mg/m^{2}CWD). TRAEs are summarized in the table for each schedule. Durable stable disease of 12 wks or longer has been observed in 12 pts (6 BIW and 6 QW). **Conclusions:** All Part A EC1456 schedules have been well tolerated. RP2 dose for BIW is 6.0 mg/m^2 and QW is 12.5 mg/m^2; dose escalation is ongoing for CWD and QIW. Early signs of efficacy in an unselected pt population may be suggested by durable stable disease. Safety and efficacy evaluation in the ^{99m}Tc-etarfolatide-selected NSCLC population (Part B) is ongoing. Clinical trial information: NCT01999738.

2577 Poster Session (Board #69), Mon, 8:00 AM-11:30 AM

A phase Ia study of CC-90003, a selective extracellular signal-regulated kinase (ERK) inhibitor, in patients with relapsed or refractory BRAF or RAS-mutant tumors. *First Author: Monica M. Mita, Cedars-Sinai Comprehensive Cancer Center, Los Angeles, CA*

Background: CC-90003 is an irreversible inhibitor of ERK 1/2 with potent anti-proliferative activity in *KRAS* and *BRAF* mutant tumor models. We conducted a first-in-human study of CC-90003 in patients with *RAS* or *BRAF* mutant tumors. **Methods:** Patients received escalating doses of oral CC-90003 on a 21/28 day cycle. Standard safety (adverse events, chemistry/hematology, physical findings, ECGs and cardiac ECHO/MUGA scans) and PK parameters were assessed. Response was assessed per RECIST 1.1. A proprietary ELISA-based assay measured ERK levels unbound to CC-90003 in peripheral blood mononuclear cells. **Results:** Nineteen patients (median age: 60 yrs) harboring *KRAS* (n = 15), *NRAS* (n = 1), or *BRAF* (n = 3) mutant tumors received CC-90003 doses from 20 to 160 mg /day. The MTD was 120 mg based on the occurrence of Grade 3 transaminase elevations (n = 2) and hypertension (n = 1) observed at 160 mg (the NTD). Patients completed a median of 2 cycles (range: 1 to 5). AEs (mostly Grade 1 or 2) reported in ≥ 3 patients included constitutional (asthenia, fatigue), gastrointestinal (anorexia, nausea/vomiting, diarrhea), hepatic (transaminase elevations) and neurologic (dizziness, gait disturbance, paresthesias) toxicities. Grade 1-3 neurotoxicity was observed primarily at doses from 80 to 160 mg/day and resolved with dose reduction/interruption. PK parameters were highly variable, with AUC and C_{max} increasing overall, with increasing dose. CC-90003 accumulation was observed after multiple doses. There were no objective responses. Levels of free ERK were reduced by ≥80% compared to baseline by C1D8 at doses ≥ 80 mg/day. **Conclusions:** ERK inhibition may be an attractive target for the management of mutant *RAS* or *BRAF*-driven tumors, however proof-of-concept demonstration for CC-90003 was limited by a lack of objective responses, an unfavorable PK profile and unanticipated neurotoxicity. Clinical trial information: NCT02313012.

2578 Poster Session (Board #70), Mon, 8:00 AM-11:30 AM

SWOG S1221: A phase 1 dose escalation study co-targeting MAPK-dependent and MAPK-independent BRAF inhibitor resistance in BRAF mutant advanced solid tumors with dabrafenib, trametinib, and GSK2141795 (ClinicalTrials.gov NCT01902173). *First Author: Alain Patrick Algazi, University of California, San Francisco Medical Center-Mt. Zion, San Francisco, CA*

Background: Aberrant PI3K/AKT signaling in BRAF mutant cancers contributes to resistance to MAPK pathway blockade. We conducted parallel phase 1 dose escalation studies of the doublet of the BRAFi dabrafenib with the AKT inhibitor GSK2141795 and of the triplet of dabrafenib, the MEKi trametinib, and GSK2141795. **Methods:** Patients (pts) with BRAF-V600E/K mutant advanced solid tumors with adequate end-organ function were eligible regardless of prior BRAFi and MEKi exposure. All pts received dabrafenib at 150 mg twice daily (bid), in the doublet cohorts together with dose escalation (3 + 3 scheme) of GSK2141795 started at 50 mg daily (qd), and in the triplet cohorts with dose escalation of both trametinib starting at 1.5 mg qd and GSK2141795 starting at 25 mg qd. DLTs included significant grade 3 and 4 adverse events (CTCAE v4) within the first 56 days of treatment. Radiographic responses were assessed at 8-week intervals. **Results:** No DLTs were observed in the doublet cohorts (N = 8) up to dabrafenib 150 mg bid and GSK2141795 75 mg qd. In the triplet cohorts (N = 11), no DLTs were observed at doses of up to trametinib 1.5 mg daily with GSK2141795 75 mg daily. At the highest triplet dose with dabrafenib 150 mg bid, trametinib 2 mg qd with GSK2141795 75 mg qd, 1 of 2 evaluable pts had a DLT of grade 3 febrile neutropenia and grade 3 maculopapular rash. 2/2 treatment-naïve in the doublet cohorts had PRs (1 melanoma and 1 thyroid) the latter lasting over 1 year. 1/6 BRAF inhibitor-refractory (melanoma) pts also had an objective response. In the triplet cohorts, 3 of 6 treatment-naïve pts had a PR (1 melanoma, 2 lung). One lung pt remains in PR at 2 months and the otherhas an uPR at 1.2 months. **Conclusions:** Inhibition of both MAPK and PI3K/AKT pathways was well tolerated, leading to durable objective responses in pts with metastatic melanoma, thyroid cancer, and lung cancer. Further study of dual pathway inhibition is warranted. Funding: Supported in part by NIH/NCI grants CA180888, CA180819; and in part by Novartis Pharmaceuticals Corporation and GlaxoSmithKline, LLC. Clinical trial information: NCT01902173.

2579 Poster Session (Board #71), Mon, 8:00 AM-11:30 AM

A phase 1 dose escalation study of eFT508, an inhibitor of mitogen-activated protein kinase-interacting serine/threonine kinase-1 (MNK-1) and MNK-2 in patients with advanced solid tumors. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: Dysregulated translation of messenger RNA (mRNA) plays a role in the pathogenesis of multiple solid tumors. eFT508, a potent and highly selective small molecule inhibitor of MNK-1 and 2 blocks activation of eIF4E, a key regulator of mRNA translation, and thereby selectively regulates translation of a small set of mRNAs. In addition to direct antitumor activity, eFT508 triggers an anti- tumor immune response and enhances responses to checkpoint inhibitors in preclinical models. **Methods:** Using a 3+3 dose escalation schema, cohorts of solid tumor patients (pts) were treated with eFT508 administered orally once daily at doses ranging from 50 mg to 600 mg. **Results:** 28 pts were treated, and the most common tumor types were colorectal cancer (8), prostate cancer (3), and soft tissue sarcoma (3). Median number of prior therapies was 4. The most common observed adverse events (AEs) included nausea (47%), vomiting (47%), dyspepsia (23%), fatigue (20%), and constipation (20%). Two pts treated at 600 mg experienced Gr 3 related AEs, including one pt with Gr3 nausea and vomiting (met criteria for dose limiting toxicity) and one pt with reversible Gr3 AST/ALT elevation. 6 pts achieved stable disease with duration ranging from 82 to 196 days. Pharmacokinetic analysis revealed that eFT508 is bioavailable and rapidly absorbed, with median T_{max} of 2 hours and a mean $T_{1/2}$ of 12 hours. Minimal accumulation was observed between Days 1 and 14/15, with mean accumulation factor of 1.2-fold. Analysis of eIF4E phosphorylation in peripheral blood cells suggested that doses ≥ 300 mg achieved engagement sufficient for maximal efficacy as predicted by preclinical models. **Conclusions:** Preliminary results suggest that eFT508 is well tolerated, and dose escalation continues with a cohort of pts providing pretreatment and on treatment biopsies for evaluation of target engagement and immunomodulatory effects. After determination of the recommended phase 2 dose, further evaluation will include monotherapy cohorts in specific tumor types as well as cohorts to evaluate efficacy and tolerability in combination with checkpoint inhibitors. Clinical trial information: NCT02605083.

2580 Poster Session (Board #72), Mon, 8:00 AM-11:30 AM

Phase I dose escalation study of CVM-1118, a novel anti-vascular mimicry agent, in patients with advanced cancers. *First Author: Anthony W. Tolcher, START, San Antonio, TX*

Background: CVM-1118 is an oral NCE that demonstrated potent anti-tumor effects in several tumor xenograft models, via multiple MOAs including induction of cancer cell cycle arrest and apoptosis, and reducing vasculogenic mimicry (VM) network formation in cancer cells, providing a promising therapeutic means in the treatment of malignant tumors that have metastatic potential. **Methods:** Patients with advanced tumors are being enrolled into 2 ongoing open-label Phase I dose escalation studies in both US (CVM-001) and Taiwan (CVM-002) to evaluate ethnic differences in drug responses. CVM-1118 capsules are administrated orally QD/BID in a 28-day cycle for 4 cycles. The primary objectives are to evaluate the safety, tolerability and pharmacokinetics (PK) and establish the Recommended Phase 2 Dose (RP2D). The secondary objective is to evaluate the therapeutic response after receiving treatment. Beyond 4 cycles, patients showing clinical benefit with CVM-1118 may enter extension cohort to continue the treatment. **Results:** To date, 28 pts (16 M/12 F)received CVM-1118 across 6 dose levels (50 to 800 mg daily). Median number of days was 52 (range 2 to 135). For CVM-001, 2 DLTs (grade 5 dehydration and grade 3 fatigue) were reported at cohort 6 (800 mg/daily) and the MTD is currently under evaluation. For CVM-002, 3 cohorts (100 to 400 mg/daily) have been completed without DLT. Enrolment to cohort 5 (600 mg/daily) is in progress. From both studies, the most common drug-related AEs included manageable diarrhea, nausea, and vomiting. Rapid oral absorption was observed with Tmax $<$ 2 hr. Bioconversion to active metabolite, CVM-1125, occurred rapidly and the drug exposure increased with increasing dose levels. However, patients in US study showed higher drug exposure than those in Taiwan study. Two patients at 200 mg/daily cohort in Taiwan completing 4-cycle treatment and showing stable disease continued into extension cohort with higher dose. **Conclusions:** In this ongoing study, Asian patients in Taiwan appear to have better tolerance for CVM-1118 than those in US, likely due to lower drug exposure at same dose level, and some patients have experienced clinical benefit. Clinical trial information: NCT02507544; NCT02703298.

2581 Poster Session (Board #73), Mon, 8:00 AM-11:30 AM

Molecular markers to predict response to selective fibroblast growth factor receptor inhibitors (FGFRinh) in patients (pts) with FGFR-amplified (amp) or mutated (mut) tumors. *First Author: Cinta Hierro, Medical Oncology Department, Vall d'Hebron University Hospital, Molecular Therapeutics Research Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Several FGFR and ligand (11q) alterations have been described in cancer. While FGFR fusions are recognized biomarkers of response to FGFRinh, it is still unclear to what extent FGFRamp, FGFR mRNA high expression (mRNAh) or FGFRmut predict sensitivity in the clinic. **Methods:** Retrospective analysis of pts with molecularly-selected FGFRamp/mRNAh/mut tumors treated with FGFRinh in phase 1 trials at our institution. Mut were detected with IlluminaÒ or Foundation OneÒ. FGFR1-2amp were analyzed by in situ hybridization and mRNA levels by qRT-PCR or nCounterÒ. Clinical benefit (ClinBen) was defined as any tumor shrinkage plus disease control for ³ 4 months (m). Time to progression (TTP) was defined as time between start of FGFRinh and end for any cause. **Results:** From 2011 to 2016, 36 pts with FGFRamp(25)/mRNAh(5)/mut(6) received an FGFRinh (irreversible- [11 cases (c)] or reversible-FGFR1-4inh [23 c], isoform-specific FGFRinh [3 c] or combo with PI3Kinh [1 c]). Median age 55 yrs (34-76); median prior palliative lines was 3 (0-8); tumor types: breast (17), colorectal (3), esophagus (3), liver (3), lung (3), others (7). Median TTP was 1.67 m (CI 95%; 1.40-2.87). In the FGFRamp/mRNAh population (30), 7 pts achieved ClinBen (23%). 4 out of these seven pts had mRNAh (1 FGFR2amp breast with FGFR2 mRNAh, 1 bladder FGFR3 mRNAh and 2 liver FGFR4 mRNAh without known amp), and 2 pts harboured 11q co-amplification (1 FGFR2amp breast, 1 FGFR2amp head and neck). There was no correlation between ClinBen and level of FGFRamp in the overall population ($p = 0.51$) or in the breast cancer group ($p = 0.29$). Of 6 FGFRmut pts, one with bladder cancer had ClinBen (clonal oncogenic FGFR3 S249C). The remaining 5 unresponsive FGFRmut pts had subclonal events, some of these FGFRmut were of unknown functional significance, and had coexisting oncogene mut in MAPK or PI3K pathways. **Conclusions:** Our results suggest that ClinBen with FGFRinh in the FGFRamp setting is enriched in pts with high mRNA expression and/or ligand co-amplification, and in the FGFRmut population may be dependent on clonality and functionality of the event and co-existence of driver mut.

2582 Poster Session (Board #74), Mon, 8:00 AM-11:30 AM

Clinical next generation sequencing for precision oncology in rare cancers. *First Author: Roman Groisberg, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Rare tumors receive little financial support or interest from major drug developers or clinical investigators. They are by nature difficult to study even in a large academic medical center. As such, no standard of care exists for many of these cancers and treatment is often extrapolated. ESMO defines rare tumors as 5/100,000 persons per year. We examined patients with rare tumors for potentially targetable genomic alterations using next generation exome sequencing (NGS). **Methods:** We reviewed charts of patients with rare tumors per the ESMO definition. Sarcomas were excluded. Patients were referred to investigational therapeutics department and underwent CLIA certified comprehensive genomic profiling (Foundation Medicine). Actionable alterations were defined as targeted by a drug available on-label, off-label, or in clinical trials. **Results:** Among the 95 patients analyzed median age was 51 years (range 2-75). M:F ratio 46:49. Overall, there were 47 different subtypes in our dataset with the most common being adenoid cystic (13%), cholangiocarcinoma (7%), metaplastic breast (6%), gallbladder (5%), and carcinoid (4%). Eighty-seven out of 96 patients (92%) had at least one genomic alteration identified with mean of 2.6 mutations per patient. Of the patients with identifiable mutations, the most common were *TP53* (23%), *KRAS* (10%), *PIK3CA* (9%), *CDKN2A/B* (8%), *BRAF* (7%), *MLL* (7%), and *ARID1A* (6%). Thirty-six patients (38%) had at least one potentially actionable alteration in 21 different tumors (eg: PI3K in metaplastic breast and adenoid cystic carcinomas and $BRAF^{V600E}$in Erdheim-Chester disease). Nine patients received targeted therapy. Of these 9 patients, 3 had PR, 4 had SD, and 2 had PD as best response (table). **Conclusions:** The addition of CGP to management of rare tumors adds a potential line of therapy especially in RAF pathway altered ultra-rare cancers that have no standard of care.

Disease	Aberration	Therapy	Best Response
Cholangiocarcinoma	$BRAF^{V600E}$	BRAFi	PR
Erdheim-Chester	$BRAF^{V600E}$	BRAFi	PR
Glioblastoma Multiforme	$BRAF^{V600E}$	BRAFi	PR
Adenoid Cystic	PIK3R1 E515fs*1	Akt i	SD x 24 cycles
Salivary gland adenocarcinoma	$BRAF^{V600E}$	BRAFi	PR
Erdheim-Chester	$BRAF^{V600E}$	BRAFi	SD x 3 years

2583 Poster Session (Board #75), Mon, 8:00 AM-11:30 AM

Proof-of concept phase I study of everolimus, letrozole and trastuzumab in hormone receptor-positive, HER2-positive/amplified or mutant metastatic breast cancer or other solid tumors: Evaluating synergy and overcoming resistance. *First Author: Shubham Pant, Oklahoma University Health Sciences Center, Edmond, OK*

Background: Preclinical models suggested synergistic antineoplastic activity of anti-estrogen therapy with HER2 and mTOR inhibitors. **Methods:** We designed a 3+3 dose escalation phase I study of the aromatase inhibitor letrozole 2.5mg PO daily, mTOR inhibitor everolimus 2.5-10mg PO daily and HER2 antibody trastuzumab 4-8mg loading dose followed by 2-4mg maintenance dose IV on day 1 of 21-day cycle in patients with hormone-receptor positive, HER2-positive/amplified or mutant advanced cancers (confirmed by immunohistochemistry and/or FISH and/or next-generation sequencing). The primary objectives were to determine maximum tolerated dose (MTD), dose limiting toxicities (DLT), overall safety and response. **Results:** A total of 18 patients (men, 1; women, 17; HER2 amplification, 14; HER2 mutation, 4; breast cancer, 15; ovarian cancer, 1; cervical cancer, 1; gastroesophageal junction cancer, 1), median age 56 years, median of 6 prior therapies (including letrozole [9] or other aromatase inhibitor [8]; everolimus [3]; trastuzumab [14] or other HER2 targeted therapy [1]) were enrolled in the planned 6 dose levels. The MTD has not been reached and grade 3 (G3) mucositis at the dose level 4 was the only DLT. Other G3 or G4 drug-related toxicities included G4 hyperglycemia in 1 patient, G3 hyperglycemia in 3 patients, G3 thrombocytopenia in 1 patient, G3 anemia in 1 patient and G3 headache in 1 patient. Of 18 patients, 3 (17%) had a partial response (all with heavily-pretreated breast cancer with HER2 amplification [2] or $HER2^{A775\_G776insYVMA}$ mutation [1]), 11 (61%) stable disease (SD) including 7 (39%) patients with SD $>$ 6 months (all with heavily-pretreated breast cancer), 3 (17%) progressed and 1 had pending evaluation. The median change in size of target lesions per RECIST 1.1. was -11% (-68% to +47%). Median progression-free survival was 9 months (95% CI 5.8-12.2). **Conclusions:** The combination of letrozole, everolimus and trastuzumab is well tolerated with encouraging activity in heavily-pretreated patients with HER2-amplified or mutant advanced breast cancer. Clinical trial information: NCT02152943.

2584 Poster Session (Board #76), Mon, 8:00 AM-11:30 AM

First-in-human phase 1 study of ETC-159 an oral PORCN inhbitor in patients with advanced solid tumours. *First Author: Matthew Ng, Division of Medical Oncology, National Cancer Centre, Singapore, Singapore*

Background: The Wnt signalling pathway is involved in cellular proliferation, differentiation, migration and implicated in stem cell function in several cancers. ETC-159 is a selective small molecule inhibitor of porcupine, an enzyme required for palmitoylation and secretion of all Wnt ligands. In preclinical studies, ETC-159 induced tumour regression in patient-derived xenograft models. **Methods:** Open-label, multi-centre study to determine safety, maximum tolerated dose, pharmacokinetics, pharmacodynamics (PD) of ETC-159 given orally, once every other day in a 28d cycle. PD was evaluated by AXIN2 mRNA levels in whole blood and hair follicles and bone turnover by radiological and serum markers. Dose escalation was by ordinal continual reassessment method with a dose-limiting toxicity (DLT) period of 28d. **Results:** As of 18 Jan 2017, 16 patients (pts) were treated in 6 cohorts at 1 mg (2pts), 2 mg (2pts), 4 mg (3pts), 8 mg (4pts); 16 mg (3pts), and 30 mg (2pts). 80% were male, median age (range) was 55yr (19-68). One DLT was seen at 16 mg due to hyperbilirubinaemia. Adverse events ($\geq$ 20%) were vomiting (32%); anorexia and fatigue (31%); dysgeusia and constipation (25%). ETC-159 C_{max} increased with dose with a mean $t_{1/2}$ of 14 hr. Plasma levels of ETC-159 that inhibited colony formation in vitro were attained from 4 mg onwards. Reduction of whole blood and hair follicle AXIN2 mRNA levels and doubling of serum β-CTX levels was first observed at 4 mg and at C1D15 in some patients. PD modulation increased with dose, consistent with on-target modulation of Wnt signalling. Two pts had β-CTX rise $>$ 1000 pg/mL (reference limit) and a $\geq$ 5% reduction in bone density by C3D1. Both took vitamin D and calcium supplements and were given i.v. bisphosphonates. No responses were seen but 2 pts (2 mg: colorectal and 4 mg: peritoneal carcinoma) had stable disease for 6 and 8 cycles respectively. Dose-escalation is ongoing at 30 mg. **Conclusions:** ETC-159 inhibits Wnt signalling at doses that are well tolerated. β-CTX levels increased early on, and in two pts were associated with reduced bone mineral density. Early and regular monitoring of bone turnover is indicated. This study was sponsored by D3 which is funded by NMRC, NRF and BMRC Singapore. Clinical trial information: NCT02521844.

2585 Poster Session (Board #77), Mon, 8:00 AM-11:30 AM

A phase I dose expansion cohort study of dasatinib in combination with bevacizumab in advanced solid tumors (NCT01445509). *First Author: Akosua Osei-Tutu, National Cancer Institute, Bethesda, MD*

Background: Dasatinib is a known inhibitor of the SRC family kinases and is approved for use in chronic myelogenous leukemia. Bevacizumab inhibits angiogenesis, binding to human vascular endothelial growth factor (VEGF, or VEGF-A) with high affinity. VEGF receptor signals intracellularly via a cascade regulated by SRC. Given the presence of this signaling pathway in both tumor cells and endothelial cells, we hypothesized that attenuation of both SRC and VEGF simultaneously would have synergistic antitumor activity. We previously reported the maximum tolerated dose (MTD) of dasatinib 100mg daily with bevacizumab 10mg/kg q2wk in patients with advanced solid tumors. We now report clinical activity of the combination, and translational endpoints of an expansion cohort. **Methods:** This is a phase 1 dose escalation with non-randomized expansion cohort. We monitored safety, and response was assessed every 8 weeks using RECIST criteria. Correlative endpoints include blood flow by dynamic MR imaging, endothelial cell density by CD31 immunohistochemistry, functional angiogenic potential by plasma cytokines and rat aortic ring assay, and tumor cell activation state by phosphoprotein analysis. **Results:** We enrolled 39 patients at the MTD for a total of 50 patients on study, including both the dose escalation and dose expansion phases. No patient experienced dose limiting toxicities during dose escalation. The most common adverse events were grade 2 hypertension and proteinuria. By RECIST, 5 (10%) patients had a partial response, and stable disease was seen in 29 (58%) of patients with a range from 12-145+ weeks on study. We had two exceptional responders with endometrial carcinoma who continue on study to date (112 weeks and 145 weeks). Translational endpoints were correlated with clinical outcome. **Conclusions:** Bevacizumab and dasatinib are safe in combination, with potential clinical activity. This combination warrants further investigation in solid tumors. Ongoing translational research using specimens from exceptional responders will suggest potential biomarkers of clinical benefit, to be tested in future prospective clinical trials. Clinical trial information: NCT01445509.

2586 Poster Session (Board #78), Mon, 8:00 AM-11:30 AM

Anticancer and immunostimulatory activity of the imipridone ONC201, a selective DRD2 antagonist, in advanced cancer patients. *First Author: Mark N. Stein, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: ONC201 is an orally active, small molecule selective antagonist of the G protein-coupled receptor DRD2 that has established a new class of compounds referred to as imipridones. A first-in-human trial of ONC201 defined its recommended phase II dose (RP2D) as 625mg using once every three week administration that was very well tolerated at doses that yielded antitumor effects. ONC201 also showed stimulatory effects on immune cells in preclinical studies, including increased intratumoral NK cell infiltration in xenografts. Based on the exceptional safety profile of ONC201, weekly dosing has been evaluated. **Methods:** This open-label, 3+3 dose-escalation study used a starting dose of 375mg and escalated to 625mg using a weekly administration schedule. The primary endpoint was to determine the RP2D of ONC201 and secondary endpoints included PD, PK, toxicity, and anti-tumor efficacy. Based on signs of clinical activity and preclinical tumor type sensitivity studies of ONC201, the patient population was enriched for advanced glioblastoma, prostate cancer, and endometrial cancer. Six additional patients were treated at the weekly RP2D. **Results:** The RP2D for the weekly regimen was defined as 625 mg. Twelve evaluable patients were treated at this dose level and no drug-related AEs $>$ grade 1 occurred. Five patients had stable disease by RECIST criteria for 21-29 weeks. A metastatic prostate cancer who received 375mg ONC201 weekly had significantly diminished intensity in bone scans after 6 doses. PK was consistent with previous reports: Cmax consistently reaches therapeutic micromolar plasma concentrations, ~11 hour half-life, evidence of sustained and delayed activity, no systemic accumulation. In agreement with preclinical observations of ONC201-induced NK cell populations, a 2-10 fold increase in circulating activated NK cells was observed in 5 prostate cancer patients. **Conclusions:** ONC201 is well tolerated at an oral dose of 625mg weekly, exhibits sustained and late anti-cancer activity, and increases circulating NK cells. Observation in this study, and other clinical studies, warrant further evaluation of the immune oncology effects of ONC201. Clinical trial information: NCT02250781.

2587 Poster Session (Board #79), Mon, 8:00 AM-11:30 AM

A phase IB study of the combination of selumetinib (AZD6244, ARRY-142886) and cyclosporin A (CsA) in patients with advanced solid tumors with an expansion cohort in metastatic colorectal cancer (mCRC). *First Author: Anuradha Krishnamurthy, University of Colorado-Denver, Aurora, CO*

Background: MEK inhibition is of interest in cancer drug development. However, better strategies are needed to overcome acquired resistance to MEK inhibitors. Preclinical studies have shown Wnt pathway overexpression in KRAS mutant cell lines resistant to the MEK inhibitor, selumetinib. The combination of selumetinib and cyclosporin A (CsA), a non-canonical Wnt pathway modulator, demonstrated antitumor activity in patient-derived xenograft (PDX) models. We conducted an NCI CTEP-approved Phase I/IB trial (NCI # 9571/COMIRB # 13-2628/NCT02188264) of selumetinib and CsA combination. Biomarkers of response are being co-developed. **Methods:** Patients with advanced solid tumors were treated with the combination of selumetinib and CsA in dose escalation followed by an expansion cohort in patients with irinotecan and oxaliplatin-refractory mCRC (n = 20). The expansion cohort utilized a selumetinib "run-in" to evaluate efficacy in RAS-WT and RAS-MT mCRC to identify those patients most likely to respond to the combination. **Results:** As of January 2017, 18 patients were enrolled in the dose escalation phase and 20 patients were enrolled in the dose expansion phase. The most common adverse events and grade 3/4 toxicities were rash, hypertension, and edema. Three DLTs - Grade 3 hypertension, rash and increased creatinine were reported. The maximum tolerated dose was identified as selumetinib 75 mg BID and CsA 2 mg/kg BID on a 28-day cycle. The selumetinib "run-in" did not favor a specific RAS type. Two partial responses were noted. Sixteen patients had stable disease, and 6 patients had progression of disease as their best response to therapy. **Conclusions:** Selumetinib in combination with cyclosporin A appears to be well tolerated with evidence of activity in mCRC. Tumor response data are currently being updated. FZD will be evaluated as a potential biomarker of response. Clinical trial information: NCT02188264.

2588 Poster Session (Board #80), Mon, 8:00 AM-11:30 AM

SWI/SNF complex subunit aberrations in diverse cancers: Next-generation sequencing of 539 patients. *First Author: Roman Groisberg, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The SWI/SNF complex is an ATP-dependent chromatin remodeler that is enriched at promoters and enhancers of active genes. It has been implicated as both an oncogene and tumor suppressor. Specific subunit mutations have even been associated with specific cancers with increased PRC2 component EZH2 activity. EZH2/ EED inhibitors are in early stage development to target SWI/SNF complex. **Methods:** We analyzed 539 consecutive patients with diverse malignancies who were referred for Phase 1 clinical trials and had CLIA certified targeted next-generation sequencing (Foundation one) for presence of aberrations in SWI/SNF complex genes *(ARID1A, ARID2, PBRM1, SMARCA4, SMARCB1)*. Patient charts were reviewed for general demographics (sex, age at diagnosis and death, performance status), tumor histology, stage, metastatic sites, treatment history, outcomes and co-occurring alterations. **Results:** Fifty patients had mutations in SWI/SNF subunits. Median age at diagnosis was 56 (14-79 years) and M:F ratio 21:29. Kidney, colorectal, ovary and breast were the most common among 15 different cancers. Most were stage IV at diagnosis (68%), had a strong family history of cancer (80%) & were smokers (42%). The most common mutated subunit was *ARID1A* (50%) followed by *PBRM1* (16%), *ARID2* (12%), *SMARCA4* (12%), and *SMARCB1* (10%). All mutations were predicted to be inactivating. Actionable co-occurring pathway alterations were found in 58% of patients, most commonly PI3K (26%), FGFR(16%), and NOTCH1/2 (10%). The majority of patients (62%) were enrolled on a clinical trial. Best responses on other targeted agents included 1 CR ($BRAF^{V600E}$ colon), 4 PR (transformed teratoma, skin SCC, ovarian, NSCLC), 12 SD. Exceptional responders included $BRAF^{V600E}$ colon cancer on BRAFi based therapy for 66 cycles, NSCLC on Nivolumab for 34 cycles, and MSI-H colon cancer on regorafenib/cetuximab for 27 cycles. **Conclusions:** The role of SWI/SNF in patients with extended clinical benefit from other targeted agents should be explored. Co-occurring genetic alterations are observed in PI3K, FGFR, and NOTCH pathways. Future pre-clinical and/or clinical studies could target these pathways in combination with EZH2/EED inhibitors.

2589 Poster Session (Board #81), Mon, 8:00 AM-11:30 AM

Phase 1 study of the bone-targeting cytotoxic conjugate, etidronate-cytosine arabinoside (MBC-11), in cancer patients with bone metastases. *First Author: Shawn Zinnen, MBC Pharma Inc, Aurora, CO*

Background: MBC-11 is a first-in-class therapeutic conjugate of the bone targeting bisphosphonate etidronate covalently linked to the antimetabolite cytosine arabinoside (Ara-C). In preclinical studies, MBC-11 localizes at the site of cancer-induced bone disease (CIBD) where it demonstrates both antiresorptive and antitumor activities following local release of Ara-C. Robust efficacy was observed in several rodent models of CIBD, as well as in spontaneous osteosarcoma in dogs. Herein, the results of the first-in-human study of MBC-11 are reported. **Methods:** Patients with advanced solid cancers and CIBD were treated with escalating doses (0.5-10 mg/kg/day) of MBC-11 administered as an intravenous infusion daily for 5 days every 4 weeks for up to 4 cycles. Fifteen patients (prostate cancer [PC; 7], breast cancer [BC; 7], cervical cancer [1]) received 38 total cycles. The study sought to characterize the safety, pharmacokinetics, and the effects of MBC-11 on bone turnover, and tumor response by ^{18}F-FDG-PET/CT imaging and tumor biomarkers. **Results:** Myelosuppression was generally grade 1-2, involved all lineages, and was the principal toxicity of MBC-11. Two of three patients treated at the 10 mg/kg dose level had dose-limiting toxicity (DLT), each with both grade 4 neutropenia and thrombocytopenia, the maximum tolerated dose (MTD) was 5 mg/kg. Four of 5 patients with pretreatment elevations of the bone resorption marker Trap5b had persistent decrements. ^{18}F-FDG-PET/CT imaging demonstrated partial metabolic responses in 3 patients; one BC patient treated at the 0.5 mg/kg and two CRPC patients treated at 1.0 mg/kg dose levels. An additional 3 patients had stable metabolic responses according to PERSIST. SUV values were reduced by at least 25% in 111 (53.8%) of 206 measurable bone lesions; significant activity was noted at all doses. **Conclusions:** At doses that were well tolerated and even much lower than the MTD, MBC-11 treatment resulted in substantial reductions in metabolic activity in CIBD patients, providing a foundation for further disease-directed studies to further assess efficacy. Clinical trial information: NCT02673060.

2590 Poster Session (Board #82), Mon, 8:00 AM-11:30 AM

The effect of supplemental estrogen on the outcomes of NSCLC patients in the SEER-Medicare database. *First Author: Samuel P. Heilbroner, Columbia University Medical Center, New York, NY*

Background: Women with lung cancer have better survival regardless of treatment type. Estrogen has been shown to have cancer-specific and non-cancer effects. However, there is conflicting data on the effect of estrogen hormone therapy on lung cancer incidence and mortality in women. We used the SEER-Medicare database to examine the association of estrogen use with overall and cancer cause specific survival in elderly women with non-small cell lung cancer (NSCLC). **Methods:** Patients in our cohort were women 65+ years old; were diagnosed with Stage I-IV NSCLC between 2007 and 2012; had Part A and B coverage one year before to one year after diagnosis without supplemental coverage from a HMO; had Part D coverage during the 6 months prior to diagnosis; were not in a nursing home at diagnosis. Using an intention to treat analysis, drug use was defined as having at least one Part D claim for estrogen within six months prior to diagnosis. Event free survival was assessed using a multivariate Cox proportional hazard model accounting for the patient (age, socioeconomic status, race, Charlson score) and tumor (stage, site, histology) characteristics. **Results:** There were 10,562 patients in our cohort. 688 used estrogen and 9,874 did not. The median age was 75 years with median overall survival of 1.0 year. There was a significant difference in age, socioeconomic status, race, Charlson score, stage, site, and tumor histology between the two groups ($p < 0.05$ for all). Estrogen use was associated with a significant improvement in overall and cause specific survival on univariate and multivariate regression (see table). **Conclusions:** Estrogen was associated with a significant improvement in survival. Limitations of this study are inherent to a retrospective claims-based database without knowledge of actual drug use or intent.

	Univariate		Multivariate		
Event	**HR**	**P**	**HR**	**P**	**# Events**
Overall Survival	0.78	< 0.01	0.82	< 0.01	8139
Cause specific survival	0.81	< 0.01	0.84	< 0.01	6483

2591 Poster Session (Board #83), Mon, 8:00 AM-11:30 AM

A phase 1/2 study of intermittent, high dose sunitinib in patients with advanced solid tumors. *First Author: Maria Rovithi, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Despite widespread clinical integration, refinement of treatment with sunitinib is actively pursued. Sub-therapeutic blood levels rather than true resistance and tumor adaptation through drug accumulation have been accounted as reasons for treatment failure. Based on our preclinical data with high dose sunitinib and prospective analyses supporting the concept of intermittent dosing, we designed a phase 1 trial to investigate the feasibility and tolerability of high dose, once weekly (1w) or once every two weeks (2w) sunitinib (NCT02058901). **Methods:** Eligible were patients (pts) with advanced solid tumors, refractory to standard treatment, measurable disease, WHO ≤ 1. Sunitinib was administered orally 1w or 2w. Starting dose was 200 mg, with cohorts escalating in 100 mg steps until maximum tolerated dose (MTD). Response was evaluated by RECIST 1.1. Treatment continued until progression or unacceptable toxicity. Dedicated PK sampling was performed. Sunitinib plasma concentration was measured by LC-MS. **Results:** 34 (w) and 24 (2w) pts were included, predominantly with mCRC [56% (1w) and 55% (2w)]. MTD was set at 300 mg (1w) and 700 mg (2w). Most common adverse events were fatigue (79%, one pt with G3), nausea (71%, all G1-2), anorexia (29%, all G1-2). Median PFS of evaluable pts was 2.7 mo (1w) and 2.6 mo (2w), while 39% pts (1w) and 25% pts (2w) had PFS > 5 mo. CT scans in pts with treatment benefit showed extensive tumor necrosis. Mean sunitinib plasma Cmax was 190 [300 mg (1w), range: 185-295] and 476 ng/mL [(700 mg (2w), range: 323-580]. Accumulation was minimal. **Conclusions:** Once weekly or once every two weeks, high dose sunitinib is feasible and clinically efficacious in heavily pretreated pts with advanced solid tumors, while toxicity remains well manageable. Importantly, no accumulation was recorded and sunitinib exposure was significantly increased, compared to the universal, flat dose. Since increased sunitinib exposure has been correlated to improved outcome, we consider this alternative scheduling as promising strategy to produce enduring clinical benefit in a wider patient population. Expansion cohorts are ongoing. Clinical trial information: NCT02058901.

2592 Poster Session (Board #84), Mon, 8:00 AM-11:30 AM

A dose-escalation study of imipridone ONC201 administered every one (QW) or three weeks (Q3W) in advanced solid tumors and multiple myeloma. *First Author: Anthony J. Olszanski, Fox Chase Cancer Center, Philadelphia, PA*

Background: ONC201 is an orally active, first-in-class small molecule activator of the integrated stress response that selectively upregulates ATF4 to trigger tumor cell death. A phase I study of ONC201 exploring different dosing regimens and drug exposure was conducted to determine the maximum tolerated dose (MTD), and recommended phase II dose (RP2D). **Methods:** A modified accelerated-titration dose escalation design was employed to enroll patients onto 2 sequential dose-escalation arms: ONC201 Q3W and QW. Dose escalation proceeded with the following order: 125, 250, 500, and 625mg (Q3W) and 250, 375, 500 and 625 (QW). Dose exposure ranged from 125 mg/6 wks to 1875 mg/3 wks. Key eligibility: advance/refractory solid tumor or myeloma, ECOG 0/1, and no active CNS disease. Adverse events, SAEs, laboratory values, physical exam findings, EKGs and bio-samples (for PK/PD) are collected. Pre and post ONC201 dose biopsies are being obtained from the 500mg weekly cohort and above. **Results:** 17 pts (12F:5M) with treatment-refractory tumors have been enrolled to date. Dose/#pts Q3W: 125/6, 250/1, 500/1, and 625/1; QW: 250/4, 375/4. Two patients have been enrolled at 500mg QW after database lock and not included in this assessment. Median (range) age: 57 yrs (27-72). ECOG 0/1: 2/15. MTD has not been reached. No DLTs observed. Tumor types: 8 CRC, 3 pancreatic, 2 sarcoma and 1 each cervical, endometrial, NSCLC (adeno) and small bowel. Of 17 pts, 10 (59%) had ≥1 tx-related adverse events (TRAEs), possibly related. Most common TRAEs (≥15% pts): fatigue (9,53%), anorexia (5,29%), nausea (4,24%), vomiting (4,24%), abdominal pain (3,18%), and arthralgias (2,12%). Grade ≥ 3 TRAEs were observed in 3 pts (18%). Pharmacokinetic and pharmacodynamic analysis is ongoing. Fresh frozen and paraffin-embedded biopsies (baseline and week 2) are being assessed for tumor markers implicated in the mechanism of action. No objective responses by RECIST have been seen. Final cohort is enrolling. **Conclusions:** ONC201 was well tolerated throughout the Q3W dosing and weekly dosing has been well tolerated to date without an apparent increase in AEs. Final enrollment summary, AEs and PK/PD data will be presented. Clinical trial information: NCT02609230.

2593 Poster Session (Board #85), Mon, 8:00 AM-11:30 AM

Phase I study combining the aurora kinase A (AURKA) inhibitor alisertib (Ali) with mFOLFOX in gastrointestinal (GI) cancer. *First Author: Laura Williams Goff, Vanderbilt University Medical Center, Nashville, TN*

Background: Overexpression and cellular mis-localization of AURKA in GI cancers results in chromosomal instability, activation of several oncogenic pathways, and inhibition of pro-apoptotic signaling. Inhibition of AURKA causes mitotic delays, severe chromosome congression, and activation of p53/p73 causing cell death. Our preclinical data showed synergy of Ali and platinum agents in GI cells and xenografts, and suggested an optimal timing window of the combination. The purpose of this study was to assess safety of Ali + mFOLFOX, as this is a standard platinum-based therapy for GI cancers. **Methods:** This CTEP-sponsored, investigator-initiated, study (NCT02319018) used standard 3+3 dose escalation to determine the maximum tolerated dose (MTD) of Ali + mFOLFOX. Eligible patients (pts) had metastatic or unresectable GI cancer where standard therapies did not exist or were no longer effective, or for whom FOLFOX was appropriate. Pts received escalating doses of Ali starting at 10 mg twice daily (D1-3), with leucovorin + oxaliplatin (85 mg/m^2) on D2 followed by continuous 5FU (2400 mg/m^2) infusion on D2-4 in 14-day cycles. Dose-limiting toxicity (DLT) was any treatment-related non-hematologic ≥Gr3 toxicity (except diarrhea or nausea, vomiting, controllable with meds) or ≥Gr4 hematologic toxicity observed during the first 28 days. **Results:** 13 pts were enrolled and 2 dose levels explored; 2 pts were not evaluable for DLT and replaced. Zero DLTs observed in first 3 pts. Ali was escalated to 20 mg where 2/6 had a DLT [Gr3 fatigue (n = 2); Gr3 nausea, vomiting, dehydration with hospitalization (n = 1)]. Ali was de-escalated and 2 of 3 pts have been enrolled; 0 DLTs observed thus far. Most frequent toxicities (%) were nausea (54), fatigue (46), neuropathy (46), anorexia (38), and anemia (38), most ≤Gr2. One of 10 evaluable pts had a partial response, and 6 had stable disease for a 70% disease control rate. **Conclusions:** The MTD will be 10 mg Ali (D1-3) + oxaliplatin (D2, 85 mg/m^2) + continuous 5FU (D2-4, 2400 mg/m^2). The combination was tolerable, and preliminary clinical activity was seen in a majority of pts. Correlative biomarker studies to evaluate AURKA target inhibition are ongoing and will be reported. Clinical trial information: NCT02319018.

2594 Poster Session (Board #86), Mon, 8:00 AM-11:30 AM

A phase I trial of the oral hedgehog inhibitor taladegib (LY2940680) in combination with weekly paclitaxel in patients with advanced, solid tumours. *First Author: Rosalind Margaret Glasspool, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom*

Background: Aberrant Hedgehog (Hh) signaling is implicated in carcinogenesis and is associated with poor prognosis in multiple tumours types. Hh inhibitors increase sensitivity to paclitaxel in taxane-resistant cell lines. Taladegib is an orally bioavailable, potent inhibitor of Smoothened, a key Hh pathway component, with activity in basal cell carcinoma. The single agent recommended dose is 400mg od. We present the dose escalation phase of a phase I study of weekly paclitaxel with oral taladegib. **Methods:** Primary objective: determine the dose limiting toxicity (DLT) and maximum tolerated dose (MTD) of taladegib on a continuous oral daily dosing regimen in combination with paclitaxel (80mg/m^2, iv, day 1, 8 and 15 q 28) in patients with advanced solid cancers. Secondary objectives: assess the safety and tolerability, determine the recommended phase II dose (RP2D), and evaluate the pharmacokinetics of taladegib and paclitaxel. Exploratory objective: assess preliminary efficacy. A standard 3 + 3 dose escalation design was used. All patients received up to 6 cycles of paclitaxel. In addition, successive cohorts received continuous oral taladegib continued until progression or unacceptable toxicity as follows: dose level 1: 100mg od; 2: 200mg od; 3: 400mg od. **Results:** No DLTs were seen at dose level 1 or in the first 3 patients at dose level 2. 3 DLTs of grade 2 neuropathy were seen at dose level 3 (400mg taladegib); therefore, dose level 2 was expanded to 6 patients. No DLT was seen in the fourth patient and 2 additional patients have started treatment. After the DLT period 2 patients developed G2 and 4 developed G1 neuropathy. Other non DLT, drug-related G3 toxicities: uncomplicated neutropenia x2, muscle cramp x1 and fatigue x1. To date, 3 patients have had partial responses. **Conclusions:** The combination of daily oral taladegib and weekly paclitaxel is feasible. DLT of G2 neuropathy was seen at 400mg. Promising activity has been seen in solid tumours. A dose expansion cohort is due to commence in high grade ovarian carcinoma. ISRCTN No:ISRCTN15903698 Eudract Ref:2014-004695-37 Funded by Cancer Research UK C8361/A18775 and Ignyta. Sponsored by NHS Greater Glasgow and Clyde. Clinical trial information: ISRCTN15903698.

2595 Poster Session (Board #87), Mon, 8:00 AM-11:30 AM

A sensitive QPCR assay for EGFR mutation in plasma samples of NSCLC patients. *First Author: Qin Feng, Beijing Cancer Hospital, Beijing, China*

Background: Tyrosine kinase inhibitors (TKI) have improved the overall outlook and quality of life for most of EGFR mutation positive NSCLC patients. However, tumor tissues are often absent or insufficient for testing EGFR mutations to guide EGFR TKIs treatment of patients with nonsmall cell lung cancer (NSCLC). An assay that detects EGFR mutations in the plasma would provide a noninvasive technique to assess suitability for TK inhibitor therapy. The ACCB new EGFR Mutation Kit is a ARMS-PCR test for the qualitative detection of 45 mutations in exons 18, 19, 20, and 21 of the EGFR gene in DNA derived from human plasma from NSCLC patients. **Methods:** 10 mL tubes of blood were collected from patients who never had been treated by EGFR TKI, and plasma circulating tumor DNA were extracted from plasma by Biomark Circulating DNA Kit. Qubit 2.0 Fluorometer was used to make plasma circulating DNA tumor quantitation. The concentration of final DNA sample is ≦2ng/μl. Total, 272 plasma DNA samples from 246 lung adenocarcinoma, 23 lung squamous carcinoma and 3 lung adenosquamous carcinoma patients were collected. 104 paired tissue EGFR mutations were detected by the same kit. **Results:** EGFR mutation was detected in 88 from 272 plasma DNA samples, 86 lung adenocarcinoma, 1 lung squamous carcinoma, 1 lung adenosquamous carcinoma, with EGFR mutation rate were 35.0% (86/246), 4.3% (1/23), 33.3% (1/3) respectively. In 61 I~III and 211 IV stage NSCLC patients, EGFR mutation rate were 21.3% (13/61) and 35.5% (75/211) respectively. **Conclusions:** The ACCB new EGFR Mutation Kit is a sensitive, accurate, rapid, and reproducible assay capable of testing DNA extracted from human plasma from NSCLC patients.

TPS2596 **Poster Session (Board #88a), Mon, 8:00 AM-11:30 AM**

A phase 1, open-label, dose escalation study of enoblituzumab (MGA271) in pediatric patients with B7-H3-expressing relapsed or refractory solid tumors. *First Author: Kenneth Desantes, University of Wisconsin, Madison, WI*

Background: Enoblituzumab, is an Fc optimized humanized IgG1 monoclonal antibody that binds to B7-H3 (CD276), a member of the B7 family. It is Fc-engineered to enhance effector function including antibody dependent cellular cytotoxicity (ADCC). IHC analyses with the parental anti-B7H3 mAb specificity incorporated in enoblituzmab revealed limited B7-H3 expression in normal tissues but high expression in many cancers (Loo et al., 2012). Among pediatric solid tumors, high expression of B7-H3 has been reported in neuroblastoma, rhabdomyosarcoma, osteosarcoma, Wilms tumor, Ewing's sarcoma and desmoplastic small round cell tumor. B7-H3 overexpression correlates with poor prognosis in a broad range of cancers in adults suggesting a potential role in enabling tumor immune escape. ADCC and potential modulation of T cell function resulting in enhanced antitumor immune response are presumed mechanisms of action of enoblituzumab. **Methods:** This is an open-label, dose escalation / cohort expansion phase 1 study (NCT02982941) designed to characterize the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity of enoblituzumab in children and young adults with B7-H3-expressing relapsed or refractory malignant solid tumors. A 3+3 design is used in escalating dose cohorts of weekly intravenous (IV) enoblituzumab starting at 10 mg/kg. Response is first determined at 8 weeks. irRECIST is used for response assessment for patient management. Enoblituzumab may continue up to 2 years based on response. Cohort expansion phase, to further define the safety and initial antitumor activity of enoblituzumab, will start after maximum tolerated dose is determined. The patients are assigned to 1 of 5 cohorts based on disease type as follows: 1) neuroblastoma - measurable disease, 2) neuroblastoma - non-measurable disease, 3) rhabdomyosarcoma, 4) osteosarcoma, and 5) Ewing's sarcoma, Wilms' tumor and desmoplastic small round cell tumors. Enrollment is ongoing. Ref : Development of an Fc-enhanced anti-B7-H3 monoclonal antibody with potent antitumor activity. Loo D, Alderson RF, Chen FZ, Huang L et al. Clin Cancer Res. 2012; 18:3834-45. Clinical trial information: NCT02982941.

TPS2597 **Poster Session (Board #88b), Mon, 8:00 AM-11:30 AM**

An open-label study of rovalpituzumab tesirine in patients with DLL3-expressing advanced solid tumors. *First Author: Edward Kavalerchik, AbbVie Stemcentrx, San Francisco, CA*

Background: Delta-like protein 3 (DLL3) is an inhibitory ligand of the Notch receptor family. It is highly expressed in high-grade neuroendocrine carcinoma (NEC), such as small cell lung cancer (SCLC) and large cell NEC (LCNEC), but is not expressed in normal tissue. DLL3 is expressed in melanoma, glioblastoma (GBM), neuroendocrine prostate, medullary thyroid carcinoma (MTC), and other solid cancers. Rovalpituzumab tesirine (Rova-T™) is an antibody-drug conjugate targeting DLL3, composed of a DLL3-specific IgG1 monoclonal antibody joined to a toxic DNA cross-linking agent by a cleavable linker. Rova-T binds to DLL3 on target-expressing cells, is internalized and cleaved, releasing the toxin to induce cell death. A Phase 1 study of Rova-T in SCLC showed encouraging antitumor activity in DLL3-high patients (pts), and was well-tolerated (Rudin et al., Lancet Oncol, 2016). As novel therapies are needed for multiple cancers that express DLL3, Rova-T may be effective in these tumors. **Methods:** This is a Phase 1/2, open-label, multicenter study (NCT02709889) with 8 cohorts of pts (up to ~318 total, 14 pts enrolled as of 20 January 2017) with melanoma, MTC, GBM, LCNEC, neuroendocrine prostate cancer, gastroenteropancreatic NEC, other NEC, or other solid tumor. In Part A, a 3+3 dose escalation will be used. Rova-T 0.2, 0.3, or 0.4 mg/kg will be given on Day 1 of each 42-day cycle. Dose-limiting toxicities (DLTs) will be assessed over a 21-day period. Dose escalation will proceed within cohort until a maximum tolerated dose is reached. Part B expansion, Stage 1, will explore the recommended dose in 7 pts in disease specific cohorts. Stage 2 will use an adaptive 2-stage design to determine sample size. Pt eligibility: $\geq$ 18 years; histologically confirmed, measurable, advanced solid tumor; relapsed/refractory to prior standard therapy; ECOG 0-1; no prior exposure to a pyrrolobenzodiazepine-based drug. Primary objective: assess safety and tolerability of Rova-T. Secondary objectives: explore Rova-T antitumor activity, pharmacokinetics, and incidence of anti-therapeutic antibodies. Exploratory objectives: explore the relationship between DLL3 and clinical outcome, and effects on biomarkers and pharmacodynamics. Clinical trial information: NCT02709889.

TPS2598 **Poster Session (Board #89a), Mon, 8:00 AM-11:30 AM**

A study of rovalpituzumab tesirine in frontline treatment of patients with DLL3 expressing extensive small cell lung cancer. *First Author: Christine L. Hann, Johns Hopkins University, Baltimore, MD*

Background: Treatment and survival of SCLC patients (pts) has remained mostly unchanged over past decades with high response rates to initial therapy (cisplatin/carboplatin + etoposide), but relapse is near universal with median survival $<$ 1 year in extensive disease. Delta-like protein 3 (DLL3) is an inhibitory ligand of the Notch receptor family identified as a novel target in high-grade neuroendocrine tumors, and is highly expressed in SCLC but not in normal tissue. Rovalpituzumab tesirine (Rova-T™) is an antibody-drug conjugate targeting DLL3. A Phase I study of Rova-T monotherapy in 2nd and 3rd line SCLC pts demonstrated encouraging antitumor activity with an ORR of 18% in all pts, and an ORR of 38% in DLL3-high pts (Rudin et al., *Lancet Oncol*, 2016.). **Methods:** This is a Phase I, open-label, multicenter study (NCT02819999; no pts enrolled as of 7 February 2017).In Phase Ia (escalation), 15-34 previously untreated DLL3-high pts will be enrolled and randomized to 1 of 4 cohorts. The primary objective of the Phase Ia portion is assessment of safety and dose-limiting toxicities (DLTs). Phase Ib (expansion) will enroll up to 2 cohorts of 30 pts each, and its primary objective is to characterize antitumor activity of the selected cohort(s). Secondary objectives (Phase Ia/b) include assessment of pharmacokinetics and anti-therapeutic antibodies against Rova-T, and characterization of antitumor activity (Phase Ia). Eligible pts: adults with histologically or cytologically confirmed extensive DLL3-high SCLC based on immunohistochemistry; ECOG 0-1; and life expectancy $\geq$ 12 weeks. Clinical trial information: NCT02819999.

TPS2599 **Poster Session (Board #89b), Mon, 8:00 AM-11:30 AM**

A phase 1, open-label, dose-escalation study of olaratumab as a single agent and in combination with doxorubicin, vincristine/irinotecan, or high-dose ifosfamide in pediatric patients with relapsed or refractory solid tumors. *First Author: Leo Mascarenhas, Children's Center for Cancer and Blood Diseases, Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA*

Background: Olaratumab (LY3012207, IMC-3G3), a PDGFRα antagonist, is a targeted human IgG1 monoclonal antibody that specifically binds PDGFRα, blocking PDGF-AA, -BB, and -CC binding and receptor activation. Preclinical studies of olaratumab with or without chemotherapy have demonstrated antitumor activity in human sarcoma xenograft models. Positive survival outcomes were observed in adult patients with advanced soft tissue sarcoma when they were treated with olaratumab + doxorubicin vs doxorubicin alone in a randomized phase 2 trial. **Methods:** This multicenter clinical trial (NCT02677116) includes patients $<$ 18 years of age with a diagnosis of relapsed or refractory solid tumors not amenable to curative treatment, for whom chemotherapy with doxorubicin, vincristine/irinotecan, or high-dose ifosfamide is deemed appropriate. The primary objective is to determine a recommended dose of olaratumab + $\geq$1 chemotherapy regimen (s) in pediatric patients based on any dose-limiting toxicity, and olaratumab serum exposure-matching between adult and pediatric patients. Secondary objectives include assessment of antitumor activity of each combination, immunogenicity, and pharmacokinetics. At least 12 pediatric patients will be treated with 1 cycle (21 days) of olaratumab monotherapy (dose level 1 [Part A] and dose level 2 [Part B]) on Days 1 and 8. If the patient does not experience a dose-limiting toxicity in the first cycle of monotherapy, the patient will then receive olaratumab plus either doxorubicin, vincristine/irinotecan, or high-dose ifosfamide per investigator discretion. Dose-limiting toxicity criteria will also be evaluated for the respective combinations in cycle 2. Treatment will continue until disease progression or other discontinuation criteria are met. Dose level 2 will be initiated after acceptable safety results from dose level 1 monotherapy (a minimum of 6 evaluable patients, and the pharmacokinetic profile). As of December 2016, enrollment is currently occurring in dose level 1. Clinical trial information: NCT02677116.

TPS2600 Poster Session (Board #90a), Mon, 8:00 AM-11:30 AM

A phase I study to assess the safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity of oral COH29, a novel ribonucleotide reductase (RNR) inhibitor in adult patients (pts) with advanced solid tumors. *First Author: Joseph Chao, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Human RNR catalyzes the rate-limiting step in the formation of deoxyribonucleotide triphosphates (dNTPs) necessary for DNA repair and replication. Rapidly dividing tumor cells are especially sensitive to RNR inhibition due to elevated dNTP requirements. Overexpression of the RNR RRM2 subunit is also associated with neoplasia, metastasis, and poor prognosis. COH29 is an aromatically substituted thiazole compound that is a novel small molecule inhibitor of RNR activity, and exhibits unique mechanisms and target specificity that overcomes the weaknesses of other small molecule RNR inhibitors. Preclinically, it is more potent than hydroxyurea and gemcitabine, and is not associated with iron chelating-related toxicities such as hypoxia. Cell lines deficient in BRCA1 also exhibit greater sensitivity to COH29 than BRCA1 wildtype cell lines, implicating inhibition of DNA repair mechanisms in line with PARP inhibitors. **Methods:** In this Phase I, single site, dose escalation, safety study pts will receive oral COH29 twice a day for 21 days of a 28-day cycle. Eligible pts are age $\geq$ 18 years, ECOG $\leq$ 2, able to take oral medication, have adequate organ and marrow function, and diagnosed with any solid tumor refractory to standard therapies. Dose escalation will be pursued utilizing a Simon's accelerated titration design, which allows skipping of dose levels (dose doubling) during the accelerated dose-finding phase. Primary objectives are to determine the maximum tolerated dose of COH29, toxicities per CTCAEv4, and PKs. Secondary objectives include assessment of objective response per RECIST 1.1 every 2 cycles. PD assessment includes measurement of plasma CK18 levels to determine degree of cellular apoptosis, evaluation of dNTP pool levels in peripheral blood mononuclear cells (PBMCs) to evaluate RNR inhibition, as well as measurement of PAR expression in PBMCs to assess PARP inhibition. Quantitation of tumor RRM2 expression using dual-color immunohistochemistry will be explored as a predictive biomarker of anti-tumor response to COH29. Clinical trial information: NCT02112565.

TPS2601 Poster Session (Board #90b), Mon, 8:00 AM-11:30 AM

A phase I study to assess the safety, pharmacokinetics (PK), pharmacodynamics (PD) and antitumor activities of daily oral BAL101553, a novel tumor checkpoint controller (TCC) in adult patients with progressive or recurrent glioblastoma (GBM) or high-grade glioma. *First Author: Alvaro Henrique Ingles Garces, The Royal Marsden Hospital and The Institute of Cancer Research, London, United Kingdom*

Background: BAL101553 (prodrug of BAL27862) is a novel TCC that promotes tumor cell death by modulating the spindle assembly checkpoint. BAL27862 is a lipophilic, small molecule (MW 387) shown in rats to penetrate the brain (1:1 plasma ratio) and has shown promising antitumor activity in orthotopic preclinical models of GBM as monotherapy or in combination with radiotherapy (RT) with/without chemotherapy. In a completed Phase 1 study with 2-h IV infusions (Days 1, 8, 15, q28d, NCT01397929, CDI-CS-001, Lopez et al. J Clin Oncol 34, 2016 suppl; 2525), dose-limiting vascular effects were observed and appeared C_{max} related. Preclinical data suggest that antiproliferative effects of BAL101553/27862 are driven by exposure (AUC); thus vascular toxicity and antitumor activity are mediated by different PK drivers. In this ongoing study (NCT02490800, CDI-CS-002), daily oral BAL101553 was initially examined in solid-tumor patients; no vascular toxicities were observed at doses up to the MAD of 30 mg QD. Given this absence, the study was amended to enroll separate cohorts of patients with progressive or recurrent GBM or high-grade glioma. **Methods:** This is an ongoing multicenter, open-label, Phase 1 dose-escalation study using a 3+3 design to determine the MTD, characterize dose-limiting toxicities and assess the PK, PD and antitumor activities of daily oral administration of BAL101553 in consecutive 28-day cycles at a starting dose of 8 mg QD. Patients with histologically-confirmed GBM or high-grade glioma, with progressive or recurrent disease after prior RT with/without chemotherapy, are eligible for enrollment. This includes patients with histologically-confirmed low-grade glioma with unequivocal evidence by imaging of transformation to high-grade glioma. Adverse events are assessed using CTCAEv4; tumor response by RANO (every 2 cycles). The dose escalation allows for doubling of dose levels depending on observed toxicities. PD assessments include circulating tumor cells. PK profiles are assessed throughout the first two treatment cycles. Clinical trial information: NCT02490800.

TPS2602 Poster Session (Board #91a), Mon, 8:00 AM-11:30 AM

A phase I study to assess the safety, pharmacokinetics (PK), pharmacodynamics (PD) and antitumor activities of BAL101553, a novel tumor checkpoint controller (TCC), administered as 48-hour infusion in adult patients with advanced solid tumors. *First Author: Markus Joerger, Cantonal Hospital St. Gallen, St. Gallen, Switzerland*

Background: BAL101553 (prodrug of BAL27862), is a novel TCC that promotes tumor cell death by modulating the spindle assembly checkpoint. BAL27862 has shown potent antitumor activity in diverse preclinical tumor models, including models refractory to standard therapies. In a completed Phase 1 study using 2-h IV infusions (Days 1, 8, 15, q28d, NCT01397929, CDI-CS-001, Lopez et al. JCO 34, 2016 suppl; 2525) dose-limiting vascular effects were observed and appeared C_{max} related. The recommended Phase 2 dose for 2-h IV BAL101553 is 30 mg/m^2. Vascular toxicity was not observed in an ongoing study with oral BAL101553 (NCT02490800, CDI-CS-002) at daily doses up to 30 mg (QD). Preclinical data suggest that antiproliferative effects of BAL101553/27862 are driven by exposure (AUC); thus vascular toxicity and antitumor activity are mediated by different PK drivers. BAL27862 has a half-life of ~15 h. Based on PK-modeling, extending the infusion from 2 h to 48 h was expected to result in ~4-fold higher AUC at a given C_{max}level and thereby improve the therapeutic window. **Methods:** This is an ongoing multicenter, open-label, Phase 1 dose-escalation study (NCT02895360, CDI-CS-003/SAKK67/15) using a 3+3 design to determine the MTD, characterize dose-limiting toxicities and assess the PK, PD and antitumor activities of 48-h infusions of BAL101553 in consecutive 28-day cycles at a starting dose of 30 mg/m^2 administered on Day 1, 8 and 15 (q28d). The dose escalation scheme foresees up to ~ 50% dose increments depending on observed toxicities. During cycle 2, patients receive 7 days oral (QD) BAL101553 (Day 15–21) instead of the weekly IV infusion to assess absolute oral bioavailability. Patients with histologically-confirmed advanced or recurrent solid tumors are eligible for enrollment. Adverse events are assessed using CTCAEv4; tumor response by RECIST 1.1 (every 2 cycles). PD assessments include optional tumor biopsies and circulating tumor cells. PK profiles are assessed during the first 2 cycles. Two dose cohorts (30 and 45 mg/m^2) have completed without DLTs or signs of vascular toxicity. Clinical trial information: NCT02895360.

TPS2603 Poster Session (Board #91b), Mon, 8:00 AM-11:30 AM

Phase IB study to evaluate the safety of selinexor in combination with multiple standard chemotherapy agents in patients with advanced malignancies. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Selinexor is a first-in-class, slowly reversible, Selective Inhibitor of Nuclear Export (SINE) compound that specifically blocks XPO1. Inhibition of XPO1 results in nuclear localization, accumulation, and reactivation of tumor suppressor proteins, therefore selectively inducing apoptosis in cancer cells, while largely sparing normal cells. This unique property of XPO1 inhibition has been deployed as a novel therapeutic strategy with success in several solid tumors and hematologic malignancy clinical trials. Preclinical studies have shown that SINE compounds behave synergistically to enhance cancer cell death with combined with different therapeutic agents. This Phase I trial is based on such preclinical evidence. The primary objective of the study is to establish the safety and tolerability of selinexor when given in combination with thirteen standard chemotherapy regimens. The secondary objectives are to determine disease control and progression-free survival of patients receiving selinexor administered with standard chemotherapy treatments in specific tumor subsets. **Methods:** Adult patients $\geq$ 18 years of age are eligible if they have histologically confirmed neoplasms (excluding hematological malignancies and brain tumors) that are refractory to established therapy known to provide clinical benefit for their condition. Patients are required to have either measurable disease (RECIST 1.1) or evaluable disease, and an ECOG performance status of 0-1. Enrollment is ongoing for dose escalation with the plan for dose expansion as follows: Clinical trial information: NCT02419495.

Treatment Arm	Dose Expansion (N)
Selinexor + Carboplatin	Any Histology (9)
Selinexor + Paclitaxel	Ovarian (25)
	Breast (25)
Selinexor + Eribulin	Any Histology (9)
Selinexor + Doxorubicin/ Cyclophosphamide	Any Histology (9)
Selinexor + Carboplatin / Paclitaxel	Ovarian (25)
	NSCLC (25)
Selinexor + Carboplatin / Pemetrexed	Any Histology (9)
Selinexor + Topotecan	Ovarian (25)
Selinexor + FOLFIRI	CRC (25)
Selinexor + Irinotecan	CRC (25)
Selinexor + XELOX	CRC (25)
Selinexor + Olaparib	Ovarian (25)
Selinexor + Pembrolizumab	Melanoma (25)
	NSCLC (25)
Selinexor + Nivolumab	Melanoma (25)
	NSCLC (25)
	RCC (25)

TPS2604 Poster Session (Board #92a), Mon, 8:00 AM-11:30 AM

EphA2 gene targeting using neutral liposomal small interfering RNA (EPHARNA) delivery: A phase I clinical trial. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EphA2 is a member of the largest subfamily of receptor tyrosine kinases, with over 14 receptors and 8 ligands. EphA2 overexpression is common in many human cancers, including lung, breast, prostate, colorectal, pancreatic, melanoma, esophageal and endometrial cancers. EphA2 can function as an oncoprotein when introduced into cells with low expression. In addition, downregulation of constitutive expression reduces tumorigenicity in breast, endometrial, ovarian and pancreatic cancers *in vitro* and *in vivo* models. EphA2 is a desirable target because of its selective expression in cancer (vs. adult normal tissue), and its important role in promoting tumor growth and metastasis. It has kinase-dependent and independent functions, making it an ideal target for RNAi-based targeting. We have previously reported that EphA2 siRNA incorporated in DOPC nanoliposomes (EPHARNA) was highly effective in reducing EphA2 protein levels after a single dose. In addition, three weeks of treatment with EPHARNA (150 μg/kg twice weekly) in an orthotopic mouse model of ovarian cancer (HeyA8 or SKOV3ip1) significantly reduced tumor growth compared with non-silencing siRNA, and demonstrated synergistic anti-tumor activity when combined with conventional chemotherapy. EPHARNA underwent GLP development in 2 animal models (murine and primate) at M.D. Anderson to support the IND (#72924). The first-in-human trial (NCT01591356) is ongoing and recruiting study subjects. **Methods:** Adult Patients > 18 years of age with histologic proof of advanced recurrent solid tumors, who are not candidates for known regimens or protocol treatments of higher efficacy or priority. All patients (dose escalation and dose expansion phases) must be willing to undergo pre- and post-treatment biopsies. For dose expansion phase, patients must have EphA2 overexpression by IHC evaluation. Enrollment is ongoing for the dose escalation with the plan for dose expansion. A total of 16 patients have been enrolled and treated in the dose escalation phase. Clinical trial information: NCT01591356.

TPS2605 Poster Session (Board #92b), Mon, 8:00 AM-11:30 AM

GCT1021-01, a first-in-human, open-label, dose-escalation trial with expansion cohorts to evaluate safety of Axl-specific antibody-drug conjugate (HuMax-Axl-ADC) in patients with solid tumors (NCT02988817). *First Author: Ulrik Niels Lassen, Rigshospitalet, Copenhagen, Denmark*

Background: HuMax-AXL-ADC is an antibody-drug conjugate (ADC) composed of an Axl-specific human monoclonal immunoglobulin G1 (IgG1κ) conjugated via a protease-cleavable valine-citrulline linker to the microtubule disrupting agent monomethyl auristatin E (MMAE). *In vivo*, HuMax-AXL-ADC demonstrated therapeutic anti-tumor efficacy in patient-derived xenograft models representing a variety of solid cancers, including pancreas, thyroid, lung, esophageal, cervical cancers and malignant melanoma. The non-clinical safety profile and pharmacokinetics (PK) of a once every 3 weeks (1Q3W) dosing schedule were established in cynomolgus monkeys. **Methods:** The primary objective of this trial is to determine the MTD and to establish the safety profile of HuMax-AXL-ADC in a mixed population of patients with specified solid tumors: ovarian, cervical, endometrial, thyroid cancer, NSCLC, and malignant melanoma. The trial consists of two parts, a phase I dose escalation part and a phase IIa expansion part. The dose escalation part explores two different dosing regimens: the first investigates doses from 0.3 up to 2.8 mg/kg to be administered 1Q3W. The second investigates doses in the range of 0.45 to 1.4 mg/kg to be administered weekly for 3 weeks followed by one treatment-free week (3Q4W dosing schedule). The second arm has a delayed start to inform a safe starting dose: when at least 8 patients have been evaluated for dose limiting toxicities, the 1.5 mg/kg cohort of the 1Q3W arm has been declared safe, and the predicted PK parameters of the starting dose in the 3Q4W arm are below pre-defined limits, the 3Q4W arm will be initiated. The 1Q3W arm follows a modified Bayesian Continuous Reassessment Method including escalation with overdose control in up to 41 patients on up to 7 main and 4 intermediate dose levels while the 3Q4W arm is run as a standard 3+3 trial design on up to 5-6 dose levels. In the phase IIa expansion part, further safety and biological activity data will be generated in selected indications using cohorts of 22 patients (11+11 patients in each cohort applying the Simon's two-stage design). Clinical trial information: NCT 02988817.

TPS2606 Poster Session (Board #93a), Mon, 8:00 AM-11:30 AM

A phase Ib, first-in-human, dose escalation and expansion study of XMT-1522, a novel antibody-drug conjugate (ADC) directed against HER2, in patients with advanced breast cancer and other advanced tumors expressing HER2. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Nashville, TN*

Background: XMT-1522 is an ADC consisting of a novel human IgG1 anti-HER2 monoclonal antibody conjugated to an auristatin-based cytotoxic payload (AF-HPA). An average of 12 AF-HPA molecules is conjugated to each antibody via a biodegradable polymer. In pre-clinical xenograft experiments XMT-1522 achieved complete, durable tumor regressions in models of HER2-positive and HER2 1+/2+ breast cancer, HER2 2+/3+ NSCLC, and HER2-positive and HER2 1+ gastric cancer. **Methods:** This study (NCT02952729) is comprised of two parts: a dose escalation segment (DES) and an expansion segment (EXP). The primary objectives of the DES are determination of the maximum tolerated dose and recommended Phase 2 dose (RP2D) and assessment of safety and tolerability. The DES will enroll patients with advanced or metastatic breast cancer who have progressed following standard therapies and have HER2 protein at least 1+ by IHC. XMT-1522 will be administered intravenously every 3 weeks. DES uses a 3+3 design. Post-dose assessments include LVEF measurement at the end of cycles 1, 3, then every 3 cycles, ophthalmologic exams at the end of cycles 1, 2, then every 2 cycles, and re-staging CT scans every 2 cycles. Pharmacokinetics of antibody, AF-HPA payload and an AF-HPA metabolite will be measured. Two patients have completed dose level 1 without DLT. The EXP segment will open at the RP2D and will further assess safety and tolerability of XMT-1522 and assess efficacy in selected patient populations. EXP will enroll 4 cohorts (N = 20 each).

- Cohort 1: HER2 1+/2+ advanced breast cancer with 2-3 prior chemotherapy regimens
- Cohort 2: HER2-positive advanced breast cancer with prior pertuzumab and ado-trastuzumab emtansine (T-DM1)
- Cohort 3: HER2-positive advanced gastric cancer with prior trastuzumab
- Cohort 4: HER2 2+/3+ NSCLC with at least 1 prior platinum regimen

The protocol requires archival tumor tissue for central confirmation of HER2 status, alternative HER2 measurements, and targeted gene expression and sequencing studies. Tumor biopsies will be requested at the time of progression from patients who responded to XMT-1522. Clinical trial information: NCT02952729.

TPS2607 Poster Session (Board #93b), Mon, 8:00 AM-11:30 AM

A phase I study of SRA737 (formerly known as CCT245737) administered orally in patients with advanced cancer. *First Author: Maxime Chenard-Poirier, CHU de Québec-Université Laval, Québec, QC, Canada*

Background: SRA737 is a highly selective, orally bioavailable small molecule inhibitor of Checkpoint kinase 1 (Chk1), a key cell cycle checkpoint and central regulator of the DNA Damage Response (DDR) network. In cancer cells, replication stress induced by genomic alterations in oncogenes (eg, *MYC* and *RAS*) combined with loss of function in tumor suppressors (eg, *TP53* and *ATM*) results in persistent DNA damage and genomic instability. Targeted inhibition of components of the DDR network such as Chk1 by SRA737 may be synthetically lethal to cancer cells and have utility as a monotherapy in a range of tumor indications. SRA737 is currently being investigated in two Phase 1 trials in patients with advanced cancer. We now describe the Phase 1 multicenter, dose-escalation, monotherapy study of SRA737 (NCT02797964). **Methods:** Up to 40 patients with advanced cancer will receive oral SRA737 administered daily on a 28-day schedule. For dose-escalation, an accelerated titration design with 100% dose escalation and single patient cohorts is allowed until Grade 2 related toxicity is observed, followed by a rolling-6 design. Dose expansion will include 6 patients with any solid tumor treated at the recommended Phase 2 dose (RP2D). Eligibility criteria include WHO performance status of 0-1 and ≤ 3 prior lines of cytotoxic chemotherapy for metastatic disease. Primary objectives are to assess the safety profile of monotherapy SRA737 and to establish a RP2D. The PK profile and PD biomarkers will be investigated. The study was opened to enrollment in mid-2016. An amendment, which includes the addition of indication specific expansion cohorts of subjects with genetically-defined tumors known to have Chk1-sensitizing aberrations such as gene mutations and amplifications/deletions, has been submitted and is pending regulatory review while enrollment continues. At the Annual Meeting, the amended design will be described. The dose and schedule identified in this trial will inform the design and conduct of Phase 2 studies of SRA737 as a single agent and in combination with other targeted or immunomodulatory agents. Clinical trial information: NCT02797964.

TPS2608 Poster Session (Board #94a), Mon, 8:00 AM-11:30 AM

A phase I, open-label, first-time-in-patient dose escalation and expansion study to assess the safety, tolerability, and pharmacokinetics of nanoparticle encapsulated Aurora B kinase inhibitor AZD2811 in patients with advanced solid tumours. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Nashville, TN*

Background: Aurora kinase B performs key roles in the regulation of the cell cycle and represents a potential target for anticancer therapy. AZD2811, formerly designated AZD1152 hydroxy-quinazoline pyrazole anilide (AZD1152 hQPA), is a potent and selective inhibitor of Aurora B kinase activity and has been incorporated into a polymer nanoparticle carrier for intravenous (IV) administration. The phosphate pro-drug of AZD2811, known as AZD1152 (barasertib), reached Phase II of clinical development as a continuous IV infusion. While promising efficacy was seen with barasertib in elderly acute myeloid leukaemia (AML) patients (Kantarjian HG et al., Cancer 2013;119:2611-19), continuous intravenous drug delivery precluded subsequent development in this disease setting and there were limited clinical responses in solid tumour patients due to dose-limiting myelotoxicity. AZD2811 nanoparticle has been designed to overcome these issues. **Methods:** Patients with relapsed advanced solid malignancies with no standard treatments are eligible for the part A dose escalation. Primary endpoint is to determine the maximum tolerated dose of AZD2811 nanoparticle using a 3+3 design. Patients with refractory/relapsed small cell lung cancer (SCLC) will be eligible for the part B expansion, where the safety, PK and anti-tumour activity of AZD2811 nanoparticle will be assessed as monotherapy and in combination with chemotherapy. Study enrolment is ongoing. Clinical trial information: NCT02579226.

TPS2609 Poster Session (Board #94b), Mon, 8:00 AM-11:30 AM

Phase I trial of the triplet veliparib + VX-970 + cisplatin in patients with advanced solid tumors. *First Author: Geraldine Helen O'Sullivan Coyne, Early Clinical Trials Development Program, DCTD, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: The DNA damage response (DDR) pathway is a key element of cellular integrity. Platinum compounds form covalent bonds with purine bases causing DNA cross-links that stall replication forks halting transcription. Poly (ADP-ribose)polymerase-1 (PARP-1) plays a pivotal role in DDR and base-excision repair. Ataxia-telangiectasia-related (ATR) protein kinase is also central to DDR and homologous recombination, activating a series of phosphorylation cascades culminating in cell cycle arrest to allow time for DNA repair. Veliparib (ABT-888) is a PARP 1/2 inhibitor (PARPi) with clinical evidence of antitumor activity in combination with cisplatin in BRCA mutation carriers (Rodler *et al*, Cancer Res. 2011). VX-970 is a potent ATR inhibitor, with antitumor activity across a range of cell lines in combination with DNA damaging agents, including cisplatin (Huntoon *et al*, Cancer Res. 2013). In this trial, we will evaluate whether the combination of veliparib + VX-970 impairs DNA repair, inducing a "BRCA null"-like phenotype leading to potentiation of the antitumor activity of cisplatin. **Methods:** Open label phase I trial of the veliparib+VX-970+cisplatin combination, following a 3+3 design, with dose limiting toxicities defined during cycle 1. Estimated enrollment: 24 patients (pts); Dana Farber and MD Anderson planned as additional sites. Drug administration over a 21-day cycle: VX- intravenously (IV) on Days 2 and 9; Veliparib orally twice daily (q12 hours $\pm$ 1 hour) Days 1-3 and 8-10; cisplatin 40 mg/m^2 IV Day 1 (with Day 8 added from DL3 onwards). Pts must be $\geq$ 18 years of age; have histologically confirmed solid tumors that have progressed on standard of care therapy known to prolong survival or without known standard, ECOG PS $\leq$2, and life expectancy $\geq$3 months. Pts with treated brain metastasis with stable disease $\geq$4 weeks without requiring steroids or anti-seizure medication are eligible. Exclusion criteria include a prolonged QTc interval, and sensory/motor neuropathy $\geq$grade 2 by CTCAE v.4. At this time, cohort 3 has enrolled 1 of 3 planned pts. Assessment of DDR and apoptosis biomarkers at the maximally tolerated dose using a validated and quantitative immunofluorescence assay is planned. Clinical trial information: NCT02723864.

TPS2610 Poster Session (Board #95a), Mon, 8:00 AM-11:30 AM

Combination immunotherapy with IDO vaccine and PD-1 inhibitors in advanced NSCLC. *First Author: Anders Mellemgaard, Herlev University Hospital, Herlev, Denmark*

Background: Multible checkpoints regulate host immune response, and development has focused on three of these: IDO, CTLA-4 and PD-1. Presently, several checkpoint inhibitors have been approved for advanced NSCLC including nivolumab, pembrolizumab, and atezolizumab all targeting PD-1 and PD-L1. Depending on level of PD-L1 tumor expression, response rates vary, and a substantial proportion of patients do not respond to treatment with immune checkpoint inhibitors. The combination of checkpoint inhibitors have been shown in malignant melanoma and other tumor types to clearly increase the effect. IO102 is a synthetic peptide under development as an immune-modulatory agent targeting cells expressing indoleamine 2,3-dioxygenase (IDO). IDO potently inhibits T-cell immunity in patients with cancer. Treatment with IO102 in NSCLC patients after first line palliative chemotherapy lead to long PFS in a number of patients in a small single arm study. **Methods:** IO102-001 is a randomized, double-blinded Phase 2 trial to evaluate the safety and efficacy of IO102 in combination with anti-PD-1 mAb in locally advanced and/or metastatic NSCLC stage III-IV patients eligible for anti-PD-1 mAb 2nd line treatment after first line of chemotherapy. Patients are randomized (2:1) to either a PD-1 inhibitor + IO201 vaccine or a PD-1 inhibitor (SOC). The PD-1 inhibitor will be administered according to label while IO102 will be given as s.c. injection every 2 weeks for the first 12 weeks, and subsequently every 4 weeks for 12 months or until progression, death or withdrawal from trial, whichever comes first. Treatment is continued to progression, unacceptable toxicity or withdrawal of consent. Main inclusion criteria is patients diagnosed with locally advanced and/or metastatic NSCLC Stage III-IV, measurable disease according to RECIST (1.1), patients eligible for anti PD-1 mAb treatment after 1st line of chemotherapy , ECOG performance status 0 or 1 and available tumor tissue for further analysis. A total of 90 patients will be included in the trial, and the trial will be active in countries in Europe and the US from Q2 2017.

TPS2611 Poster Session (Board #95b), Mon, 8:00 AM-11:30 AM

Phase Ib study of rebastinib plus antitubulin therapy with paclitaxel or eribulin in patients with metastatic breast cancer (MBC). *First Author: Jesus Del Santo Anampa Mesias, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: TMEM (Tumor Microenvironment of Metastasis) are microanatomic structures formed by a Mena-expressing tumor cell, Tie2-expressing macrophage, and endothelial cell in direct content, which serve as the primary portal for tumor cell intravasation into the circulation and subsequent metastasis. Paclitaxel (P) induces the formation of TMEM in the primary tumors of patients treated with neoadjuvant chemotherapy (NAC), and in the primary tumor and distant metastases in the PyMT/PDX models. Tumor cell intravasation is mediated by release of VEGF at TMEM sites from TMEM-associated Tie2^{HI}/VEGF^{HI} macrophages upon binding of the Tie2 receptor to angiopoietin. The Tie2 inhibitor rebastinib (R) inhibits intravasation at TMEM sites, reduces circulating tumor cell (CTC) burden, prevents distant metastases, and improves survival in breast cancer animal models when added to either P or eribulin (E). We hypothesize that the addition of R to antitubulin therapy in patients with HER2-negative MBC will prevent hematogenous dissemination and distant metastasis by inhibiting TMEM function, reduce CTC burden; and improve clinical outcomes. **Methods:** Primary objective of this phase Ib study (NCT02824575) is to evaluate safety and tolerability of R in two dose levels (DL) (50mg or 100mg PO BID) combined with IV P 80mg/m2 (day 1, 8 and 15) or E 1.4mg/m2 (day1 and 8) for four 21-day cycles. Key eligibility includes histologically confirmed HER2 negative MBC, $\leq$ 2 non-taxane chemotherapy regimens for R plus P arm or $\geq$ 2 chemotherapy regimens (including a taxane) for E plus R arm, $\geq$2 endocrine therapies (including CDK4/6 inhibitor) for ER positive patients, ECOG PS 0 or 1; and normal organ and marrow function. Exclusion criteria include significant ocular or cardiac disease. Pharmacodynamic biomarkers to be measured during cycle 1-3 include CTCs, angiopoietin 1/2 levels and Tie-2 expressing monocytes. Tissue biopsy after two treatment cycles in 6 patients will be performed to evaluate TMEM score and function. With two DL of rebastinib, and 3-6 patients at each DL, it is anticipated that 6-12 patients will be required. This trial has enrolled two patients assigned to P arm combined with R 50mg BID. Clinical trial information: NCT02824575.

TPS2612 Poster Session (Board #96a), Mon, 8:00 AM-11:30 AM

First-in-human, first-in-class phase I study of MTL-CEBPA, a small activating RNA (saRNA) targeting the transcription factor C/EBP-α in patients with advanced liver cancer. *First Author: Debashis Sarker, King's College London, London, United Kingdom*

Background: saRNAs are small oligonucleotide drugs designed to selectively upregulate therapeutic proteins by recruiting endogenous transcriptional complexes to a target gene, leading to increased expression of naturally processed mRNA. Transcription factor C/EBP-α (CCAAT/enhancer-binding protein alpha) is a leucine zipper protein which acts as a master regulator of liver homeostasis and multiple oncogenic processes including cell cycle control, proliferation and angiogenesis. MTL-CEBPA comprises a double stranded RNA payload formulated inside a SMARTICLES liposomal nanoparticle to specifically target the CEBPA gene and has been shown to improve liver function and inhibit hepatocellular cancer (HCC) tumor growth in preclinical models (Reebye et al, Hepatology, 2014). MTL-CEBPA is the first saRNA and the first drug targeting C/EBP-α to enter clinical trials. **Methods:** Pts with advanced HCC (Child-Pugh A or B7 only) or secondary liver cancer refractory to or ineligible for standard treatment, ECOG PS 0-1, acceptable haematologic, liver and renal function, are currently being enrolled in a standard 3+3 dose escalation study. Once the RP2D is defined, 12-15 patients with advanced HCC will be evaluated further in a dose expansion cohort. MTL-CEBPA is administered as a 1-hr IV infusion on Day 1, 8 and 15 of a 28-day cycle. RECIST tumor response is assessed after every 2 cycles. The primary objective is to determine safety and tolerability; secondary objectives include PK, liver function improvement and anti-tumor activity. Correlative studies include C/EBP-α mRNA levels in PBMCs and optional tumor tissue, evaluation of C/EBP-α downstream target genes (e.g. TGFβ) and distal target engagement in white blood cells (e.g.IL-6, NF-κB, IFN-γ). Recruitment to cohort 2 is shortly to be completed, with no DLTs reported to date. Clinical trial information: NCT02716012.

TPS2613 Poster Session (Board #96b), Mon, 8:00 AM-11:30 AM

A phase I study of oral SRA737 (formerly CCT245737) given in combination with gemcitabine plus cisplatin or gemcitabine alone in patients with advanced cancer. *First Author: Alvaro Henrique Ingles Garces, Brazilian National Cancer Institute, Rio De Janeiro, Brazil*

Background: SRA737 is a highly selective, orally bioavailable small molecule inhibitor of Checkpoint kinase 1 (Chk1), a key cell cycle checkpoint and central regulator of the DNA Damage Response (DDR) network. In cancer cells, replication stress induced by genomic alterations in oncogenes (eg, *MYC* and *RAS*) combined with loss of function in tumor suppressors (eg, *TP53* and *ATM*) results in persistent DNA damage and genomic instability. Targeted inhibition of components of the DDR network such as Chk1 by SRA737 may be synthetically lethal to cancer cells. Chk1 is also believed to facilitate tumor cell resistance to chemotherapy or radiation-induced DNA damage and the combination of SRA737 with these standards-of-care may provide synergistic antitumor activity. SRA737 is being investigated in two Phase 1 trials in patients with advanced cancer. We now describe the Phase 1 multicenter, dose-escalation study of SRA737 in combination with gemcitabine/cisplatin (GC) or gemcitabine (G) alone (NCT02797977). **Methods:** Up to 70 patients will receive escalating doses of SRA737+GC in Stage 1 or SRA737+G in Stage 2 until a recommended Phase 2 dose (RP2D) is established, followed by expansion cohorts. Patients will receive a single SRA737 PK run-in dose followed by Gem on D1 and 8, Cis on D1, SRA737 on D2, 3, 9 and 10 of each 21-d cycle or Gem on D1, 8 and 15, SRA737 on D2, 3, 9, 10, 16, 17 of each 28-d cycle. Eligibility criteria include WHO performance status of 0-1 and ≤ 3 prior lines of cytotoxic chemotherapy for metastatic disease. Primary objectives are to assess the safety profile of SRA737 combination therapy and to establish a RP2D. The PK profile and PD biomarkers (eg, phosphorylation of Chk1 at Ser296, Ser345 and γH2AX foci in PBMCs and tumor tissue) will be explored. The study was opened to enrollment in mid-2016. An amendment, which includes the addition of an indication specific expansion cohort of subjects with genetically-defined tumors known to have Chk1-sensitizing aberrations (eg, gene mutations and amplifications/deletions), has been submitted and is pending regulatory review while enrollment continues. At the Annual Meeting, the amended design will be described. Clinical trial information: NCT02797977.

TPS2614 Poster Session (Board #97a), Mon, 8:00 AM-11:30 AM

A phase 1b, open label, single institution trial of nintedanib in combination with bevacizumab in patients with advanced solid tumors. *First Author: Ankit Madan, University of Alabama, Hoover, AL*

Background: Vascular endothelial growth factor (VEGF) is a potent factor in inducing angiogenesis. VEGF inhibitors have produced demonstrable but limited and transient clinical benefit for various cancers. One mechanism of resistance includes revascularization secondary to up-regulation of alternative pro-angiogenic signals such as platelet derived growth factor receptor (PDGF) and fibroblast growth factor receptor (FGFR) pathway. Nintedanib is an oral triple kinase inhibitor that blocks the VEGFR, PDGFR and FGFR pathways. Our study is using combination of Nintedanib (Nin) and Bevacizumab (Bev) which will block VEGF as well as salvage pathway of angiogenesis (PDGFR and FGFR). Phase I dose selection studies revealed that Nin is generally well tolerated (Clin Can Res 16:47, 2010). LUME-Lung 1 phase 3, international, double blind, placebo controlled trial using Nin and docetaxel in non-small cell lung cancer (NSCLC) showed significant improvement in progression free survival (PFS) regardless of histology and improvement in overall survival (OS) in lung adenocarcinoma (Lancet oncology 15:2, 2014). **Methods:** This is a phase 1b, open label, single institution trial with standard 3+3 design. Primary objective is to evaluate the safety and tolerability of combination of Nin and Bev. The secondary objective is to determine clinical efficacy (objective response), PFS, and evaluation of plasma levels of angiogenic and anti-angiogenic biomarkers like VEGF, PDGF, VEGF-R and FGF. Patients (pts) in cohort I will be treated with Bev 15 mg/kg day 1 intravenously every 3 weeks and Nin 150 mg orally (PO) twice daily (BID) from day 2-21. In the absence of dose limiting toxicities, Nintedanib dose will be increased to 200 mg PO BID in cohort II. Major inclusion criteria includes advanced solid tumors for which Bev has an indication (non-squamous, NSCLC, colon, ovarian, cervical and renal cancer), progression after at least 1 line of systemic treatment, and measurable disease. Pts with prior treatment with Bev can be enrolled. We will enroll 18 patients. Cohorts I has been completed without DLT (n = 3). Cohort II has enrolled 10 patients. Clinical trial information: NCT02835833.

TPS2615 Poster Session (Board #97b), Mon, 8:00 AM-11:30 AM

A phase Ib/II, open-label, dose escalation study to evaluate the safety, pharmacokinetics, and efficacy of SM88 in patients with prostate cancer. *First Author: Giuseppe Del Priore, Morehouse School of Medicine, Atlanta, GA*

Background: Non-hormonal treatments for biochemically recurrent non-metastatic prostate cancer (nmPC) are limited. SM88 is a novel combination of proprietary tyrosine isomer (TI) and other repurposed agents (CYP3a4 inducer, mTOR inhibitor and catalyst) designed to selectively increase metabolic oxidative stress in cancer cells. Early data reported SM88 activity in solid tumors without significant toxicity (Hoffman et al J Clin Oncol 2013; e22095, Hoffman et al Ann Onc 2016: vi551). **Methods:** This is an open-label multi-center, dose escalating, dose expansion study in nmPC who have failed or refused androgen deprivation. The study includes a dose escalation phase Ib and dose expansion phase 2. The primary objectives are to determine the effect of SM88 on circulating tumor cells (CTC), and progression-free survival. Secondary objectives are: LDH, bone-specific alkaline phosphatase, urinary N-telopeptide, neutrophyll/llymphocyte ratio, cutaneous hyper-pigmentation correlation, PSA doubling times, safety, and patient reported outcomes. As of Jan '17, Phase 1b cohorts 1 and 2, with TI and component PK evaluations, have completed enrollment with adequate numbers to establish the Phase 2 dose without DLT. Phase 2 has begun, with 33 patients planned for at least 6 cycles (@28d) to reach the desired power. This would be followed by a pivotal Phase 3 study in the same group of patients. We propose to conduct a pivotal randomized phase 3 of SM88 in rising PSA, nmPC versus patient's and clinician's choice, limited to 2 options i.e. observation or ADT therapy. Inclusion would include doubling time < 9 months, elevated CTCs and recurrent disease after localized curative intent therapy (the same population as our completed Phase I and ongoing phase II). Outcomes will include delay of radiographic PFS, and delay of time to subsequent toxic therapy i.e. cytotoxic systemic chemo and/or radiation therapy. We proposed this pivotal trial will lead to a successful NDA for an indication in this population of patients. Rapid accrual is expected at several institutions because of the urgent need for less toxic alternatives to androgen deprivation therapy.

TPS2616 Poster Session (Board #98a), Mon, 8:00 AM-11:30 AM

A phase 1, multicenter, dose-escalation study of PRN1371, an irreversible covalent FGFR1-4 kinase inhibitor, in patients with advanced solid tumors, followed by expansion cohorts in patients with FGFR genetic alterations. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: FGFR inhibition is a promising and clinically proven therapeutic approach in a number of solid tumors where genetic alterations of FGFR drive oncogenesis. PRN1371 is a highly selective oral, irreversible inhibitor of FGFR1-4 that exhibits high potency in cancer cell lines harboring FGFR alterations, including mutations and fusions. **Methods:** Part A of this phase 1 clinical trial explores ascending doses of PRN1371 in adult patients with advanced solid tumors in a "3 + 3" design, where cohorts of three patients are studied at each level until additional patients need to be added to better assess safety, establish the maximum tolerated dose and define the recommended phase 2 dose (RP2D). PRN1371 is dosed once or twice daily in continuous, 28-day cycles until disease progression. Part B studies include two or three expansion cohorts of different tumor types, 10 patients each with FGFR1-4 gene mutations, fusions, or amplification at the RP2D. The on-target effect of serum phosphorus and FGF23 increases are measured as potential pharmacodynamic biomarkers. Elevated serum phosphorus is managed with oral phosphate binding medications and a low phosphate diet, with dose interruptions and use of acetazolamide if certain thresholds are exceeded. Circulating tumor DNA from patients at baseline and during follow up is analyzed for FGFR genetic alterations. Pre and on-treatment tumor biopsies in Part B will be tested for a panel of pharmacodynamic biomarkers of FGFR inhibition. Clinical trial information: NCT02608125.

TPS2617 Poster Session (Board #98b), Mon, 8:00 AM-11:30 AM

Phase 1 study of onalespib, HSP90 inhibitor, and AT7519M, CDK9 inhibitor, in patients with advanced solid tumors. *First Author: Khanh Tu Do, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: The 90kDa heat shock chaperone protein (HSP90) exerts housekeeping functions within cells. HSP90 participates in the folding, stabilization, activation, and proteolytic turnover of mutant or over-expressed "client proteins" that contribute to the growth and survival of cancer cells. HSP90 inhibition leads to degradation of these aberrant proteins through the ubiquitin-proteasome pathway, allowing for simultaneous targeting of multiple pathways. Inhibition of HSP90 alone stimulates a compensatory upregulation of HSP70, which is anti-apoptotic at the pre-mitochondrial, mitochondrial and post-mitochondrial levels. The transcriptional induction of HSP70 has been linked to the activity of CDK9. *In vitro* and *in vivo* studies show that disruption of HSP70 induction by CDK9 inhibition can augment HSP90 inhibitor responses. Combined inhibition of HSP90 and CDK9 may produce synergistic anti-tumor activity. **Methods:** We are conducting an a phase I trial of the combination of the HSP90 inhibitor onalespib, and the CDK9 inhibitor AT7519, utilizing a 3+3 trial design, with dose-limiting toxicities defined during cycle 1. Estimated enrollment: 37 patients. Onalespib and AT7519M are both administered on days 1, 4, 8, and 11 of a 21-day cycle following a 1-week lead-in of onalespib alone to facilitate PK/PD endpoints. Patients must have histologically confirmed solid tumors that have progressed on standard of care therapy or for which no standard treatment exists, with an ECOG 0-1. Exclusion criteria include a prolonged QTc interval (Fridericia formula), pre-existing retinal disease, or cardiac dysfunction with EF $<$ 50% at study entry. Current pharmacodynamic analyses include the analysis of HSP70 expression in plasma and peripheral blood mononuclear cells after treatment with onalespib, and after the combination, as proof-of-principle of target inhibition. At this time, DL1 has completed enrollment; accrual is ongoing with measurement of HSP90 client proteins and HSP70 levels in patient plasma and PBMC samples. This trial is open through the ETCTN. Clinical trial information: NCT02503709.

TPS2618 Poster Session (Board #99a), Mon, 8:00 AM-11:30 AM

An open-label, phase II study of tipifarnib for the treatment of HRAS mutant solid tumors, including squamous cell carcinomas of the head and neck. *First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tipifarnib is a potent and highly selective inhibitor of farnesyltransferase (FT). FT catalyzes the post-translational attachment of farnesyl groups to signaling proteins that are requisite for localization to the inner cell membrane. While all RAS isoforms (KRAS/NRAS/HRAS) are FT substrates, only HRAS is exclusively dependent upon farnesylation for membrane localization and signaling activation, making HRAS mutant tumors uniquely susceptible to tipifarnib mediated inhibition of FT. Tipifarnib has demonstrated robust activity in HRAS mutant head and neck squamous cell carcinoma (HNSCC) and HRAS mutant squamous non-small cell lung cancer (NSCLC) patient derived xenograft (PDX) models resistant to standard therapies. **Methods:** This is a multi-institutional, open-label Phase II trial evaluating the efficacy and safety of tipifarnib for pts with HRAS mutant solid tumors. Pts must have either unresectable, locally advanced or metastatic non-hematological malignancies that harbor a missense HRAS mutation. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, PFS, duration of response. Two cohorts (N = 18 each) are enrolling, each being evaluated with a Simon two-stage design. Cohort 1 is for patients with malignant thyroid tumors of any histology. Cohort 2 was originally designated for pts with any other solid tumor. The prespecified activity goal for the first stage of accrual in Cohort 2 was met. Based on data observed in the first stage of this group, enrollment to the second stage of Cohort 2 has been limited to HRAS mutant HNSCC since August 2016. Enrolled patients are treated with tipifarnib 900 mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Clinical trial information: NCT02383927.

TPS2619 Poster Session (Board #99b), Mon, 8:00 AM-11:30 AM

Phase I study of CFI-402257, an oral TTK inhibitor, in patients with advanced solid tumors. *First Author: David W. Cescon, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: TTK (MPS1), a dual-specificity serine-threonine kinase, is critical for the spindle assembly checkpoint (SAC), chromosome alignment and error correction in mitosis. Inhibition of TTK causes premature mitotic exit with unattached chromosomes, resulting in chromosomal mis-segregation, aneuploidy and cell death. TTK is overexpressed in several tumor types, which may contribute to survival and proliferation of aneuploid cells, and higher expression correlates with adverse outcomes. The Campbell Family Therapeutics Group at the University Health Network (UHN) has developed CFI-402257, a potent (Ki = 0.09 nM, IC50 = 1.2 nM), highly selective and orally active inhibitor of TTK, with negligible activity towards 265 other kinases. Robust suppression of tumor growth was achieved upon oral dosing of single agent CFI-402257 at tolerated doses in several cell line (breast, colorectal) and patient-derived (ovarian) xenograft models. Pharmacodynamic effects including reduction in phospho-histone H3 were observed. In syngeneic mouse colorectal cancer models, CFI-402257 + PD-1 immune checkpoint blockade demonstrated greater activity than either agent alone, and resulted in tumor regressions and immunity to rechallenge. **Methods:** This multi-center Phase I dose escalation study (3+3 design) will determine the safety, tolerability and maximum tolerated dose (MTD) of CFI-402257 administered as daily continuous oral treatment. Secondary and correlative endpoints include plasma PK, antitumor activity, and molecular features associated with response or clinical benefit. An expansion cohort (n = 12) will be enrolled at the MTD. Key inclusion criteria: adult patients with advanced solid tumors, measurable disease (RECIST 1.1), adequate organ function and performance status (ECOG 0-1). Exclusion criteria: uncontrolled medical illness, CNS metastases (unless stable x 3 months). CFI-402257 will be dosed once daily on a continuous schedule in 28-day cycles, beginning at 5 mg/day with planned escalation to 56 mg/day. DL1 completed enrolment 01/2017 and accrual is ongoing. Phase II studies are planned (Stand Up to Cancer Canada Breast Cancer Dream Team). Funding: UHN, CIRM. Clinical trial information: NCT02792465.

TPS2620 Poster Session (Board #100a), Mon, 8:00 AM-11:30 AM

Sorafenib administered using a high-dose, pulsatile regimen in patients with advanced solid malignancies: A phase I exposure escalation study. *First Author: Lemonitsa Hillegonda Mammatas, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Sorafenib is currently prescribed at a standard fixed dose of 400 mg twice daily in a continuous schedule. Increased exposure to sorafenib is associated with improved outcome. However, further increase in the dose of this continuous schedule is precluded due to toxicity. A high-dose, pulsatile schedule may result in increased sorafenib exposure while maintaining acceptable toxicity and has demonstrated promising preclinical antitumor activity.[1] Sorafenib plasma concentrations present with large interpatient variability. As drug effectivity is largely dependent on AUC exposure, personalized dose titration based on the sorafenib plasma $AUC_{0\text{-}12h}$ of an individual patient seems more suitable than a standard fixed dose. In this phase I trial, a high-dose, weekly schedule of sorafenib is being studied, using exposure escalation cohorts based on a target $AUC_{0\text{-}12h,}$ instead of conventional dose escalation cohorts. **Methods:** Adult patients are included with locally advanced or metastatic solid tumors for whom no standard therapy exists. High-dose sorafenib is administered once a week. Pharmacokinetic monitoring is performed during the first 3 weeks of treatment in each patient to evaluate if the target plasma sorafenib $AUC_{0\text{-}12h}$ of the cohort is reached and sorafenib dose is adjusted accordingly. Cohorts consist of 3-6 patients per exposure level, starting with target $AUC_{0\text{-}12h}$ 25-50 mg x h/L, analogous to the continuous schedule. The target $AUC_{0\text{-}12h}$ is increased in subsequent cohorts until exposure limiting toxicity occurs. Main objectives are to assess safety and establish the maximum tolerated plasma $AUC_{0\text{-}12h}$ of high-dose, pulsatile sorafenib. At this dose level 10 extra patients will be included. Tumor biopsies are required in all patients of this expansion cohort to study antitumor effects and for direct comparison of plasma and intratumor sorafenib concentrations. Furthermore, a simplified method will be developed for measurement of plasma sorafenib exposure using dried blood spot sampling at 1-2 time points. Nine patients have already been included. Reference: [1]Wang X. et al. J Transl Med 2011;9:220. Clinical trial information: NCT02636426.

TPS2621 Poster Session (Board #100b), Mon, 8:00 AM-11:30 AM

The Molecular Screening and Therapeutics (MoST) Program: A precision medicine framework for biomarker-driven signal-seeking clinical studies for rare cancers. *First Author: Dominique Hess, Garvan Institute of Medical Research, Darlinghurst, Australia*

Background: Precision medicine aims to link molecular targets in tumors to cognate therapies and has the potential to yield new treatments for cancer patients with unmet clinical need. With the accelerating pace of discovery and genomic capacity, innovative approaches are needed to translate molecular opportunities into clinical care. The MoST program tests a novel paradigm for evaluation of biomarker-driven treatment of patients with advanced cancer. The key elements of the design are a molecular screening platform to identify 'actionable' variants and an overarching protocol for multiple, parallel, signal-seeking clinical substudies. **Methods:** 1000 patients with advanced solid cancer of any histologic type, having failed all standard therapies will undergo tumor molecular profiling on archival tissue with a 393-gene panel and other molecular assays. Eligibility for biomarker-driven substudies of targeted treatments is based on tumor variants assessed by a Molecular Tumor Board. A novel framework design allows expedited addition of substudies, with ≥12 open-label, single-arm, signal-seeking substudies planned. The primary objective is to identify signals of clinical activity, as measured by objective tumor response or the ratio of time-to-progression on study treatment over the preceding period. Cohorts of 16 patients will be recruited to each substudy. Substudies with ≥3/16 responding patients will be considered sufficiently interesting to investigate further.As of Feb 2017, 65 patients have been screened, and 8 recruited to 2 open sub-studies: CDK4/6 inhibitor (palbociclib) for Rb pathway defects; CTLA-4 plus PD-L1 checkpoint inhibitors (durvalumab + tremelimumab) for patients with no actionable mutations. Additional substudies under development include: PARP plus PD-L1 inhibitors (olaparib + durvalumab) for HR DNA repair defects; SMO inhibitor (vismodegib) for Hh pathway defects. The modular signal-seeking trial design will be evaluated and is intended to expedite testing of biomarker-based therapies for rare cancers. Clinical trial information: ACTRN12616000908437; ACTRN12616000931471; ACTRN12616001019493.

3000 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Open label, non-randomized, multi-cohort pilot study of genetically engineered NY-ESO-1 specific NY-ESO-1^{c259}t in HLA-A2^{+} patients with synovial sarcoma (NCT01343043). *First Author: Crystal Mackall, Stanford University School of Medicine, Stanford, CA*

Background: NY-ESO-1 is expressed in ~70% of synovial sarcomas (SS). NY-ESO-1^{c259}T cells recognizing an NY-ESO-1 derived peptide complexed with HLA-A*02 are being studied in SS. **Methods:** Eligible patients (pt) are HLA-A*02:01, 02:05 or 02:06, with unresectable, metastatic or recurrent SS expressing NY-ESO-1. Primary endpoint of ORR (CR+PR) is evaluated in high (≥ 50% tumor cells express 2+/3+) and low (≥ 1+ in ≥ 1% cells, not exceeding 2+/3+ in ≥ 50% cells) NY-ESO-1 expressers with different lymphodepleting regimens. Secondary endpoints are safety, DOR, PFS, OS, and gene-marked cell persistence. Lymphocytes are obtained by leukapheresis, isolated, activated, transduced to express NY-ESO-1^{c259}T, and expanded. Target dose is $1–6 \times 10^9$cells. Disease is assessed at wk 4, 8 and 12 post-T-cell infusion, and then every 3 months. **Results:** 34 pt have been enrolled with 24 treated. 50% are male; median age is 30 yr (range 15 – 73). 12/15 pt in cohort 1 were treated. ORR was 50% (1 CR; 5 PR). Time to response was 6 wk (range 4-9) and median DOR 31 wk (range 13-72). Cohort 3 was closed due to only 1 PR out of 5 pt. Evaluation is ongoing in cohorts 2 (6 enrolled; 5 treated) and 4 (8 enrolled; 2 treated) as of 1/9/17. The most common AE are leukopenia (96%), nausea and pyrexia (88%), neutropenia (88%), lymphopenia (83%), anemia (79%), and thrombocytopenia (79%). 11 events of CRS were reported (3 G3; 1 G4), with no events of seizure, cerebral edema or fatal neurotoxicity; all resolved with supportive therapy. One fatal SAE (bone marrow failure) occurred in cohort 2; investigations have not identified a mechanism by which NY-ESO-1^{c259}T may have caused this event. **Conclusions:** NY-ESO-1^{c259}T has promising efficacy and acceptable safety. CRS is not associated with severe neurotoxicity and appears manageable with appropriate supportive care. Cohort 3 data indicate that Flu may be important for efficacy. Efficacy and safety data will be further evaluated and presented. Clinical trial information: NCT01343043.

Cohort	NY-ESO-1 expression	Lymphodepletion
1*	high	Fludarabine (Flu) 30 mg/m^2/day × 4
2	low	cyclophosphamide (Cy) 1800 mg/m^2/day × 2
3*	high	Cy 1800 mg/m^2/day × 2
4	high	Flu 30 mg/m^2/day × 3, Cy 600 mg/m^2/day ×3

*Closed

LBA3001 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Durable remissions with BCMA-specific chimeric antigen receptor (CAR)-modified T cells in patients with refractory/relapsed multiple myeloma. *First Author: Frank (Xiaohu) Fan, Nanjing Legend Biotech, Nanjing, China*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Monday, June 5, 2017, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2017, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

3002 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Phase Ia and Ib studies of the novel carcinoembryonic antigen (CEA) T-cell bispecific (CEA CD3 TCB) antibody as a single agent and in combination with atezolizumab: Preliminary efficacy and safety in patients with metastatic colorectal cancer (mCRC). *First Author: Josep Tabernero, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: CEA CD3 TCB (RG7802, RO6958688) is a novel T-cell bispecific antibody targeting CEA on tumor cells and CD3 on T cells. In preclinical models, CEA CD3 TCB displays potent anti-tumor activity, leads to increased intratumoral T cell infiltration and activation and upregulates PD-1/PD-L1. **Methods:** Intwo ongoing dose-escalation phase I studies, RO6958688 is given as monotherapy (S1) i.v. QW or in combination (QW) with atezolizumab 1200 mg Q3W (S2) in adult patients (pts) with advanced CEA+ solid tumors. In S1, 80 pts (mCRC: 68) were treated at dose levels from 0.05 mg to 600 mg; in S2, 38 pts (mCRC: 28) from 5 mg to 160 mg. In S1, a Bayesian logistic regression model with overdose control guided dose escalation. Data cutoff 25.01.17. **Results:** At doses ≥60mg (36 pts in S1; 10 in S2), CT scans revealed tumor inflammation within days of first dose, consistent with the mode of action of RO6958688. 2 (5%) pts in S1 (both microsatellite stable (MSS) and 2 (20%; 1 MSS) in S2 had a partial response (RECIST v1.1). Preliminary tumor size reduction (> -10% and < -30% [stable disease]) was observed in 4 (11%) additional pts in S1 and 5 (50%) in S2. At week 4-6 FDG PET scan assessment, 10 (28%) pts with mCRC in S1 and 6 (60%) in S2 had a metabolic partial response (EORTC criteria). At all doses in S1, the most common related AEs were pyrexia (56.3%), infusion related reaction (IRR, 50%) and diarrhea (40%). The most common grade ≥ 3 (G3) related AEs were IRR (16.3%) and diarrhea (5%). 5 patients experienced DLTs: G3 dyspnea, G3 diarrhea, G3 hypoxia, G4 colitis and G5 respiratory failure (G4-5 at 600mg). DLT events were likely associated with tumor lesion inflammation. In S2, there was no evidence of new or additive toxicities, with 1 DLT at 160 mg (G3 transient increase of ALT in a patient with liver metastases). PK/PD data are reported separately. **Conclusions:** Evidence of antitumor activity was observed with RO6958688 monotherapy in ongoing dose escalation. Activity appeared to be enhanced with doses in combination with atezolizumab, with a manageable safety profile. Updated data will be presented. Clinical trial information: NCT02324257 and NCT02650713.

3003 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Epacadostat plus nivolumab in patients with advanced solid tumors: Preliminary phase I/II results of ECHO-204. *First Author: Raymond P. Perez, University of Kansas Clinical Research Center, Fairway, KS*

Background: ECHO-204 is an ongoing, open-label, phase 1/2 (P1/2) study of epacadostat (E; potent and selective oral inhibitor of the immunosuppressive enzyme indoleamine 2,3-dioxygenase 1) plus PD-1 inhibitor nivolumab (N) in patients (pts) with advanced cancers (NSCLC, MEL, OVC, CRC, SCCHN, B-cell NHL [including DLBCL], GBM). Preliminary P1/2 safety and tolerability outcomes for the overall study population and P2 response for select tumor types (SCCHN, MEL, OVC, CRC) are reported. **Methods:** In P1 dose escalation, pts received E (25, 50, 100, 300 mg BID) + N (3 mg/kg Q2W); in P2 cohort expansion, pts received E (100 or 300 mg BID) + N (240 mg Q2W). Safety/tolerability was assessed in pts receiving ≥1 E + N dose. Response was assessed in RECIST v1.1 evaluable pts; for recently enrolled pt subgroups, only preliminary DCR (CR+PR+SD) is presented. **Results:** As of 29OCT2016,241 pts (P1, n = 36; P2, n = 205) were enrolled. No DLT was observed in P1. Most common TRAEs (≥15%) in pts treated with E 100 mg (n = 70) and E 300 mg (n = 135) were rash (33% and 22%, respectively), fatigue (26% and 31%), and nausea (24% and 19%). Rash was the most common grade ≥3 TRAE in E 100 mg and E 300 mg subgroups (10% and 12%). TRAEs led to discontinuation in 7% (E 100 mg) and 13% (E 300 mg) of pts. There were no TR-deaths. For the 23 recently enrolled, efficacy-evaluable SCCHN pts treated with E 300 mg, preliminary DCR was 70% (n = 16). Of 30 MEL pts, 8 were treated with E 100 mg and 22 were more recently enrolled and treated with E 300 mg. ORR (CR+PR) and DCR in MEL pts treated with E 100 mg were 75% (n = 6; all PR) and 100% (n = 8; 2 SD), respectively. Preliminary DCR in MEL pts treated with E 300 mg was 64% (n = 14). Of 29 OVC pts, 18 were treated with E 100 mg and 11 with E 300 mg.ORR and DCR for OVC pts treated with E 100 mg were 11% (n = 2; 2 PR) and 28% (n = 5; 3 SD); for 11 OVC pts treated with E 300 mg, ORR and DCR were 18% (n = 2; 2 PR) and 36% (n = 4; 2 SD).For 25 CRC pts (all E 100 mg), ORR and DCR were 4% (n = 1; PR) and 24% (n = 6; 5 SD).Safety/efficacy evaluations are ongoing for all cohorts. **Conclusions:** E + N was generally well tolerated up to the maximum E 300-mg dose. P2 ORR/DCR outcomes are promising, particularly in SCCHN and MEL pts. Updated data will be presented at the meeting. Clinical trial information: NCT02327078.

3004 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Safety and clinical activity of adenosine A2a receptor (A2aR) antagonist, CPI-444, in anti-PD1/PDL1 treatment-refractory renal cell (RCC) and non-small cell lung cancer (NSCLC) patients. *First Author: Lawrence Fong, University of California, San Francisco, San Francisco, CA*

Background: Adenosine production in the tumor leads to immunosuppression through A2aR on infiltrating immune cells. CPI-444 is an oral A2aR antagonist with single agent(SA) anti-tumor activity in pre-clinical models. This phase 1/1b clinical trial uses a 2-step adaptive design to evaluate CPI-444 as a SA and in combination (combo) with the anti-PDL1 antibody, atezolizumab (atezo). We report results of RCC and NSCLC cohorts. **Methods:** Primary objectives: safety, efficacy and to identify optimal dose/schedule. Step 1 utilized 3 SA and 1 combo cohort to select dose/schedule. Step 2 included disease-specific expansion cohorts including RCC and NSCLC. Eligible pts had selected advanced cancers and failed standard therapies including checkpoint inhibitors. **Results:** 34 pts have enrolled and 25 pts were evaluable for response (Table 1). Median prior regimens: 3 (range,1-5) and most pts were resistant/refractory to anti PD1/PDL1 therapy (R/R). Most common AEs were Gr 1 nausea (n = 3) and pyrexia (n = 3); Gr 3 tachycardia was the only possibly related SAE. The selected Step 2 doses were CPI-444 100mg BID as a SA and in combo with atezo 840mg IV q2 weeks. The disease control rate (DCR, CR+PR+SD; duration 2 mo to $>$ 8 mo) for pts with RCC and NSCLC cohorts were 86% and 50%, (100% and 43% for R/R pts), respectively. DCRs were similar in the SA and combo cohorts. Of 7 evaluable RCC pts, 1 pt has an ongoing PR (SA cohort, $>$ 4 mo) and 5 have ongoing SD, duration 3 mo to $>$ 8 mo (2 SA, 3 combo). Biopsy of the PR pt showed no detectable tumor and infiltration with CD8+ lymphocytes. In 18 evaluable NSCLC pts, 1 PR (PDL1 negative pt) and 8 SD were seen. PRs and SDs were seen in R/R pts and in PDL1 negative pts in both diseases. **Conclusions:** CPI-444 is well tolerated and shows anti-tumor activity in RCC and NSCLC pts as a SA and in combo. Pts who are R/R to anti PD1/PDL1 therapy and who are PDL1 negative can also benefit. Clinical trial information: NCT02655822.

	RCC	NSCLC
n	8	26
Median age (range)	64 (44-73)	72 (41-85)
% PD1/PDL1 R/R	75% (6/8)	68% (18/26)
Regimen: SA/Combo (n)	5/3	15/11
Median followup(range)	15 wks (6-32)	11 wks (1-19)

3005 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

CX-1158-101: A first-in-human phase 1 study of CB-1158, a small molecule inhibitor of arginase, as monotherapy and in combination with an anti-PD-1 checkpoint inhibitor in patients (pts) with solid tumors. *First Author: Kyriakos P. Papadopoulos, START, San Antonio, TX*

Background: Arginase is secreted by myeloid-derived suppressor cells (MDSCs) and polymorphonuclear cells (PMNs) in the tumor microenvironment, depleting arginine, an amino acid required for T-cell activation and proliferation. CB-1158 is an oral small molecule inhibitor of arginase. CB-1158 reverses PMN- and MDSC-mediated suppression of T-cells in *ex vivo* human models, and increases plasma and tumor arginine levels in mouse syngeneic tumor models leading to increased pro-inflammatory markers and activated CD8 T-cells in the tumor. CB-1158 has single agent efficacy in mouse tumor models and synergistically enhances the antitumor efficacy of checkpoint inhibitors. **Methods:** This is an ongoing phase 1 study to evaluate safety and tolerability of CB-1158 as a monotherapy and in combination with anti-PD-1 in pts with solid tumors. Pharmacokinetics (PK), anti-tumor effects, and biomarkers, including plasma arginine, arginase activity, and effects on immune function in blood and in tumors will be evaluated. CB-1158 was administered BID orally in 28-day cycles. Escalating doses were administered to cohorts for safety evaluation. Additional pts were enrolled at dose levels determined to be safe to support biomarker objectives. **Results:** Nine pts have been enrolled across two monotherapy dose escalation cohorts (50 and 100 mg) and biomarker cohorts. CB-1158 was rapidly absorbed (T_{max} = 4 h) and was cleared with a half-life of 6 h. At doses of 50 and 100 mg, steady-state plasma trough levels were 1.6 and 4.5 μM, sufficient to achieve $>$ 90% arginase inhibition, and plasma arginine levels increased 2.4- and 4-fold, respectively. CB-1158 has been well tolerated with no DLTs or drug-related Grade 3 AEs. Dose escalation is ongoing and updated safety, PK and biomarker data will be presented. **Conclusions:** CB-1158 is a first-in-class inhibitor of the myeloid-derived immunosuppressive enzyme arginase. CB-1158 has been well tolerated and achieves on-target inhibition resulting in increases in plasma arginine, an amino acid required for T-cell immune responses. Clinical trial information: NCT02903914.

3006 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Preliminary results from a phase 1 trial of M7824 (MSB0011359C), a bifunctional fusion protein targeting PD-L1 and TGF-β, in advanced solid tumors. *First Author: James L. Gulley, Genitourinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: M7824 (MSB0011359C) is a novel bifunctional fusion protein comprised of a fully human IgG1 monoclonal antibody against programmed death ligand 1 (PD-L1) fused to the soluble extracellular domain of transforming growth factor-β (TGF-β) receptor II, which acts as a TGF-β trap. We report preliminary data from a phase 1 trial of M7824 in patients (pts) with advanced solid tumors. **Methods:** NCT02517398 is a phase 1, open-label, 3+3 dose-escalation study. Eligible pts receive M7824 at 1, 3, 10, or 20 mg/kg Q2W until confirmed progressive disease, unacceptable toxicity, or trial withdrawal; treatment beyond progression is generally allowable. The primary objective is to determine the safety and maximum tolerated dose of M7824; secondary objectives include pharmacokinetics (PK), immunogenicity, and best overall response per RECIST v1.1. **Results:** 16 heavily pretreated pts with ECOG performance status 0-1 have received M7824. Our PK data show a dose-linear increase in exposure starting at a dose of 3 mg/kg; furthermore, M7824 saturates peripheral PD-L1 and sequesters any released plasma TGF-β1, -β2, and -β3 throughout the dosing period in a dose-dependent manner. Grade 3 drug-related treatment-emergent adverse events (TEAEs) occurred in 3 pts (skin infection secondary to grade 2 bullous pemphigoid [BP], lipase increased, and colitis with associated anemia); there were no grade 4-5 drug-related TEAEs. BP and colitis responded well to steroids. Colitis and its secondary events of anemia and rectal hemorrhage (in a previously radiated area) were considered dose limiting in 1 pt. There was preliminary evidence of efficacy across all dose levels, including 1 ongoing confirmed complete response (cervical), 1 durable partial response (pancreatic), a 25% reduction in the sum of diameters of target lesions after 2 doses of M7824 (cervical), and 2 cases of prolonged stable disease (pancreatic; carcinoid). **Conclusions:** Preliminary data from this phase 1 dose-escalation study suggest that M7824 has a manageable safety profile in pts with heavily pretreated advanced solid tumors. Early signs of clinical efficacy warrant further study. Clinical trial information: NCT02517398.

3007 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Clinical results with combination of anti-CD27 agonist antibody, varlilumab, with anti-PD1 antibody nivolumab in advanced cancer patients. *First Author: Rachel E. Sanborn, Robert W. Franz Cancer Research Center, Earle A. Chiles Research Institute, Providence Cancer Center, Portland, OR*

Background: A phase 1 trial to assess the safety and immunological activity of the combination of varlilumab (V) and nivolumab (N), and recommend a dose of V for the phase 2 study was conducted. **Methods:** The study was performed using the approved dose of N (3 mg/kg Q2W) and escalating doses of V (0.1, 1, or 10 mg/kg Q2W) in anti-PD-(L)1 naïve patients with advanced cancer. **Results:** A total of 36 patients (21 CRC, 8 ovarian [OVA], 4 melanoma and 3 SCCHN) were enrolled. Toxicity was consistent with the safety profile of each agent individually; no unexpected toxicities were seen with the combination. No MTD was identified. An OVA cancer patient in the 10 mg/kg cohort had a DLT: hepatitis (G4) and acute kidney injury (G3). A CRC patient in the 10 mg/kg cohort had a drug-related SAE of mixed motor sensory neuropathy (G2) and a CRC patient in the 1 mg/kg cohort had rash (G3). No additional drug related SAEs or DLTs were reported. The majority of tumors were PD-L1 negative (24/27) by IHC at baseline. For patients with post treatment biopsies, PD-L1 expression was observed in 43.5% (10/23) and correlated with increases in CD8 T cell infiltration, consistent with the generation of anti-tumor immunity. Other treatment related biomarker changes included transient increases in serum chemokine levels, and a prominent decrease in circulating Tregs. Biomarker analysis did not clearly differentiate between dose levels, or delineate an optimal V dose. Three patients had objective PR by RECIST [CRC MSI-low (1 mg/kg V), SCCHN (10 mg/kg V) and OVA (10 mg/kg V, uPR)]. The response in the CRC patient is ongoing with a 94% decrease in target lesion diameter and a PFS of 19+ months. There were also 11 patients with SD. Phase 2 cohorts are ongoing in RCC, SCCHN, OVA, CRC and GBM. The Phase 2 portion includes exploration of different dose/regimens of V, including high and low exposure, to better characterize the optimal dosing strategy for V, in combination with a fixed dose of N (240 mg Q2W). **Conclusions:** The combination of V and N was well tolerated, associated with strong biological signals, and has evidence of clinical activity in subsets of patients with tumor types that are typically resistant to PD-1 inhibitor monotherapy. Clinical trial information: NCT02335918.

3008 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Association of the diversity and composition of the gut microbiome with responses and survival (PFS) in metastatic melanoma (MM) patients (pts) on anti-PD-1 therapy. *First Author: Jennifer Ann Wargo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Significant advances have been made in cancer therapy with immune checkpoint blockade. However, responses in pts with MM are variable, and insights are needed to identify biomarkers of response and strategies to overcome resistance. There is a growing appreciation of the role of the microbiome in cancer, and evidence in murine models that modulation of the gut microbiome may enhance responses to immune checkpoint blockade, though this has not been well studied in pts. Thus we evaluated the microbiome in a large cohort of pts with MM, focusing on responses to anti-PD-1. **Methods:** We collected oral (n = 234) and gut microbiome samples (n = 120) on a large cohort of of MM patients (n = 221). Of note, the majority of pts were treated with PD-1 based therapy (n = 105). Pts on anti-PD1 were classified as either responders (R) or non-responders (NR) based on RECIST criteria, and 16S rRNA and whole genome shotgun (WGS) sequencing were performed. Immune profiling (via immunohistochemistry, flow cytometry, cytokines and gene expression profiling) was also done in available pre-treatment tumors at baseline. **Results:** Significant differences in diversity and composition of the gut microbiome were noted in R vs NR to anti-PD-1, with a higher diversity of bacteria in R vs NR ($p = 0.03$). Differences were also noted in the composition of gut bacteria, with a higher abundance of Clostridiales in R and of Bacteroidales in NR. Immune profiling demonstrated increased tumor immune infiltrates in R pts , with a higher density of CD8+T cells; this correlated with abundance of specific bacteria enriched in the gut microbiome ($r = 0.59, 0.014$). Other features of enhanced immunity were also noted, and WGS revealed differential metabolic signatures in R vs NR. Furthermore, diversity ($p = 0.009$; HR = 7.67) and abundance of specific bacteria in R ($p = 0.007$; HR = 3.88) was associated with improved PFS to anti-PD-1 therapy. **Conclusions:** Diversity and composition of the gut microbiome differ in R vs NR pts with MM receiving anti-PD-1 therapy. These have potentially far-reaching implications, though results need to be validated in larger cohorts across cancer types.

3009 Poster Discussion Session; Displayed in Poster Session (Board #104), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

A phase I/II clinical trial of E6 T-cell receptor gene therapy for human papillomavirus (HPV)-associated epithelial cancers. *First Author: Christian S. Hinrichs, National Institutes of Health, National Cancer Institute, Bethesda, MD*

Background: Engineered T-cell therapy has shown promise in B-cell malignancies and melanoma, but clinical investigation in epithelial cancers has been limited. **Methods:** We conducted a phase I/II clinical trial of T cells genetically engineered to express a T-cell receptor that targets an HLA-A*02:01-restricted epitope of E6 (E6 TCR T Cells) for patients with metastatic HPV-16+ carcinoma. The cell dose was escalated in cohorts of single patients (1×10^9, 1×10^{10}, and $1\text{-}2 \times 10^{11}$cells). Patients received a nonmyeloablative conditioning regimen of cyclophosphamide and fludarabine, a single infusion of E6 TCR T Cells, and systemic high-dose aldesleukin. **Results:** Twelve patients were treated, 9 at the highest cell dose, plus one retreatment. The cancer types were 6 cervical, 4 anal, 1 oropharyngeal, and 1 vaginal. No dose-limiting toxicity, autoimmune adverse events, or cytokine storm were observed. Two patients with anal cancer treated at the highest cell dose experienced partial tumor responses lasting 6 and 3 months after treatment. The patient with a 6-month response had complete regression of one tumor and partial regression of two tumors that were resected upon progression; she has no evidence of disease 22 months after treatment. T-cell receptor gene transfer efficiency was 45 and 51% in the responding patients, and 47-76% (median 61%) in the non-responding patients. Responding patients showed robust levels of E6 TCR T cell memory (30 and 46% of circulating T cells 1-month after treatment). Non-responding patients showed wide-ranging levels of E6 TCR T cell memory (range 4-53%, median 29%). Expression of programmed cell death protein 1 (PD-1) by circulating E6 TCR T Cells 1-month after treatment was low in all patients ($< 5\%$). The patient with a 6-month response had 7% E6 TCR T Cells in a resected tumor 10 months after treatment, 25% of which expressed PD-1. A patient with no response had no detectable E6 TCR T Cells in a resected tumor 3 months after treatment. **Conclusions:** E6 TCR T-cell therapy was safe at doses up to 2×10^{11} cells. Regression of metastatic HPV+ carcinoma occurred in two patients following treatment, suggesting that TCR T-cell therapy can mediate epithelial cancer regression. Clinical trial information: NCT02280811.

First-in-human multicenter study of bb2121 anti-BCMA CAR T-cell therapy for relapsed/refractory multiple myeloma: Updated results. *First Author: Jesus G. Berdeja, Sarah Cannon Research Institute, Nashville, TN*

Background: To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy following initial results (Berdeja et al, ENA 2016). **Methods:** CRB-401 (NCT02658929) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received $\geq$ 3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent, or are double-refractory, and have $\geq$ 50% BCMA expression on plasma cells. Peripheral blood mononuclear cells are collected via leukapheresis. Patients undergo lymphodepletion with Flu (30 mg/m^2) / Cy (300 mg/m^2) daily for 3 days then receive 1 infusion of bb2121. The study follows a standard 3+3 design with planned dose levels of 5, 15, 45, 80 and 120×10^7 CAR+ T cells. **Results:** As of November 18, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose-limiting toxicities and no $>$ Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS had been reported in 8/11 (73%) treated patients. All patients treated with doses of 15.0×10^7or higher remained on study and the overall response rate (ORR) in the 6 evaluable patients at these doses was 100%, including 2 sCRs and 2 MRD-negative responses (1 sC, 1 VGPR). CAR+ T cell expansion has been demonstrated consistently. An additional 6 months of follow up on previously reported results and initial data from an additional ~10 patients will be presented. **Conclusions:** bb2121 shows promising efficacy at dose levels above 5×10^7 CAR+ T cells, including 2 sCRs and ongoing clinical responses at 6 months, with mild and manageable CRS to date. These initial data support the potential of CAR T therapy with bb2121 as a new treatment paradigm in MM. Study sponsored by bluebird bio. Clinical trial information: NCT02658929.

Effect of chimeric antigen receptor (CAR) T cells on clonal expansion of endogenous non-CAR T cells in patients (pts) with advanced solid cancer. *First Author: Rebecca H Kim, University of Pennsylvania, Philadelphia, PA*

Background: CAR T cells have produced remarkable responses in heme malignancies, but efficacy in solid cancers is limited. Poor in vivo persistence and heterogeneous expression of the CAR target on tumors are potential barriers to the success of CAR T cell therapy. However, even with transient persistence, CAR T cells may elicit a "vaccine" effect by inducing cancer cell death and subsequent release of tumor antigens that could stimulate tumor-specific T cell activity. **Methods:** 6 pts with pancreatic ductal adenocarcinoma (PDAC) received repeated 3x per week intravenous (iv) infusions of mRNA-transfected mesothelin-redirected CAR T cells (CARTmeso). Pts with PDAC (n = 5), ovarian carcinoma (n = 5), and mesothelioma (n = 5) received iv infusion of lentiviral-transduced (lenti) CARTmeso with or without cyclophosphamide (Cy) preconditioning. Peripheral blood samples were collected from pts at baseline and defined time points after treatment. Genomic DNA from these samples or from pre-infused CAR T cell product was used for deep sequencing of the TCRbeta chain using the ImmunoSEQ platform. A TCRbeta clone was considered to have expanded from baseline to defined time points after treatment if it showed a two-fold change from baseline and met statistical significance by Fisher's exact test ($p < 0.05$). **Results:** mRNA CARTmeso cells persisted *in vivo* for $<$ 24 hrs. Unexpectedly, therapy induced clonal T cell expansion detected in the blood by day 14 in all 6 pts. Expanded clones underwent contraction by day 28 in 3 pts. In one pt, peripherally expanded clones were also detected in a tumor biopsy, but without significant intratumoral clonal expansion. Lenti CARTmeso therapy also induced peripheral expansion of T cell clones both present and not present in the infused CAR T cell product. However, with Cy preconditioning, clonal expansion seen after lenti CARTmeso therapy was predominately restricted to clones detected in the CAR T cell product. **Conclusions:** In pts with advanced solid cancers, CARTmeso stimulates clonal expansion of endogenous T cells, which is lost with Cy conditioning. Findings suggest that CAR T cells may elicit a "vaccine" effect with potential therapeutic implications.

Safety of epacadostat 100 mg bid plus pembrolizumab 200 mg Q3W in advanced solid tumors: Phase 2 data from ECHO-202/KEYNOTE-037. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: The immunosuppressive enzyme indoleamine 2, 3-dioxygenase 1 (IDO1) facilitates immune tolerance in cancer via T-cell suppression, and IDO1 overexpression is associated with poor survival. Epacadostat, an oral inhibitor of IDO1, has been shown to be well tolerated as monotherapy and in combination with checkpoint inhibitors. ECHO-202/KEYNOTE-037 is a phase 1/2 study evaluating the safety and efficacy of oral epacadostat plus IV pembrolizumab in patients (pts) with advanced tumors. Based on phase 1 outcomes, epacadostat 100 mg BID plus pembrolizumab 200 mg Q3W was selected for phase 2 evaluation. This analysis summarizes phase 2 safety experience in the overall population of ECHO-202/KEYNOTE-037 (pooled across tumor types) at an October 29, 2016 data cutoff. **Methods:** Phase 2 pts were ≥18 years of age with advanced or recurrent melanoma (MEL), non–small cell lung cancer (NSCLC), renal cell carcinoma (RCC), urothelial carcinoma (UC), triple-negative breast cancer, squamous cell carcinoma of head and neck (SCCHN), ovarian cancer, diffuse large B-cell lymphoma, or microsatellite instability–high colorectal cancer. **Results:** The overall safety population comprised 244 pts receiving ≥1 study treatment dose. Median age was 63 years, 52% were women, and 91% were white. As of data cutoff, 134 study pts (55%) discontinued study treatment, primarily due to disease progression (n = 97). Median exposure to study treatment was 86 days (range, 1–374 days). TRAEs occurring in ≥5% of pts were fatigue (23%); rash (16%); diarrhea and nausea (7% each); increased alanine aminotransferase, increased aspartate aminotransferase, and pruritus (6% each); and pyrexia (5%). A total of 37 pts (15%) had grade ≥3 TRAEs; the most common grade ≥3 TRAEs were increased lipase (asymptomatic) and rash (3% each). TRAEs led to discontinuation in 3% of pts. **Conclusions:** Epacadostat 100 mg BID plus pembrolizumab 200 mg Q3W was associated with an acceptable safety profile in pts with advanced cancers, supporting continued evaluation of the combination. The phase 3 ECHO-301/KEYNOTE-252 MEL study is ongoing and additional phase 3 studies (NSCLC, UC, RCC, SCCHN) are planned. Clinical trial information: NCT02178722.

3013 Poster Discussion Session; Displayed in Poster Session (Board #108), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

A phase 1b study of the anti-PD-1 monoclonal antibody BGB-A317 (A317) in combination with the PARP inhibitor BGB-290 (290) in advanced solid tumors. *First Author: Michael Friedlander, The Prince of Wales Hospital, Randwick, Australia*

Background: The release of tumor-associated antigens may enhance the response to immunotherapy. BGB-A317, a humanized IgG4 variant monoclonal antibody engineered to have no Fc gamma receptor binding, targets the programmed cell death-1 (PD-1) receptor. It is being developed in solid and hematologic malignancies at a dose of 200 mg IV Q3W. BGB-290, a potent inhibitor of PARP 1/2, is hypothesized to promote neoantigen release that will potentially increase the efficacy of BGB-A317. A phase 1 study identified 60mg BID as the recommended Phase 2 dose (RP2D) for BGB-290. This study consists of initial dose escalation to determine the maximum-tolerated dose (MTD), safety, PK profile, and preliminary anti-tumor activity of the combination, followed by expansion into ovarian, breast, prostate, gastric, bladder, pancreatic and small cell lung cancers. **Methods:** Cohorts of 6 -12 pts with advanced solid tumors were treated in each of 5 planned dose levels (DLs). In DLs 1-3, BGB-290 doses ranged between 20-60mg PO BID with BGB-A317 2mg/kg IV Q3W. In DLs 4 - 5, BGB-290 doses were 40 or 60 mg BID; A317 was given at 200 mg IV Q3W based on PK data from a single agent Phase 1 study. **Results:** As of 16 Jan 2017, 38 pts [median age 59 years (34-75)] were treated in DLs 1-4; enrollment to DL5 is ongoing. One DLT of persistent Gr 2 nausea was reported in DL 4. The most common adverse event (AE) considered related to both study drugs was fatigue (10.5%). Immune-related AEs were Gr 3 hypophysitis (n = 1), Gr 3 or 4 autoimmune hepatitis(n = 2), and Gr 2 elevated AST/ALT (n = 1). Decreases in tumor burden have been observed in 16 pts; 7 achieved a PR (5 with ovarian and one each with uterine and pancreatic cancer) and one CR was observed in ovarian cancer. Six pts had SD for > 6 months including 2 pts with pancreatic cancer who received BGB-A317+BGB-290 for 189 and 281 days. Plasma/serum exposure of BGB-290 and BGB-A317 were consistent with those in single-agent trials. **Conclusions:** BGB290 and BGB-A317 can be combined. Dose expansion in multiple tumor types is planned to commence in 2017 once the RP2D is determined. Clinical trial information: NCT02660034.

3014 Poster Discussion Session; Displayed in Poster Session (Board #109), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Activity of a novel immunotherapy combination of intralesional Coxsackievirus A21 and systemic ipilimumab in advanced melanoma patients previously treated with anti-PD1 blockade therapy. *First Author: Brendan D. Curti, Providence Cancer Center and Earle A. Chiles Research Institute, Portland, OR*

Background: CAVATAK is a novel bio-selected oncolytic and immunotherapeutic strain of Coxsackievirus A21 (CVA21) that when injected into melanoma lesions can increase immune-cell infiltration, up-regulation of γ-INF response and immune-checkpoint genes, including CD122, which may be a potential marker for enhanced anti-tumor activity by anti-CTLA-4 blockade. Intratumoral replication of CVA21 may act as a strong "immune-sequestration signal" to circulating activated T-cells following CTLA-4 blockade. A large unmet need exists for active therapies in melanoma patients (pts) following treatment (tx) with anti-PD1 therapies. We present in a Phase 1 study, the clinical activity of a CVA21/ ipilimumab (ipi) combination following anti–PD1 therapy in advanced melanoma pts. **Methods:** The Phase Ib MITCI study (NCT02307149) investigated the efficacy and safety of i.t. CVA21 and i.v. ipi in 26 pts with unresectable Stage IIIB/C-IVM1c melanoma with 13 pts previously treated with anti-PD1 therapies. Pts received up to 3 x 10^8 $TCID_{50}$CVA21 i.t. on study days 1, 3, 5, 8 and 22, and then q3w for a further 6 series of injections. Ipi (3 mg/kg) q3w was given as 4 i.v. infusions starting at Day 22. **Results:** Analysis of the prior anti–PD1 treated pts (n=13) revealed that the combination tx was generally well-tolerated with one case of Gr 3 ipi-related liver toxicity observed. Of the tx population, 54% (7/13) had received prior ipi tx in addition to anti-PD1, 85% (11/13) of pts were stage IV M1b/c, with the median time between the last anti-PD1 and first CVA21 and ipi doses being 5.7 and 8.7 weeks, respectively. The mean number of prior systemic therapies including anti-PD1 tx was 2.6. For all pts completing at least the first investigator response assessment (irWHO criteria at Day 106) we observed a confirmed BORR of 38.0% (3/8) and a DCR (CR+PR+SD) of 88% (7/8). **Conclusions:** Intratumoral CVA21 + ipilimumab treatment in anti–PD1 treated pts has displayed promising clinical activity together with low adverse toxicity and as such this regimen may represent a valuable tx option for pts that have been administered previous lines of immune checkpoint therapy. Clinical trial information: NCT02307149.

Antibiotics prescription to decrease progression-free survival (PFS) and overall survival (OS) in patients with advanced cancers treated with PD1/PDL1 immune checkpoint inhibitors. *First Author: Lisa Derosa, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Villejuif, France*

Background: Use of antibiotics (ATB) alters the gut microbiota composition and decreases bacterial diversity. Pre-clinical evidences demonstrated the impact of the microbiota in the efficacy of immune checkpoint blockades (ICB) in cancer. Interaction between ATB and ICB has not been extensively investigated in cancer patients (pts). Our study evaluated the effect of ATB in cancer pts treated with PD-1/PD-L1 inhibitors. **Methods:** We conducted a retrospective analysis of pts treated with PD-1/PD-L1 inhibitors for advanced Renal Cell Carcinoma (RCC), Urothelial Cancer (UC) and Non-Small Cell Lung Cancer (NSCLC) and data on ATB use were collected. ATB(+)/(-) groups were defined as pts treated or not with ATB before (2 months period) or within the first month of ICB. PFS and OS were compared between both groups among all pts and then according to tumor site. Statistical analyses were performed using the Kaplan-Meier method. Cox regression analyses were performed separately for each cancer type adjusting for its specific risk factors. **Results:** Among 175 pts included, 51 (29%) received ATB (mostly beta-lactamases and fluoroquinolones). ATB(+) group had shorter PFS and OS when compared to ATB(-) group: 3.4 vs. 5.2 months, $p < 0.013$, and 12.2 vs. 20.8 months, $p < 0.001$, respectively. According to tumor type, ATB(+) group translated into decrease OS (7.0 vs. 13.8 months, $p < 0.038$) in NSCLC. In RCC and UC pts, ATB (+) group had shorter PFS when compared to ATB(-) group (4.3 vs. 7.4 months, $p < 0.013$ and 1.8 vs. 4.3 months, $p = 0.048$, respectively). The negative impact of ATB was maintained after multivariate analyses adjusting for risk factors in each tumor type. **Conclusions:** ATB prescription preceding or concomitant to the first injection of PD-1/PD-L1 inhibitors impaired the outcome in patients with advanced cancers. This reduction in efficacy seems to be independent of classical prognostic factors in RCC, UC and NSCLC. These data should be validated in larger cohort. In addition, the role of gut composition to explain this interaction is ongoing, as well as novel diagnosis tools based on microbiota to predict response/resistance to ICB.

Loss-of-function of PBRM1 to predict response to anti-PD-1/PD-L1 therapy in metastatic renal cell carcinoma. *First Author: Diana Miao, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors targeting programmed cell death-1 (PD-1) substantially improve patient survival in clear-cell renal cell carcinoma (ccRCC), but predictive biomarkers for efficacy have not yet been identified. **Methods:** We analyzed whole exome sequencing (WES) from a clinical trial of anti-PD-1 monotherapy (nivolumab) for ccRCC (N = 34) to discover genomic predictors of response to immune checkpoint therapy, and validated our findings in 28 ccRCC patients from 2 institutions treated with anti-PD-1 or anti-PD-L1 therapies. We defined 3 response groups: clinical benefit (CB) – complete or partial response by RECIST or stable disease with objective decrease in tumor burden and progression free survival (PFS) $>$ 6 months - and no clinical benefit (NCB) – progressive disease with PFS $<$ 3 months, with all other patients in intermediate benefit (IB). We further validated our findings in WES from 212 melanoma patients treated with immune checkpoint therapies in 3 published cohorts. **Results:** Biallelic loss of the chromatin remodeling subunit *PBRM1*, mutated in 34/62 (55%) patients across both cohorts and up to 41% of ccRCC overall, was the only gene mutation associated with CB in both the training (p = 0.0064; Pearson's chi-squared) and validation cohorts (p = 0.043), and predicted both PFS and overall survival (OS) (p = 0.042 and 0.014, respectively; Kaplan-Meier). In 212 melanomas, truncating alterations in *ARID2* – a closely related chromatin remodeler - were also enriched in responders after correcting for tumor mutational burden (p = 0.036), and having a truncating alteration in either *PBRM1* or *ARID2* significantly predicted overall survival (p = 0.022). In this ccRCC cohort, tumor mutational burden and loss of antigen presentation machinery were not associated with CB or NCB. **Conclusions:** Loss of chromatin remodeling subunits may impact response to immune checkpoint therapy in both ccRCC and melanoma. Further study in larger cohorts of immunotherapy-treated patients and functional characterization of *ARID2* and *PBRM1* in the context of the tumor-immune microenvironment will help to determine potential for further biomarker development.

Expression quantitative trait loci (eQTLs) as germline determinants of melanoma immunotherapy response. *First Author: Robert Ferguson, New York University, New York, NY*

Background: Approximately 40-60% of metastatic cutaneous melanoma (CM) patients do not respond to the current immunotherapy (IT) regimens, pointing to other yet unknown factors conferring IT resistance. Based on our recent findings showing that germline expression quantitative trait loci (eQTLs) in immune pathways associate with overall CM survival, in this study we tested whether germline immune-specific eQTLs also impact IT outcomes in CM. **Methods:** By interrogating a healthy twin cohort expression dataset (MuTHER), we have identified 50 eQTLs most significantly associated with the expression of 265 immune genes. Using the MassARRAY system, these 50 SNPs were genotyped in 138 anti-CTLA-4 treated patients, 59 PD-1 treated patients and 38 patients from combined (COMBO) treatments collected from multi-institutional collaborations. To test the association of SNPs with IT response, logistic regression was performed for each treatment group adjusting by demographic and clinical covariates. **Results:** We found significant associations with COMBO IT resistance for rs6673928 (OR = 4.249, p = 0.0167), an eQTL in *IL10/IL19* which we have recently identified for association with melanoma survival; interestingly, it is a previously established locus associated with the risk of several autoimmune diseases. Additionally, we also identified eQTLs that are associated with IT sensitivity: rs4848306 in *IL1-β* with resistance to anti-CTLA-4 (OR = 0.373, p = 0.000733) and rs2071304 in *SPI1* with resistance to anti-PD-1 (OR = 0.3328, p = 0.0271). **Conclusions:** In this study we report that rs6673928, an eQTL from the *IL19/IL10* locus previously shown to predict autoimmunity risk and CM survival, is also a surrogate marker of response to COMBO IT. The associations of rs6673928 with both IT response and CM survival indicate a strong relationship between interleukin pathways and the level of tumor immunogenicity. In addition to its apparent function in immune response, the putative multi-faceted role of this locus in predicting better survival and IT outcomes indicates high potential as a novel clinical target. Additional genetic and functional validation of these findings is currently underway in a large collaborative setting.

FDA analysis of patients with baseline autoimmune diseases treated with PD-1/PD-L1 immunotherapy agents. *First Author: Chana Weinstock, U.S. Food and Drug Administration, Silver Spring, MD*

Background: With FDA approval of three novel agents targeting the PD-L1/PD-1 checkpoint pathway in multiple tumor types, use of these agents in the clinical setting is becoming increasingly common. However, little is published on their use in patients with a history of autoimmune diseases. We therefore aimed to collect safety data on patients with a history of autoimmune diseases treated with PD-1/PD-L1 immunotherapy agents in a clinical trial setting. **Methods:** Data on patients with a history of autoimmune disease were collected for four different PD-1/PD-L1 immunotherapy agents. Information collected included name of autoimmune disease, corticosteroid dependency at baseline, duration of dosing, immune-related adverse events (iRAEs) and worsening of underlying autoimmune disease. **Results:** In total, 552 patients enrolled in 22 clinical trials of PD-1/PD-L1 immunotherapy agents were identified with a history of autoimmune disease. None were known to be dependent on systemic corticosteroids at baseline. The most common autoimmune diseases identified were thyroid disorder (n = 188), psoriasis (n = 70), and vitiligo (n = 44). For the four agents identified, mean duration of dosing was 183, 187, 196, and 145 days. Worsening of underlying autoimmune disease occurred in 16%, 6%, 13% and 6%. There were two grade 4 cases of hyperglycemia in patients with diabetes, three cases each of grade 3 AEs related to the underlying disorder in patients with psoriasis, interstitial lung disease, and hypothyroidism, and one grade 3 AE in a patient related to ankylosing spondylitis.For two of these agents, data were available on the development of grade 1-4 irAEs (per investigator) that required treatment with systemic steroids, which occurred in 8% and 9% of patients. **Conclusions:** Clinical trial data demonstrates relative safety of the use of PD-1/PD-L1 immunotherapy agents in patients with a history of autoimmune disease compared to their use in patients without such history. No consistent pattern of worsening of baseline autoimmune disease was identified. These results should be interpreted with caution, as diagnostic method and clinical manifestations of reported baseline autoimmune conditions are not known.

Biomarkers associated with neurotoxicity in adult patients with relapsed or refractory B-ALL (R/R B-ALL) treated with CD19 CAR T cells. *First Author: Bianca Santomasso, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CD19-specific chimeric antigen receptor (CAR) modified T cells produce high and durable anti-tumor activity, but can be associated with treatment-related toxicities including cytokine release syndrome (CRS) and neurotoxicity (NTX). NTX is poorly understood and it hasn't been clear where to focus further research. We report cerebrospinal fluid (CSF) data and neuroimaging characteristics of patients (pts) who developed severe NTX (sNTX) during our phase I clinical trial of CD19-specific 19-28z CAR T cells for adult pts with R/R B-ALL, which suggest new avenues for future research. **Methods:** 51 adult pts with R/R B-ALL were treated with 19-28z CAR T cells following conditioning chemotherapy at MSKCC. We analyzed the incidence and grade of NTX, CRS and correlative biomarkers in blood and CSF. **Results:** 21/51 treated pts developed sNTX (grade $\geq$3) complications such as encephalopathy, aphasia, depressed level of consciousness, myoclonus, and seizure. No pt developed grade 5 NTX and, in all but one case, neurologic symptoms fully resolved. We collected CSF by lumbar puncture and blood from 14 pts at the time of peak NTX. sNTX was correlated with pre-infusion disease burden (p = 0.013) and peak CAR T cell expansion in the blood (p = 0.0001), but we found no significant correlation between NTX grade and the CAR T cell concentration in the CSF during NTX. Instead CSF protein level was correlated with neurotoxicity grade (p = 0.0109). The cytokines IL6, IL8, IL10, IFNγ and GCSF were elevated in CSF over serum at the time of NTX and correlated with CSF protein levels (all p $<$ 0.005). These were distinct from serum cytokines significantly associated with sNTX at d3 of T cell infusion: GMCSF, IFNγ, IL15, IL5, IL10, and IL2 (all p $<$ 0.01). 4/21 patients developed a pattern of reversible MRI T2/FLAIR hyperintensity involving the bilateral thalami, dorsal pons, and medulla. **Conclusions:** NTX is predominantly reversible. MRI findings suggesting transient toxicity to deep grey structures and findings of a CSF-specific cytokine profile expand the hypotheses on the mechanism of NTX. Future studies will focus on determining the etiology of the CSF protein elevation and the distinct cytokine profile. Clinical trial information: NCT01044069.

Cytokine release syndrome (CRS) and neurotoxicity (NT) after CD19-specific chimeric antigen receptor- (CAR-) modified T cells. *First Author: Cameron John Turtle, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: CD19 CAR-T cells have produced impressive responses in $CD19^+$ ALL, NHL and CLL. Detailed understanding of the presentation and pathogenesis of CRS and NT will facilitate safe CAR-T cell use in multicenter trials. **Methods:** We treated 161 adults with B-ALL, NHL or CLL with anti-CD19 CAR-T cells, formulated in a 1:1 CD4/CD8 ratio and infused after lymphodepletion chemotherapy in a dose finding study (NCT 01865617) to identify a MTD in each disease. **Results:** 133 patients (pts) completed toxicity assessment. CRS developed in 71% (60% gr 1-2, 4% gr 3, 8% gr $\geq$4). Fever was the first sign of CRS and preceded organ toxicity, allowing safe outpatient administration of CAR-T cells. NT was observed in 40% (19% gr 1-2, 16% gr 3, 5% gr $\geq$4) and gr $\geq$3 NT presented a median of 4.5 days after CRS onset. The time from onset to peak of NT was 2 days. CRS and NT were reversible with the exception of 6 pts who died, 4 during the dose-finding phase of the study. In multivariable analyses, higher CAR-T cell dose and malignant B cells in marrow (BM) were associated with CRS; and CAR-T cell dose, malignant BM B cells, more intensive lymphodepletion, and prior neurologic comorbidities were associated with NT. Probability curves of response, CRS and NT in relation to blood CAR-T cell counts show that toxicity mitigation by CAR-T cell dose reduction may be feasible in B-ALL without impairing BM response; however, dose reduction may reduce nodal response in NHL and CLL. Analysis of clinical parameters revealed that pts who later developed severe CRS or NT could be identified early after CAR-T cell infusion by higher fever, greater vascular instability, and more severe hypoalbuminemia. Paired serum-CSF studies and autopsy data suggest blood-brain barrier disruption in severe NT. High serum IL-6, IL-15, MCP-1 and IL-10, and endothelial activation markers on day 1 after infusion correlated with subsequent toxicity, which identifies pts for early intervention to prevent severe toxicity. **Conclusions:** CAR-T cells can be safely administered in the outpatient setting. Clinical and laboratory biomarkers allow early identification of a small subset of pts who might develop serious toxicity, facilitating study of preventive strategies. Clinical trial information: NCT 01865617.

3021 Poster Session (Board #116), Mon, 8:00 AM-11:30 AM

Maintenance immunotherapy in stage IV cancer patients who have a clinical benefit from chemotherapy. *First Author: Francesco Recchia, Fondazione Carlo Ferri, Monterotondo, Italy*

Background: Even if patients with stage IV cancer (AC) may have prolonged remissions with chemotherapy (CT), the majority of them, will eventually relapse. In vitro studies suggest that natural killer (NK) cells mediate lytic activity against cancer cell lines and that high expression of vascular endothelial growth factor (VEGF) promotes tumor progression through neoangiogenesis. We have shown that low-dose interleukin-2 (IL-2) and 13-cis retinoic acid (RA) increased NK cells and decreased VEGF, in patients with AC and a clinical benefit on CT (Clin Cancer Res 7: 1251, 2001). We hypothesized that IL-2 and RA, increasing NK and decreasing VEGF, could improve disease-free survival (DFS) and overall survival (OS) in a minimal residual disease setting. Primary endpoint was the evaluation of NK cells and VEGF; secondary endpoints were DFS, OS and toxicity. **Methods:** 500 patients with AC, and a clinical benefit from CT, were given subcutaneous IL-2, 1.8×10^6 IU and oral RA, 0.5 mg/Kg, 5 days/week, 3 weeks/month, until progression. NK cells, VEGF, response and toxicity were assessed every 4 months. **Results:** After a median follow-up of 112 months (range 63-200), a total of 4400 courses of CT and 2634 courses of immunotherapy were delivered. A statistically significant improvement of NK cells [from a mean of $309 \pm 76/mm^3$ to a mean of $579 \pm 74/mm^3$ ($p < 0.001$)] and a decrease of VEGF [from a mean of 520 ± 75 pg/mm^3 to a mean of 150 ± 12 pg/mm^3, ($p < 0.001$)], were observed. Eighteen-years DFS and OS were 29% and 32%, respectively. A significant improvement, with respect to NCI SEER data (*), was observed in the 5-year OS rate for the most common treated AC: Breast cancer 55% vs. 6% *; Lung cancer 22% vs. 4.3% *; Colorectal cancer 43.5% vs. 21%*. No WHO grade 3 or 4 toxicity was observed, while grade 2 cutaneous toxicity and fever occurred in 20% and 13% of patients, respectively. **Conclusions:** Our data show that immunotherapy with IL-2/RA, may determine, with an acceptable toxicity profile, a statistically significant improvement of NK cells, a decrease of VEGF, and better 5-year survival rates with respect to NCI SEER data, for all major stage IV cancers.

3022 Poster Session (Board #117), Mon, 8:00 AM-11:30 AM

PRKDC: A new candidate for checkpoint blockade immunotherapy? *First Author: Ming Huang Chen, Taipei Veterans General Hospital, Taipei, Taiwan*

Background: Immunologic checkpoint blockade with antibodies that target CTLA-4 or PD-1/PD-L1 have demonstrated promise in a variety of malignancies. However, the treatment response rate of these immunologic checkpoint blockades remains low. Identifying predictive biomarkers to assist patient selection for immunotherapy have become a priority in both clinical and research settings. **Methods:** Mutations in patients who responded to immunotherapy were identified by Next-Generation Sequencing (NGS). Relationship between mutation of *PRKDC*, mutation load and known immune biomarkers were analyzed using datasets from The Cancer Genome Atlas (TCGA). Following up, the PRKDC protein expression was evaluated in 439 gastric cancer patients by immunohistochemical staining and their MSI statuses were evaluated by PCR. **Results:** We first identified *PRKDC* mutations in two responders to immune checkpoint therapy (1 HCC, 1 gastric cancer). From published literature, we further discovered that 66.7% (2/3) of lung cancer patients and 63.6% (7/11) of melanoma patients whose tumor harbored *PRKDC* mutation and responded to immunotherapy. Most of these mutations detected in responders were either truncating or located in functional domains. Further analysis showed that *PRKDC* mutation is significantly associated with high mutation load in cervical cancer, colon adenocarcinoma, head and neck squamous cell carcinoma, lung adenocarcinoma, gastric adenocarcinoma and endometrial cancer ($p = 0.008$, $p = 0.0108$, $p = 0.0166$, $p = 0.0183$, $p < 0.001$ and $p < 0.001$, respectively). Interestingly, gastric cancer patients harboring *PRKDC* mutations or with MSI-H demonstrated significantly higher gene expression in *PDL1, TIM3, LAG3, IFNG, CXCL9, CXCL10, GZMA* and *PRF1*, compared to MSS patients ($p = 0.0016$, $p = 0.0142$, $p = 0.0017$, $p = 0.0034$, $p = 0.0118$, $p < 0.0001$, $p = 0.0001$, $p < 0.0102$, respectively). Finally, we discovered low expression of PRKDC was a poor prognostic factor and significantly correlated with MSI-H in gastric cancers. **Conclusions:** PRKDC may be a potential biomarker that can identify responders to immune checkpoint inhibition.

3023 Poster Session (Board #118), Mon, 8:00 AM-11:30 AM

Product characteristics associated with in vivo expansion of anti-CD19 CAR T cells in patients treated with axicabtagene ciloleucel (axi-cel). *First Author: Frederick Lundry Locke, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Axi-cel (formerly KTE-C19) is an autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy. ZUMA-1 is a multicenter, registrational trial of axi-cel in patients (pts) with refractory aggressive non-Hodgkin lymphoma. In a prespecified interim analysis, ZUMA-1 met its primary endpoint, with a 76% objective response rate and a 47% complete response rate (*Blood* 2016;128:LBA-6). Post-treatment CAR T cell blood levels were associated with objective response. Here, we describe novel associations between product characteristics and CAR T cell levels in pts. **Methods:** CAR T cell characteristics in axi-cel produced from 62 pts were analyzed by flow cytometry and modeled against CAR T cell levels. *In vivo* CAR T cell levels were measured by qPCR. T cell expansion during production (fold expansion/total days in culture) was compared with CAR T cell blood levels, using a partition analysis with expansion rates of $\geq$1 vs $<$ 1. Wilcoxon 2-sample test and linear regression were used. **Results:** Axi-cel contained CCR7+ T cells (median, 42%; range, 15–73%), with naïve (CD45RA+/CCR7+; median, 12%; range, 1–57%), central memory (CD45RA−/CCR7+; median, 29%; range, 12–49%) phenotypes, and more differentiated CCR7− effector memory and effector T cells. On infusion, CAR T cells expanded rapidly, reaching peak levels within 2 weeks (median, 43 cells/μL; range, 1–1513), and were also measurable in all pts at 1 month (median, 2 cells/μL; range, 0.03–89). The CCR7+/CCR7− T cell ratio in axi-cel associated positively with peak (P=0.001) and cumulative (P=0.003) CAR T cell levels through 1 month. Axi-cel lots that expanded more rapidly during production ($\geq$1.0-fold/d; n = 18/62) associated with higher cumulative levels of CAR T cells (P=0.03). Other product characteristics, eg, CD4/CD8 ratio or number of infused T cells, were not significantly associated with CAR T cell blood levels. **Conclusions:** An association was observed between CAR T cell expansion *in vivo* and both the T cell growth rate during production and product cell phenotype pretreatment. A key attribute of axi-cel product was the presence of CCR7+ naïve/central memory T cells, without upfront T cell subset selection. Clinical trial information: NCT02348216.

3024 Poster Session (Board #119), Mon, 8:00 AM-11:30 AM

Updated results from ZUMA-3, a phase 1/2 study of KTE-C19 chimeric antigen receptor (CAR) T cell therapy, in adults with high-burden relapsed/refractory acute lymphoblastic leukemia (R/R ALL). *First Author: Bijal D. Shah, H. Lee Moffitt Cancer Canter and Research Institute, Tampa, FL*

Background: Promising results have been observed with KTE-C19, an anti-CD19 CAR T cell therapy, in refractory aggressive NHL in the ZUMA-1 trial (Blood 2016;128:LBA-6). We present here updated results from the ZUMA-3 phase 1 trial of KTE-C19 in adult patients (pts) with R/R ALL. **Methods:** Adult (≥18 y) pts with R/R ALL (Ph+ eligible), ≥25% bone marrow (BM) blasts, adequate organ function and ECOG status 0-1 received 1 or 2×10^6 CAR T cells/kg after conditioning with cyclophosphamide + fludarabine. Phase 1 primary endpoint is incidence of dose-limiting toxicity (DLT). Secondary endpoints include efficacy outcomes and biomarker associations. **Results:** As of Nov 1, 2016, 11 pts were enrolled; 10 received KTE-C19. One pt had a serious adverse event (SAE) prior to dosing and was not treated. KTE-C19 was successfully manufactured in all pts across a broad range of baseline absolute lymphocyte counts in 6 days in a centralized facility, with an approximate 2-week turnaround time. Pts were 60% men with 1-4 prior lines of therapy and high disease burden (median, 70% BM blasts). No pt (0/3) experienced a DLT at the 2×10^6 dose. Phase 1 was expanded to 6 pts at the same dose; 1 grade (Gr) 5 AE (multiorgan failure due to cytokine release syndrome [CRS]) was observed. Subsequent pts (4) received 1×10^6 CAR T cells/kg. Overall, the most common Gr≥3 AEs were cytopenias (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Gr≥3 CRS and neurologic events (NEs) were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS (except Gr5) and 5 of 6 NEs (1 Gr3 ongoing at cut-off) resolved. Of the 8 efficacy evaluable pts, 6 achieved an MRD-negative (MRD^-) complete response (CR, or CR + partial or incomplete hematopoietic recovery). Updated results will include additional pt follow-up and biomarker data. **Conclusions:** No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt had G5 CRS after the DLT cohort. Manufacturing was successful in all pts; most pts achieved an MRD^- CR. Based on these results, ZUMA-3 continues to enroll pts with additional measures implemented to further enhance safety. Clinical trial information: NCT02614066.

3025 Poster Session (Board #120), Mon, 8:00 AM-11:30 AM

Characterization of anti-CD19 chimeric antigen receptor (CAR) T cell-mediated tumor microenvironment immune gene profile in a multicenter trial (ZUMA-1) with axicabtagene ciloleucel (axi-cel, KTE-C19). *First Author: Jerome Galon, Laboratory of Integrative Cancer Immunology, INSERM, Paris, France*

Background: Axi-cel is an autologous anti-CD19 CAR T cell therapy. ZUMA-1 is a multicenter, registrational trial of axi-cel in patients (pts) with refractory/aggressive B-cell non-Hodgkin lymphoma (NHL). In a pre-specified interim analysis, ZUMA-1 met its primary endpoint with 76% objective response rate and 47% complete response (Blood 2016;128:LBA-6). We describe, for the first time, a tumor microenvironment immune gene signature associated with CAR T cell treatment (tx) of NHL pts. **Methods:** Paired biopsies, pre- and within 3 weeks post-axi-cel tx, were analyzed by digital gene expression followed by a pre-specified bioinformatics algorithm applied to IGES15 and IGES21 genes involved in immune-mediated tumor regression (Immunosign; Galon Immunity 2013). Immunosign profiles expression of a pre-defined set of effector T cell, Th1, chemokine, and cytokine genes. Expression analysis and hierarchical clustering were used to define an axi-cel-related tumor immune gene signature. Wilcoxon signed rank test with multiple test correction by FDR (Benjamini-Yekutieli) was used. **Results:** Gene expression profile comparisons of pre- and post-axi-cel tx biopsies from 14 pts showed profound changes in gene expression within the tumor environment after infusion. The most upregulated genes post-axi-cel tx were CCL5 (RANTES), CTLA4, and GZMA ($\log_2$ fold change > 2, $P< 0.05$, FDR < 0.050). Immune checkpoints PD-L1 and LAG3 were also upregulated post-axi-cel ($\log_2$ fold change > 1.6, $P< 0.05$, FDR < 0.055). Other genes associated with T cell proliferation, homing, and effector function were also upregulated: IL-15, GZMK, CXC3CL1 (Fractalkine), CD8A, and STAT4 ($\log_2$ fold change > 1.6; $P< 0.05$, FDR $<$ 0.074). Additional baseline tumor characteristics and associative analysis will be presented. **Conclusions:** We define a mechanistic tumor immune gene signature in NHL pts associated with axi-cel tx. This signature comprises upregulation of T cell activation, effector, chemokine, and immune checkpoint genes. These data will potentially lead to rational optimization of T cell interventions in cancer Clinical trial information: NCT02348216.

3026 Poster Session (Board #121), Mon, 8:00 AM-11:30 AM

Response to first-line chemotherapy regimen to predict efficacy of nivolumab in lung cancer. *First Author: Coureche Guillaume Kaderbhai, Centre Georges-François Leclerc, Dijon, France*

Background: Nivolumab is a monoclonal antibody, targeting PD-1 receptor and demonstrating durable clinical benefit in 20% of metastatic NSCLC patients in second and further treatment lines. The expression of one of the PD-1 ligand, PD-L1 assessed by IHC is associated with better outcome. However, robust predictive markers of efficacy are lacking. **Methods:** 115 pts with stage IV NSCLC (42 squamous, 73 adenocarcinoma) were included in this retrospective study in 4 different institutions. They received nivolumab (3 mg/kg IV Q2W) after at least one line of systemic platinum-based chemotherapy. Response to first line chemotherapy and to nivolumab (RECIST 1.1) was determined on CT scan by two physicians. Association between best response to first-line regimen and PFS, OS or response to nivolumab was determined using both Chi2 and Cox analysis. **Results:** 46 (40%), 44 (38%) and 25 (22%) patients experimented PR, SD and PD to first-line platinum-based chemotherapy. 25 (22%), 34 (29.5%), 56 (48.5%) experimented PR, SD and PD to nivolumab. 59.5% (53/89) of patients who experimented clinical benefit (SD+PR) to first-line also experimented clinical benefit to nivolumab while only 20% (5/25) of patients with PD as best response to chemotherapy experimented clinical benefit to nivolumab (Chi2 test p = 0.002). The type of first-line doublet chemotherapy did not influence the response rate to nivolumab. Cox uni and multivariate models included age, histology and performance status underlined that patients with clinical benefit from chemotherapy had improved PFS with nivolumab (P = 0.002) (median PFS on nivolumab regimen of 4.9, 3.3 and 1.8 months for patients with PR, SD and PD to first-line, respectively). Similar results were obtained for OS (P = 0.03). **Conclusions:** Our data suggest that response to first-line chemotherapy may be a good surrogate marker of response, PFS and OS to post-platinum nivolumab in metastatic NSCLC.

3027 Poster Session (Board #122), Mon, 8:00 AM-11:30 AM

The relationship of pharmacodynamics (PD) and pharmacokinetics (PK) to clinical outcomes in a phase I study of OX40 agonistic monoclonal antibody (mAb) PF-04518600 (PF-8600). *First Author: Anthony B. El-Khoueiry, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: PF-8600 is a novel fully human IgG2 agonistic mAb against human OX40, a TNF receptor superfamily member expressed primarily on activated T cells. This ongoing phase 1 study (NCT02315066) is investigating the safety, efficacy, PK and PD of PF-8600 in patients (pts) with solid tumors. **Methods:** PF-8600 (0.01–10 mg/kg) was given IV every 14d. Expression of free/total OX40 receptor, proliferation marker ki67 and activation markers HLA-DR/CD38 were measured in T cell subsets in peripheral blood by flow cytometry in all pts. CD4, CD8, OX40 and FOXP3 were evaluated in paired tumor biopsies (bx), collected from a subset of pts (≥0.1 mg/kg) at baseline (BL) and Wk6, by immunohistochemistry. **Results:** As of 21Sep2016, 48 pts with melanoma (n = 14), hepatocellular carcinoma (HCC, n = 19), head and neck squamous cell (n = 6) or renal cell carcinoma (n = 9) enrolled in the dose-escalation cohorts (0.01-3 mg/kg). No immune related adverse events (AE) were reported. The most frequent treatment related AEs in > 3 pts were fatigue (27.1%) and nausea and vomiting (8.3% each); all Gr 1-2. 2 pts had a partial response: melanoma at 0.1 (Pt1) and HCC at 0.3 (Pt2) mg/kg. 25 pts had best ORR (BOR) of stable disease (SD; 3 pts ≥24 wks). A majority of pts at 0.1, 0.3, and 3 mg/kg, including Pt1 and Pt2, had increases in ki67 and HLA-DR/CD38 expression in peripheral CD4+ central memory T cells. Pt1, Pt2 and all pts at ≥0.3 mg/kg had full receptor occupancy. Paired bx were only available from pts with BOR of SD or progressive disease. In 10 pts with available paired tumor bx and defined date of radiographic progression (rPD), longer time to rPD correlated with increases in %OX40+ in bx from BL to Wk6, regardless of dose level, tumor type or prior immunotherapy (R^2= 0.52, p = 0.0188); no correlation between rPD and CD4+, CD8+ or FOXP3+ expression changes was observed. Updated efficacy, safety, PK and PD data will be presented. **Conclusions:** PF-8600 is well tolerated with evidence of single agent efficacy. Initial observations of PD markers that change with treatment and correlate with rPD support efforts to confirm these findings as more clinical outcomes and larger sample sizes become available. Clinical trial information: NCT02315066.

3028 Poster Session (Board #123), Mon, 8:00 AM-11:30 AM

Epitope mapping of PD-L1 primary antibodies (28-8, SP142, SP263, E1L3N). *First Author: Kelly Schats, HistoGeneX, Antwerp, Belgium*

Background: Currently, programmed death-ligand 1 (PD-L1) immunohistochemistry (IHC) assays received approval in combination with an anti-PD-1 or anti-PD-L1 compounds. However, the FDA blueprint and other publications revealed differences in staining pattern between PD-L1 IHC assays. More precisely the SP142 assay detects less tumor cells (TC), but more immune cells (IC), while the 28-8 assay is more sensitive for TC and less appropriate for IC detection. SP263 stains TC and IC equally well. E1L3N IHC reveals IC and slightly more TC staining than SP142. This study investigates whether these staining discrepancies can be partly explained by specific epitope recognition. **Methods:** Linear epitope mapping was performed for PD-L1 antibody clones 28-8, E1L3N, SP142 and SP263. In brief, the PD-L1 sequence (Q9NZQ7, Uniprot) was split into 15 amino acid (AA) peptides with a peptide overlap of 14 AA . Each peptide was printed in duplicate on the PD-L1 microarray. The microarray was exposed to different concentration of the four PD-L1 antibodies. For the detection, sheep anti-rabbit IgG DyLight800 was used. **Results:** Epitope mapping for the E1L3N antibody revealed a linear epitope in the intracellular domain. The other clones showed weaker binding to multiple peptides. The 28.8 clone demonstrated binding to predominantly intracellular epitopes, while SP142 and SP263 clones showed binding to both intracellularly and extracellularly located epitopes. Blasting the epitope sequences of the PD-L1 antibodies did not disclose identity with another (non-PD-L1) human protein. **Conclusions:** Different binding characteristics were found for all four PD-L1 antibody clones in a linear epitope mapping experiment. This could lead to particular staining patterns depending on PD-L1 conformation (folding) or isoform expression. Two PD-L1 isoforms are known, with isoform 2 lacking AA 19-132 of the extracellular domain. Especially SP142 binding can be impacted in the case of dominant isoform 2 presence, since epitopes were observed in this spliced domain. Further investigation is needed into the potentially conformational epitopes of SP142, SP263 and 28.8 antibody clones as well as in the PD-L1 conformation and isoform expression in TC and IC.

3029 Poster Session (Board #124), Mon, 8:00 AM-11:30 AM

Overall survival prognosis of patients in immuno-oncology phase I trials: The Gustave Roussy score. *First Author: Frederic Bigot, Drug Development Department (DITEP), Gustave Roussy, Villejuif, France*

Background: The evaluation of patient's life expectancy is crucial to select patients who may benefit from phase I studies. The Royal Marsden Hospital (RMH) prognostic score, based on 3 objective variables (number of metastatic sites, LDH and serum albumin) was validated in patients treated with cytotoxic and targeted therapies. We aimed to determine if those factors were applicable to immunotherapy (IT) phase I trials. **Methods:** A retrospective analysis for risk factors of survival was conducted in a discovery cohort of 155 patients enrolled into IT phase I trials at our institution. We computed univariate and multivariate analysis (MVA) of demographics, clinical and biological data to assess their prognostic value for overall survival (OS). MVA results were used to build a prognostic score for OS. A validation cohort of 113 patients enrolled in IT phase I trials was used to prospectively re-validate this score. **Results:** 155 patients receiving an experimental IT between March 2012 and January 2016 were included in the discovery cohort. A MVA assessing the RMH Score variables showed that albumin < 35 g/dL (HR 1.73, 95% CI 1.05-2.86) and LDH $>$ upper normal limit (1.88, 95% CI 1.12-3.15) were independent negative prognostic factors for OS. As opposed to the RMH score, number of metastases was not associated with a poorer outcome for this IT cohort (0.83 95% CI 0.51-1.35). Interestingly, a neutrophil to lymphocyte ratio (N/L) > 6 (1.75, 95% CI 1.04-2.95) was associated with a worse OS. A risk analysis based on the results of the MVA showed that patients presenting a high score (2-3) had a significantly shorter OS (20.4 weeks; 95% CI 5.7-35.2) compared to those with a low score (0-1) (68.9 weeks; 95% CI 50-83.7) (HR = 2.9 95% CI 1.87-4.64). In the validation cohort of 113 patients, the patients presenting a high score showed an inferior OS (HR = 6.3, 95% CI 2.7-14.8). **Conclusions:** In phase I trials of IT, traditional prognostic variables included in the RMH Score are suboptimal to determine patient's prognosis. In this context, the N/L ratio, which reflects the immune contexture, is a significant prognostic variable. The new Gustave Roussy Score, based on albumin, LDH and N/L ratio allows to better select patients for IT phase I trials.

3030 Poster Session (Board #125), Mon, 8:00 AM-11:30 AM

Very early molecular marker of tumor response to PD-1 inhibition in plasma of patients with advanced non-small cell lung cancer (NSCLC). *First Author: Thijo Jeroen Nicolaas Hiltermann, University Medical Center Groningen, Groningen, Netherlands*

Background: Nivolumab shows a durable tumor response in 20 % of advanced NSCLC patients. While a PD-L1 immunohistochemistry complementary diagnostic has been approved, there is a need to identify a predictive biomarker with greater diagnostic accuracy. **Methods:** In an ongoing study of patients, treated with nivolumab every 2 weeks for advanced recurrent NSCLC and a known KRAS mutation in the primary tumor, liquid biopsies were taken by a simple blood draw at baseline (before treatment), 1, 2, 4, 6 and thereafter every 12 weeks until disease progression. Circulating tumor DNA (ctDNA) was extracted from cell free plasma and tested with a specific digital droplet PCR (ddPCR)-KRAS G12/G13 screenings assay (BIORAD). Mutation levels in plasma were compared with tumor response on CT scans by RECIST v.1.1. CT scans were performed at baseline and thereafter every 6 weeks until disease progression. **Results:** Patient characteristics are shown in table 1. In this prospective analysis specific patterns could be demonstrated in plasma ctDNA testing of KRAS mutation levels. All 4 responders showed an increase of mutant copies/ml plasma in the first week followed by a clear drop to non-detectable KRAS mutations at all CT evaluated tumor responses. The 2 non-responders however, did not show the increase in mutant copies/ml at one week and showed a gradual increase in mutant copies/ml in the following weeks. **Conclusions:** Specific plasma ctDNA testing seems a very promising early biomarker (1 week) for tumor response to PD-1 therapy.

	Sex	Age	KRAS mutation (plasma)	Cycles of Nivolumab	Responder (RECIST)	ECOG PS	PFS (weeks)	Deceased
Patient 1 (980)	M	59	c.34G>T; p.G12C	28+	R	0	NR	No
Patient 2 (1032)	F	59	c.35G>A; p.G12D	9	R	0	42	No
Patient 3 (1035)	M	68	c.34G>T; p.G12C	27+	R	1	NR	No
Patient 4 (1067)	F	64	c.34G>T; p.G12C	3	NonR	1	5	Yes
Patient 5 (1083)	F	60	c.34G>T; p.G12C	2	NonR	0	7	Yes
Patient 6 (1096)	F	53	c.35G>A; p.G12D	16+	R	1	NR	No

R=responder; NonR= non-responder; NR= not reached.

3031 Poster Session (Board #126), Mon, 8:00 AM-11:30 AM

Association of changes in T regulatory cells (Treg) during nivolumab treatment with melanoma outcome. *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: PD-1 blocking antibodies have significant efficacy in the treatment of melanoma; however, many patients fail to respond and resistance mechanisms remain unknown. We addressed the role of T_{regs}, an immunosuppressive T-cell population, in patient outcome after treatment with nivolumab. **Methods:** Peripheral blood mononuclear cells (PBMC) were obtained from patients on trials with nivolumab as adjuvant therapy for resected disease or as treatment for metastatic melanoma. To measure suppression, T_{regs} were flow-sorted from PBMC and evaluated in allogeneic mixed lymphocyte reactions. T_{regs} and conventional CD4 T-cells were evaluated for gene expression changes by RNA-sequencing. T_{reg} percentages and phosphorylated STAT3 (pSTAT3) expression were evaluated by flow cytometry. The effects of PD-1 blockade with nivolumab were evaluated *in vitro* using T-cells from baseline patient PBMC samples. **Results:** T_{regs} from responding patients or adjuvant patients without evidence of disease (NED) had reduced suppressive function post-nivolumab ($p < 0.05$), but no changes were observed in relapsing/non-responding patients; their T_{regs} were more suppressive than NED/responding T_{regs} ($p < 0.001$). NED T_{regs} had unique gene expression changes and associated pathways post-nivolumab compared to relapsing patient T_{regs} and conventional CD4 T-cells, including up-regulation of proliferation pathways ($q < 8e\text{-}19$) and downregulation of oxidative phosphorylation ($q < 7e\text{-}5$). NED T_{regs} had upregulation of pSTAT3 expression post-nivolumab ($p < 0.05$), which was not observed in relapsing patients. Evaluation of T_{regs} from patients with active disease also showed upregulation of pSTAT3 in responders ($p < 0.05$) but not non-responders. The relative increase in T_{reg} pSTAT3 was associated with increased overall survival ($R^2 = 0.49$, $p < 0.05$). *In vitro* assays using PD-1 blocking antibodies recapitulated the increase in pSTAT3 ($p < 0.05$) and T_{reg} percentages ($p < 0.001$), which were diminished with the addition of a STAT3 inhibitor ($p < 0.01$). **Conclusions:** These results demonstrate previously unknown roles of decreased T_{reg} suppressive function and induction of STAT3 as biomarkers of patient's outcome to nivolumab therapy.

3032 Poster Session (Board #127), Mon, 8:00 AM-11:30 AM

Excision repair cross complementation group 1 (ERCC-1) gene polymorphisms and response to nivolumab in advanced non-small cell lung cancer (NSCLC). *First Author: Marco M. Aiello, Medical Oncology, University Hospital Policlinico, Vittorio Emanuele, Catania, Italy*

Background: Anti PD1 antibodies showed significant clinical activity in different cancer types. Recently, it was observed that cancers with higher somatic mutation burden, as tumors with genome instability due to DNA repair defects, develop more elevated anti PD1 induced neoantigen specific T cell reactivity which results into increased susceptibility to PD1 blockade. We hypothesize that NSCLC pts with single nucleotide polymorphisms (SNPs) of the ERCC-1 gene, a key enzyme of DNA nucleotide excision repair pathway, may be more responsive to PD-1 blockade due to their genetic instability. **Methods:** We evaluated the rs11615 and rs3212986 ERCC1 SNPs by pyrosequencing analysis on tumor DNA of stage IIIb-IV previously treated NSCLC patients receiving Nivolumab (Nivo) 3 mg/kg q2w. To be eligible for this study, pts had to have a complete record of clinical and radiological parameters. Objective tumour response was assessed according to RECIST 1.1 criteria. **Results:** Between Jul 2015 and Jan 2016, 45 NSCLC pts received Nivo. Pts characteristics were as follows: M/F = 37/8; median age (range) = 64 (38-80); ECOG PS, 0/1/2 = 33/9/3; Stage IIIb/IV = 8/37; sqNSCLC/non sq NSCLC = 11/34; current-former smokers/non-smokers = 40/5; EGFR status, mutant/wildtype/unknown = 4/35/6; median cycles (range) = 12 (1-28). Only two pts presented the rs11615 SNP. 16 pts were positive for the rs3212986 SNP. ORR for all pts was 26.6% (95% CI, 10 to 47). The ORR was significantly higher in NSCLC pts positive for the rs3212986 SNP than for wild-type NSCLC patients (62.5% vs. 6.9%. p = 0.0001). For all pts median PFS was 4.3 mos (95% CI, 1.2 to 7.4)and median OS not-reached. Among pts positive for the rs3212986 SNP, median PFS and OS were 8.2 mos and not-reached respectively. In contrast wild-type patients presented a median PFS of 3.1 mos (HR = 0.21 95% CI, 0.07 to 0.57; p = 0.02) and a median OS of 6.5 mos (HR = 0,403 95% CI = 0,131-1,237 p = 0.11). Multivariate analyses confirmed the effect of rs3212986 SNP after adjustment for age, PS, sex and disease stage for PFS. **Conclusions:** This study suggests that genetic instability due to tumor ERCC1 SNPs in advanced NSCLC pts may be of value to predict clinical benefit from Nivo.

3033 Poster Session (Board #128), Mon, 8:00 AM-11:30 AM

Phase 1 safety of ICOS agonist antibody JTX-2011 alone and with nivolumab (nivo) in advanced solid tumors; predicted vs observed pharmacokinetics (PK) in ICONIC. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Nashville, TN*

Background: JTX-2011 is an agonist monoclonal antibody that targets ICOS, Inducible CO-Stimulator of T cells. A dual mechanism of action is intended to activate antigen-specific CD4 T effector cells and selectively deplete intratumoral T regulatory cells. JTX-2011 is equally potent across human, rodent, and non-human primate species. **Methods:** A quantitative systems pharmacology (QSP) model describing target binding by JTX-2011 and target mediated drug disposition in blood, tumor and non-tumor tissues was based on preclinical potency and non-linear PK data across species. The model was translated to predict PK and target engagement (TE) in humans to facilitate dose selection. The QSP model predicts $>$ 95% TE for 21 days at the top planned dose. We present safety and actual/predicted PK from a Phase 1 study of JTX-2011 alone (Part A) and safety in combination with nivo (Part B). **Results:** 25 subjects have been dosed, 19 in 4 cohorts of JTX-2011 alone at .003, .01, .03, and .1 mg/kg IV q 21 days, and 6 in 2 cohorts of JTX-2011 .01 mg/kg and .03 mg/kg IV plus nivo 240 mg IV q21 days. Safety data from $\geq$ 1 cycle is available for 12 subjects in Part A (7 $\geq$ 3 cycles), and 3 in Part B (all $\geq$ 3 cycles). PK data is available for cycle 1 of Part A. Mean age ($\pm$SD) is 60 ($\pm$10.6). Mean prior systemic therapies is $>$ 5 (range 1-11). Tumor types include endometrial, triple negative breast, melanoma, lung, pancreatic and colorectal cancers. No dose limiting toxicities have been reported. 3 Grade 3 adverse events (AEs) were reported in 2 Part A subjects: anemia and hypoxia (unrelated SAE) at .003 mg/kg and JTX-2011 related diarrhea at .1 mg/kg. Grade 1-2 AEs in $\geq$2 subjects are chills, pyrexia, neck pain, dizziness, and nausea. 5 subjects had JTX-2011 related Grade 1-2 infusion reactions up to 6 hours post infusion. Non-linear exposure increase was observed. While PK at lower doses is consistent with model predictions, AUC and $t_{1/2}$at 0.03 and 0.1 mg/kg doses are higher than predicted, suggesting higher than predicted TE. **Conclusions:** JTX-2011 has been well tolerated up to 0.1 mg/kg and with nivo at .01 mg/kg IV q 21 days. Greater than linear exposure increase was observed and TE may be higher than QSP model prediction. Clinical trial information: NCT02904226.

3034 Poster Session (Board #129), Mon, 8:00 AM-11:30 AM

Non-invasive clinical visualization of tumor infiltrating lymphocytes in patients with metastatic melanoma undergoing immune checkpoint inhibitor therapy: A pilot study. *First Author: Svetomir Markovic, Mayo Clinic, Rochester, MN*

Background: Unique to modern immune therapy for cancer is that early in the course of treatment, patients frequently exhibit transient tumor enlargement (pseudo-progression, pPROG) due to tumor infiltration by lymphocytes (TIL). Currently, pPROG cannot be reliably distinguished from true tumor progression (PROG). There is a need for biomarker techniques to discriminate pPROG (effect of therapy) and PROG (therapy failure). Nuclear medicine offers radiopharmaceuticals capable of imaging immune cells; images can be fused to evaluate functional and anatomic characteristics of tumors, and potentially discriminate pPROG from PROG. **Methods:** In our study of metastatic melanoma patients, SPECT/CT imaging with ^{99m}Tc-interleukin-2 (^{99m}Tc-IL2) was performed to visualize TIL. Images were collected before/after 12 weeks of ipilimumab (IPI) or pembrolizomab (PEMBRO) therapy. The ^{99m}Tc-IL2 tracer was synthesized by conjugating succinimidyl-6-hydrazinopyridine-3-carboxylate (HYNIC-NHS) with commercial interleukin-2 (Aldesleukin). HYNIC-IL2 was incubated with tricine, $^{99m}TcO_4^-$ (370-740 MBq) and $SnCl_2$. After labelling ^{99m}Tc-IL2 was purified by reverse-phase chromatography and diluted in 5% glucose with 0.1% human albumin before injection. Five patients were enrolled in this study. Two patients failed to complete the 12 week ^{99m}Tc-IL2 scan due to discontinuation of IPI after: 1) grade 3 colitis and 2) patient refusal for adverse events attributed to IPI. No adverse events attributable to the tracer infusion were reported. **Results:** Metastatic lesions could be visualized by the tracer. Some lesions decreased in size, while others increased. A positive correlation was found between size and ^{99m}Tc-IL2 uptake, before and after therapy, suggesting the potential discrimination of tumor PROG (no ^{99m}Tc-IL2 uptake) from pPROG (high ^{99m}Tc-IL2 uptake). Immunohistochemical staining for TIL of ^{99m}Tc-IL2 positive and negative lesions are illustrated. **Conclusions:** The results demonstrate feasibility of ^{99m}Tc-IL2 imaging as a clinically useful tool capable of discriminating tumor PROG from pPROG. A clinical validation study is in progress. Clinical trial information: NCT01789827.

3035 Poster Session (Board #130), Mon, 8:00 AM-11:30 AM

Tumor shrinkage and increased overall survival are associated with improved albumin, neutrophil lymphocyte ratio (NLR) and decreased durvalumab clearance in NSCLC and UC patients receiving durvalumab. *First Author: Thomas Powles, Barts Cancer Institute, London, United Kingdom*

Background: Progression of cancer is often associated with biomarkers of cancer inflammation, cachexia, and increased protein catabolism. Anti-PD1 and PD-L1 therapy have demonstrated durable responses across a number of tumor types. Durvalumab is a human monoclonal antibody that binds to PD-L1 and blocks its interaction with PD-1 and CD80. The primary objective of this analysis was to prospectively assess potential correlations of longitudinal changes in ALB and NLR and durvalumab clearance (CL) rate to maximum decrease in tumor size and overall survival (OS) in patients (pts) with NSCLC and UC receiving durvalumab. **Methods:** Longitudinal target lesion size, serum chemistry, hematology and pharmacokinetic data were obtained from 3L+ NSCLC pts (n = 418) in study ATLANTIC and 2L+ UC pts (n = 182) in study 1108 during durvalumab treatment. Nonparametric correlations (Spearman's rho) were evaluated between OS, maximum percent change in target lesion size, and the maximum percent change from baseline observed in ALB, NLR, and CL. **Results:** In NSCLC, maximum decrease in tumor size was correlated with increased ALB ($r = 0.46$, $p < 0.0001$), decreased NLR ($r = 0.44$, $p < 0.0001$), and decreased CL ($r = 0.66$, $p < 0.0001$). OS was similarly correlated with increased ALB ($r = 0.47$, $p < 0.0001$), decreased NLR ($r = 0.41$, $p < 0.0001$), and decreased CL ($r = 0.76$, $p < 0.0001$). In UC, decreased tumor size also correlated with increased ALB ($r = 0.43$, $p < 0.0001$), decreased NLR ($r = 0.38$, $p < 0.0001$), and decreased CL ($r = 0.65$, $p < 0.0001$). OS in UC also correlated with increased ALB ($r = 0.50$, $p < 0.0001$), decreased NLR ($r = 0.33$, $p < 0.0001$) and decreased CL ($r = 0.82$, $p < 0.0001$). **Conclusions:** In NSCLC and UC pts receiving durvalumab, tumor shrinkage and longer survival are associated with increased ALB, decreased NLR and decreased clearance of durvalumab. These findings support the hypothesis that durvalumab may be associated with a decrease in protein catabolism, inflammation and cachexia among pts who benefited from therapy. Additional biomarkers of cancer, inflammation and cachexia will be evaluated for relationships to clinical outcomes.

3036 Poster Session (Board #131), Mon, 8:00 AM-11:30 AM

Metabolomic correlates of response in nivolumab-treated renal cell carcinoma and melanoma patients. *First Author: Marios Giannakis, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune-checkpoint inhibition has been shown to be effective in a variety of cancers, including renal cell carcinoma (RCC) and melanoma. However, only a subset of patients with RCC and melanoma respond to anti-PD1 therapy. Given the importance of metabolism in the tumor immune microenvironment, we performed serum metabolomics in nivolumab-treated patients towards identifying novel non-invasive correlates of response and progression-free survival in immunotherapy-treated patients. **Methods:** We performed liquid chromatography-mass spectrometry on pre- and on-treatment serum samples from 79 patients with advanced melanoma (CA209-038 study) and 82 patients with metastatic RCC (CA209-009 study) receiving nivolumab. We precisely measured more than one-hundred named metabolites at baseline (prior to starting nivolumab), at 4 weeks and at 6 (melanoma) or 9 weeks (RCC) after initiation of treatment and correlated these with best overall response as well as progression-free survival (PFS). **Results:** In melanoma patients treated with nivolumab, the difference in mean levels of kynurenine (the product of IDO / TDO activity in tryptophan catabolism) between weeks 4 and 6 compared to baseline was significantly different between responders and non-responders (t-test with unequal variance p-value = 0.043 and p-value = 0.044 respectively). In RCC patients, we observed that patients with no response to nivolumab had significantly higher adenosine levels, than those who responded, at baseline and at 4 weeks after initiation of treatment (158% and 138% higher, t-test p-value = 0.0019 and p-value = 0.0011 respectively). RCC nivolumab-treated patients with higher (top quartile) baseline adenosine levels also had a significantly worse PFS (log rank test p-value = 0.004). **Conclusions:** In this first-of-its kind metabolomic analysis of peripheral blood from nivolumab-treated patients, we find that the change in kynurenine levels in melanoma patients correlates to response. In addition, higher baseline levels of adenosine in RCC patients are associated with worse PFS and lack of response to nivolumab. These results suggest a possible role for serum metabolites as biomarkers of benefit to PD1 inhibition.

3037 Poster Session (Board #132), Mon, 8:00 AM-11:30 AM

Biologic and clinical relevance of an IFNG mRNA signature (IFNGS) and PD-L1 protein expression in tumor and immune cells in urothelial cancer (UC) patients (pts) treated with durvalumab (D). *First Author: Carlos Bais, MedImmune, Gaithersburg, MD*

Background: PD-L1 can be induced by IFNG in tumor cells (TC) and immune cells (IC). TC PD-L1 expression prevalence in UC is low and the relevance of scoring TC (in addition to IC) is not fully understood. We recently reported a positive correlation between high levels of an IFNGS and outcome in a cohort of 30 UC pts treated with D. Here, we assessed the potential predictive value of the IFNGS in an additional 32 pts (total N = 62) and further explored the relationship between the IFNGS and TC and/or IC PD-L1 IHC expression patterns. **Methods:** Study CP1108 was a phase 1/2 trial evaluating D in pts with solid tumors; 191 UC pts received 10 mg/kg D with median follow up of 8.4 mo. 144 of these pts have available ORR and PD-L1 data and 62 pts have ORR, PD-L1 and IFNGS data. Pts with ≥25% TC or IC were scored as PD-L1 high (TC+ or IC+). Pts within the top tertile of IFNGS (*LAG3*, *PDL1*, *CXCL9*, and *IFNG* mRNAs) tumor expression were scored positive. Cox proportional hazards models were used adjusting for age, gender, ECOG, smoking status, line of therapy, and liver metastasis at baseline. ORR was evaluated using RECIST v1.1. **Results:** IFNGS+ pts had increased ORR (45 vs 16%) and improved PFS (adj HR 0.3; p = 0.005) and OS (adj HR 0.18; p = 0.016) over IFNGS- pts. IFNGS expression was significantly higher in pts who were PD-L1 high (TC+/IC+) compared with TC-/IC- (low/negative) pts (mean IFNGS expression 3.5 vs 1.1; p = 0.0155) and also in TC+ or IC+ vs TC-/IC- (mean IFNGS 2.2 vs 1.1; p = 0.000127). TC-/IC+ and TC+/IC- groups had a mean IFNGS expression of 2 and 2.2 respectively. ORR in all 1108 UC pts with available IHC and ORR data (N = 144) was 29% for TC+/- pts, 36% in TC-/IC+ pts, and 7% in the TC-/IC- pts. **Conclusions:** IFNGS predicted improved outcomes in a cohort of 62 2L+ UC pts treated with D. TC-/IC- PD-L1 pts had lowest levels of IFNGS expression. Observations that TC+ (and IC+) pts contribute to IFNGS enrichment and that TC+/IC-, and TC-/IC+ pts have increased response vs TC-/IC-pts provides rationale for TC+ inclusion (in addition to IC+) in the SP263 PD-L1 scoring algorithm for UC. IFNGS is an additional potential predictive biomarker in UC pts that warrants further investigation.

3038 Poster Session (Board #133), Mon, 8:00 AM-11:30 AM

Association of liver metastases (LM) with survival in NSCLC patients treated with durvalumab (D) in two independent clinical trials. *First Author: Luis G. Paz-Ares, Medical Oncology Department, Hospital 12 de Octubre, Madrid, Spain*

Background: Immunotherapies have improved survival in NSCLC but not all pts benefit. Besides baseline PDL1 expression, routinely measured clinical factors may predict clinical outcomes in immunotherapy trials. LM are associated with poor prognosis in melanoma and bladder cancer pts treated with anti-PD1/L1, respectively. We examined correlation between pretreatment LM and survival in D-treated NSCLC pts. **Methods:** CP1108/NCT01693562 and ATLANTIC/NCT02087423 were nonrandomized phase 1/2 and 2 trials, respectively, of D 10 mg/kg Q2W in advanced NSCLC. As of Oct 24/Jun 3 2016, 304/265 primarily pretreated pts were enrolled in CP1108/ATLANTIC Cohort 2. Cox proportional hazards analysis was conducted, first among LM+/− pts, then LM+/− and PDL1 high/low pts. Both models accounted for tumor stage, ECOG/WHO PS, histology, sex, age, smoking and PDL1 status. PDL1 high was defined as ≥25% tumor cells immunostained for PDL1 at any intensity. **Results:** LM absence was a positive independent predictor of OS and PFS in both trials. LM− and PDL1 high or low pts had improved OS and PFS vs PDL1 low/LM+; PDL1 high/LM+ pts had improved PFS vs PDL1 low/LM+. An independent tumor kinetic model indicated LM as a predictive covariate of rapid tumor growth in D-treated pts. **Conclusions:** LM are associated with shorter survival in D-treated NSCLC pts in 2 trials irrespective of PDL1 status. Clinical trial information: NCT02087423 and NCT01693562.

Mutational burden of tumors with primary site unknown. *First Author: Laurie M. Gay, Foudation Medicine, Inc., Cambridge, MA*

Background: Higher levels of tumor mutational burden (TMB) can predict sensitivity to immunotherapies (IO), which are FDA approved to treat NSCLC, melanoma, and urothelial carcinoma (Ca). TMB may be a biomarker for sensitivity to IO, irrespective of tumor type. TMB has not been explored widely for tumors of unknown primary site, but may reveal additional treatment options. **Methods:** Comprehensive genomic profiling of DNA from FFPE tissue samples was performed using hybrid-capture, next-generation sequencing. TMB was calculated by counting all coding short variant alterations (base substitutions and indels), including synonymous alterations, and subtracting from this functionally oncogenic or germline alterations (per ExAC, dbSNPT, or internal algorithmic analysis). To calculate the TMB per Mb, the total number of relevant mutations is divided by the coding region of the bait set (0.8 Mb, 1.1 Mb, or 1.2 Mb). High, intermediate, and low TMB were defined as ≥20 mut/Mb, ≥6 and <20 mut/Mb, or <6 mut/Mb, respectively. Tumor types with >100 samples were analyzed. **Results:** From a database of 102,878 samples sequenced during routine clinical care, 6116 samples for which the primary tumor site was unclear at sequencing were identified. Table shows TMB metrics (mut/Mb) and median patient age for these cohorts. **Conclusions:** Significant numbers of patients with each tumor type have high TMB that may indicate benefit from IO, excepting GIST. As expected, urothelial tumors have higher than average TMB and more patients have high TMB. SCC tumors are commonly TMB high (23%), as are tumors difficult to define histologically (15%). For ACUP or CUP, the most common tumors, 8-11% have high TMB. Analysis of responses to treatment with IO are ongoing.

Unknown Primary Tumor Type	Total Cases	TMB-High (%)	Average TMB	1st Quartile TMB	Median TMB	3rd Quartile TMB	90th Percentile TMB	Max TMB	Median Age
Adenocarcinoma (ACUP)	2530	8	7.8	1.8	3.8	8.1	17.1	278.4	63
Ca NOS (CUP)	1366	11	11.5	2.7	5.4	10.8	21.6	445	62

3040 Poster Session (Board #135), Mon, 8:00 AM-11:30 AM

Germ-line biomarkers disrupting microRNA regulatory pathways to predict toxicity and response to anti-PD-1 and anti-PD-L1 therapies. *First Author: Joanne B. Weidhaas, University of California, Los Angeles, Los Angeles, CA*

Background: Identifying responders to developing immune therapies is of high priority, yet identifying patients who will suffer from toxicity, which represents a unique spectrum of side effects, termed immune-related adverse events (irAEs), is critical. The complex host-specific response to immune therapies led us to hypothesize that germ-line mutations, present in both the tumor and in the host's immune system, may be a source of biomarkers. As there is compelling evidence that recently discovered germ-line mutations disrupting microRNA (miRNA) networks act as biomarkers of treatment response and baseline immune status, we evaluated such mutations in patients treated with these therapies. **Methods:** Patients treated with anti-PD1 or anti-PDL1 therapy alone and clinically documented response and toxicity were tested with a panel of over 150 vetted germ-line miRNA based biomarkers. Of 85 patients evaluated for response, 75 had melanoma, and 10 had NSCLC. For analysis of toxicity, an additional 4 patients with other cancer types were included. Subjects were classified as responders (Complete, Partial) versus non-responders (Progressive, Stable), or as experiencing low irAEs (grade 0 and 1) versus high irAEs (grade 2 and above). We used Chi-squared analysis for base evaluation and then compared three classification techniques including classification trees, random forests and Bayesian probit regression with non-local priors. We estimated classification performance via leave-one-out cross validation. **Results:** By Chi-Squared analysis we found over a dozen biomarkers associated with response, and a dozen biomarkers associated with toxicity. These included germ-line mutations in 3' untranslated regions as well as in miRNA promoter regions. We found that both classification trees and Bayesian probit compared reasonably well with random forests. We found a response signature with a specificity of 89% by Random Forests, and a toxicity signature with a specificity of 76% by Random Forests. **Conclusions:** We have shown that a new class of germ-line mutations disrupting miRNA regulatory networks can act as biomarkers of response and toxicity to anti-PD1 and anti-PDL1 therapy.

3041 Poster Session (Board #136), Mon, 8:00 AM-11:30 AM

Gene expression analysis of tumor biopsies from a trial of durvalumab to identify subsets of NSCLC with shared immune pathways. *First Author: Katie Streicher, MedImmune, Translational Medicine (currently with EMD Serono), Gaithersburg, MD*

Background: We previously reported that NSCLC pts with high pretreatment tumoral IFNG mRNA signature (sig) expression have improved outcomes (ORR, PFS, OS) to the anti-PD-L1 therapy durvalumab (D). To explore the relationship of other immunotherapy targets with the IFNG sig, we evaluated expression of *CD137, PD1, PDL1, CTLA4, GITR, OX40, TLR7, TLR8, CD73, TIM3, NKG2A, IDO1, CD40, LAG3, A2AR, CXCR4, iNOS, ARG1, and STAT3* in D-treated NSCLC. **Methods:** CP1108/NCT01693562 was a nonrandomized phase 1/2 trial evaluating D (10 mg/kg Q2W) in advanced NSCLC. As of 24OCT16, 304 primarily previously-treated pts were enrolled. RNA sequencing was conducted on available tumor specimens from 98 pts. ORR was evaluated using RECIST v1.1. 19 genes were z-scored, scaled and clustered across pt tumors. Each gene was coded binary using 0 as a cut point. The proportion of tumors with concordant or discordant over-expression between a gene and the IFNG sig was calculated. **Results:** In 43% of evaluable NSCLC pts, mRNAs for *PD-1, IDO1, PD-L1, CD40, CTLA4, LAG3, TIM3, TLR8, NKG2A*, and *CD137* were co-expressed with IFNG sig (Spearman's rho $>=$ 0.7). In 34% of evaluable pts, *TLR7, OX40, GITR, A2AR*, and *CXCR4* mRNAs had moderate concordance with IFNG sig ($0.5 <$ rho < 0.7) and in 23% of evaluable pts *iNOS, CD73, ARG1*, and *STAT3* had low concordance (rho < 0.5). Within the cluster of pts including high IFNG sig, a small subset expressed high *iNOS* and *CD73*; however, pts with high *STAT3* or *ARG1* formed a distinct cluster within the low IFNG sig subset. The subset with high IFNG sig had an ORR of 24% compared to only 10% in all other subsets combined. **Conclusions:** Our findings enrich understanding of the immune microenvironment of NSCLC by identifying three broad categories of tumors: tumors with pre-existing immunity that have high IFNg sig and select other IO pathways with enhanced responses to D; tumors with moderate expression of IO genes in which the local microenvironment is crucial; finally a distinct "cold" subset of tumors with high expression of *STAT3* or *ARG1* and characterized by low or no expression of IFNG sig and other IO genes. These results may aid in identifying the right pts for anti-PD-L1 and in prioritizing immunotherapy combinations.

3042 Poster Session (Board #137), Mon, 8:00 AM-11:30 AM

CD133-redirected chimeric antigen receptor engineered autologous T-cell treatment in patients with advanced and metastatic malignancies. *First Author: Yao Wang, Department of Molecule and Immunology, Bio-therapeutic Ward, Chinese PLA General Hospital, Beijing, China*

Background: Expressed by cancer stem cells of various epithelial cell origins, CD133 is an attractive therapeutic target for cancers. Autologous chimeric antigen receptor-modified T cells directed CD133 (CART-133) were firstly tested in this clinical trial. We aimed to determine the safety dosage, toxicity and biological activity of CART-133 in epithelium-derived solid tumors. **Methods:** The initially enrolled 8 patients with sorafenib-refractory hepatocellular carcinoma (HCC), treated by CART-133 monotherapy, were assigned into 3 dose cohorts (1, $0.5\text{-}1.5\times10^5$/kg; 2, $5\text{-}10\times10^5$/kg; 3, $1\text{-}2\times10^6$/kg). For the additional 16 patients (6 HCCs, 7 pancreatic carcinomas, 2 colorectal carcinomas, and 1 cholangiocarcinoma), all non-HCCs were conditioned by regimen (Nab-pacitaxel/cyclophosphamide or anti-PD1 antibody) before cell infusions. **Results:** For the initial 8 HCCs, 1 from cohort 2 occurred hemoglobin/platelet decline and direct hyperbilirubinemia (Grade 3), 4 from cohort 2/3 reported delayed low fever, nausea accompanied with elevation of CRP and serum cytokines. The 4-6 week persistence of relatively higher CAR copy numbers and its reverse relationship with the count of $CD133^+$ cells harboring pro-metastatic epithelial progenitor cells in peripheral blood led to the determination of acceptable cell infusion dose from 0.5 to 2×10^6/kg and reinfusion cycle in 24 patients. Similar toxicities ($\leq$ Grade 3) were observed in 15 cases. The cholangiocarcinoma patient who uniquely received 1 cycle of CART-133 infusion after anti-PD1, developed Grade 3 skin/mucosal vasculature damage, blood three-lineage decline and cytokine release syndrome, whereas, obtained a 4.5 month-lasting partial remission. Although no marked reduction of tumor volume was observed in most patients, 21 out of 23 patients had an 8-22 week progression-free survival, 2 patients without bulky tumor burden attained 8/10-month ongoing stable disease by the cut-off data (Jan 1, 2017). **Conclusions:** This trial showed the feasibility, controllable toxicities and effective biological activity of CART-133 transfer for the treatment of late-stage tumor patients. Clinical trial information: NCT02541370.

3044 Poster Session (Board #139), Mon, 8:00 AM-11:30 AM

Augmentation of adoptive T-cell therapy for Merkel cell carcinoma with avelumab. *First Author: Kelly Garneski Paulson, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: 80% of Merkel cell carcinomas (MCCs) are caused by Merkel cell polyomavirus (MCPyV) oncoproteins. Although absent in most cases, abundant MCPyV-specific CD8+ TIL are associated with good MCC outcomes, implying tumor susceptibility to immune attack. Indeed, anti-PD-1 axis blockade has a response rate of 32-56%. However, half of patients do not respond, suggesting a lack of adequate MCPyV-specific T cells and/or tumor evasion from MCC-related reduced HLA expression. We hypothesized the combination of adoptive transfer of MCPyV-specific T cells with HLA upregulation and PD1 axis blockade would be more effective than either approach alone. **Methods:** 8 adult patients with MCPyV-associated metastatic MCC without pre-existing immune deficiencies were enrolled. The safety and efficacy of *ex vivo* expanded MCPyV-specific T-cells plus HLA-upregulation (radiation or interferon) with (triple therapy) and without (double therapy) avelumab (mAb against PD-L1, dose 10 mg/kg IV q2weeks) were compared in 2 related phase I/II studies. **Results:** All 4 patients who received triple therapy (100%) are alive (median follow-up 10 months), and experienced objective responses (RECIST 1.1) with 3 of 4 sustained complete responses (CRs) at last follow-up (longest 13 mo). This compared favorably to outcomes among the 4 patients who received double therapy (3 with progression and 1 CR (25%) for 14 months before progression) and published data for avelumab monotherapy – response rate 32% and CR rate 9% in patients who had failed chemotherapy (Kaufman et al, *Lancet Oncol*, 2016). Grade 3-4 T cell-related adverse events were similar and anticipated in both groups, including transient lymphopenia (n = 7) and modest cytokine release syndrome lasting $<$ 24 hours, manageable on the general ward (n = 4). No grade 3-4 toxicities were attributed to avelumab. Among patients receiving triple therapy, transferred T cells persisted, and peak frequencies correlated with rate of tumor regression. **Conclusions:** The combination of MCPyV-specific T cells, avelumab and HLA upregulation is safe and correlative studies suggest avelumab enhances the T cell responses to MCC. This strategy has potential for MCC treatment, and can be readily applied to other solid tumors. Clinical trial information: NCT01758458 and NCT02584829.

3045 Poster Session (Board #140), Mon, 8:00 AM-11:30 AM

Efficacy of single administration of tumor-infiltrating lymphocytes (TIL) in heavily pretreated patients with metastatic melanoma following checkpoint therapy. *First Author: Amod Sarnaik, Moffitt Cancer Center, Tampa, FL*

Background: Adoptive cell therapy with TIL involves collection of autologous lymphocytes from the tumor via surgical resection, *ex vivo* expansion of TIL, lymphodepletion of the patient prior to infusion of TIL using Fludarabine and Cyclophosphamide, followed by infusion of TIL. Up to 6 doses of IL-2 (600,000 IU/kg) is administered to support multiplication of TIL and engraftment. Here, we present the preliminary results from an ongoing, multi-site Phase 2 study of TIL for advanced metastatic melanoma. **Methods:** Patients with advanced metastatic melanoma who have failed at least one prior systemic therapy were enrolled. Primary objective of the study was to characterize safety profile of LN-144. At baseline, patients had a median age of 56 (41-72) years; 44% were ≥ 60 years old. Median sum of tumor diameters for the target lesions was 10.4 cm, and median of 3 prior therapies. All enlisted patients had prior anti-PD1 as well as anti-CTLA4 and 67% had received ≥ 3 prior therapies. Responses were assessed by RECIST 1.1. TIL products were centrally manufactured. No complications arose from shipment of tumors or TIL. **Results:** Results are presented through 31 Jan 2017 for the first 9 infused patients evaluable by two assessments. Eight of 9 patients received all 6 doses of IL-2 per protocol. The most common (≥3 patients) non-hematologic grade 3-4 TEAE was hypophosphatemia. No neurotoxicity of grade ≥ 3 was reported. There were no deaths or discontinuations due to SAEs related to study treatment. ORR was 33% (CR = 11%, PR = 22%, SD = 22%, PD = 33%, NE = 11%). Mean time to best response was 3.0 months and median duration of follow up was 3.6 months (1.1+, 12.1). Responses were observed in patients with tumors carrying wild type or BRAF mutations. All patients demonstrated persistence of TIL on day 14 post-infusion. **Conclusions:** Cell therapy with TIL is an effective treatment with acceptable safety profile for advanced metastatic melanoma patients who are refractory to anti-PD1. TIL products can be centrally manufactured for broad clinical application. This study will be expanded to enroll patients with a shorter manufacturing process as well as offering retreatment for study patients. Clinical trial information: NCT02360579.

3046 Poster Session (Board #141), Mon, 8:00 AM-11:30 AM

Feasible and efficient identification of neoantigens for personalized cancer immunotherapy in advanced refractory epithelial cancer patients. *First Author: Fangjun Chen, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University and Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: Recent genomic and bioinformatic technological advances have made it possible to dissect the immune response to personalized neoantigens encoded by tumor-specific mutations.However, rapid and efficient identification of neoantigens is still fraught with difficulty, and a systematic evaluation of personalized neoantigens based immunotherapy in advanced refractory epithelial tumors is lacking. **Methods:** Tumor and ctDNA samples from 16 advanced epithelial cancer patients were underwent mutational profiling by cancer-associated genes panel. Neoantigens identification were performed by two strategies: As classic mode, somatic mutations were subjected to in silico analysis to predict potential high-affinity epitopes and mutated peptides were denovo synthesized; Hotspot mutations were matched to our customized driver mutation-derived neoantigens peptide library. Candidate neoepitopes were identified. Approximately 10^8 neoantigen loaded DC vaccine and 10^{10} bulk T cells composed of 10^9 neoantigen reactive CD8+T cells were generated for personlized immunotherapy. **Results:** Among the sequenced patients, 3 of 4 patients who utilized the classic mode and 6 of 12 patients who performed customized neoantigens library have successfully identified 1~2 neoantigens recognized by autologous T cells, respectively. Subsequently, a total number of 6 patients received immunotherapy targeting personalized neoantigen. To date, one patient with metastatic thymoma is achieving a complete and durable response beyond 9 months. In addition, immune related partial response was observed in another advanced pancreatic cancer patient. The remaining 4 patients achieved prolonged stabilization of disease with median PFS of 8.6 months. **Conclusions:** Our costomized neoantigens library can provide a novel approach for neoantigens screening in advanced epithelial cancer patients. Besides, targeted sequencing is sufficient for somatic variant and neoantigen identification. The combination of two strategies can accelerate the neoantigen-based translational immunotherapy research into the paradigm of precision medicine.

3047 Poster Session (Board #142), Mon, 8:00 AM-11:30 AM

Anti-PD-1 monoclonal antibody combined CD3-retronectin activated T cell in heavy-treated renal cell cancer. *First Author: Lingdi Zhao, Cancer Hospital Affiliated to Zhengzhou University and Henan Cancer Hospital, Zhengzhou City, China*

Background: Metastatic renal cell carcinoma (MRCC) has a poor prognosis after failure of multitargeted tyrosine kinase inhibitors. New immunomodulators, such as anti-programmed death (PD)-1 antibody drugs, have made progress in the treatment of MRCC, but their objective response rate is only about 25%. Therefore, it is important to enhance the response rate of anti-PD-1 therapy. **Methods:** Patients with MRCC were eligible if they were failed to at least one kinase inhibitors, ECOG PS 0-2. Patients received nivolumab (2mg/kg, q2w) or keytruda (2mg/kg, q3w), followed by CD3-retronectin activated T cell, and the total number of CD3-retronectin activated T cell each time was about 5×10^9/L. The primary objective was to determine the objective response rate, secondary objectives included time to symptom relief, time to efficacy, safety. **Results:** 8 pts were enrolled (median age 58 [31-79], male 6). Pts had received a median of 2 (1-4) prior regimens. To date there is 2 patients that the efficacy can not be evaluated. The other 6 pts got remission (3 complete remission and 3 partial remission), the median time to efficacy was 10 weeks (6-12 weeks) and the time to symptom relief was 4 weeks (3-6 weeks). There was no grade 3/4 adverse effects. family:'';font-size:12.0000pt;mso-font-kerning:1.0000pt;" $> 10^9$/L. The primary objective was to determine the objective response rate, secondary objectives included time to symptom relief, time to efficacy, safety. **Conclusions:** CD3-retronectin activated T cell might improve the efficacy of anti-PD-1 therapy without increasing the side effects. This combination therapy has many implications in the age of immunotherapy, and should be explored across cancer types. mily:'';font-size:12.0000pt;mso-font-kerning:1.0000pt;" $> 10^9$/L. The primary objective was to determine the objective response rate, secondary objectives included time to symptom relief, time to efficacy, safety.

3048 Poster Session (Board #143), Mon, 8:00 AM-11:30 AM

High-fidelity genome editing using NextGEN CRISPR (Clo51-dCas9) system for the production of allogeneic CAR-T cells. *First Author: Xinxin Wang, Poseida Therapeutics, Inc., San Diego, CA*

Background: Autologous chimeric antigen receptor (CAR) T therapies are highly efficient at targeting hematological malignancies, but the clinical applications have been limited by individualized manufacturing. Furthermore, there has been little success in treating solid tumors due to immunosuppressive microenvironments. Currently, genome editing technologies are being used to address both issues. However, the CRISPR/Cas9 system has significant safety concerns due to high incidence of off-target mutations and TALEN only works sufficiently in activated cells. A hybrid gene editing system, NextGEN (NG) Clo51-dCas9, can be targeted using gRNA, like CRISPR/Cas9, but exhibits little-to-no off-target cutting like TALEN, thereby overcoming limitations in the genome editing of resting T cells. **Methods:** We successfully developed a platform for production of allogeneic CAR-T cells with reduced receptivity to inhibitory signaling. Here, T cells were modified by piggyBac-mediated BCMA CAR gene delivery, along with NG reagents to knock out critical genes mediating rejection responses. Gene edited CAR-T cells were assessed by mixed lymphocyte reaction (MLR) and tumor killing. In addition, NG was used to knockout multiple checkpoint inhibitory receptors known to mediate key suppressive signals in T cells. **Results:** NG demonstrated high gene disruption efficiencies for all targets (84% for TCRα, 91% for TCRβ, 64% for β-2 microglobulin, and 40-60% for the surface inhibitory receptors PD-1, CTLA-4, Tim3, Lag-3, and TGFBRII). In contrast to CRISPR/Cas9, no off-target mutations were detected for multiple targets by deep-sequencing. In MLRs, disruption of TCR eliminated the GvHD response, while disruption of MHCI completely abrogated graft-rejection. Lastly, TCR/MHCI double knockout did not affect the ability to kill BCMA+ multiple myeloma cells *in vitro*. **Conclusions:** NG overcomes significant limitations of the CRISPR/Cas9 and TALEN systems with highly efficient genome editing in resting T cells. NG has great potential and flexibility for the manufacture of allogeneic CAR-T cells and for enhancing efficacy against solid tumors.

3049 Poster Session (Board #144), Mon, 8:00 AM-11:30 AM

A phase I study of anti-GPC3 chimeric antigen receptor modified T cells (GPC3 CAR-T) in Chinese patients with refractory or relapsed GPC3+ hepatocellular carcinoma (r/r GPC3+ HCC). *First Author: Bo Zhai, Department of Interventional Oncology, Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China*

Background: HCC was commonly diagnosed and identified as leading causes of cancer death in China. Using a 10% cutoff score, GPC3 was detected in 63.6% of HCCs. Safety and preliminary efficacy of a GPC3 CAR-T was evaluated in 13 Chinese patients (pts) with r/r GPC3+ HCC in a Phase I trial. **Methods:** Pts between 18 and 70 yrs old with histopathological confirmed r/r GPC3+ HCC, Child-Pugh score≤B7, ECOG≤1, lymphocyte ≥□0.7 x10^9, post-transduction positive T cells □≥30%, amplification by α CD3/CD28 ≥5□, and without ascites and HIV infection were enrolled. Eligible pts undergo leukapheresis or whole blood colletion, which further developed into GPC3 CAR-T via lentiviral transduction. Standard release tests were conducted before administering GPC3 CAR-T in pts. Adverse events were graded per NCI CTCAE v.4.03. Efficacy was evaluated per modified RECIST (mRECIST). **Results:** All 13 pts, who received at least one infusion of GPC3 CAR-T, tolerated the treatment well. No dose-limiting toxicity (DLT) was identified, and only one SAE of grade 3 fever was reported. Preliminary analysis compared the clinical outcomes in pts who received GPC3 CAR-T without lymphodepleting conditioning (LDC) (Group A) vs. with LDC (Group B) at baseline. In Group A (N = 5), all pts developed progressive disease (PD) shortly after received a total infusion of GPC3 CAR-T ranging from 0.92x10^7 to 8.72 x10^7 cells/kg. In Group B (N = 8), following the LDC with fludarabine and cyclophosphamide, pts received a total infusion of GPC3 CAR-T ranging from 0.013x10^7 to 14.68 x10^7 cells/kg. Except two non-evaluable pts, the best response for the rest 6 pts are 1 PR, 3 SD, 2 PD. As of Feb 1, 2017, the PR pt remains alive for 385 days; 2 SD pts remain alive for 384 and 562 days, respectively; and one SD deceased at 108 days. Also worth to mention, one pt in Group A decided to remain on the study after PD, further received a total of 6.23 x10^7cells/kg infusions following a LDC given around Day 150, remains stable for 571 days as of Feb 1, 2017. **Conclusions:** Phase I trial shows GPC3 CAR-T is feasible and safe for Chinese pts with r/r GPC3+ HCC, and holds promising antitumor potential when LDC is applied along with GPC3 CAR-T. Clinical trial information: NCT02395250.

3050 Poster Session (Board #145), Mon, 8:00 AM-11:30 AM

Chimeric antigen receptor (CAR) T cells genetically engineered to deliver IL-12 to the tumor microenvironment in ovarian cancer. *First Author: Oladapo O. Yeku, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chimeric antigen receptor (CAR) T cell therapy for solid tumor malignancies has not shown the same degree of clinical efficacy observed in hematologic malignancies. The presence of an immunosuppressive cytokine and cellular microenvironment has been hypothesized as one reason for the failure of adoptive immunotherapy for solid tumors. In ovarian cancer, the presence of tumor associated macrophages (TAMs) and immunosuppressive cytokines in the ascitic microenvironment have been reported. IL-12 is a proinflammatory cytokine produced by macrophages, dendritic cells (DC) and NK cells, and has been shown to increase proliferation of T cells and enhance antigen presentation by macrophages. We hypothesized that CAR T cells genetically modified to constitutively secrete IL-12 would overcome a hostile tumor microenvironment in a peritoneal carcinomatosis model of ovarian cancer. **Methods:** CAR T cells were generated from retroviral transduction of second generation and IL-12 modified CAR's directed to either an irrelevant CD-19 antigen or $Muc16^{ecto}$. **Results:** Here we report increased production of IL-12, improved proliferation and cytotoxic activity of 4H1128-IL12 CAR T cells. We show increased levels of inflammatory cytokines at 24 and 48hrs after treatment of tumor-bearing mice, leading to increased survival at advanced stages of disease. Mice treated with 4H1128-IL12 CAR T cells had decreased levels of $F4/80^+$ $CD11b^+$TAM's. Genetic analysis of recovered TAM's from the ascites of treated animals showed skewing towards an M1-phenotype via upregulation of cytokines, chemokines, MHC-II and down-regulation of Arg1. Recovered 4H1128-IL12 CAR T cells showed upregulation of FAS-L and recovered TAMs showed increased expression of FAS suggesting FAS/FAS-L engagement was responsible for decreased TAMs. Blocking the FAS/FAS-L pathway led to recovery of TAM populations in 4H1128-IL12 treated mice. Finally, clodronate-mediated depletion of TAM's further enhanced survival in mice treated with 4H1128-IL12 CAR T cells. **Conclusions:** These results demonstrate the mechanisms of efficacy of localized delivery of IL-12 to the tumor microenvironment by 4H1128-IL12 CAR T cells.

3051 Poster Session (Board #146), Mon, 8:00 AM-11:30 AM

Peritoneum metastasis (PM) as a prognostic factor in metastatic gastric cancer (MGC) treated with anti-PD-1/PD-L1 monotherapy. *First Author: Yukiya Narita, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: Anti-PD-1 monotherapy has proven effective for the patients (pts) with MGC. However, the identification of biomarkers for predicting clinical outcomes remain as critical needs. We aimed to identify baseline characteristics associated with time to treatment failure (TTF) or overall survival (OS) for anti-PD-1/PD-L1 monotherapy as second- or later-line therapy in MGC. **Methods:** Routine blood count parameters and clinical characteristics at baseline were retrospectively investigated in 31 pts with MGC in Aichi Cancer Center Hospital. Endpoints were TTF and OS following anti-PD-1/PD-L1 monotherapy. Kaplan-Meiyer and Cox regression analysis were applied for survival analyses. **Results:** Patient characteristics were as follows: median age (range), 68 (47–83); ECOG performance status (PS) 0/1, 21/10; PM +ve/-ve, 12/19; No. of metastatic sites 1–2/≥3, 18/13; No. of prior chemotherapy regimens 1–2/≥3, 11/20; and absolute eosinophil count (AEC) <150/≥150 /μl, 14/17. Objective response rate and disease control rate (RECIST ver. 1.1) were 26% vs. 0% (odds ratio [OR], 3.76; $P = 0.12$) and 79% vs. 50% (OR, 3.58; $P = 0.12$) in the PM -ve group (Cohort A) and the PM +ve group (Cohort B), respectively. On univariate analysis, the pts with poor PS, PM +ve, and high AEC were significantly poor TTF; and poor PS and PM +ve were significantly identified as prognostic factors of poor OS. On multivariate analysis, only PM +ve was independent negative impact not only for TTF but also for OS. Median TTF and OS were 5.4 vs. 1.3 months (M) (adjusted hazard ratio [HR], 4.29; 95%CI, 1.60–11.5; $P < 0.01$) and 28.2 vs. 7.5 M (adjusted HR, 3.68; 95%CI, 1.25–10.8; $P = 0.02$) in Cohort A and Cohort B. Six-months TTF probabilities of 42% vs. 0% ($P = 0.03$) and one-year OS probabilities of 58% vs. 8% ($P < 0.01$) were observed in Cohort A compared to in Cohort B. **Conclusions:** PM -ve in the pts treated with anti-PD-1/PD-L1 monotherapy was associated with better efficacy. In the pts with PM -ve, anti-PD-1/PD-L1 monotherapy could be adapted in first-line therapy.

		TTF	OS
		Multivariate HR (*P* value)	
ECOG PS	0 vs. 1	1.58 (0.42)	1.95 (0.21)
Peritoneum metastasis	No vs. Yes	4.29 (< 0.01)	3.68 (0.02)
Absolute eosinophil count	<150 vs. ≥150 /μL	2.28 (0.12)	

3052 Poster Session (Board #147), Mon, 8:00 AM-11:30 AM

Durvalumab and tremelimumab in metastatic breast cancer (MBC): Immunotherapy and immunopharmacogenomic dynamics. *First Author: Cesar Augusto Santa-Maria, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: PD-1/PD-L1 inhibitors produce modest responses in MBC; adding CTLA-4 inhibitors can augment anti-tumor activity in other cancers. Immunopharmacogenomics characterize immune-cancer cell interactions and may predict response. **Methods:** A single arm study was designed to determine the efficacy of durvalumab (PD-L1 inhibitor) and tremelimumab (CTLA-4 inhibitor), and immunopharmacogenomics in pts with metastatic ER+ or TNBC. The primary clinical endpoint was to assess ORR using a Simon 2-stage design (28 pts needed for type 1 error rate of 4%, 80% power). 18 pts were enrolled in the first stage; ≥4 responses were needed to proceed with the second stage. Pts were treated with durvalumab 1500mg IV and tremelimumab 75mg IV monthly for 4 doses, then durvalumab 750mg every 2 weeks to complete 1 year of therapy (option to renew for an additional year); biopsies at baseline and 2 months were collected. T-cell receptor (TCR) sequencing using mRNA isolates was conducted at baseline and 2 months, whole exome sequencing and immune-gene expression profiling were conducted at baseline. **Results:** From 01-09/2016, 18 evaluable pts were accrued (11 ER+; 7 TNBC). Responses are shown in the table below; the ORR did not meet criteria to proceed to the second stage. Notably, one pt with TNBC with PD had pseudoprogression, thus 5/7 (71%) pts with TNBC had clinical benefit. Median PFS was 3.8 months (95%CI 2.2-11.2) for the entire cohort (TNBC not reached), and median OS has not been reached. No grade 4 AEs were observed; grade 3 immune-related AEs included hepatitis (n = 3), nephritis (n = 1), and myocarditis (n = 1). Proportions of abundant TCR-β clonotypes (≥ 0.5% frequency) were increased in 2-month samples compared to baseline in TNBC compared to ER+, p = 0.004, and associated with responses. Remaining correlative analysis is ongoing and will be presented at ASCO. **Conclusions:** Response rates to PDL-1 and CTLA-4 inhibition were low in unselected MBC, however, high rates of clinical benefit were observed in TNBC. Immunopharmacogenomic may help identify phenotypes most likely to respond. Future studies in TNBC are warranted to confirm findings. Clinical trial information: NCT02536794.

	All pts (n = 18)	TNBC (n = 7)	ER+ (n = 11)
PR	3	3	0
SD ≥6 months	1	1	0
PD	14	3*	11
ORR	17%	43%	0%

3053 Poster Session (Board #148), Mon, 8:00 AM-11:30 AM

Paracrine wnt-β-catenin signaling inhibition as a strategy to enhance the efficacy of anti-PD-1 antibody (Ab) therapy in a transgenic model of melanoma. *First Author: Nicholas C. DeVito, Tufts Medcl Ctr, Medford, MA*

Background: Activation of the Wnt-β-catenin signaling pathway is associated with poor T cell infiltration of tumors. We have previously demonstrated that paracrine Wnt5a-β-catenin signaling is a critical trigger of dendritic cell (DC) tolerization and regulatory T cell (Treg) differentiation in the melanoma microenvironment. In a transgenic $BRAF^{V600E}PTEN^{-/-}$ model, the genetic silencing of melanoma-derived Wnt5a potently enhances infiltrating $CD8^{+}$T cell effector function and promotes responses to anti-PD-1 Ab therapy. Ipafricept (IPA) is a recombinant Wnt decoy receptor and Vantictumab (VAN) is a Fzd receptor monoclonal Ab. Both molecules inhibit Wnt-β-catenin signaling and have been well-tolerated in ongoing phase I/Ib clinical trials. We explored the ability of IPA/VAN to reverse tumor-mediated immune tolerance and enhance the efficacy of anti-PD-1 Ab immunotherapy in a pre-clinical model that closely recapitulates human melanoma. **Methods:** Both IPA and VAN were utilized to investigate Wnt-β-catenin inhibition as a strategy for suppressing melanoma-induced DC indoleamine 2,3-dioxygenase (IDO) expression and Treg differentiation in vitro. These agents were further tested for their ability to enhance anti-tumor T cell responses and to augment the efficacy of anti-PD-1 Ab therapy in syngeneic and autochthonous models of $BRAF^{V600E}PTEN^{-/-}$ melanoma. **Results:** IPA and VAN effectively inhibit Wnt5a and melanoma-induced DC IDO expression and Treg differentiation in vitro. Further studies demonstrate that IPA and VAN significantly augment anti-PD-1 Ab-mediated suppression of primary and metastatic tumor progression in both syngeneic and autochthonous $BRAF^{V600E}PTEN^{-/-}$ melanoma models. These anti-tumor effects correlated with suppressed IDO enzymatic activity, enhanced tumor-infiltrating $CD8^{+}$T cell/Treg ratios, and increased activation of TRP2 antigen-specific effector T cells. **Conclusions:** The pharmacological inhibition of paracrine Wnt-β-catenin signaling with IPA and VAN augment the anti-tumor efficacy of anti-PD-1 Ab therapy and represent a promising strategy for further phase I testing in melanoma and other solid tumors.

3054 Poster Session (Board #149), Mon, 8:00 AM-11:30 AM

Phase 2 study of pembrolizumab in combination with azacitidine in subjects with metastatic colorectal cancer. *First Author: James J. Lee, Division of Hematology-Oncology, Department of Medicine, University of Pittsburgh Cancer Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Microsatellite stable (MSS) metastatic colorectal cancer (mCRC) has relatively poor tumoral infiltration of $CD8^{+}$ T cells and is resistant to pembrolizumab (Pembro) when compared to MSI-H mCRC. DNA hypomethylating agent induces epigenetic expression of multiple genes including cancer-testis antigens in CRC, which are recognized by cytotoxic $CD8^{+}$ T cells *in vitro* and *in vivo*. This trial tested whether concurrent treatment with azacitidine (Aza) could enhance the anti-tumor activity of Pembro. **Methods:** This is a phase 2 trial to evaluate anti-tumor activity and safety of Pembro plus Aza in patients (pts) with previously treated mCRC without any further standard chemotherapy option. Pts received Pembro 200 mg IV on day 1 of each cycle Q3W and Aza 100 mg daily SQ injection on days 1-5 of each cycle Q3W. Primary endpoint was response rate (ORR) using RECIST v1.1. Secondary endpoints included progression-free survival (PFS) and overall survival (OS). Tumor tissues were collected for correlative studies. **Results:** Thirty-one pts were enrolled [median age, 61 years (range, 30-79); 17 M/14 F; ECOG PS 0/1 (58%/42%); 30 pts with MSS mCRC]. Pts received at least 2 lines of prior systemic chemotherapy for mCRC (median, 3; range, 1-5). Thirty pts received at least one dose of study therapy (median, 3 cycles; range, 1-8). Ten pts could not complete the first 3 cycles due to rapid symptomatic tumor progression. One pt with MSS mCRC achieved PR and 3 pts had SD as best response. The ORR was 3% (1/30; 95% CI, 0.1-17%). Seven pts with PD at the end of cycle 3 continued on study therapy, and 2 pts had stabilization of tumor progression. Median PFS was 2.1 months (95% CI, 1.8-2.8), and median OS was 6.2 months (95% CI, 3.5-8.7). While treatment-related adverse events (TRAEs) were reported in 63% of pts, most of the TRAEs were Gr 1/2 (96%). Frequent TRAEs possibly related to Aza were anemia (n = 5), constipation (n = 5), and leukopenia (n = 4); and possibly related to both Aza and Pembro were nausea (n = 5) and fatigue (n = 5). Gr 3 TRAEs included anemia (n = 1), ALT elevation (n = 1), and alkaline phosphatase elevation (n = 1). **Conclusions:** Pembro plus Aza is feasible with a tolerable safety profile but appears to have minimal anti-tumor effect for MSS mCRC. Clinical trial information: NCT02260440.

3055 Poster Session (Board #150), Mon, 8:00 AM-11:30 AM

Predictive and prognostic value of systemic inflammatory response biomarkers in patients receiving nivolumab for metastatic non-small cell lung cancer (NSCLC). *First Author: Claire Gervais, Department of Medical Oncology, Cochin Hospital, Paris Descartes University, AP-HP, CARPEM, Immunomodulatory Therapies Multidisciplinary Study group (CERTIM), Paris, France*

Background: Nivolumab is the first checkpoint immunotherapeutic agent approved for NSCLC. By enabling host immune-mediated cytotoxic activity against tumor cells, nivolumab induces a tumor response in 15% of patients (pts). However, host-related parameters to predict nivolumab activity are still missing. We evaluated the predictive and prognostic value of the presence of a systemic inflammatory response. **Methods:** From July 2015 to December 2016, we measured at nivolumab initiation the Glasgow Prognostic Score (GPS), a cumulative prognostic score based on C-reactive protein and albumin, the neutrophil-lymphocyte ratio (NLR), the Nutrition Risk Index (NRI) and the Prognostic Nutritional Index (PNI). Univariate and multivariate analyses tested the association between initial patient characteristics and clinical outcome. **Results:** The characteristics of the 57 consecutive pts analyzed are: median age of 66 years (range 41-78), 65% non-squamous cell lung cancer, 61.4% males and 52.6% Performance Status (PS) 0-1. GPS was 0 in 27 (47.4%), 1 in 21 (36.8%) and 2 in 9 (15.8%) pts. In multivariate analysis, parameters associated with disease progression (per RECIST 1.1) were GPS (1-2 vs 0; HR 1.45 [1.11-1.90], p= 0.009) and number of metastatic sites (>2 vs ≤ 2; HR: 0.75 [0.57-0.98], p = 0.04). Overall survival was significantly worse for pts with PS 2-3 vs PS 0-1 (p=0.01) and for pts with GPS 2 vs GPS 0-1 (p=0.01). The GPS was an independent predictive marker of progression and was superior to other inflammation-based prognostic scores in our cohort (Table). **Conclusions:** The Glasgow Prognostic Score (GPS) allows identifying patients with disease progression and long survivors among metastatic NSCLC patients treated with nivolumab.

	GPS 0 n=27 (47.4%)	GPS 1 n=21 (36.8%)	GPS 2 n=9 (15.8%)	HR (GPS 1-2 versus 0)	univariate p
Median overall survival (months)	6.30 [2.17-15.10]	4.87 [1-11.77]	3.77 [2.17-10.50]	3.30 [1.43-7.61]	0.05
Median number of cycles	8.5 [4-22]	4 [1-22]	3 [1-14]		$<10^{-4}$
Progression	10 (37%)	14 (67%)	8 (89%)	4.54 [1.33-16.83]	0.008
Disease control rate	17 (63%)	7 (33%)	1 (11%)		

3056 Poster Session (Board #151), Mon, 8:00 AM-11:30 AM

The scope of possible combination therapy with immunotherapy and targeted therapy. *First Author: Leandro Machado Colli, National Cancer Institute, National Institutes of Health, Rockville, MD*

Background: Combination treatment of two recent trends in cancer therapy, namely immunotherapy with checkpoint inhibitors and drugs that target specific gene mutations, could improve cancer survivorship overall. Targeted drugs usually induce rapid tumor death leading to the release of neoantigens, and can affect immune development pathways, which could increase the efficacy of checkpoint inhibitor treatment. Assessment of somatic mutation profiles from large public databases provides an estimate of the prevalence of targetable somatic mutations and the burden of somatic nonsynonymous mutations (NsM), used as a surrogate for overall neoantigen load, which, in turn, correlates with clinical utility of checkpoint inhibitors for melanoma and lung adenocarcinoma. The rational design of these combinations based on somatic genomic profiles offers a prioritization scheme for new clinical trials. **Methods:** We surveyed 13,349 genomic profiles from public databases for cases with specific mutations targeted by current agents and/or a burden of exome-wide non-synonymous mutations (NsM) that exceeds a recently suggested threshold for response to checkpoint inhibitors. **Results:** Overall, 8.9% of cases have profiles that could benefit from combination therapy, which corresponds to approximately 11.2% of US annual incident cancer cases; the most commonly targetable mutations were observed in *PIK3CA*, *BRAF*, *NF1*, *NRAS*, and *PTEN* genes. Interestingly, cases with mutations in *SMO*, *DDR2*, *FGFR1*, *PTCH1*, *FGFR2*, and/or *MET* appear to be enriched in those with high burdens of NsM, who have a higher likelihood of responding to immunotherapy. Of the 13,349 cases that could benefit from combination therapy, 50.9% had *BRAF*, *NF1*, *GNAQ* and/or *GNA11* mutations which can be targeted by Trametinib; 26.1% by Taselisib (targets *PIK3CA* mutations); and 19.8% by Afatinib (*EGFR* and *ERBB2* mutations). **Conclusions:** Our results indicate a significant proportion of solid tumor patients are eligible for combination therapy and suggest prioritizing specific cancers for combination trials using target drugs and checkpoint inhibitor therapy.

3057 Poster Session (Board #152), Mon, 8:00 AM-11:30 AM

Atezolizumab (A) + cobimetinib (C) in metastatic melanoma (mel): Updated safety and clinical activity. *First Author: Wilson H. Miller, Segal Cancer Centre, Jewish General Hospital, McGill University, Montreal, QC, Canada*

Background: A, an anti–programmed death-ligand 1 (PD-L1) monoclonal antibody, inhibits PD-L1/programmed death-1 (PD-1) and PD-L1/B7.1 binding and shows promising clinical activity in patients (pts) with cutaneous mel (objective response rate [ORR] 33%; median progression-free survival [mPFS] 5.5 months; Hodi et al SMR 2014). C promotes intratumoral T-cell infiltration, major histocompatibility complex 1 upregulation, and PD-L1 expression via targeted MEK inhibition in preclinical models (Ebert et al *Immunity* 2016) and tumor biopsy specimens (Bendell et al ASCO 2016). Therefore, clinical benefits may be enhanced by combining A + C vs A. This Phase Ib dose-escalation and -expansion study (NCT01988896) suggested higher ORR/disease control rate (DCR, ORR + stable disease) and longer PFS may be achieved with A + C vs A or C alone in mel. We present updated safety and efficacy data. **Methods:** Oral C, escalated 20 mg→40 mg→60 mg, was given qd for 21 days followed by 7 days off. Intravenous (IV) A was given at 800 mg q2w. Tumor-specific expansion cohorts were enrolled at maximum tolerated doses (C 60 mg/d 21/7; A 800 mg IV q2w). No prior anti–PD-L1 or –PD-1 therapy was allowed. **Results:** Data cut-off was Oct 12, 2016; 22 patients were safety-evaluable (two ocular, 20 non-ocular [ten each *BRAF*-mutant and -wild-type]). Median safety follow-up was 14.4 months (range 2.1–23.2). Adverse events (AEs) were experienced in all pts (diarrhea [20 pts, 90.9%] and rash [15 pts, 68.2%] were most common); related grade (G)3–4 AEs in 54.5% (diarrhea [three pts, 13.6%] and dermatitis acneiform [two pts, 9.1%] were most common; no related G5 AEs); related serious AEs in 13.6%. All were manageable. One pt discontinued A + C due to an AE. RECIST v1.1-confirmed ORR was 45.0% in pts with non-ocular mel (median duration of response was not reached); DCR was 75.0%; mPFS was 12.0 months (95% CI 2.8–not evaluable). ORR was similar for pts with *BRAF*-mutant and wild-type mel. **Conclusions:** Updated results confirm previous findings that suggest higher ORR/DCR and longer PFS may be achieved with A + C vs A or C monotherapy for mel. Together with biomarker data from other cohorts, our data suggest that the immune contexture may be altered by C, enhancing A activity. Clinical trial information: NCT01988896.

3058 Poster Session (Board #153), Mon, 8:00 AM-11:30 AM

Immune related adverse events (irAE) with platinum chemotherapy (CT) with durvalumab (D) ± tremelimumab (T): CCTG IND226. *First Author: Nathalie Daaboul, Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: CT is immunomodulatory and requires corticosteroids (CS) premedication. We hypothesized that the incidence of irAE may be lower when D ± T is given with CT or CS. **Methods:** Patients (pts) receive CT (pemetrexed, nab-paclitaxel, etoposide or gemcitabine + cisplatin or carboplatin; usual 4-6 cycles) with D ± T, followed by D ± T alone (1 year total); pts with ≥ g2 (selected) or ≥ g3 irAE discontinued D ± T. Cycles were coded as CT + D ± T or D ± T; pts could contribute to both. CS: high (dexamethasone > 10mg/day for 5 days) or low CS. irAE were D ± T related gastrointestinal (GI), skin, endocrine, neurologic, hypersensitivity, pneumonitis (PN) or other immune (nephritis (GN), pancreatitis, hepatitis). Biochemistry (BIO; all causality): creatinine, transaminases/bilirubin (LFTS) and amylase/lipase was summarised. **Results:** In this ongoing study, 118 pts received 723 cycles. Pts had good performance status (PS 0-1), 78 had thoracic malignancies and 84 no prior CT. 44 pts continue on D ± T alone; 32 pts continue on CT + D ± T while 76 pts discontinued D ± T primarily due to disease progression; 15 discontinued for ≥ g2 irAE [PN (3), hepatitis (1), GN (2), adrenal (1), myocarditis (1), GI (3), thrombocytopenia (1), hyperthyroidism (1), encephalitis (1), pt decision (1)]. 67 pts had high CS cycles while 78 pts had low. 50% pts had irAE and 10% had ≥ g3 irAE, most commonly skin and GI. GI (15 vs 11%), skin (26 vs 20%) and PN (3 vs 0%) were reported in more pts during CT + D ± T cycles (non significant (NS)) ; hypothyroidism was more common with D ± T alone (18 vs 10%; p = NS). IrAE rates and severity were similar between high (67 pts) or low CS (78 pts) except for GI (19 vs 10%; p = NS). BIO were more common during CT + D ± T (74% of pts vs 48% p = 0.003); rates in high CS were similar to low CS. LFTs (ALT/AST - 41% vs 16%; 38% vs 9%; p = 0.005) and amylase/lipase (18 vs 9%; 19 vs 14%; p = NS) were more common in pts with CT + D ± T cycles vs pts with D ± T alone cycles. **Conclusions:** There is no evidence that CT or CS abrogates irAE in this exploratory analysis. GI, skin, pneumonitis, LFTS and amylase/lipase were more common during CT + D ± T suggesting additive/multifactorial causes; hypothyroidism is more common in D ± T cycles, which may reflect time on treatment. Clinical trial information: NCT02537418.

3059 Poster Session (Board #154), Mon, 8:00 AM-11:30 AM

Safety profile of avelumab in patients with advanced solid tumors: A JAVELIN pooled analysis of phase 1 and 2 data. *First Author: Karen Kelly, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Avelumab is a fully human IgG1 anti–PD-L1 antibody with clinical activity in several tumor types. Pooled safety data from a large phase 1 trial in various tumors and a phase 2 trial in Merkel cell carcinoma (NCT01772004, NCT02155647) were analyzed to further characterize the safety profile of avelumab. **Methods:** Patients (pts) received avelumab 10 mg/kg 1-hour IV Q2W until progression, unacceptable toxicity, or withdrawal. Treatment-related adverse events (TRAEs) were graded by NCI CTCAE. In post hoc analyses, immune-related adverse events (irAEs) were identified via an expanded AE list and medical review, and infusion-related reaction (IRR) events were identified based on prespecified MedDRA terms, occurring within 1 day or related symptoms that resolved within 2 days of infusion. **Results:** In 1,738 pts analyzed (phase 1, n = 1,650; phase 2, n = 88) who received ≥1 dose of avelumab for a median of 12 weeks (range 2-138), the most common any grade TRAEs were fatigue (n = 307, 18%), IRR (n = 295, 17%), and nausea (n = 150, 9%). 177 pts (10%) had a grade ≥3 TRAE; most common were fatigue and elevated lipase (17 [1%] each). TRAEs led to discontinuation in 107 pts (6%). Four pts (0.2%) died due to a TRAE. Any grade irAEs occurred in 247 pts (14%), which were grade ≥3 in 39 pts (2%) and considered serious in 43 pts (2%). The most common any grade irAEs were thyroid disorder (n = 98, 6%) and rash (n = 90, 5%). Other irAEs (eg, colitis, hepatitis, pneumonitis, adrenal insufficiency, myositis) each occurred in < 2%. irAEs led to discontinuation in 34 pts (2%). IRR or related symptoms (eg, chills, pyrexia, hypersensitivity) occurred in 439 pts (25%), which were grade 3 in 9 pts (0.5%) and grade 4 in 3 pts (0.2%). An IRR occurred at first infusion in 79% and within first 4 doses in 99%; 63/439 pts (14%) had IRR recurrence in later cycles. IRR led to dose interruption in 152 (9%), infusion rate reduction in 124 (7%), and discontinuation in 35 pts (2%). **Conclusions:** This large pooled analysis confirms that avelumab has an acceptable safety profile. A minority of pts experienced a grade ≥3 TRAE or irAE and discontinuation due to TRAEs was uncommon. IRRs mostly occurred at first infusion and the rate of recurrence was low. Clinical trial information: NCT01772004, NCT02155647.

3060 Poster Session (Board #155), Mon, 8:00 AM-11:30 AM

PD-1 blockade using pembrolizumab in adolescent and young adult patients with advanced bone and soft tissue sarcoma. *First Author: Tahlia Scheinberg, Chris O'Brien Lifehouse, Camperdown, Australia*

Background: Sarcomas represent 1015% of cancers in adolescent and young adult (AYA) patients, and survival for those with metastatic disease or after relapse is poor. Immunotherapy with checkpoint inhibition has improved outcomes in multiple tumour types, but there are limited data on the efficacy of immunotherapy in advanced sarcomas, particularly within the AYA population. **Methods:** We retrospectively reviewed AYA patients with advanced bone and soft tissue sarcoma who received self-funded pembrolizumab at Chris O Brien Lifehouse and Children s Hospital Westmead. Initial response was evaluated after cycle three or four using RECIST v1.1 criteria. **Results:** Fourteen AYA patients with sarcoma received pembrolizumab 2mg/kg IV every 3 weeks from May 2015 to December 2016. Median age was 24 (14 35), male to female was 7:7, ECOG PS was 0 1 in 6 patients, 2 in 6 patients and 3 4 in 2 patients. Malignancy type included three patients with osteosarcoma (OS), five patients with Ewing sarcoma (ES), two patients with synovial sarcoma (SS), two patients with alveolar soft part sarcoma (ASPS), and one patient with each of embryonal rhabdomyosarcoma (RMS) and clear cell sarcoma (CCS). The median number of pembrolizumab doses was four (range 1 16), with one patient still receiving treatment at the time of last follow up. Treatment was generally very well tolerated with no G3-4 toxicity. One patient with ES had an excellent, sustained response; of the two patients with ASPS one had a radiological partial response with an excellent clinical response and one patient achieved stable disease. Three patients (two ES, one RMS) died of disease prior to first scheduled assessment and thus their response was not evaluable. The remaining 8 patients had progressive disease. **Conclusions:** Our data suggest further evaluation of the role of pembrolizumab in AYA patients with advanced sarcoma is warranted.

3061 Poster Session (Board #156), Mon, 8:00 AM-11:30 AM

Sustained oligoclonal T cell expansion correlates with durable response to anti-PD1 therapy. *First Author: Sope Omowale Olugbile, University of Chicago, Chicago, IL*

Background: Immune checkpoint blockers have demonstrated durable response in many tumor types including lung cancer. This clinical benefit is however restricted to a subset of patients in whom longitudinal assessments of their tumor microenvironment have revealed increase CD8+ T cell infiltration. However detailed characterization of this T cell dynamics at clonal levels in a large population of patients is yet to be reported. Such analyses will provide vital insight into the mechanism of tumor eradication in responders. **Methods:** We performed next-generation sequencing of T cell receptor β chain in longitudinal tumor and peripheral blood samples obtained from lung cancer patients treated with immunotherapies. We first extracted RNA from these samples and synthesized cDNA with 5'RACE adapter using SMART library construction kit (Clontech). We then amplified TCR β gene products to prepare sequence libraries which were analyzed with MiSeq system (Illumina). **Results:** Here we report on TCR receptor β chain sequencing data for 29 patients in whom we had 3 or more serial samples. Thirteen (45%) of the selected patients in this cohort had durable response and seven (24%) had radiological complete response. We confirmed that there is concordance between the expanded T cell clone at tumor site and the peripheral blood. In one responder, we found expansion of a dominant T cell clone (20%) at a metastatic site where he had pathological complete response on day 17 of treatment and the same clone remained persistent in his peripheral blood (24%) at week 48 of therapy. Similarly in other responders, there were T cell clonal expansions detected as early as week 2 after only one cycle of treatment and such clones remained at high frequencies several months afterwards. Such pattern of early and sustained clonal expansions were absent among non-responders even while they remained on therapy. **Conclusions:** We found durable response to immune checkpoint blockade to correlate with early and sustained expansion of one to two dominant T cell clones in this selected patient cohort.

3062 Poster Session (Board #157), Mon, 8:00 AM-11:30 AM

A randomized phase II neoadjuvant study (GeparNuevo) to investigate the addition of durvalumab, a PD-L1 antibody, to a taxane-anthracycline containing chemotherapy in triple negative breast cancer (TNBC). *First Author: Sibylle Loibl, German Breast Group, Neu-Isenburg, Germany*

Background: Adding an anti-PD-L1 checkpoint inhibitor durvalumab to standard chemotherapy (CT) may increase pathological complete response (pCR) in patients (pts) with TNBC. **Methods:** GeparNuevo randomizes pts to durvalumab (D) 1.5 g i.v. or placebo (pl) every 4 weeks (wks). D/pl monotherapy (0.75 g i.v.) is given for the first 2 wks (window phase), followed by a biopsy and D/pl plus nab-paclitaxel (nP) 125 mg/m^2 weekly for 12 wks, followed by D/pl plus epirubicin/cyclophosphamide (EC) q2 wks for 4 cycles. Randomization is stratified by stromal TILs (sTILs) (low (≤10%), intermediate (11-59%), high (≥60%)). Pts with primary cT1b-cT4a-d disease, centrally confirmed TNBC, and sTILs status can be included. Primary objective compares pCR (ypT0 ypN0) rates. Secondary objectives are pCR rates in stratified subpopulations and according to other pCR definitions; response rates; breast conservation rate; toxicity; compliance and survival. Change in sTILs, Ki67 and other immune biomarkers before CT, after the window phase and after CT will be correlated with outcome. The first 10, 20 and 30 pts will be included in safety interim analyses (SIA). Sample size was planned assuming a pCR rate of 48% for pl (nP treated TNBC cohort in GeparSepto) and of 66% for D (as clinically meaningful benefit), requiring 158 pts to show superiority of D (2-sided $\alpha = 0.2$, 80% power). Assuming a 10% drop-out rate 174 pts will be randomized. **Results:** Since 6/2016, 50 pts were recruited within 16 sites; data are presented as available until 01/2017. Median age is 49 years; 86% NST and G3 tumors; sTILs categories 40% low, 40% intermediate and 20% high. Blinded SIA was performed. No pt interrupted D/pl, one nP and one EC. Treatment delay was observed in 9 pts (20.0%) in D/pl, 18 (41.9%) in nP and 2 (13.3%) in EC; dose was reduced in 10 pts (23.3%) in nP and in 4 (26.7%) in EC. 10 pts (20%) had at least one grade 3-4 AE: 4 haematological and 6 non-haematological AEs. 4 SAEs and 5 immune related AEs were reported. 2 pts discontinued study treatment prematurely in the EC phase. **Conclusions:** The addition of D to standard nP-EC is feasible and does not result in an increased toxicity. Clinical trial information: NCT02685059.

3063 Poster Session (Board #158), Mon, 8:00 AM-11:30 AM

Atezolizumab (A) + cobimetinib (C) + vemurafenib (V) in BRAF^{V600}-mutant metastatic melanoma (mel): Updated safety and clinical activity. *First Author: Ryan J. Sullivan, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Targeted inhibition of MEK with C and BRAF with V in BRAF^{V600}-mutant mel can lead to both anticancer immune activation and direct tumor cell death. A, an anti–PD-L1 monoclonal antibody, inhibits PD-L1/PD-1 signaling. Combining C + V with A may enhance antitumor activity, potentially leading to improved clinical responses and durability. Preliminary data from this phase Ib study (NCT01656642) showed that A + C + V had a manageable safety profile and promising antitumor activity in patients (pts) with untreated BRAF^{V600}-mutant unresectable/metastatic mel, with increases in CD8-positive T-cell infiltration observed after C + V (Sullivan et al SMR 2016). We present updated safety and efficacy data. **Methods:** Pts received A + C + V after a 28-day run-in with C + V. A was given at 800 mg q2w, C at 60 mg qd for the first 21 days of each 28-day cycle, and V at 960 mg bid during day 1–21 of run-in and 720 mg thereafter. Safety was evaluated in pts who had ≥1 dose of A; efficacy, in pts who had ≥1 dose of A by the data cutoff date and received ≥1 dose of A, C, or V by the dosed-by date. **Results:** Thirty-four patients were treated and evaluated for both safety and efficacy. Median survival follow-up was 7.1 months (range 2.5–19.9). Elevated AST/ALT, diarrhea, arthralgia, fatigue, photosensitivity, pyrexia, nausea, flu-like symptoms, maculopapular rash, and pruritus were reported as A- and/or C- and/or V-related in > 20% of pts at any grade (G). A/C/V-related G3–4 adverse events (AEs) were seen in 15 pts (44.1%) with the triple combination (none G5). Three serious AEs were A-related. All AEs were manageable and reversible. Elevated ALT/AST (three pts each) and rash (one pt) led to discontinuation of any drug. Unconfirmed RECIST V1.1 responses were observed in 29 pts (85.3%; six complete, 23 partial). Three pts with confirmed partial responses had resolution of target lesions. Twenty of the 29 responding patients continue to respond at the time of the data cutoff. **Conclusions:** Updated results confirm preliminary findings that A + C + V has a manageable safety profile and promising antitumor activity in pts with BRAF^{V600}-mutant metastatic mel. Continued exploration of A + C + V is warranted. Clinical trial information: NCT01656642.

3064 Poster Session (Board #159), Mon, 8:00 AM-11:30 AM

DETERRED: PD-L1 blockade to evaluate the safety of lung cancer therapy using carboplatin, paclitaxel, and radiation combined with MPDL3280A (atezolizumab). *First Author: Steven H. Lin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint blockade in non-small cell lung cancer (NSCLC) may be enhanced when combined with radiation therapy. Atezolizumab (atezo) is a humanized and Fc receptor modified monoclonal antibody that blocks programmed death-ligand-1 (PD-L1) interacting with PD-1 or B7.1 sparing PD-L2, which may result in less pulmonary toxicity. We report the early safety data of combining atezo added sequentially after standard concomitant chemoradiation (CRT) for locally advanced NSCLC (LA-NSCLC). **Methods:** This is a phase II study in LA-NSCLC assessing the safety and feasibility of adding atezo to CRT in two parts: I) sequentially (N = 10) with CP after completing CRT, or II) concurrently (N = 30) with CRT followed by consolidation atezo with CP. We report on the early toxicity results from part I of the trial. Atezo was given at 1200 mg IV Q3 weeks with consolidation CP for 2 cycles after CRT followed by atezo monotherapy for up to one year. Radiation dose at 60-66 Gy in 30-33 fractions was combined with weekly low dose CP, followed by 2 cycles of full dose CP. Dose limiting toxicities were defined as any adverse events (AEs) ≥ grade 3 within 15 weeks of start of therapy or any immune-related AEs during atezo treatment. **Results:** From January to December 2016, 10 evaluable patients were enrolled. Seven patients have received consolidation atezo ranging from 1 to 14 doses, with 3 yet to receive atezo after completing CRT. Three patients reported potential immune-related AEs. One patient developed grade 3 arthralgia, and another developed grade 2 radiation-induced pneumonitis, which resolved with steroids. A third patient who experienced grade 3 dyspnea due to COPD exacerbation after 1 dose of atezo discontinued additional therapy. Of the 7 patients who have received atezo, 2 patients developed progression of disease after 6 and 8 doses of atezo. **Conclusions:** Atezo consolidation with 2 cycles of CP after CRT appears to be feasible and well tolerated with manageable toxicities. Additional data from part I will be reported. Conditions for proceeding after part I are met and part II of the study which adds atezo to CRT followed by atezo-CP consolidation is open for accrual. Clinical trial information: NCT02525757.

3066 Poster Session (Board #161), Mon, 8:00 AM-11:30 AM

A phase II randomized, double-blind study of sipuleucel-T followed by IDO pathway inhibitor, indoximod, or placebo in the treatment of patients with metastatic castration resistant prostate cancer (mCRPC). *First Author: Gautam Gopalji Jha, University of Minnesota, Minneapolis, MN*

Background: The indoleamine 2,3-dioxygenase (IDO) pathway is a key counter-regulatory mechanism exploited by tumors in order to prevent and defeat anti-tumor immunity. Sipuleucel-T has overcome this tumor mediated anergy only in part by its ex-vivo sensitization. Small-molecule inhibitors of the IDO pathway, such as indoximod, are an increasingly validated class of potential cancer therapeutics. We tested the hypothesis whether targeting the IDO pathway by indoximod will inhibit Treg and abrogate tumor-mediated immunosuppression permitting a robust and sustained immune response to sipuleucel-T. **Methods:** Patient (pts) with mCRPC received either indoximod or placebo orally for 10 weeks after completion of sipuleucel-T therapy. In the absence of radiographic or clinical progression, pts were continued on study drug for 3 more months. Immune monitoring was done similar to IMPACT study (NEJM 2010; 363:411-422) starting prior to sipuleucel-T therapy. The primary endpoint was augmentation of immune response to PA2024 measured at 14 weeks. Secondary endpoints include safety, clinical efficacy (PFS, OS) and HR-QOL **Results:** Of the 63 pts with CRPC screened, 46 eligible pts were randomized to indoximod (n = 22) or placebo (n = 24). Pts tolerated therapy with indoximod with no significant difference in adverse events between two arms. There was no difference in PSA progression nor difference in the primary endpoint of immune response to PA2024 for 35 pts who have completed study and have samples analyzed. Median OS has not yet been reached in the study. Median radiographic PFS was 10.3 months in the treatment arm vs 4.1 months in placebo arm ($p = 0.011$), 4.1 months being similar to PFS in the pivotal 'IMPACT' study. More Pts continued to complete maximum treatment on indoximod arm (40.9% vs 25%). **Conclusions:** Treatment with indoximod post sipuleucel-T therapy is well tolerated and led to a significant improvement in radiographic and clinical progression. Augmentation of immune response to PA2024 by ELISPOT or ELISA might not be right biomarker for augmented response assessment while studying inhibition of IDO pathway. Clinical trial information: NCT01560923.

3067 Poster Session (Board #162), Mon, 8:00 AM-11:30 AM

A phase I study of JS001, a humanized IgG4 mAb against programmed death-1 (PD-1) in patients with advanced solid tumors. *First Author: Zhihong Chi, Peking University Cancer Hospital and Institute, Beijing, China*

Background: JS001 blocks the interaction between PD-1 and its ligands and eradicates established tumor in human PD-1 Knock-in mouse model. **Methods:** A Phase I open-label study is designed to evaluate the safety and tolerability of JS001 in advanced solid tumor pts who are refractory to standard therapy. The study has a 3+3 dose escalation design with planned cohorts at 1, 3, and 10 mg/kg followed by a dose expansion. (Clinical Trial ID: NCT02836795). **Results:** As of January 27, 2017, pts enrollment has been completed with 36 pts from 3 indications (22 Melanoma; 9 Urothelial Carcinoma; 5 Renal Cell Carcinoma). The majority of melanomas are acral and mucosal origin. No DLT was observed and no MTD was reached in the study. The most common treatment-related AEs were grade 1/2, including hyper- or hypo-thyroidism (42%), rash (39%), fever (28%), leukopenia (22%), elevation of liver enzymes (19%), anorexia (17%), and fatigue (14%). Treatment–related grade 3 AEs include proteinuria (n = 1), and lipase increase (n = 2). The emergence of AEs is not dose related. JS001 PK shows dose-dependent exposure with the elimination half-life of 6 to 12 days. Among 32 evaluable pts, 1 pt have complete response (melanoma), 6 pts have partial response (3 melanoma, 2 RCC and 1 UC), and 10 pts achieve stable disease, for an ORR of 22% and a DCR of 53%. 6 out of 7 CR/PR pts still have ongoing response. Two groups of pts benefited most from JS001 treatment, pts with high tumor-infiltrating lymphocytes (TIL) (50% ORR) and pts with $>$ 1% PD-L1 expression in tumor biopsy (46% ORR). **Conclusions:** JS001 exhibited a favorable safety profile in human. Treatment related AEs are in line with those from approved drugs in the same class. JS001 has demonstrated promising anti-tumor activity, especially in previously under-evaluated acral (20% ORR, 53% DCR) and mucosal (25% ORR, 50% DCR) melanomas. Clinical trial information: NCT02836795.

3068 Poster Session (Board #163), Mon, 8:00 AM-11:30 AM

Racial disparities in the use of programmed death-1 checkpoint inhibitors. *First Author: Jeremy O'Connor, Yale School of Medicine, New Haven, CT*

Background: There are concerns about racial disparities in access to trials of new cancer drugs, including the programmed death 1 checkpoint inhibitors (anti-PD1s). It is unknown whether these disparities extend to anti-PD1 treated patients in real-world practice. **Methods:** We used retrospective data from Flatiron Health's electronic health record database, which includes more than 250 cancer clinics and 1.5 million patients with cancer. We identified patients diagnosed after January 1, 2011 who underwent systemic therapy for: advanced non-small cell lung cancer (aNSCLC; n = 13,473), metastatic renal cell carcinoma (mRCC; n = 1,537), and advanced melanoma (n = 1,221). Within each cohort, we identified treatment type (anti-PD1 versus non-anti-PD1). Therapy lines containing study drugs were excluded. We used logistic regressions to model the use of anti-PD1s by race, adjusting for factors such as age, sex, stage at diagnosis and line of therapy. **Results:** Of 16,231 patients in our sample, 4,643 (28.6%) were treated with anti-PD1s. Racial distributions differed for anti-PD1 treated patients compared to non-anti-PD1 treated patients in the aNSCLC cohort (Table: $p < 0.01$), but not in the mRCC cohort ($p = 0.84$) or the advanced melanoma cohort ($p = 0.96$). In bivariate analyses of patients with aNSCLC, anti-PD1 treatment was associated with other race, male sex, stage II at diagnosis, squamous histology, smoking history and line of therapy (all $p < 0.05$). Adjusted models showed there were no significant differences in likelihood of receiving anti-PD1s when comparing black and white patients undergoing systemic therapy for aNSCLC (aOR for black vs. white: 0.86, 95% CI 0.72-1.02), mRCC (aOR 0.90, 95% CI 0.53-1.49), or melanoma (aOR 2.02, 95% CI 0.42-14.59). **Conclusions:** Among patients undergoing systemic therapy in a large national network of cancer clinics, we found no significant racial disparities in the use of anti-PD1s.

	aNSCLC			mRCC			Melanoma

3069 Poster Session (Board #164), Mon, 8:00 AM-11:30 AM

Phase 1 study to evaluate the safety and tolerability of MEDI4736 (durvalumab, DUR) + tremelimumab (TRE) in patients with advanced solid tumors. *First Author: Margaret K. Callahan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: DUR is a human IgG1 monoclonal antibody (mAb) that blocks PD-L1. TRE is a human IgG2 mAb inhibitor of CTLA-4. Blocking these checkpoints can result in antitumor activity in some solid tumors. The targets for DUR and TRE are non-redundant, providing sound rationale for clinical testing of the combination. **Methods:** This is an ongoing Phase 1, multicenter, open label study (NCT01975831) with a dose escalation (3+3 design) and subsequent expansion phase. Patients (pts) with renal cell carcinoma (RCC), cervical (CC), colorectal (CRC), non-triple-negative breast (NTNBC), ovarian (OC), non-small cell lung, or head and neck cancer are eligible. Primary endpoints are safety/tolerability and identification of maximum tolerated dose (MTD) of the combination. Secondary objectives include tumor response and progression-free/overall survival. **Results:** As of 16 Dec 2016, 105 pts were treated. DUR 1500 mg every 4 weeks (Q4W) and TRE 75 mg Q4W X 4 was the regimen used for opening the expansion phase. Dose-limiting toxicities were reported in 4 pts: diarrhea, colitis, abnormal liver function tests (abn LFTs), and hyponatremia. The majority of treatment-related AEs (TRAEs) were Grades (Gr) 1 and 2. TRAEs $\geq$ Gr 3 were reported in 12 pts; the majority were diarrhea/colitis (n = 5) and abn LFTs (n = 4) and responded to established treatment algorithms. There was 1 Gr 5 TRAE: multi organ failure. No new toxicities were identified. The preliminary responses by tumor type with n $\geq$ 10 pts are shown in the table below. Responses were seen in OC and RCC at the Cohort 2 dose escalation level (DUR 1/TRE 3 mg/kg). There were 4 cases of SD $>$ 24 weeks: CC, n=2; CRC, n=1; OC, n=1. PD-L1 status was not tested. **Conclusions:** The DUR + TRE combination has a manageable safety profile, with preliminary evidence of clinical activity. These data support continued study of the combination therapy; the study is ongoing. Clinical trial information: NCT01975831.

		Preliminary Best Response by irRC		
Tumor Type	Evaluable Pts (n)	Stable Disease* (SD, n)	Partial Response (PR, n)	SD + PR Rate** (%)
CC	13	6	0	46.2
CRC	11	3	1	36.4
NTNBC	10	2	1	30.0
OC	25	10	2	48.0
RCC	11	8	1	81.8

*Includes pts with at least 1 post-baseline assessment (SD $\geq$ 6 weeks); majority observed $<$ 24 weeks; **No complete responses were observed

3070 Poster Session (Board #165), Mon, 8:00 AM-11:30 AM

Validation of the Princess Margaret immune oncology prognostic index (PM-IPI) for patients (pts) treated in immune oncology (IO) early phase trials. *First Author: Daphne Day, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: We previously developed the PM-IPI (ECOG performance status [PS] > / = 1, albumin < lower limit of normal [LLN] and > 2 metastatic sites) from a retrospective cohort of 192 pts treated in phase I IO trials (development cohort). The PM-IPI prognosticated for overall survival (OS), 90-day mortality (90DM) and was associated with improved overall response rate (ORR) and progression free survival (PFS). Our aim was to prospectively validate the PM-IPI in an independent cohort of pts treated on IO trials. **Methods:** We included 152 consecutively treated advanced solid tumor pts at PM from Aug 2015 to Aug 2016 in 24 IO early phase trials, targeting immune checkpoints and/or co-stimulatory molecules. Pts from the development cohort were excluded. The ability of the PM-IPI to prognosticate OS and 90DM, and predict PFS and ORR was compared with the previously published Royal Marsden Hospital prognostic score (RMI: albumin < 35g/L, LDH > upper limit of normal and > 2 metastatic sites) using the C-index (0.5 = no discrimination, 1 = perfect discrimination) and Area Under the Curve (AUC). **Results:** Median age was 59y (range 20-86), 28%/72% of pts were ECOG PS 0/1, and 88% had at least 1 prior systemic therapy (range 0-7). The most common tumor sites were gastrointestinal (23%), gynecological (16%), head and neck (15%) and urological (10%). Median PFS and OS were 9.0 and 39.7 wk respectively and 90DM was 14%. ORR was 7% by RECIST 1.1, immune related RECIST or immune related response criteria. In multivariable analysis, ECOG PS > / = 1 (HR 2.7, p = 0.01), albumin < LLN (HR 2.1, p = 0.01) and > 2 metastatic sites (HR 1.8, p = 0.04) were independently prognostic for OS. Pts with a PM-IPI score of 2-3 compared to 0-1 had significantly shorter OS (HR 3.3, p < 0.0001), PFS (HR 1.7, p = 0.005) and higher 90DM (OR 12.2, p = 0.019), and a trend towards lower ORR (OR 0.4, p = 0.15). The prognostic performance of PM-IPI was superior to the RMI for OS and 90DM, but not PFS and ORR (Table). **Conclusions:** In this independent validation cohort, the PM-IPI prognosticated for OS and 90DM and was associated with PFS. Validation in a large external cohort is ongoing.

	OS	PFS	90DM	ORR
	C-index		AUC	
PM-IPI	0.69	0.57	0.80	0.64
RMI	0.63	0.57	0.70	0.70

3071 Poster Session (Board #166), Mon, 8:00 AM-11:30 AM

Pembrolizumab therapy for microsatellite instability high (MSI-H) colorectal cancer (CRC) and non-CRC. *First Author: Luis A. Diaz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mismatch repair deficient cancers harbor high levels of microsatellite instability and somatic mutations. Treatment with anti-PD-1 antibodies has resulted in durable objective responses in MSI-H cancer. As part of the ongoing, global, multicenter phase 2 studies KEYNOTE(KN)164 and KN158, we assessed the efficacy of pembrolizumab in patients (pts) with MSI-H tumors. **Methods:** Both studies enrolled pts with MSI-H status determined locally by IHC or PCR. KN164 enrolled pts with MSI-H CRC and ≥2 prior therapies, whereas the multicohortKN158 study included pts with MSI-H non-CRC and ≥1 prior therapy. Eligible pts in both studies received pembrolizumab 200 mg Q3W until progression, unacceptable toxicity, or pt/investigator decision. Tumor response was assessed every 9 wk by independent review per RECIST v1.1. Primary endpoint was ORR. Secondary endpoints included DOR, PFS, OS, and safety. Analyses were performed in pts from KN164 and KN158 who had ≥27 wk of follow-up as of Aug 3, 2016 and Oct 19, 2016, respectively. **Results:** KN164 enrolled 61 pts with MSI-H CRC (90% with ≥2 prior therapies) whereas KN158 included 21 pts with MSI-H non-CRC (42% with ≥2 prior therapies). In KN158 the most common tumor types were endometrial and small intestinal cancer (n = 4 each), cholangiocarcinoma (n = 3), and gastric and pancreatic cancer (n = 2 each). Median follow-up was 7.4 mo for MSI-H CRC and 4.5 mo for MSI-H non-CRC. ORR for MSI-H CRC was 26.2% (95% CI, 15.8%-39.1%), with 15 confirmed responses and 1 unconfirmed response, and ORR for MSI-H non-CRC was 42.9% (21.8%-66.0%), with 8 confirmed responses and 1 unconfirmed response. DCR was 50.8% (n = 31; 37.7%-63.9%) for MSI-H CRC and 66.7% (n = 14; 38.4%-83.7%) for MSI-H non-CRC. Median duration of response was not reached for either MSI-H CRC or non-CRC, and 100% of responses were ongoing. Survival and safety analyses are ongoing. **Conclusions:** Early results from KN164 and KN158 confirm the robust antitumor activity of pembrolizumab in heavily pretreated pts with MSI-H cancers. Clinical trial information: NCT02628067; NCT02460198.

3072 Poster Session (Board #167), Mon, 8:00 AM-11:30 AM

Relationship between liver metastases and PD-1 blockade in melanoma. *First Author: James Chi-Chiang Lee, University of California, San Francisco, San Francisco, CA*

Background: WhilePD-1 blockade is effective in melanoma, durable responses remain elusive. We have previously reported that liver metastasis is associated with reduced response rates and that the fraction of CTLA4 hi/PD-1 hi CD8+ cells ("activated-exhausted" or T-ex cells) within the TIL is predictive of response to PD-1 blockade. Here, we explore the biology behind liver metastasis in human melanoma and in animal models. **Methods:** Patients with metastatic melanoma with or without liver metastasis were biopsied pre- PD-1 treatment and immune infiltrates were analyzed by FACS. The CD8 fraction was gated on CTLA4 and PD-1. C57BL/6 mice were implanted with a "primary" subcutaneous tumor and a "metastatic" tumor in the liver or the lungs (control), and given systemic PD-1 blockade therapy. **Results:** Patients with melanoma and liver metastasis (n = 25) had 15.2% T-ex cells while those without liver metastasis (n = 76) had 26.5 % T-ex cells, p = 0.0092. A T-ex fraction < 20% was significantly associated with lack of PD-1 response, p < 0.005. In C57BL/6 mice implanted with a B16 tumor (subQ & liver) treated with PD-1 antibody, 0/35 mice achieved subQ tumor rejection while in the SubQ only mice 9/30 mice (30%) rejected their tumors. The mean tumor size of mice with Sub Q+liver metastasis was 139.2 mm2 vs subQ only mice 23.4 mm2 at d 14, p = 0.002. Mice with liver metastasis showed a T-ex fraction 31.9% vs 67.3%without liver met, p = 0.0003. In contrast, in mice made lung metastatic, the subQ tumor rejection rate was 7/20 (35%), with T-ex infiltrate at 57.9%. The implantation of liver metastases from an unrelated MC38 tumor does not protect the subQ tumor from immune rejection. **Conclusions:** The presence of liver metastases is associated with reduced response to PD-1 blockade and reduced T-ex infiltrate in patients with stage IV melanoma. Mechanistic studies using a mouse model of syngeneic organ site specific metastasis confirms that the liver metastasis results in reduced antigen specific T cell at distant sites, resulting in reduced response. Site of metastasis may determine immune responsiveness in both mouse models and in humans with melanoma.

3073 Poster Session (Board #168), Mon, 8:00 AM-11:30 AM

Managing immune checkpoint-inhibitor-induced severe autoimmune-like hepatitis by liver-directed topical steroids. *First Author: Mirjana Ziemer, Department of Dermatology, Universtiy of Leipzig, Leipzig, Germany*

Background: The CTLA4-antibody ipilimumab, and PD-1-antibodies pembrolizumab as well as nivolumab have revolutionized antineoplastic therapies. Induction of autoimmune-like drug-induced liver injury (DILI) is within the spectrum of adverse reactions of these new drugs and has been observed in about 1-5 % of patients, developing predominantly within the first 6 to 12 weeks after start of treatment. Immediate application of systemic steroids and a permanent discontinuation of immune checkpoint-inhibition therapy are recommended for any alanine aminotransferase increase ≥ WHO grade 3. In severe autoimmune-like DILI the permanent discontinuation of the immune checkpoint inhibitor is recommended, as drug re-exposure might be associated with a significant risk of a fulminant DILI. **Methods:** We report six patients with severe grade 3 autoimmune-like DILI (according to Common Terminology Criteria for Adverse Events 4.3) treated with long-term application of budesonide, a liver-directed topical steroid. **Results:** Immune checkpoint inhibitors were stopped and methylprednisolone was applied initially with a dose of 1 mg/kg body weight and tapered thereafter. To reduce systemic steroids and to minimize the exposure time to systemic steroids, the topical steroid budesonide 3 mg three times per day was additionally given in combination with N-acetylcysteine and ursodeoxycholic acid. Under this multimodal approach transaminases normalized and the respective immune-checkpoint inhibitor could be re-started without re-manifestation of DILI under the continuous treatment with budesonide. **Conclusions:** Budesonide - a liver-directed topical steroid - might be an interesting approach to target liver related autoimmune adverse reactions induced by immune checkpoint inhibitors without compromising their anti-cancer effect. We were able to safely and effectively re-introduce and continue immune checkpoint inhibitors under the continuous application of the topical steroid without showing any further liver toxicity.

3074 Poster Session (Board #169), Mon, 8:00 AM-11:30 AM

Discovery of COM701, a therapeutic antibody targeting the novel immune checkpoint PVRIG, for the treatment of cancer. *First Author: Spencer Liang, Compugen Ltd., San Francisco, CA*

Background: While inhibitors of CTLA4 and PD1 have emerged as effective cancer therapies, the majority of treated patients do not derive long term benefit. Employing our computational discovery platform, we discovered PVRIG as an immune suppressive molecule expressed on T and NK cells and identified COM701, an antibody (Ab) targeting human PVRIG that enhances T cell function and anti-tumor responses. **Methods:** Anti-human PVRIG Ab COM701 was identified as an antagonistic Ab that enhanced T cell function in multiple assays. Antagonistic anti-mouse PVRIG Abs and PVRIG deficient ($PVRIG^{-/-}$) mice were generated and characterized using syngeneic tumor models. **Results:** PVRIG was induced upon T cell activation, with long term activation leading to the highest expression. PVRL2 was identified as the ligand for PVRIG, placing PVRIG in the DNAM/TIGIT immunoreceptor axis. Compared to normal adjacent tissues, PVRIG and PVRL2 were both induced in the tumor microenvironment of several human cancers. To target PVRIG for therapeutic intervention, we identified COM701, a high affinity Ab that disrupts the interaction of PVRIG with PVRL2. COM701 enhanced CD8 T cell proliferation and IFN-g production *in vitro* and had an additive or synergistic effect on T cell activation when further combined with an anti-PD1 or anti-TIGIT Ab. Consistent with a checkpoint function for human PVRIG, mouse $PVRIG^{-/-}$ T cells showed increased function compared to wild type T cells. A surrogate antagonistic anti-mPVRIG Ab reduced growth of CT26 and B16 tumors when combined with an anti-PDL1 Ab *in vivo*. MC38 tumors also grew slower in $PVRIG^{-/-}$ mice compared to wild type mice and ex vivo analysis pointed to functional differences in anti-cancer immunity. **Conclusions:** We demonstrated that targeting PVRIG with COM701, a high affinity antagonistic Ab, increased human T cell function. We further showed that PVRIG was induced in the tumor microenvironment and that disruption of PVRIG/PVRL2 interaction resulted in reduced tumor growth in preclinical models. These data demonstrate that PVRIG is a promising target for the treatment of cancer and provide the rationale for COM701 as a potential cancer immunotherapy.

3075 Poster Session (Board #170), Mon, 8:00 AM-11:30 AM

Phase 1 open-label, multiple ascending dose trial of AGEN1884, an anti-CTLA-4 monoclonal antibody, in advanced solid malignancies. *First Author: Breelyn A. Wilky, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: AGEN1884 is a fully human IgG1 monoclonal antibody targeting the co-inhibitory protein cytotoxic T lymphocyte-associated protein 4 (CTLA-4). CTLA-4 blockade has been shown to augment T cell activation and proliferation, resulting in immune infiltration of the tumor and subsequent regression. **Objectives:** Assess the safety, maximum tolerated dose (MTD), and pharmacokinetic (PK) and pharmacodynamic (PD) characteristics of AGEN1884 in patients (pts) with advanced and refractory malignancies using a "3+3" trial design. **Methods:** Eleven pts have been enrolled and treated to date. AGEN1884 was administered intravenously q3w for 4 doses and then q12w. Three (0.1, 0.3 and 1 mg/kg) of six (3, 6 and 10 mg/kg) planned dose levels have been completed. **Results:** Five pts were accrued at 0.1 mg/kg dose level (2 were not DLT evaluable) and three pts each at doses of 0.3 mg/kg and 1 mg/kg. Median age was 56 years (range 26–70), ECOG 0–2, with a median of 4 (range 1–8) prior therapies. No DLT events have been observed thus far. Data from 5 pts were available for PK evaluation. Half-life of AGEN1884 post first dose was 8.8 and 9.6 days for 0.3 mg/kg and 0.1 mg/kg dose levels, respectively, as measured by ELISA. As of Jan 31, 2017, pts across cohorts were followed for a median of 6 weeks (range 0-28). Six pts (54.5%) have come off study due to disease progression, while 5 (45.5 %) remain on study. One confirmed partial response (80% reduction) by RECIST criteria was seen at 0.1 mg/kg in a patient with angiosarcoma. **Conclusions:** AGEN1884 is safe at 0.1 and 0.3 mg/kg dose levels. Dose escalation is ongoing and updated safety and PK data will be presented. Clinical trial information: NCT02694822.

3076 Poster Session (Board #171), Mon, 8:00 AM-11:30 AM

Molecular characterization of immune-related severe adverse events (irSAE). *First Author: Justin M. Balko, Vanderbilt University Medical Center, Nashville, TN*

Background: Immune checkpoint inhibitors (ICIs; anti-CTLA-4 and anti-PD-1) have shown clinical success in many cancers, but may cause rare irSAE. The molecular features of irSAE have not been extensively explored. Therefore, we characterized the immune composition of tissue affected by ICI-mediated inflammation with a focus on colitis and neurologic toxicity. **Methods:** We performed retrospective T-cell receptor (TCRβ) sequencing, RNA-sequencing (HTG EdgeSeq; $>$ 2500 immune-related genes), and digital spatial profiling (NanoString) for 20 protein markers in 10 regions across tissues representing ICI-induced colitis, autoimmune inflammation (e.g. Crohn's) and normal colon. Matched tumors were also included in a subset. We also analyzed the encephalitic and healthy brain of a unique presentation of anti-PD-1-induced encephalitis. **Results:** Patient-matched melanoma and colitis biopsies (n = 3) demonstrated shared T cell clones in all samples ranging from several shared clones to several hundred (0.4%, 2.7%, and 3% of rearrangements, respectively), including high-frequency clones. Shared TCRβ sequences were also identified among and between colon-irSAE and Crohn's specimens. Gene expression patterns of inflammation in colon-irSAE resembled that of Crohn's disease in principle components and clustering analysis, highlighting likeness between these diseases/SAEs. NanoString digital spatial profiling of regions of inflammation across samples showed higher CD68 and PD-L1 positivity in colon-irSAE specimens versus normal colon or Crohn's specimens and reduced beta-catenin levels in both Crohn's and colon-irSAE specimens relative to normal controls. Finally, we detected a high degree of TCR clonality in the encephalitic brain, including a single sequence present in ~20% of $>$ 12,000 T cells, suggesting a distinct antigen-specific response. **Conclusions:** We report the molecular characteristics of irSAE in colon and brain specimens from patients receiving ICIs. Highly clonal TCRβ sequences were frequently detected, particularly in a unique case of encephalitis-irSAE. Furthermore, we identify molecular distinctions and similarities between autoimmune and colon-irSAEs at the gene expression and proteomic levels.

3077 Poster Session (Board #172), Mon, 8:00 AM-11:30 AM

Interrogating resistance mechanisms to PD-1 blockade therapy with CRISPR. *First Author: Davis Yuri Torrejon, University of California Los Angeles Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: We tested the biological significance of the loss of function (LOF) mutations in JAK1 or JAK2 within the IFN-receptor-pathway and in beta-2-microglobulin (B2M), which had been found in patient biopsies with resistance to anti-PD-1 therapy. **Methods:** We used CRISPR/Cas9 genome editing to generate JAK1, JAK2 and B2M knockout (KO) sublines of HLA-A*02:01 MART-1 or NY-ESO-1 positive human melanoma cell lines, tested using *in-vitro* T cell co-culture systems and in a syngeneic mouse model (MC38) to analyze the *in-vivo* antitumor activity with anti-PD1 therapy. **Results:** The JAK2-KO cell line was insensitive to IFN-gamma induced signaling and growth arrest ($p < 0.001$ compared with IFN-alpha or beta), while the JAK1-KO cell line was insensitive to all three IFNs. Baseline MHC class I expression after JAK1-KO was unaffected (baseline-MFI 1230 JAK1-KO vs 1570 parental, $p = 0.66$), but the magnitude of change was lower upon IFN-gamma exposure compared to the parental (MFI change with IFN-gamma, 26% decrease for JAK1-KO vs 50% increase for parental). There was no difference in *in-vitro* cytotoxicity by NY-ESO-1-TCR transgenic T-cells against JAK1-KO-NY-ESO-1+ melanoma cells compared to the parental (78% vs 82% cytotoxicity at 10:1 E:T ratio, p NS). However, B2M-KO was resistant to killing by MART-1 specific T-cells (2% vs 96% cytotoxicity at 10:1 E:T ratio, $p < 0.0001$). On the other hand, in the MC38 model the significant antitumor activity of anti-PD-1 against the wild type cells was lost in both JAK2-KO and B2M-KO. The percentage of CD8+ T cells has a trend of increase with anti-PD1 compared to untreated in the MC38 wild type ($p = 0.1$ d12), and a trend of decrease in MC38 B2M-KO ($p = 0.2$ d12), but no change in JAK2-KO tumors ($p = 0.7$ d12). **Conclusions:** JAK1/2 LOF mutations result in insensitivity to IFN induced antitumor effects, but does not impair T cell recognition and cytotoxicity, while B2M LOF results in lack of antigen presentation to T cells and loss of antitumor activity. However both lead to in-vivo resistance to anti-PD-1 therapy, suggesting they do so by independent mechanisms.

3079 Poster Session (Board #174), Mon, 8:00 AM-11:30 AM

Mutually exclusive expression of CD73 and PDL1 in tumors from patients (pt) with NSCLC, gastroesophageal (GE) and urothelial bladder carcinoma (UBC). *First Author: Philip Martin, Medimmune/AstraZeneca, Gaithersburg, MD*

Background: Tumors use multiple means of immune evasion, notably the programmed death-1 (PD1)/PDL1 pathway. Anti-PD1/PDL1 therapy induces anti-tumor activity and has improved pt outcomes. Activation of the immunosuppressive CD39/CD73/adenosine pathway might play a role in pts who do not benefit from anti-PD1/PDL1 therapies. We evaluated expression of CD73 and PDL1 and explored the association between CD73 and intraepithelial (IE) CD8+ cells (TILs) to begin to understand their potential interplay in cancer. **Methods:** Immunohistochemistry for PDL1, CD73 and CD8 was conducted on tumors of non-squamous NSCLC (NSq) (n=42), GE (n=50), and UBC (n=50). PDL1 and CD73 were scored by image analysis with Definiens software. IE CD8+ TILs were scored semi-quantitatively by a pathologist (0-2 = low; 3-4 = high). Using the top tertile of PDL1 and CD73 for high expression levels, a Fisher's meta-analysis was calculated across the three indications. **Results:** Across all tumors, 25% (35/142) were PDL1 high (+), but CD73 low (-) and another 25% (35/142) were CD73+ but PDL1- (p=0.06, see table). This trend for mutually exclusive high expression of PDL1/CD73 was strongest in GE ($p<0.01$). In the PDL1+ group 76% (35/46) had high IE CD8+ TILs whereas in the CD73+ group only 35% (16/46) had high TILs ($p<0.0001$ using a proportions test). In the PDL1+/CD73- pt subset 77% (27/35) were CD8+ high vs only 23% (8/35) in the PDL1-/CD73+ subset. **Conclusions:** The identification of distinct pt subsets based on high PDL1 and/or CD73 expression suggests that tumors have multiple mechanisms of immune evasion. Increased IE CD8+ TILs were associated with PDL1 expression. The finding that PDL1-/ CD73+ tumors have lower IE CD8+ TILs compared to PDL1+/CD73- tumors suggests a role for CD73 in excluding IE TILs. Larger sample sets are needed to confirm these findings and to further explore any relationship with the tumor microenvironment. Our data suggests potential approaches to identify subsets of pts likely to benefit from immunotherapy targeting PDL1 and CD73.

	PDL1-/CD73-	PDL1+/CD73-	PDL1-/CD73+	PDL1+/CD73+
NSq (n=42)	48%	19%	19%	14%
UBC (n=50)	44%	24%	24%	8%
GE (n=50)	38%	30%	30%	2%
Total (n=142)	43%	25%	25%	8%

3080 Poster Session (Board #175), Mon, 8:00 AM-11:30 AM

Characterization of the T-cell receptor repertoire and immune microenvironment in patients with locoregionally advanced squamous cell carcinoma of the head and neck. *First Author: Vassiliki Saloura, University of Chicago Medical Center, Chicago, IL*

Background: Immunotherapy with checkpoint blockade was recently approved for patients with recurrent/metastatic SCCHN, however it has not been investigated in the curative-intent setting yet. In this study, we investigated the T-cell receptor repertoire and the immune microenvironment in tumor tissues of SCCHN patients with locoregionally advanced disease. **Methods:** T-cell receptor sequencing and polymerase chain reaction for immune-related genes of tumor tissues from 44 patients with locoregionally advanced SCCHN prior to treatment with definitive chemoradiotherapy were conducted. T-cell receptor clonality and the mRNA expression levels of immune-related genes were correlated with various clinicopathological parameters. **Results:** In patients with locoregionally advanced SCCHN, tumor infiltrating T-cells clonally expand and*GRZB* mRNA levels were associated significantly with longer progression-free survival (PFS) ($p = 0.003$) independent of HPV status, tumor and nodal stage. The TCR-β DI was significantly lower in HPV-negative compared to HPV-positive tumors ($p = 0.002$), signifying more clonal T-cell expansion in HPV-negative tumors. A higher percentage of HPV-negative tumors expressed HLA-A protein compared to HPV-positive tumors ($p = 0.049$), suggesting that the greater T-cell clonal expansion might be due to more robust antigen presentation by HPV-negative tumors. **Conclusions:** This study suggests the pre-existence of clonally expanded T-cells in patients with locoregionally advanced SCCHN prior to treatment, and provides rationale to introduce immunotherapy in the curative-intent setting. The association of high *GRZB* mRNA levels with favorable PFS independent of HPV-status, tumor and nodal stage supports that the pre-existence of an intrinsically inflamed microenvironment enhances chemoradiotherapy effects. Finally, in HPV-positive tumors, the T-cell infiltrate seemed to be more diverse which could be secondary to virally-induced defective expression of HLA class I molecules.

3081 Poster Session (Board #176), Mon, 8:00 AM-11:30 AM

Ensituximab (E) in patients (pts) with refractory metastatic colorectal cancer (mCRC): Results of a phase I/II clinical trial. *First Author: Richard D. Kim, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: E is an investigational, novel, chimeric monoclonal IgG1 antibody derived from an immunogenic neoantigen with sequence homology to MUC5AC that is preferentially expressed with exquisite specificity to pancreatic cancer and CRC. Its mechanism of action is via antibody-dependent cellular cytotoxicity (ADCC). The efficacy and safety of E was evaluated in a single-arm, open-label, phase 1/2 clinical trial of adult pts with refractory mCRC. **Methods:** Pts were selected based on > 20% expression of tumor antigen, as measured by immunohistochemistry. Based on phase 1 results, E was administered 3 mg/kg IV every 2 weeks until unacceptable toxicity or disease progression. Primary endpoint was overall survival (OS). Serum cytokine levels were analyzed at baseline, day 4, and day 15. E-mediated ADCC of CD16 genotype V/V, V/F, and F/F pt PBMCs was measured with an IN-111 release assay using the E target-expressing ASPC-1 pancreatic cancer cell line. **Results:** Fifty-seven and 63 pts were evaluable for OS and safety, respectively. Median OS was significantly longer than historical control: 6.8 vs 5.0 months (mo); $p = 0.007$; 95% CI: 5.39,8.02. Three pts were alive at end of study (21, 21, and 24 mo); 21 pts survived ≥ 12 mo. Pts had a median of 4 prior therapies (range 2-9); 25% had received regorafenib. Forty-seven pts were evaluable by RECIST, and 20 (43%) had stable disease of target lesions at end of first course (day 57). E was well tolerated, with < 2% grade 3 and no grade 4 toxicities. There were no trends in serum cytokine and chemokine levels. Analysis of 56 samples (8 V/V, 26 V/F, 17 F/F, and 5 undetermined) showed that V/V PBMCs had significantly higher E-mediated ADCC than PBMCs harboring other genotypes. No correlation between CD16 polymorphism and pt outcome was observed. **Conclusions:** E demonstrated excellent tolerability and encouraging OS in this heavily pretreated population. Correlative in vitro data suggest that E can mediate higher levels of ADCC activity in individuals with a V/V versus other genotypes. The lack of correlation between CD16 polymorphism and pt outcomes in this study suggests that other immune-related factors (under investigation) may impact the efficacy of E in vivo. Clinical trial information: NCT01040000.

3082 Poster Session (Board #177), Mon, 8:00 AM-11:30 AM

First-in-human clinical trial with intratumoral BO-112 in solid malignancies: A novel immunotherapy based in double-stranded RNA (dsRNA). *First Author: Ivan Marquez Rodas, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: BO-112 is a double stranded synthetic RNA, formulated with the cationic carrier polyethyleneimine that preclinically improves its intracellular delivery and resistance towards nuclease degradation. In melanoma mouse models, systemic administration activates MDA-5 and NOXA, leading to anti-tumoral activity connected to a sustained and extended expression of IFN-response genes. Intratumoral (IT) delivery, seeking a safer and more focused enhancement of local and systemic antitumor effects has been tested in transplanted mouse models. The potential of its IT use as an immune-modulatory treatment, as well as its toxicity profile, is being analyzed in this first in human, proof of concept, clinical trial (NCT02828098). **Methods:** Four patients with malignant solid tumors and palpable cutaneous/subcutaneous or lymph node metastases >1 cm were treated with a single BO-112 dose of 0.6 mg/ml IT. Pre and post treatment biopsies from the injected metastatic lesion were obtained. Pharmacokinetics, serum cytokines and circulating immune cells were sequentially studied in pre and post treatment samples. **Results:** Patients did not experience relevant toxicity with the exception of a single episode of completely reversible grade 4 thrombocytopenia in one patient, attributed to the drug. BO-112 was not detectable in bloodstream following IT delivery. No changes in circulating cytokines were detected. Main immunobiological effects are summarized in the table. **Conclusions:** BO-112 has shown changes in tumoral immune cells in 1/4 patients, while in 3/4 induced both necrosis and changes in circulating immune cells. This ongoing trial will compile more safety data with repeated sequential administrations, escalated to higher doses of BO-112, and will thoroughly characterize its biological effects in humans with solid malignancies amenable to IT injection. Clinical trial information: NCT02828098.

Patient	Tumor	G3-4 AE	CD4/CD8 Infiltrate increase	Necrosis	Increased circulating immune cells
1	Melanoma	Thrombocytopenia	NA	NA	CD8, CD4reg, NK
2	Neuroendocrine	No	+	+	CD8, CD4, CD4reg, monocytes
3	Triple negative breast cancer	No	-	+	CD8, CD4, CD4reg, monocytes
4	Melanoma	No	-	+	CD4reg, monocytes, NK

3083 Poster Session (Board #178), Mon, 8:00 AM-11:30 AM

An open-label, multi-center phase I study of the safety and tolerability of the novel immunomodulatory agent PG545 in subjects with advanced solid tumors. *First Author: Keith Dredge, Zucero Therapeutics Pty. Ltd., Brisbane, Australia*

Background: PG545 (pixatimod, pINN) is a novel immunomodulatory agent which stimulates dendritic cells (DC) via TLR9/IL-12 pathway to activate natural killer (NK) cells. It also inhibits tumour-associated macrophages in cancer models. We report on safety, PK, PD, and antitumor activity of PG545 monotherapy. **Methods:** In this dose escalation (3+3 design) study, eligible pts (ECOG≤1) with advanced solid malignancies who failed standard therapies received PG545 once weekly as a 1-hour i.v. infusion until disease progression or discontinuation due to intolerability. The primary objective was determination of the maximum tolerated dose (MTD). Secondary objectives evaluated safety, antitumor activity based on RECIST (1.1) criteria, PK and PD (plasmacytoid DC & NKp46$^+$NK cells from PBMC, and plasma cytokines/chemokines). **Results:** The study recruited 23 subjects across four cohorts (25, 50, 100 & 150 mg). Three dose limiting toxicities (DLTs) - hypertension (2), epistaxis (1) - occurred in the 150 mg cohort, which was identified as a non-tolerated dose level. No DLTs occurred in the 100 mg cohort, which was identified as the MTD. Six SAEs were reported to be possibly or likely related to PG545 treatment. No RECIST 1.1 objective responses were reported; best response was prolonged stable disease up to 24 weeks (mCRC), with disease control rate in evaluable subjects of 38% (6/16) at eight weeks. Exposure ($AUC_{0\text{-}last}$) was proportional up to 100mg and mean half-life was 144 hours. At 50 and 100mg dose levels, two subjects in each cohort exhibited up to 4-fold increased numbers of NKp46$^+$NK cells, IFN-α-producing pDCs, and increases (up to 25-fold) in plasma IFN-γ, TNF-α, IP-10 and MCP-1. **Conclusions:** PG545 is well tolerated up to 100 mg once-weekly via i.v. infusion. Human exposure data at 50mg and 100mg reach exposures consistent with those required for preclinical efficacy. Preliminary PD data support the proposed mechanism of action, which represents a promising approach to improve the efficacy of existing therapies. These data, and the absence of toxicities associated with chemo- or immunotherapies, support the development of PG545 in combination clinical trials. Clinical trial information: NCT02042781.

3084 Poster Session (Board #179), Mon, 8:00 AM-11:30 AM

PEGylated human IL-10 (AM0010) in combination with pembrolizumab in anti-PD1 and CTLA-4 refractory melanoma. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Melanoma has a high response rate to anti-PD-1 alone. More than 50% of melanoma on anti-PD-1 progress within one year. IL-10 inhibits inflammation and stimulates the cytotoxicity and proliferation of tumor infiltrating CD8+ T cells at higher concentrations. IL-10 receptors and PD1 are induced on activated CD8 T cells, providing a mechanistic rationale for combining AM0010 and anti-PD1. AM0010 alone has established tolerability and anti-tumor activity in a phase 1 study. Objective responses were observed in 4 of 15 pts with RCC, one patient with uveal melanoma and cutaneous T cell lymphoma, each. **Methods:** 25 melanoma pts who had progressed on prior anti-CTLA4 and on prior anti-PD-1 containing regimen were treated with AM0010 (20mg/kg qd, SQ) and pembrolizumab (2mg/kg, q3wk IV). Patients had a median of 3.5 prior therapies (range 2-6) and a median of 2 prior immune therapies (range 1-6). Tumor responses were monitored following irRC. Immune responses were measured by analysis of serum cytokines, activation of blood derived T cells and peripheral T cell clonality. **Results:** AM0010 plus pembrolizumab was well tolerated. All treatment related adverse events (TrAE) were reversible. DLTs and SAEs leading to study discontinuation were not observed. G3/4 TrAEs were observed in 11 of 25 pts and included fatigue (8) thrombocytopenia (6), anemia (4), rash (1) and hypertriglyceridemia (1). There were no objective tumor responses. 9 of 20 evaluable pts had stable disease (DCR = 45%). As of Jan. 31 2017, the mPFS was 2.0 mo. and the mOS was not reached, with a mFU of 15.5 mos (range 10.0-18.4). AM0010 plus pembrolizumab increased Th1 cytokines as well as the number and proliferation of PD1+ Lag3+ activated CD8 T cells in the blood while reducing inflammatory cytokines and TGFb. A de-novo oligoclonal expansion of T cell clones in the blood and an increase of tumor infiltrating Granzyme+ PD1+ CD8+ T cells in tumor biopsies of treated patients was observed. **Conclusions:** AM0010 in combination with anti-PD1 is well-tolerated in refractory melanoma pts. The clinical activity and the observed CD8+ T cell activation may suggest to study AM0010 in combination with an anti-PD-1 in melanoma patients with less prior treatments. Clinical trial information: NCT02009449.

3085 Poster Session (Board #180), Mon, 8:00 AM-11:30 AM

LTX-315, an oncolytic peptide, to convert immunogenically 'cold' tumors to 'hot' in patients with advanced or metastatic tumours: Results from an ongoing phase I study. *First Author: James F. Spicer, King's College London, London, United Kingdom*

Background: Intratumoral LTX-315 disintegrates cytoplasmic organelles with release of tumor antigens in preclinical models accompanied by increase in tumor-infiltrating lymphocytes (TILs). LTX-315 induced complete regression in several rodent models, with systemic immune responses. LTX-315 is strongly synergistic preclinically with immune checkpoint inhibitors (ICI). We are conducting a phase 1 trial to evaluate LTX-315 in combination therapy. **Methods:** Patients with advanced metastatic solid tumours received injections of LTX-315 into a single accessible tumour over 6 weeks. Additional injections could be administered thereafter every 2 weeks. Biopsies of injected lesions were taken at baseline, and on treatment. **Results:** 28 have been enrolled to date, median age is 58 (range 32-80) and median prior treatments 2 (range 1-14). LTX-315 monotherapy was administered at doses of 2-7mg to a median of 1.8 tumour lesions (range 1-6) for a median of 9 weeks (range 1-33). In 24 patients all LTX-315-related adverse events were CTC grade 1 or 2, most commonly local erythema, flushing, pruritis and hypotension, most resolving within minutes of injection. Related grade 3 (3 patients) or 4 (1) allergic/anaphylaxis adverse event occurred and resolved without sequelae. Best response in 44 injected lesions in 20 evaluable patients included 2 complete responses, > 50% reduction in 5 tumours, and 20 stable (injected). Significant increases in TILs occurred in 67% (14 of 21) patients with biopsies of injected tumours available. Regression of distant non-injected tumour has been observed clinically on biopsy (abscopal effect). No irRC response in non-injected tumours has been observed in 16 evaluable patients. Stable disease (median duration 14 weeks) occurred in 50% of patients as best response (melanoma (4), sarcoma (3), breast (1)). **Conclusions:** This phase 1 study demonstrates that intratumoural LTX-315 has a manageable safety profile and induces increases in TILs in pre-treated patients. Partial and complete regression was seen in some injected tumours. Evaluation of LTX-315 in combination with ICIs in breast and melanoma is ongoing. Clinical trial information: NCT01986426.

3086 Poster Session (Board #181), Mon, 8:00 AM-11:30 AM

A phase I study of novel multi-HLA-binding peptides and a new combination of immune adjuvants against solid tumors. *First Author: Hiroto Matsui, Department of Gastroenterological, Breast and Endocrine Surgery, Yamaguchi University, Ube, Japan*

Background: Based on the exploratory analysis of our previous studies of peptide vaccine, we concluded that the combination of adjuvants hLAG-3Ig + Poly-ICLC is essential for controlling negative immune checkpoints and enhancing the induction of CTLs to overcome the traditional peptide studies. Another issue with peptide vaccines is human leukocyte antigen (HLA) restriction. Hence, we developed novel multi-HLA-binding peptides derived from the tumor antigens, HSP70 and GPC3, and confirmed the high expression in many types of cancer. **Methods:** For the identification of peptides, HSP70- and GPC3-derived peptides that have high binding affinity to each of HLA-A2402, 0201, and 0206 were selected as candidate peptides by a binding prediction system (NEC Corporation). We then identified priority candidate peptides by using a peptide-binding assay. Using peripheral mononuclear blood cells from cancer patients, CD8+ T lymphocytes were stimulated with the candidate peptides, and an enzyme-linked immunospot assay was performed. Finally, we identified HSP70- and GPC3-peptide. In this phase I study of a novel peptide cancer vaccine for metastatic solid cancer, primary objective was to evaluate its safety and toxicity. Secondary objective was to examine the immune and clinical response, and also to determine the recommendable dose. This study used a three-tiered dose-escalation strategy with 3 patients' cohorts. In addition to the 3 scheduled cases, 3 more cases were added and 6 cases were enrolled at the recommended dose. **Results:** Twelve HLA-A*24:02-, 02:01-, and 02:06-matched patients (esophagus, 3; colon, 4; liver, 3; pancreas, 1; stomach, 1) were treated in this study. No severe adverse effects related to the treatment were encountered. Peptide-specific CTL induction with HSP70 and GPC3 was observed in 10 and 11 patients, respectively. We observed decreased tumor marker expression in 6 cases, and disease control was observed in f5 patients (4, 3, 8, 2, 2 months, respectively). **Conclusions:** The combination cancer vaccine therapy using multi-HLA-restricted peptides and hLAG-3Ig + Poly-ICLC was safe and effective for treating solid tumors; it therefore warrants further clinical studies. Clinical trial information: UMIN000020440.

3087 Poster Session (Board #182), Mon, 8:00 AM-11:30 AM

Results of a first-in-human phase I study of INVAC-1, an optimized plasmid DNA encoding an inactive form of human telomerase reverse transcriptase (hTERT), in patients with advanced solid tumors. *First Author: Luis Teixeira, Service d'Oncologie Médicale, Hôpital Saint-Louis, APHP, Paris Diderot University, Paris, France*

Background: INVAC-1 is an optimized plasmid encoding an inactive form of human telomerase reverse transcriptase (hTERT). hTERT is a prototype of shared tumor antigen expressed in more than 85% of human tumors. Telomerase activation is associated with maintenance of telomere length and accounts for the unlimited proliferative capacity of cancer cells. In preclinical models, INVAC-1 triggered Th1-polarized hTERT-specific $CD8^+$ and $CD4^+$T-cell immune responses and anti-tumor effects. Here, we report clinical and pharmacodynamics results of the first clinical study with INVAC-1 as a single agent in solid tumors. **Methods:** A 3+3 design phase 1 First in Human study evaluating INVAC-1 given monthly for 3 cycles using electroporation-based intra-dermal (ID) injection was conducted. Primary objectives included safety, tolerability and dose limiting toxicities to identify the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Secondary objectives included immune response and anti-tumor activity. **Results:** 20 patients (pts) with refractory/progressive solid tumors were enrolled in two centers. 3 escalating doses were studied: 100 μg (3 pts), 400 μg (3 pts) and 800 μg (14 pts). At 3-month data cut-off, no dose limiting toxicities or treatment related SAEs have been reported; no MTD was defined. The most common treatment-related adverse events were grade 1 or 2: asthenia and local reaction at injection site. 12 pts experienced stable disease and clinical benefit. For 10 pts, the treatment was extended beyond the per-protocol 3-month duration, up to nine months for 2 pts. IFN-g polarized anti-hTERT immune responses were detected in 55% of pts, in response to INVAC-1 treatment. **Conclusions:** Results from this study indicate that INVAC-1 ID was safe, well tolerated and strongly immunogenic at the doses and schedule tested. Early anti-tumor activity has been observed. The RP2D of INVAC-1 is therefore a monthly ID injection of 800 μg. These results encourage a future evaluation of INVAC-1 is solid tumors, as well as in hematologic malignancies, either as monotherapy or in combination with various immunotherapeutic drugs. Clinical trial information: NCT02301754.

3088 Poster Session (Board #183), Mon, 8:00 AM-11:30 AM

Subgroup efficacy evaluation of the AE37 HER2 vaccine in breast cancer patients in the adjuvant setting. *First Author: Kaitlin M. Peace, San Antonio Military Medical Center, San Antonio, TX*

Background: AE37 is a Ii-Key hybrid of the HER2 peptide AE36 ($HER2_{776\text{-}790}$), which stimulates peptide-specific T cells. We have completed the active phase of a prospective, randomized, multi-center, phase II trial of the AE37 vaccine in the adjuvant setting. The primary analysis, performed after a median follow up (f/u) of 25 months (mo), did not show a significant difference in disease free survival (DFS) between vaccinated and control patients (pts). However, demonstrating the efficacy of cancer vaccines may require more time than other therapies, especially in malignancies with relatively late recurrences like breast cancer. Here, we present updated efficacy data after extended f/u in subgroups of pts stratified by clinicopathologic characteristics. **Methods:** Clinically disease-free, node positive or high-risk node negative pts with any level of HER2 expression were randomized to receive AE37 + GM-CSF (VG) or GM-CSF alone (CG) following standard of care therapy. Pts received 6 monthly intradermal inoculations during the primary vaccine series (PVS) followed by 4 boosters administered every 6 mo. Kaplan Meier and log rank analyses were performed from the time of the first inoculation in pts who completed at least the PVS, according to stage, node status, tumor size, HER2 expression and ER/PR status. **Results:** There were no clinicopathologic differences between groups in the 298 enrolled pts (VG = 153, CG = 145). The vaccine is safe and well tolerated. After a median f/u of 55 mo, there was a trend toward improved DFS in the VG among stage IIB/III pts (VG, n = 73, DFS 82% vs CG, n = 61, 67%, HR = 0.48, p = 0.06) and those with low HER2 expression (HER2 LE, VG, n = 68, 89% vs CG, n = 66, 51%, HR = 0.47, p = 0.1). Improved DFS in the VG was documented in patients with both stage IIB/III disease and HER2 LE (VG, n = 39, 90% vs CG, n = 38, 32%, HR 0.3, p = 0.02) and triple negative (TNBC) pts (VG, n = 21, 89% vs CG, n = 21, 0%, HR 0.26, p = 0.05). **Conclusions:** The AE37 vaccine is safe and well tolerated and has statistically significant efficacy in stage IIB/III pts with HER2 LE and in TNBC pts. This justifies further evaluation in a phase III study enrolling stage IIb/III pts not eligible for trastuzumab treatment and the very high risk TNBC group. Clinical trial information: NCT00524277.

3089 Poster Session (Board #184), Mon, 8:00 AM-11:30 AM

Association of autologous AdHER2 dendritic cell vaccination with antitumor activity and number of circulating tumor cells. *First Author: Lauren Virginia Wood, Vaccine Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: We achieved cure of large established tumors in syngeneic BALB/c mice using an adenoviral vector vaccine expressing rodent HER2 extracellular (EC) and transmembrane (TM) domains mediated by the induction of anti-HER2 antibodies. We report clinical translation utilizing an autologous adenoviral- transduced dendritic cell (DC) vaccine expressing human HER2 EC and TM domains (AdHER2ECTM) in adults with advanced metastatic tumors with 1-3+ HER2 expression. **Methods:** In this two-part phase I study (NCT01730118) subjects with HER2+ metastatic solid tumors naïve to HER2-targeted therapies (Part 1) or HER2+ treatment-experienced breast cancer (Part 2) received 5 doses of vaccine at Weeks 0, 4, 8, 16 and 24. Part 1 dose escalation involved 3 cohorts of 6 patients utilizing $5x10^6$, $10x10^6$ and $20x10^6$ viable DCs per dose, respectively. With no DLTs or evidence of cardiac toxicity, dose escalation to $40x10^6$ viable DCs per dose was allowed in the Part 1 Expansion Cohort and Part 2 treatment was begun at a starting dose of $20x10^6$ viable DCs per vaccine. Adjuvant muscle-invasive bladder cancer patients were allowed to enroll with safety documented out to 12 weeks in > 10 treated patients. Re-staging was assessed using immune-related response criteria (irRC). Remaining study accrual: Part 1 (N = 9), Part 2 (N = 24). **Results:** A total of 27 cancer patients (7 colon, 6 breast, 5 ovarian, 3 bladder, 6 other) have received > 2 vaccine doses (median 4): 19F, 8M, median age 60 yrs, median 3 prior treatment regimens (range 1-11); HER2 IHC 1+ N = 6, 2+ N = 9, 3+ N = 12. Of metastatic patients receiving $10x10^6$viable DCs per dose or higher, 7 of 19 (37%) had evidence of response by irRC: 1 CR (ongoing at 100 weeks), 1 PR (-71% lasting 44 weeks) and 5 SD (median duration 24 weeks, range 8 to 48 weeks). Two adjuvant bladder cancer patients remain without disease at 100 weeks. Adverse events were limited to local injection site reactions < G2. Of patients with paired baseline samples, 40% (8/20), 83% (5/6) and 100% (2/2) exhibited decreases in circulating tumor cells at 12, 28 and 48 weeks, respectively. **Conclusions:** AdHER2 DC vaccination is safe and is associated with evidence of clinical benefit and anti-tumor activity. Clinical trial information: NCT01730118.

3090 Poster Session (Board #185), Mon, 8:00 AM-11:30 AM

Association of CMB305 or LV305-induced and baseline anti-NY-ESO-1 immunity with survival in recurrent cancer patients. *First Author: Seth Pollack, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The correlation of immune response (IR) and clinical benefit in patients (pts) who receive active immunotherapy remains controversial. CMB305 is an active immunotherapy designed to generate and expand anti-NY-ESO-1 T cells, consisting of LV305 (a DC targeting lentiviral vector encoding NY-ESO-1) and a boost (NY-ESO-1 recombinant protein plus GLA-SE, a TLR-4 agonist). Phase 1 studies of LV305 and CMB305 evaluated the IR and survival of pts with NY-ESO-1 positive tumors. **Methods:** 62 pts with recurrent NY-ESO-1 expressing (by IHC) solid tumors were enrolled in 2 Phase 1 trials (31 pts each: 43 sarcomas, 12 ovarian, 4 melanomas, and 3 NSCLC). Peripheral blood was assessed pre and post therapy for anti-NY-ESO-1 T cell responses (IFNγ ELISPOT) and antibodies (Ab) (ELISA) (n = 62), TCR-β CDR3 repertoire and conserved (public) TCR (n = 28), and antigen spreading (ELISA, ELISPOT) (n = 23). Relationship between progression-free survival (PFS), overall survival (OS) and up to 15 biomarkers were analyzed by the Kaplan-Meier method. **Results:** Preexisting anti-NY-ESO-1 T cells and Ab were identified in 34% and 40% of pts. LV305 and CMB305 induced (de novo or increased) anti-NY-ESO-1 T-cells in 51% and 65% pts, and anti-NY-ESO-1 Ab responses in 13% and 68% pts, respectively. LV305 and CMB305 induced antigen spreading in 17% and 36% pts. TCR clonality increased after CMB305 as compared to LV305. The TCRβ-CDR3 amino acid sequences of three NY-ESO-1 specific TCR clones in a patient with a > 2-year response were fully conserved in 20/28 patients. Biomarkers showing the strongest association with OS and PFS were pre-existing anti-NY-ESO-1 T-cell response and Ab, integrated IR (T cells and antibodies), and NY-ESO-1 expression level. Presence of public TCRs was associated with longer survival, particularly in pts with high (> 50%) NY-ESO-1 expression. **Conclusions:** While LV305 and CMB305 are both immunogenic, CMB305 resulted in a stronger and broader integrated IR, including antigen spreading. The three identified survival variables, preexisting and treatment-induced NY-ESO-1 IR and the presence of public TCRs, warrant validation in randomized studies of CMB305.

TPS3091 Poster Session (Board #186a), Mon, 8:00 AM-11:30 AM

A phase I study of the bispecific antibody T-cell engager GBR 1302 in subjects with HER2-positive cancers. *First Author: Martin Wermke, Universitatsklinikum Carl Gustav Carus an der TU Dresden, Dresden, Germany*

Background: GBR 1302, a bispecific antibody based on Glenmark's BEAT platform, is designed to recruit cytotoxic T-cells (independent of their specificity) to HER2-positive cancer cells where they are activated by the CD3e-specific domain of the molecule. Preclinically, GBR 1302 has demonstrated potent killing of HER2-positive human cancer cells (HER2 3+ or 2+ by IHC HercepTest), as well as growth suppression of the trastuzumab-resistant cell line JIMT-1. In contrast, the GBR 1302 concentration required to kill primary cardiomyocytes with normal HER2 levels was up to 1000 times greater than the concentration needed to kill HER2 3+ tumor cell lines. This study will determine safety and tolerability of GBR 1302 monotherapy in subjects with HER2-positive cancers. **Methods:** Part 1 (dose-finding) of this ongoing phase 1 study (NCT02829372) is enrolling adults with progressing HER2-positive solid tumors for which no standard treatment is available. Intravenous GBR 1302 is given every 2 weeks in 28-day cycles at escalating doses (Table). Each of the first 4 cohorts includes a single subject; subsequent cohorts enroll subjects using a standard 3+3 design. Primary endpoints are: maximum tolerated dose (MTD) of GBR 1302; and relationship of GBR 1302 with the incidence, nature, and intensity of adverse events. After Cycle 1, subjects continue GBR 1302 treatment until disease progression or unacceptable toxicity. Part 2 (expansion) will treat subjects at the MTD to further evaluate anti-tumor activity, as well as safety and pharmacokinetics. Due to the known cardiotoxic potential of classic HER2-targeting strategies, this study incorporates a rigorous serological and echocardiographic surveillance schedule. The effects of GBR 1302 on the adaptive immune system will also be studied at cellular and serological levels in translational research. Clinical trial information: NCT02829372.

GBR 1302 dose-escalation schedule.

	Cycle 1 (28 days)		Subsequent Cycles (28 days per cycle)	
Cohort	Day 1 Dose, ng/kg	Day 15 Dose, ng/kg	Day 1 Dose, ng/kg	Day 15 Dose, ng/kg
Single subject				
1	1	3	3	3

TPS3092 Poster Session (Board #186b), Mon, 8:00 AM-11:30 AM

Phase 1 study of intraperitoneal infusion of autologous monocytes with peginterferon alfa-2b and interferon gamma-1b in women with recurrent or refractory ovarian cancer, fallopian tube cancer, or primary peritoneal cancer. *First Author: Ana Tablante Nunes, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Monocytes can differentiate into classic M1 macrophages inhibiting tumor proliferation and promoting natural killer (NK) cell differentiation. We previously demonstrated that the combination of human monocytes, human interferon alfa-2b (IFNα-2b), and interferon gamma-1b (IFNγ 1b) act synergistically against tumor cells *in vitro* and in mouse models, providing a long and durable response. Additionally, monocytes, IFNα and IFNγ have been individually shown in early phase clinical trials to be safely administered intraperitoneally. As ovarian cancer is largely confined to the peritoneal cavity, it is likely that the administration of IFNs and monocytes intraperitoneally will create a strong anti-tumor environment and can overcome the immunosuppressive environment of epithelial ovarian cancer. We hypothesize that the monocyte and interferon administration will be tolerable to women with relapsed ovarian cancer. **Methods:** A Phase 1 single arm study to determine the maximum tolerated dose of intraperitoneal monocytes and pegylated IFNα-2b and IFNγ-1b is currently enrolling patients with recurrent or refractory ovarian cancer, fallopian tube cancer or primary peritoneal cancer without standard therapy options. Autologous monocytes obtained through apheresis 24 hours prior will be mixed with pegylated IFNα-2b and IFNγ-1b in a 3 + 3 dose escalation and administered intraperitoneally once every 28 days. **Results:** As of February 2017 we are enrolling our first cohort of patients and are evaluating for dose limiting toxicities. **Conclusions:** This is a novel therapy that if successful, may be efficacious alone or used to create a backbone on which to add novel agents such as SMAC mimetics or PD-L1 blockade, in order to increase immune-mediated killing of ovarian cancer. Clinical trial information: NCT 02948426.

TPS3093 Poster Session (Board #187a), Mon, 8:00 AM-11:30 AM

A NKG2D-based CAR-T therapy in a multinational phase I dose escalation and expansion study targeting multiple solid and hematologic tumor types. *First Author: Bikash Verma, Celyad, Boston, MA*

Background: Chimeric Antigen Receptor (CAR)-T therapy has potentially serious limitations related to target antigen loss, toxicity due to pre-conditioning regimen, and lack of activity in many tumor types. To overcome these limitations, we have developed a novel CAR-T, called NKR-2, incorporating the full-length human natural killer receptor NKG2D fused with the human CD3 zeta signaling domain. When expressed in T-cells, the naturally-expressed DAP10 provides co-stimulatory signals to NKR-2 to produce cytokines and selectively target tumor cells upon recognition of up to 8 different stress-induced NKG2D ligands expressed in many solid and hematologic malignancies. In preclinical studies, NKR-2 demonstrated long-term anti-tumor activity towards a breadth of tumor indications, in the absence of pre-conditioning, whilst simultaneously targeting tumor cells and cells from the local tumor neo-vasculature and suppressive immune environment. In our recently completed First-in-Human Phase 1 study (NCT02203825) in hematologic cancers, a single administration of autologous NKR-2 was safe with initial signs of clinical benefit. **Methods:** Exploiting the multiple ligand targeting capability and unique mode of action of NKR-2, the THINK trial (THerapeutic Immunotherapy with NKR-2) is an open-label Phase I study that will assess the safety and clinical activity of multiple infusion NKR-2 treatment (every 2 weeks x 3 infusions) in relapse/refractory patients with metastatic or locally advanced CRC, urothelial carcinoma, TNBC, pancreatic cancer, recurrent epithelial ovarian and fallopian tube carcinoma, AML/MDS and MM, post standard treatment. The study contains two consecutive segments. The dose escalation segment will enroll 18 patients in two separate hematologic and solid malignancy arms, and will evaluate 3 dose levels of NKR-2 ($3x10^8$, $1x10^9$ and $3x10^9$ per injection) following a 3+3 design. The expansion segment will then enroll 96 additional patients in 7 separate cohorts for each indication with 3 steps of statistical analysis (overall futility, cohort futility and final evaluation). The study is open for recruitment in both EU and US. Clinical trial information: NCT03018405.

TPS3094 Poster Session (Board #187b), Mon, 8:00 AM-11:30 AM

A phase I/IIa, open label, clinical trial evaluating the safety and efficacy of autologous T cells expressing enhanced TCRs specific for NY-ESO-1 in patients with recurrent or treatment refractory ovarian cancer (NCT01567891). *First Author: Kunle Odunsi, Roswell Park Cancer Institute, Buffalo, NY*

Background: Epithelial ovarian cancer comprises the majority of malignant ovarian neoplasms (~80%) and is the leading cause of death from gynecologic cancer in the US. Due to lack of effective screening strategies, the majority (63%) of patients are diagnosed with ovarian cancer at advanced stages. New therapies are needed to address the unmet medical need of patients with ovarian cancer. 11-40% of ovarian cancers express NY-ESO-1 cancer testis/antigen. This study is evaluating affinity enhanced autologous NY-ESO-1^{c259}T cells recognizing an NY-ESO-1 derived peptide complexed with HLA-A*02 in ovarian cancer. **Methods:** This single arm, open label clinical trial is evaluating safety and tolerability, antitumor activity (response rate by RECIST v1.1, progression free survival, overall survival, duration of response), and translational research endpoints. The study evaluates two lymphodepleting regimens: cyclophosphamide (enrolment completed; n = 7) and cyclophosphamide plus fludarabine (at least 10 subjects to be enrolled). Subjects must be ≥ 18 years old; HLA-A*02:01, *02:05, or *02:06 positive; have recurrent epithelial ovarian, primary peritoneal or fallopian tube carcinoma with refractory or platinum-resistant disease expressing NY-ESO-1 by IHC; have measurable disease; have ECOG status 0 or 1; and have adequate organ function. Following apheresis, the T cells are isolated and expanded with CD3/CD28 beads, transduced with a lentiviral vector containing the NY-ESO-1^{c259} TCR, and $1 - 6 \times 10^9$ transduced T cells are infused intravenously on Day 0 after lymphodepletion with fludarabine 30 mg/m^2/day and cyclophosphamide 600 mg/m^2/day on days -7 to -5. Response is assessed at weeks 4, 8, 12 and 24, and then every 3 months until confirmation of disease progression. Clinical trial information: NCT01567891.

TPS3095 Poster Session (Board #188a), Mon, 8:00 AM-11:30 AM

A phase 1b/2 study of CD30-specific chimeric antigen receptor T-cell (CAR-T) therapy in combination with bendamustine in patients with CD30+ Hodgkin and non-Hodgkin lymphoma. *First Author: Steven I. Park, Levine Cancer Institute, Charlotte, NC*

Background: CAR-T therapy has emerged as one of the most promising therapeutic approaches for lymphoma. CD30 antigen is expressed on virtually all Hodgkin (HL) and various subtypes of non-Hodgkin lymphoma (NHL). HL and NHL are both sensitive to the cellular immune response and antibody-directed therapy, which makes CD30 an excellent target for CAR-Ts. In the "first-in-human" clinical trial of CD30.CAR-Ts, the dose of 2×10^8 CD30.CAR-Ts/m^2 was found to be safe; however, no conditioning therapy was given prior to CD30.CAR-T infusion and the expansion of CAR-Ts was thus limited. In the current study, we have further developed the CD30.CAR-T-based therapy by combining it with bendamustine. We hypothesized that bendamustine may improve therapeutic efficacy of CD30.CAR-Ts by causing sufficient depletion of endogenous immune cells to facilitate the expansion and persistence of CAR-Ts *in vivo*. **Methods:** In this phase 1b/2 clinical study, patients with CD30+ HL or NHL receive bendamustine followed by CD30.CAR-Ts (NCT02690545). The primary objective is to establish the safety of CD30.CAR-Ts in combination with bendamustine. Secondary objectives include estimation of 2-year overall and progression-free survival rates. Patients receive bendamustine (90 mg/m^2 on days 1 and 2) followed by CD30.CAR-Ts within 1 to 4 days of lymphodepletion. The maximal tolerated dose is determined based on 3 + 3 design for dose escalation starting at 1×10^8 CD30.CAR-Ts/m^2. If the first 3 enrolled subjects do not experience a DLT within 6 weeks of the cell infusion, the number of cells for the infusion is increased to 2 x 10^8/m^2. Once the number of cells for infusion is established, up to 25 subjects will be enrolled in the Phase 2 portion of the study to further establish the safety and efficacy of this treatment regimen. Response will be assessed at 6 weeks after CD30.CAR-Ts infusion, and a second CD30.CAR-Ts infusion equal to or lower than the dose may be administered to patients with partial response or stable disease. Patient's peripheral blood samples will be evaluated at various time points to monitor safety, function, and persistence of transduced T-cells. Clinical trial information: NCT02690545.

TPS3096 Poster Session (Board #188b), Mon, 8:00 AM-11:30 AM

Two phase I/II open label clinical trials evaluating the safety and efficacy of autologous T cells expressing enhanced TCRs specific for NY-ESO-1 or MAGE-A10 in subjects with stage IIIb or stage IV non-small cell lung cancer (NCT02588612/NCT02592577). *First Author: Ben C. Creelan, Moffitt Cancer Center, Tampa, FL*

Background: Non-small cell lung cancer (NSCLC) accounts for 84% of lung cancer. Survival has recently been impacted by molecularly targeted therapies and checkpoint inhibitors (CPI), and the promising CPI results implicate a role for the immune system in NSCLC. 10-40% of NSCLC express NY-ESO-1 or MAGE-A10 cancer/testis antigens. These studies will evaluate the safety and antitumor activity of genetically engineered affinity enhanced TCRs (NY-ESO-1^{c259}T or MAGE-$A10^{c796}$T) directed towards a NYESO-1 or MAGE-A10 derived peptides complexed with HLA-A*02. In addition, correlative studies to evaluate persistence, phenotype, functionality of engineered T cells, mechanisms of resistance and antigen spreading will be performed. **Methods:** Patients (pt) are screened (NCT02636855) to identify those who have the relevant HLA-A*02 alleles and NY-ESO-1 or MAGE-A10 tumor expression. For entry into either treatment protocol, pt must have Stage IIIb or IV NSCLC, have failed at least one platinum-containing regimen (may have received CPIs), have measurable disease, ECOG 0-1, adequate organ function, and be without brain metastases, history of severe autoimmune disease or current uncontrolled illness. Following apheresis, T cells are isolated and expanded with CD3/CD28 beads, transduced with a lentiviral vector containing the NY-ESO-1^{c259}T or MAGE-$A10^{c795}$ TCR, and infused into the pt following lymphodepleting chemotherapy with fludarabine and cyclophosphamide. The NY-ESO-1^{c259}T study is a 10 pt study utilizing a dose of 1-6 x 10^9 transduced T cells. The MAGE-$A10^{c796}$T first-in-human study is a modified 3+3 design in up to 28 pt with escalating doses of 0.1, 1.0 and 1-6 x 10^9 transduced T cells, with staggered treatments to allow for safety review; dose escalation will be guided by the DLT observed and by safety review committee guidance. Response to treatment will be assessed by RECIST v1.1 at weeks 4, 8, 16, 24, every 3 months (for 2 yr) and every 6 months until disease progression. Clinical trial information: NCT02588612/NCT02592577.

TPS3097 Poster Session (Board #189a), Mon, 8:00 AM-11:30 AM

A pilot study of NY-ESO-1^{c259} T cells in subjects with advanced myxoid/round cell liposarcoma (NCT02992743). *First Author: Sandra P. D'Angelo, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Myxoid/round cell liposarcomas (MRCLS) account for 6-10% of soft tissue sarcomas. Although a chemosensitive tumor, metastatic MRCLS has a poor prognosis and is inevitably fatal. More effective, durable and less toxic therapies are needed. NY-ESO-1 is a cancer/testis antigen that is expressed in 80-90% of MRCLS tumors. This study will evaluate the safety and efficacy of genetically engineered affinity enhanced autologous NY-ESO-1^{c259}T cells recognizing an NY-ESO-1 derived peptide complexed with HLA-A*02 in MRCLS. **Methods:** This open label phase I/II non-randomized pilot study will evaluate efficacy (overall response rate by RECIST v1.1, time to response, duration of response, progression free survival, overall survival), safety, and translational research endpoints. Patients must meet these criteria: ≥ 18 yrs old; HLA-A*02:01, *02:05 or *02:06 positive; have advanced (metastatic or inoperable) MRCLS expressing NY-ESO-1 at 2+/3+ intensity in ≥30% of tumor cells by IHC; measurable disease; prior systemic anthracycline therapy; have ECOG status 0 or 1; and adequate organ function. Initially, ten patients are planned to be enrolled, with potential to enroll an additional 5 patients. Patients who do not receive the minimum cell dose or who do not receive the T-cell infusion may be replaced. Following apheresis, the T cells are isolated and expanded with CD3/CD28 beads, transduced with a lentiviral vector containing the NY-ESO-1c259 TCR, and 1– 8 $\times$ 10^9 transduced T-cells are infused intravenously on Day 1 after lymphodepletion with fludarabine 30 mg/m^2/day and cyclophosphamide 600 mg/m^2/day on days -7 to -5. Response is assessed at 4, 8, 12 and 24 weeks, and then every 3 months until confirmation of progression of disease. On study tumor biopsies and blood samples will be evaluated to compare the pre- and post-T cell infusion immune profile for association with treatment outcome. Clinical trial information: NCT02992743.

TPS3098 Poster Session (Board #189b), Mon, 8:00 AM-11:30 AM

A phase I single arm, open label clinical trial evaluating safety of MAGE-$A10^{c796}$T in subjects with advanced or metastatic head and neck, melanoma, or urothelial tumors (NCT02989064). *First Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MAGE-A10 is a cancer/testis antigen that has been identified in 42, 26 and 17% of urothelial, melanoma and head and neck tumors, respectively. This study will evaluate the safety and antitumor activity of genetically engineered affinity enhanced autologous MAGE-$A10^{c796}$T cells directed towards a MAGE-A10 peptide expressed on tumors in the context of HLA *02:01 and/or *02:06. **Methods:** This first-in-human T cell dose escalation study utilizes a modified 3+3 design to evaluate safety, including dose limiting toxicities (DLT). Secondary objectives include anti-tumor activity (overall response, duration of response, time to response, PFS, OS) and translational research assessments. Patients are screened under a separate protocol (NCT02636855). Those who are HLA*02:01 and/or *02:06 positive and have inoperable or metastatic (advanced) urothelial cancer, melanoma, or squamous cell head and neck tumors with MAGE-A10 expression and meet all other entry criteria are eligible for treatment. Patients must have received standard of care therapies and have progressive disease. Following apheresis, the T cells are isolated and expanded with CD3/CD28 beads, transduced with a lentiviral vector containing the MAGE-$A10^{c796}$ TCR, and infused into the subject (Day 1) after receiving lymphodepleting chemotherapy (fludarabine 30 mg/m^2/day and cyclophosphamide 600 mg/m^2/day, on days -7, -6 and -5). The DLT observation period will be during the first 30 days following the infusion of MAGE-$A10^{c796}$T for each patient in all groups. Up to 10 patients will be enrolled at the target dose. Disease assessments will be conducted at week 6, 12, 18 and 24, and then every 3 months until confirmation of disease progression. On study tumor biopsies and blood samples will be evaluated to compare the pre- and post-T cell infusion immune profile for association with treatment outcome. Clinical trial information: NCT02989064.

Group	Number of Subjects	Transduced cells
1	3-6	$0.1x10^9$ (±20%) transduced cells
2	3 - 6	$1x10^9$ (±20%) transduced cells
3	3 -6	$5x10^9$ (range: >1.2 - $6x10^9$) transduced cells

TPS3099 Poster Session (Board #190a), Mon, 8:00 AM-11:30 AM

Phase 1 trial of CA-170, a novel oral small molecule dual inhibitor of immune checkpoints PD-1 and VISTA, in patients (pts) with advanced solid tumor or lymphomas. *First Author: James J. Lee, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Programmed-death 1 (PD-1) and V-domain Ig suppressor of T-cell activation (VISTA) are independent immune checkpoints that negatively regulate T-cell function and are implicated in various malignancies. Preclinical studies have demonstrated that dual blockade of these pathways is synergistic. CA-170 is a first-in-class oral small molecule that directly targets both PD-1/PD-L1 and VISTA pathways and has shown anti-tumor activity in multiple preclinical models. **Methods:** The dose escalation phase has a target enrollment of 50 pts with advanced solid tumors or lymphomas onto escalating doses; the first four single-pt cohorts are accelerated titration but then switch to 3+3 design. The dose expansion phase has a target enrollment of 250 pts with select tumor types known to be responsive to anti-PD-1/L1 inhibitors and/or known to express PD-L1 or VISTA. Key eligibility criteria include: age $\geq$ 18 years, ECOG $\leq$1, adequate organ function, and ineligible for/did not respond to standard therapy including anti-PD-1/L1 inhibitors, where available. Primary objectives of this first-in-human study: safety, maximum tolerated dose, and recommended phase 2 dose. Secondary objectives: pharmacokinetics (PK) and anti-tumor activity. Exploratory endpoints: biomarkers and pharmacodynamic (PD) effects, which include changes in immune cell and peripheral cytokine populations in tumor (IHC/mRNA) and blood (flow cytometry/mRNA). Oral CA-170 is administered once daily in 21-day cycles. Response will be evaluated every other cycle per RECIST (v1.1) and Immune-related Response Criteria or by Cheson criteria (2007). Patients who discontinue treatment for reasons other than progressive disease will be followed for progression-free survival. Serial plasma, blood, and tumor samples will be collected for PK and PD evaluation. Clinical trial identifier: Clinical trial information: NCT02812875.

TPS3100 Poster Session (Board #190b), Mon, 8:00 AM-11:30 AM

A phase 1 study to evaluate the safety, pharmacokinetics, pharmacodynamics, immunogenicity, and antitumor activity of the OX40 agonist MEDI0562 in combination with tremelimumab or durvalumab in adult aubjects with advanced solid tumors. *First Author: Brendan D. Curti, Providence Cancer Center and Earle A. Chiles Research Institute, Portland, OR*

Background: Recent advances in treatment of solid tumors include single or combined use of monoclonal antibodies (mAbs) against the immune checkpoints CTLA-4 or PD-1/PD-L1 that can reactivate antitumor cytotoxic tumor-infiltrating lymphocytes (TILs) and significantly improve OS (Menon S, et al. *Cancers (Basel).* 2016;8:E106.) (Antonia S, et al. Lancet Oncol. 2016; 17:299-308). Activation of TILs via the costimulatory OX40 (CD134) molecule, may offer an alternative and non-redundant pathway for increasing antitumor immunity. OX40 costimulation promotes effector T cell expansion and longevity, overcomes regulatory T cell suppression and provides survival benefit in animal models of tumor challenge (Linch SN, et al. *Front Oncol.* 2015;5:34). MEDI0562 is an investigational, humanized IgG1κ anti-OX40 mAb that triggers OX40 signaling. Coadministration of an OX40 agonist and either a CTLA-4 or PD-1/PD-L1 pathway inhibitor may promote synergistic effects against certain solid tumors and may be tolerable administered in combination. **Methods:** A Phase 1, multicenter, open-label study (NCT02705482) is underway to evaluate safety (primary endpoint), pharmacokinetics, pharmacodynamics, immunogenicity and antitumor activity (secondary endpoints) of MEDI0562 in combination with either anti-PD-L1 mAb durvalumab or anti-CTLA-4 mAb tremelimumab in adult subjects with previously treated advanced solid tumors. Subjects with primary CNS tumors and hematologic malignancies are excluded. The study includes a dose escalation and expansion phase, with 2 treatment arms in each: MEDI0562/durvalumab combination (Arm A) and MEDI0562/tremelimumab combination (Arm B). Safety assessments include AEs, serious AEs, dose-limiting toxicities, abnormal laboratory parameters, vital signs, and electrocardiogram results. Antitumor efficacy will be assessed as OR, disease control, duration of response, PFS, and OS using RECIST Version 1.1. Subjects will remain on treatment until unacceptable toxicity, progressive disease or other reasons for discontinuation. Clinical trial information: NCT02705482.

TPS3101 Poster Session (Board #191a), Mon, 8:00 AM-11:30 AM

A phase 1 dose-escalation trial of intratumoral TTI-621, a novel immune checkpoint inhibitor targeting CD47, in subjects with relapsed or refractory percutaneously-accessible solid tumors and mycosis fungoides. *First Author: John A. Thompson, University of Washington Seattle Cancer Care Alliance, Seattle, WA*

Background: CD47 is an immune checkpoint that binds to signal regulatory protein alpha (SIRPα) and delivers a "do not eat" signal to suppress macrophage phagocytosis. Tumor cells frequently overexpress CD47 and exploit this pathway to evade macrophage-mediated destruction. CD47 blockade promotes both innate (macrophage phagocytosis) and adaptive immunity (T cell responses). TTI-621 (SIRPαFc) is an immune checkpoint inhibitor designed to bind human CD47 and block the "do not eat" signal. The IgG1 region of TTI-621 engages Fcγ receptors on macrophages, converting the inhibitory signal to one that activates, thereby enhancing phagocytosis, and antitumor activity. A Phase 1 study is ongoing to evaluate the safety/tolerability and preliminary efficacy of IV administered TTI-621 in subjects with relapsed/refractory hematologic malignancies. It is hypothesized that employing direct intratumoral injections will result in very high local target engagement, promoting the development of innate and adaptive immune responses. **Methods:** A Phase 1 multicenter, open-label study was initiated to characterize the safety and tolerability of delivering TTI-621 directly into cancer lesions to achieve high local CD47 engagement to increase phagocytosis of tumor cells (NCT02890368). Subjects are being enrolled in sequential cohorts that gradually increase in dose and dosing frequency to characterize the feasibility of intratumoral TTI-621 injections and their safety, PK, pharmacodynamics, and preliminary antitumor activity. Eligible subjects are adults with relapsed or refractory percutaneously-accessible solid tumors or mycosis fungoides (MF), which have progressed on standard anticancer therapy or for which no other approved therapy exists. TTI-621 is delivered by intratumoral injection at protocol-defined doses and dosing regimens starting at 1 mg/injection. Serial biopsies are being collected to characterize local anti-tumor responses and assess the impact of TTI-621 on the tumor microenvironment. Clinical trial information: NCT02890368.

TPS3102 Poster Session (Board #191b), Mon, 8:00 AM-11:30 AM

Nivolumab in combination with daratumumab, with or without pomalidomide and dexamethasone, for relapsed/refractory multiple myeloma: 2 cohorts of the phase 1 CheckMate 039 safety study. *First Author: Alexander M. Lesokhin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Multiple myeloma (MM) is largely incurable despite available therapies, including immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs), and monoclonal antibodies (mAbs). As most MM patients (pts) eventually have relapsed/refractory (RR) disease, there is an unmet need. Myeloma cells upregulate PD-L1 [Liu et al, 2007]. Nivolumab (nivo), an immuno-oncology mAb, binds PD-1 on T cells and natural killer cells and inhibits signaling by PD-L1–expressing tumor cells, thus augmenting antitumor immunity. Nivo monotherapy has shown acceptable safety and modest clinical activity in RRMM [Lesokhin et al 2016]. Daratumumab (dara) is a cytolytic mAb that targets CD38+ myeloma cells, inducing antibody-dependent cellular cytotoxicity, complement-dependent cytotoxicity, antibody-dependent cellular phagocytosis, and apoptosis, and may have an immunomodulatory role via depletion of CD38+ immune-suppressor cells [Dimopoulos et al 2016]. Dara is approved as monotherapy (US: after $\geq$3 prior lines of therapy; EU: after a prior PI and IMiD and progression on last therapy), and with lenalidomide/dexamethasone (dex) or bortezomib/dex (US: after $\geq$1 prior line of therapy for both combinations). Combining PD-1 and CD38 mAbs, immunotherapies with different mechanisms of action, may overcome resistance and improve outcomes. This phase 1 safety study (NCT01592370) includes multiple cohorts of nivo as monotherapy or in combination regimens across RR hematologic malignancies; 2 MM cohorts will evaluate nivo plus dara, with or without pomalidomide and dex. **Methods:** Eligible pts are aged $\geq$18 y, with RRMM after $\geq$2 prior therapies. Pts are RR to their last regimen, RR to prior IMiD and PI therapy, and agreed to bone marrow aspiration. Primary outcome of safety/tolerability will be measured by incidence of drug-related adverse events (AEs), serious AEs, and laboratory test abnormalities. Secondary endpoints include minimal residual disease, overall response rates and duration of response, and progression-free survival. Study funding: BMS. Writing support: C Tomas, Caudex, funded by BMS. Clinical trial information: NCT01592370.

TPS3103 Poster Session (Board #192a), Mon, 8:00 AM-11:30 AM

Phase II study for the evaluation of efficacy of pembrolizumab (MK-3475) in patients with cancer of unknown primary. *First Author: Gauri R. Varadhachary, The University of Texas MD Anderson Cancer Center, Department of Gastrointestinal Medical Oncology, Houston, TX*

Background: Cancer of unknown primary is a biopsy proven malignancy for which an anatomic primary remains unidentified after a focused search. It accounts for 3-4 % of all solid cancers and most investigators limit it to epithelial and undifferentiated cancers. Patients with metastatic melanoma and sarcoma are excluded. Sophisticated imaging, robust pathologic evaluation including immunostains, and genomic and proteomic characterization of these cancers have challenged the management of CUP. The paradigm has shifted from empiric platinum based combination doublets to a personalized approach. Nevertheless, without an anatomic primary, clinical trial opportunities are limited. There remains an unmet research need to evaluate the role of immunotherapy, specifically checkpoint blockade drugs in specific subsets of CUP patients. **Methods:** Adult Patients ≥ 18 years of age with ECOG PS 0-1, must meet the definition of a CUP cancer. Patients must be intolerant and/or refractory to at least one line of established therapy known to provide clinical benefit for their condition within the last 6 months (often, a platinum based therapy for carcinomas). Patients must have either measurable (RECIST 1.1) or evaluable disease. Although not limited to subtypes, there is a signficant interest in enrolling patients with isolated disseminated lymphadenopathy, HPV (+) CUP and those who have an IHC profile of those known cancers for which anti-PD therapy has been approved (lung, renal, others) The primary objective of this trial is to evaluate efficacy by evaluation of non-progression rate (NPR) at 27 weeks (9 cycles) as defined as the percentage of CUP patients who are alive and progression-free at 27 weeks (9 cycles) as assessed by RECIST 1.1. Secondary objectives include evaluating safety and tolerability of pembrolizumab (MK-3475); correlating efficacy, non-progression rate (NPR) at 27 weeks (9 cycles), objective response (CR or PR), progression-free survival (PFS), overall survival (OS) and duration of response (DOR) to PD-L1 status; and identifying imaging characteristics associated with immunological changes in tumor following treatment with pembrolizumab. Enrollment is ongoing. Clinical trial information: NCT02721732.

TPS3104 Poster Session (Board #192b), Mon, 8:00 AM-11:30 AM

A phase 1b study to evaluate TAK-659 in combination with nivolumab in patients (pts) with advanced solid tumors. *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: TAK-659 is an investigational, reversible, potent dual inhibitor of SYK and FLT-3. In ongoing early-phase studies (NCT02000934; NCT02323113), TAK-659 demonstrated an acceptable pharmacokinetic and safety profile, with evidence of preliminary activity in pts with DLBCL, follicular lymphoma, CLL, and AML (Kaplan et al. Blood 2016;128:624/2834). In preclinical studies, TAK-659 in combination with nivolumab, an anti-PD-1 checkpoint inhibitor, resulted in loss of myeloid suppressor cells (MDSCs), increased T-cell activation, and complete tumor growth suppression (Kannan et al. Eur J Cancer 2016;69:S92). This first-in-human combination study will investigate the efficacy and safety of TAK-659 and nivolumab in pts with advanced solid tumors. **Methods:** This open-label, multicenter, phase 1b study (NCT02834247) will include dose-escalation and expansion phases. Pts with advanced solid tumors who have failed ≥1 prior lines of therapy and have no effective therapeutic options available by investigator assessment will be eligible for the dose-escalation phase. Pts will receive oral TAK-659 at doses of 60–100 mg QD in a standard 3+3 schema, plus nivolumab 3 mg IV on days 1 and 15 of 28-day cycles. The expansion phase at the recommended phase 2 dose (RP2D) will include 3 cohorts of pts with relapsed/refractory metastatic triple-negative breast cancer, locally advanced/metastatic NSCLC, or locally advanced/metastatic head and neck squamous cell carcinoma (n = 30 response-evaluable pts in each cohort; 24 naïve, 6 relapsed/refractory to prior anti-PD-1/PD-L1 therapy). Ten pts in each cohort will receive 2 weeks of single-agent TAK-659 before starting combination therapy; the other 20 pts will receive combination therapy throughout. The primary endpoints are maximum tolerated dose/RP2D (dose-escalation phase) and overall response rate by investigator per RECIST v1.1 (expansion phase). Secondary endpoints include adverse events, disease control rate, duration of response, progression-free survival, overall survival, and TAK-659 pharmacokinetics. There are currently 7 pts enrolled; recruitment to the 100 mg dose-escalation cohort is ongoing. Clinical trial information: NCT02834247.

TPS3105 Poster Session (Board #193a), Mon, 8:00 AM-11:30 AM

A multicenter, open-label, phase II study of PGG beta-glucan and pembrolizumab in patients (pts) with advanced melanoma (MEL) following progression on treatment with checkpoint inhibitors (CPI) or triple negative breast cancer (TNBC) failing front-line chemotherapy for metastatic disease. *First Author: Jose Luis Iglesias, Apobiologix, Toronto, ON, Canada*

Background: Imprime PGG (Imprime) is a *P*athogen-*A*ssociated *M*olecular *P*attern that enhances innate immune cell killing, counteracts immune suppression and triggers activation and maturation of antigen presenting cells. Imprime's ability to trigger a coordinated innate and adaptive immune response is critical for enhancing the efficacy of CPIs in several pre-clinical tumor models. We are now exploring the combination of PGG beta-glucan and Pembrolizumab, a humanized mAb against programmed death receptor-1 (PD-1) in the clinic. In previous trials, Pembro yielded a 33% ORR and 23 mo mOS in 655 pts with advanced MEL and an 18.5% ORR and 11.2 mo mOS in 27 evaluable pts with metastatic/recurrent TNBC (Ribas et al., 2016; Nanda et al., 2016). Pre-treatment levels of anti-beta glucan antibodies (ABA) are correlated with pt response to Imprime. **Methods:** This Phase 2 study is enrolling ABA positive pts with advanced MEL following progression on treatment with a CPI or metastatic TNBC failing front-line chemotherapy. The study is a Simon optimal 2-stage design with sample size of 12 pts of each tumor type in Stage 1. If response and AE criteria (≤ 4 [or ≤ 33%] pts with grade 3/4 in Cycle 1) for each tumor type are met, an additional 17 pts with MEL and 30 pts with TNBC will be enrolled in Stage 2. Primary endpoints of the study are ORR (based on RECIST 1.1) and safety. Secondary endpoints include TTR, CRR, DoR, PFS, and OS. PK data will be profiled. Exploratory endpoints include ORR and PFS based on irRECIST, analysis of an ABA biomarker, immune cell activation markers, and changes in the tumor immune microenvironment. Screening and enrollment are underway in the US. Biothera Pharmaceuticals, Inc. is sponsoring the trial (ClinicalTrials.gov NCT02981303) under a collaborative agreement with Merck. Clinical trial information: NCT02981303.

TPS3106 Poster Session (Board #193b), Mon, 8:00 AM-11:30 AM

Phase 1/2 study of in situ vaccination with tremelimumab + intravenous (IV) durvalumab + poly-ICLC in patients with select relapsed, advanced cancers with measurable, biopsy-accessible tumors. *First Author: Craig L. Slingluff, University of Virginia School of Medicine, Charlottesville, VA*

Background: Immunotherapy has demonstrated promising antitumor activity in various advanced cancers. Combined tumor targeting from multiple drugs with unique mechanisms may provide further improved outcomes. Tremelimumab (TRE) is a CTLA-4 antibody and durvalumab (DUR) blocks PD-L1. Poly-ICLC is a toll-like receptor 3 agonist. Intratumoral (intra-T) injection of poly-ICLC directly alters the tumor microenvironment (TME), and by creating an in situ vaccination, may trigger a clinically effective systemic anti-tumor response when also combined with DUR and TRE. **Methods:** This is an ongoing Phase 1/2, open-label, multicenter study (NCT02643303). The study evaluates the use of intra-T administration of TRE and IV DUR + poly-ICLC (intra-T and intramuscular [IM]) to determine the safety, preliminary efficacy and immune activity of this regimen in patients with advanced, measurable, biopsy-accessible tumors: head and neck squamous cell carcinoma, breast cancer, sarcoma, merkel cell carcinoma, cutaneous T-cell lymphoma, melanoma, genitourinary cancer, and other solid tumors. Phase 1 determines the recommended combination dosing (RCD) for the regimen with dose de-escalation based on dose limiting toxicities (DLTs) and standard 3 + 3 rules. Starting doses are: DUR, 1500 mg IV; TRE, 75 mg IV; TRE, 10 mg intra-T; poly-ICLC, 1 mg intra-T/IM. Phase 1 starts with Cohort 1A (DUR + poly-ICLC). Upon demonstration of tolerability, enrollment proceeds with Cohort 1B (DUR + IV TRE + poly-ICLC) and Cohort 1C (DUR + intra-T TRE + poly-ICLC). The RCD is the highest dose at which < 2/6 patients have DLTs. In Phase 2, up to 66 evaluable patients are treated using the RCD regimen, with enrollment of 6 patients per tumor type initially, and enrollment of 6 additional patients per 3 tumor types contingent upon at least 1 response among the initial 6 patients. Study endpoints are RCD and safety, objective response rate, progression-free survival, and overall survival. Exploratory endpoints are biological activity, including effects on the TME and immunological responses. Enrollment opened on 28 Dec 2016. Clinical trial information: NCT02643303.

TPS3107 Poster Session (Board #194a), Mon, 8:00 AM-11:30 AM

PROCLAIM-001: A first-in-human trial to assess tolerability of the protease-activatable anti-PD-L1 Probody CX-072 in solid tumors and lymphomas. *First Author: Alexander I. Spira, Virginia Cancer Specialists Research Institute and Oncology Research, Fairfax, VA*

Background: CX-072 is a novel Probody therapeutic (PbTx) targeting PD-L1. PbTx s are fully recombinant antibody prodrugs designed to be converted to active antibodies by tumor-associated proteases that are highly expressed malignant tissue; the PbTx remains largely inactive in normal tissues. In pre-clinical tumor models, a PD-L1-directed PbTx provided comparable anti-tumor efficacy to its parental anti-PD-L1 antibody, but displayed reduced auto-immunity in a model of Type 1 diabetes. Based on these pre-clinical data, CX-072 has the potential to enable combination therapies that are otherwise poorly tolerated. This Phase 1/2 study (PROCLAIM-001 (PRObody CLinical Assessment In Man) assesses the tolerability and antitumor activity of CX-072 in humans with an emphasis on immune-related adverse events, particularly in combinations. CX-072 will be administered as monotherapy (Part A), in combination with 2 schedules of ipilimumab (Parts B1 and B2) and in combination with vemurafenib (Part C). The expansion cohort (Part D) will include CX-072 monotherapy in PD-L1 responsive tumor types. **Methods:** Key eligibility criteria are as follows: Parts A and B1: checkpoint inhibitor-naive patients with advanced, refractory solid tumor or lymphoma (unmeasurable disease allowed) for whom approved PD agents are not available. Part B2: advanced, refractory solid tumors or lymphomas with measurable disease who have progressed on a previous treatment with a PD-(L)1 inhibitor, but did not discontinue due to toxicity. Part C: checkpoint inhibitor, BRAF-inhibitor and MEK-inhibitor-naïve metastatic V600E BRAF-mutated melanoma. Patients without an active autoimmune disease, ongoing infection, and ECOG PS 0-1 may be eligible to participate in the study. Dose escalation follows the 3+3 design in all arms. Ipilimumab (Parts B1 and B2) is dosed at the approved 3 mg/kg every 3 weeks x 4. The dose of vemurafenib (Part C) is 960 mg/kg twice daily. Exploratory biomarkers are used to characterize tumor protease activity, inflammatory changes within the tumor, and CX-072 activation in tumor versus peripheral blood. Clinical trial information: NCT03013491.

TPS3108 Poster Session (Board #194b), Mon, 8:00 AM-11:30 AM

Keynote-200 phase 1b: A novel combination study of intravenously delivered coxsackievirus A21 and pembrolizumab in advanced cancer patients. *First Author: Hardev S. Pandha, University of Surrey, Surrey, United Kingdom*

Background: Coxsackievirus A21 (CVA21, CAVATAK) is a naturally occurring ICAM-1 targeted oncolytic immunotherapeutic virus. Pembrolizumab is a human programmed death receptor-1 (PD-1) blocking antibody that has yielded significant solid tumor responses via reversal of tumor induced T-cell suppression. Intravenous (i.v.) CVA21 mono-therapy is generally well tolerated, with low toxicity and can successfully target tumors in patients with melanoma, NSCLC and bladder cancer as confirmed by detection of CVA21 viral RNA in post-treatment tumor biopsies *(Pandha et al., 2016).* Intratumoral CVA21 replication has the potential to up-regulate numerous key immune checkpoint molecules, including PD-L1 *(Andtbacka et al., 2016).* The combination of i.v. CVA21+pembrolizumab may translate to a potential enhanced benefit in the clinic. **Methods:** The Phase Ib KEYNOTE-200 (NCT02043665) *Treatment:* Primary objectives are to assess dose-limiting toxicities (DLT) of CVA21 in combination with pembrolizumab. Secondary objectives are to assess ORR by irRECIST 1.1 criteria, PFS, and OS. Patients (pts) are infused with CVA21 in 100 mL saline + pembrolizumab. In Cohort 1 (n = 3), CVA21 is administered at a dose of 1 x 10^8 $TCID_{50}$, in Cohort 2 (n = 3) at a dose of 3 x 10^8 $TCID_{50}$ and in Cohort 3 (n = ~80) at a dose of 1 x 10^9 $TCID_{50}$ on study days 1,3,5,8,29,and Q3W for 6 additional infusions. Pembrolizumab is given in all cohorts at 200 mg IV Q3W from Day 8 for up to 2 years. Treatment (tx) with CVA21 + pembrolizumab will continue until confirmed CR or PD (whichever comes first) per irRECIST 1.1 or DLT.To date the combination of intravenous CVA21 and pembrolizumab has been generally well-tolerated. At present one gr 3 CVA21-related hyponatremia with no DLT for the combination of CVA21 and pembrolizumab being observed. Enrolment in Cohorts 1 and 2 is complete with tx of pts in Cohort 3 currently underway. *Key eligibility:* Pts with advanced disease considered appropriate tx with CVA21 + pembrolizumab, lesion(s) accessible for core biopsy, ECOG PS 0-1, no active cerebral metastases, no autoimmunity/immunosuppression. Clinical trial information: NCT02043665.

TPS3109 Poster Session (Board #195a), Mon, 8:00 AM-11:30 AM

Phase 1-2 study of TI-061 alone and in combination with other anti-cancer agents in patients with advanced malignancies. *First Author: T.R. Jeffry Evans, University of Glasgow, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom*

Background: The cell surface protein CD47 is expressed or over-expressed on many tumor types. CD47 binds to signal regulatory protein alpha (SIRPα) on macrophages resulting in a "don't eat me" signal that blocks host cell phagocytosis of the tumor cells, thus allowing them to escape removal by the innate immune system. Recent data indicate that anti-CD47 antibodies also contribute to an effective anti-tumor T cell response in immune-competent mice. Therefore, anti-CD47 antibodies are a new class of immune checkpoint inhibitors that modulate both the innate and adaptive immune systems. Ti-061 is a novel IgG4 humanized monoclonal antibody that specifically binds to CD47 with Kd values range from 100 – 500 pM. Ti-061 exhibits cross-species binding to cynomolgus monkey, mouse and rat CD47, enabling efficacy and toxicity testing across species. Ti-061 binds to CD47 on RBCs; however, it does not cause agglutination of RBCs in vitro from any of the species tested. Ti-061 exhibits anti-tumor activity in several in vivo mouse tumor models. This ongoing Phase 1-2 study will assess the safety, efficacy, pharmacokinetics (PK) and pharmacodynamics (PD) of Ti-061 alone and in combination with other anti-cancer agents in patients with advanced malignancies. **Methods:** Part A is an open-label, dose-escalation study of Ti-061 administered as a weekly 1-hour IV infusion at doses ranging from 1 to 20 mg/kg. Once the MTD/RP2D or "active dose" is determined, patients with specific solid tumors and high CD47 expression will be enrolled in 4 or more expansion cohorts. Up to 160 patients with histologically confirmed solid tumors, ECOG PS 0-1, adequate blood counts (Hb≥ 10 g/dL), organ function, and archival or fresh tumor tissue will be enrolled in Part A, and will be treated until disease progression, unacceptable toxicity, or withdrawal. Primary endpoint is safety, which will be assessed using NCI-CTCAE v4.03. Secondary endpoints include PK, PD, objective response rate (ORR) and progression-free survival (PFS), which will be assessed using RECIST v1.1. The results of this study will support further development of Ti-061 in combination with checkpoint inhibitors (Part B) and other anti-cancer agents.

TPS3110 Poster Session (Board #195b), Mon, 8:00 AM-11:30 AM

A phase 1b/2 study of ARRY-382, an oral inhibitor of colony stimulating factor 1 receptor (CSF1R), in combination with pembrolizumab (Pembro) for the treatment of patients (Pts) with advanced solid tumors. *First Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

Background: CSF1, which signals via CSF1R, regulates tumor-associated macrophages and myeloid-derived suppressor cells, both critical drivers of immune escape in the tumor microenvironment. ARRY-382 is a highly selective, oral inhibitor of the CSF1R intracellular tyrosine kinase. The first-in-human study of ARRY-382 monotherapy identified the maximum tolerated dose (MTD) of 400 mg QD, with biologic activity at doses ≥200 mg QD (Bendell JC et al. *Mol Cancer Ther.* 2013;12:A252). Preclinical data supports combining a PD-1 inhibitor with a CSF1R inhibitor (Zhu Y et al. *Cancer Res.* 2014;74:5057-69). This study is designed to evaluate ARRY-382 in combination with pembro, a potent and highly selective humanized monoclonal antibody that targets PD-1. **Methods:** This is an open-label, multicenter, phase 1b/2 study (NCT02880371) to determine the MTD and/or recommended phase 2 dose (RP2D) of ARRY-382 + pembro and to evaluate the activity of the combination in select indications. In phase 1b (Part A), the primary objective is to identify the MTD/RP2D. Up to 18 pts with select advanced solid tumors (Part A) will be enrolled in 2 successive cohorts evaluating ARRY-382 at doses of 200 mg QD and 400 mg QD, respectively, in combination with pembro 2 mg/kg Q3W. Once the MTD/RP2D has been determined in phase 1b, phase 2 will concurrently evaluate the combination in up to 20 pts with advanced unresectable/metastatic melanoma (Part B) and in up to 33 pts with PD-L1-positive (tumor proportion score ≥50) non-small cell lung cancer (NSCLC) (Part C). The primary objective of Part B is to assess the pharmacodynamics and antitumor activity of ARRY-382 + pembro in pts with advanced unresectable/metastatic melanoma, and the endpoints include effects of treatment on circulating growth factors and cytokines, markers of bone resorption, and objective response rate (ORR). The primary objective of Part C is to assess the efficacy of ARRY-382 + pembro in pts with PD-L1–positive NSCLC (Part C). The primary endpoint is ORR. Immune-related response rate and safety will be evaluated in all pts in the study. Clinical trial information: NCT02880371.

TPS3111 Poster Session (Board #196a), Mon, 8:00 AM-11:30 AM

A phase I trial of ALKS 4230, an engineered cytokine activator of NK and effector T cells, in patients with advanced solid tumors. *First Author: Ulka N. Vaishampayan, Wayne State University, Detroit, MI*

Background: ALKS 4230 is an engineered fusion protein comprised of a circularly permuted interleukin-2 (IL-2) and IL-2 Receptor (IL-2R) α designed to selectively activate the intermediate-affinity (ia) IL-2R, comprised of IL-2Rβ and γ_c. The iaIL-2R is expressed predominantly on effector lymphocytes, which play an important role in driving antitumor immune responses. In contrast, unmodified IL-2 activates high-affinity (ha) IL-2R, driving the expansion of haIL-2R-expressing cell types including immunosuppressive $CD4^+$ regulatory T (T_{reg}) cells at concentrations below those at which iaIL-2R bearing effector cells are activated. Also, the haIL-2R is expressed on endothelial cells and may contribute to IL-2 mediated toxicity via capillary leak syndrome. Thus, selective activation of the iaIL-2R by ALKS 4230 has the potential to provide enhanced tumor killing as well as improved tolerability. **Methods:** ALKS 4230 is being studied in a phase 1 first-in-human trial in patients with advanced solid tumors. Key study objectives are to determine a recommended phase 2 dose and characterize the safety profile, pharmacokinetics (PK), pharmacodynamics (PD) and evidence of antitumor activity. A dose-escalation phase in patients with refractory solid tumors (Part A) will be followed by expansion cohorts in defined populations (Part B). ALKS 4230 is administered as a 30-minute intravenous infusion once daily for five days each cycle. Eligibility requires age 18, ECOG PS 0-1 and adequate bone marrow, liver and kidney function. The dose will be escalated until reaching MTD or an Optimal Biologic Dose. The first two dose cohorts will use a 3+3 design. Subsequent cohorts in Part A will enroll a minimum of 6 subjects. In Part B up to 21 patients will be enrolled into each of four tumor-specific cohorts. Peripheral blood samples will be collected for PK, immunogenicity and PD assessments. The primary PD endpoint is change-from-baseline in $CD8^+$ T, NK and T_{reg} cell counts. Other PD measures include serum concentrations of multiple proinflammatory cytokines and immunohistochemical assessment of markers of immune activation in tumor tissue from selected patients. Recruitment for Part A is ongoing. Clinical trial information: NCT02799095.

TPS3112 Poster Session (Board #196b), Mon, 8:00 AM-11:30 AM

A phase I dose escalation (DE) and cohort expansion (CE) study of ERY974, an anti-glypican 3 (GPC3)/CD3 bispecific antibody, in patients with advanced solid tumors. *First Author: Kenji Hashimoto, Chugai Pharma Europe Ltd., London, United Kingdom*

Background: Bispecific antibodies to facilitate T-cell directed cytotoxicity (TDCC) is a proven therapy strategy in cancer. ERY974 is a humanized IgG4 bispecific antibody designed to simultaneously bind to cytotoxic T-cell CD3 receptors and GPC3 (a glycoprotein expressed on cell surface of several tumors) to elicit T-cell activation and TDCC. The objectives of this multi-country, phase 1 study of ERY974 is to determine the maximum tolerated dose (MTD) and to perform a preliminary assessment of anti-tumor activity in patients with solid tumors expressing GPC3. **Methods:** ERY974 is dosed IV weekly. All patients receive premedication with dexamethasone (DEX) prior to 1^{st} and 2^{nd} ERY974 dose. DE uses an accelerated titration design (ATD), then a modified continual reassessment method (mCRM) described by one-parameter logistic model, to determine MTD, where DLT occurrence rate is 0.25. Combining ATD and mCRM is to permit rapid dose escalation whilst minimizing patient numbers exposed to sub-therapeutic doses, and to accurately determine MTD. Once grade 2 (G2) cytokine release syndrome (CRS) is observed, DEX is increased. If $\geq$G2 CRS is again observed, then at all subsequent doses the 1^{st} dose of ERY974 is fixed at the last dose level when $<$ G2 CRS was not seen, DE proceeds with the 2^{nd} dose. ATD commences with n = 1, increasing to n = 3 once drug-related $\geq$G2 toxicity is seen. mCRM starts after 1^{st} dose limiting toxicity (DLT), with the modifications of at least 3 patients required to dose escalate and up to 1.5x increment to minimize risk of toxicity. CE has 3 arms: GPC3+ gastric/gastroesophageal junction adenocarcinoma; GPC3+ squamous esophageal cancer; and other GPC3+ tumors. A 2-stage design is used to allow CE to stop early for futility. Subjects are adults with histologically confirmed, measurable malignant solid tumors and/or metastatic disease not amenable to standard therapy, and life expectancy $\geq$3 months. Patients with $>$ 1cm or $>$ 1 brain metastasis, current/previous interstitial lung disease, and acute/chronic infection are excluded. 3 cohorts have been completed without DLT. Cohort 4 began in January 2017. Clinical trial information: NCT02748837.

TPS3113 Poster Session (Board #197a), Mon, 8:00 AM-11:30 AM

INDUCE-1: A phase I open-label study of GSK3359609, an ICOS agonist antibody, administered alone and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Eric Angevin, Institut Gustave Roussy, Villejuif, France*

Background: Inducible T cell Co-Stimulator (ICOS), a member of the CD28/B7/CTLA-4 receptor superfamily expressed on T cells after engagement with cognate antigen and activation, provides a co-stimulatory signal augmenting T cell proliferation, survival and cytokine production. GSK3359609 is a humanized IgG4 antibody selected for its potent agonist activity against human ICOS. The unique mechanistic profile of an ICOS agonist antibody, such as GSK3359609, offers an opportunity to investigate the antitumor potential of targeting a T cell co-stimulator alone and in combination with other cancer immunotherapies such as pembrolizumab. **Methods:** INDUCE-1 is a first- in-human study evaluating safety, pharmacokinetics, pharmacodynamics, immunogenicity, and preliminary antitumor activity of GSK3359609 administered as an intravenous (IV) infusion once every 3 weeks (Q3W) alone (Part 1) and in combination with 200 mg pembrolizumab (Q3W IV infusion) or other immunotherapy (Part 2) in approximately 304 adult patients. In dose escalation, eligible patients are required to have selected relapsed/refractory solid tumors. Primary objective is to determine safety, tolerability, and maximum tolerated or administered dose. Modified toxicity probability interval method will inform dose escalation decisions (minimum 3 patients per dose level [DL]). In expansion, cohorts may be defined by factors such as tumor histology, biomarker features, or prior treatment. More than one GSK3359609 DL may be evaluated in an expansion cohort by random assignment. Blood immunophenotyping is monitored in all patients; tumor biopsies (before and on-treatment) are optional in escalation and required in expansion to provide biomarker data that may inform on optimal dose selection as well as mechanistic understanding of GSK3359609. Efficacy measures are every 9 weeks and are according to immune-related RECIST. As of 7 Feb 2017, the first 3 monotherapy DL cohorts completed without dose limiting toxicities; DL 4 enrollment is ongoing. Study is funded by GlaxoSmithKline and is in collaboration with Merck & Co., Inc. Clinical trial information: NCT02723955.

TPS3114 Poster Session (Board #197b), Mon, 8:00 AM-11:30 AM

A phase I study of the safety and immunogenicity of a multipeptide personalized genomic vaccine in the adjuvant treatment of solid cancers. *First Author: Chrisann Kyi, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Mutation-derived tumor antigens (MTAs) arise as a direct result of somatic variations, including nucleotide substitutions, insertions, and deletions that occur during carcinogenesis. These somatic variations can be characterized via genetic sequencing and used to identify MTAs. We propose a platform for a fully-personalized MTA-based vaccine in the adjuvant treatment of solid tumors. **Methods:** This clinical trial is a single-arm, open label, proof-of-concept phase I study designed to test the safety and immunogenicity of the Personalized Genomic Vaccine 001 (PGV001). The single-center study will enroll 20 eligible subjects with histological diagnosis of the following tumor types: (a) head and neck squamous cell cancer, (b) non-small cell lung cancer, (c) ductal or lobular breast cancer, (d) serous carcinoma of the ovary, uterine adnexa, (e) urothelial carcinoma of renal pelvis or bladder, (f) cutaneous squamous cell cancer. Subjects must have no measurable disease at time of first vaccine administration, and 5-year disease recurrence risk of $>$ 30%. Patients will receive 10 doses of PGV001 as well as 10 doses of poly-ICLC (toll-like receptor-3 agonist, vaccine adjuvant), administered 1 day after PGV001 vaccination. Toxicity (endpoint 1) will be defined by Common Terminology Criteria for Adverse Events v5.0. Blood samples will be collected at various time points for immune response monitoring of MTA-specific humoral and cellular immune responses. For each patient, immunogenicity (endpoint 2) will be defined as an epitope-specific T cell response, detectable in peripheral blood samples after PGV001 vaccination. The change in the frequency of vaccine-induced epitope-specific T lymphocyte populations post-vaccination relative to baseline will be determined using mixed effects linear regression modeling. **Conclusions:** Our clinical trial will test for the first time the safety and immunogenicity of PGV001 in patients with multiple solid cancers. The information learned from this clinical trial will instruct the next generation of MTA-based vaccines, future development of immunotherapeutic approaches and rational combinations. Clinical trial information: NCT02721043.

TPS3115 Poster Session (Board #198a), Mon, 8:00 AM-11:30 AM

A phase I study of enadenotucirev (EnAd), an oncolytic Ad11/Ad3 chimeric group B adenovirus, in combination with nivolumab in tumors of epithelial origin. *First Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

Background: EnAd is a tumor-selective chimeric Ad11/Ad3 group B oncolytic adenovirus developed using directed evolution. Phase I clinical studies have identified a well-tolerated systemic dose and regimen for EnAd monotherapy. EnAd shows a high level of selective replication and cell killing for a broad range of carcinoma cell lines with little replication in normal and non-carcinoma cells. Previous studies have shown that after systemic administration there is significant uptake and replication of EnAd in various carcinomas associated with improved CD8+ T-cell tumor infiltration. These data provide the rationale for combination of EnAd with the checkpoint inhibitor (CPI), nivolumab (anti-PD-1 antibody) to potentially enhance the response to nivolumab. This is a phase I study in subjects with metastatic or advanced carcinoma. The study design has a dose escalation stage, followed by a dose expansion stage which will evaluate the ability to improve responses in tumors normally non-responsive to CPI and also to evaluate the ability to detect meaningful responses in PDL1 negative tumors that are less responsive to CPI. **Methods:** The dose escalation phase consists of 5 cohorts of patients with metastatic or advanced epithelial tumors in a standard "3 + 3" design. Subjects will receive increasing dose levels and/or cycles of EnAd followed by a q3w regimen of nivolumab (360mg). EnAd treatment cycles comprise 3 intravenous (IV) infusions on Days 1, 3 and 5. Nivolumab is administered as an IV infusion given every 3 weeks starting on Day 15 and continuing for up to 8 treatment cycles. The Dose Expansion phase will investigate the combination of EnAd and nivolumab in expanded cohorts of colorectal cancer, urothelial cell carcinoma, squamous cell carcinoma of the head & neck, and non-small cell lung cancer patients. The primary objectives are to establish the MTD of EnAd and nivolumab combination, to evaluate the safety and to recommend doses for future studies. Secondary endpoints include overall response, duration of response and progression free survival, assessed according to RECIST Version 1.1 and irRECIST Version 1. Enrollment to cohorts 3 & 4 began in January 2017. Clinical trial information: NCT02636036.

TPS3116 Poster Session (Board #198b), Mon, 8:00 AM-11:30 AM

An open-label, phase Ib study of NEO-PV-01 + adjuvant with nivolumab in patients with melanoma, non-small cell lung carcinoma, or transitional cell carcinoma of the bladder. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cancer cells contain unique DNA mutations that result in altered amino acid sequences known as neoantigens. Growing evidence supports a central role for neoantigens as targets for tumor directed immune responses. Tumor mutational burden as well as neoantigen load have been associated with anti-tumor activity of checkpoint inhibitors. Vaccines targeting neoantigens offer a highly specific way to induce de novo T cell reactivity and to expand existing T cell responses against neoantigens. Here, we describe NEO-PV-01, a personalized, neoantigen vaccine designed specifically for the molecular profile of each individual's tumor. **Methods:** NT-001 is a single-arm, phase IB study designed to evaluate the safety of administering NEO-PV-01 + adjuvant (Poly-ICLC) with nivolumab in patients with advanced melanoma, smoking-associated non-small cell lung carcinoma, or transitional cell carcinoma of the bladder who have received no more than one prior systemic treatment. Patients undergo a baseline tumor biopsy and HLA typing. DNA and RNA sequencing is performed on the tumors as well as peripheral blood to serve as normal DNA controls. On Day 1, patients begin treatment with nivolumab at a dose of 240 mg IV while their customized vaccine is being generated. Each vaccine is custom designed for the individual patient and contains up to 20 peptides 14-35 amino acids in length. The peptides are pooled into four groups and mixed with Poly-ICLC at the time of administration. Beginning at Week 12, patients receive five priming immunizations over a three-week period followed by booster vaccinations at Weeks 19 and 23. The primary endpoint is safety. Secondary endpoints are ORR, CBR, PFS, and assessment of response conversion between Week 12 and Week 24. Exploratory endpoints include extensive immune monitoring. Clinical trial information: NCT02897765.

3500 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Three versus six months adjuvant oxaliplatin-based chemotherapy for patients with stage III colon cancer: The French participation to the International Duration Evaluation of Adjuvant chemotherapy (IDEA) project. *First Author: Thierry Andre, Department of Medical Oncology, Hopital Saint-Antoine, APHP, Paris, France*

Background: The IDEA international collaboration was established to combine data from 6 randomized trials to assess whether a 3-month (3M) of oxaliplatin/fluoropyrimidines-based adjuvant chemotherapy (CT) is non-inferior to the 6-month (6M) for 3-year disease free survival (DFS) in stage III colon cancer (CC). **Methods:** French IDEA randomized patients (pts) between 3M and 6M of CT with mFOLFOX6 or XELOX (physician/pts choice). DFS was estimated using the Kaplan–Meier method and described using 3 years DFS rate. **Results:** Among 2022 randomized pts between May 2009 and May 2014, 2010 (99.4%) received CT and were enrolled in the mITT population: 49.9 and 50.1% in 3M and 6M, respectively. 99.5% of the mITT pts had stage III (N1: 74.9%; N2: 25.2%); median age 63.9 years; mFOLFOX6: 90% and XELOX 10% of pts. DFS median follow-up is 50.2 months. There were 578 DFS events (314 in 3M and 264 in 6M arm) leading to a 3-year DFS rate of 72.1% in the 3M vs. 75.7% in the 6M (HR=1.24; 95%CI 1.05–1.46, p=0.0112). For pts receiving mFOLFOX6, 3-year DFS rate was 72.0% in the 3M vs. 76.3% in the 6M (HR=1.27; 95% CI 1.07–1.51 p=0.0069). 94.2% and 78.0% of pts completed 3 and 6 months of CT, respectively. Median oxaliplatin doses intensity were 96.9% in 3M and 72.1% in 6M (495.0 and 735.1 mg/m2). By considering the neuropathy grade with 15375 neuropathy longitudinal measurements the overall maximal neuropathy grade 0-1/2/3-4 was 63.6/28.5/7.9% in 3M and 33.4/41.3/25.3% in 6M; p<0.0001. At last follow-up assessment, with a median of 43.1 months, final residual grade 2/3-4 neuropathy was 2.1/0.4% in 3M and 5.4/1.3% in 6M; p<0.0001. **Conclusions:** The IDEA France study, with 90% of patients treated with mFOLFOX6 regimen has shown that 6 months adjuvant treatment is superior to 3 months treatment. IDEA France study results should be considered in line with the international IDEA project that will also be presented at ASCO 2017. Clinical trial information: 2009-010384-16.

3501 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

FOLFOX4/XELOX in stage II–III colon cancer: Efficacy results of the Italian three or six colon adjuvant (TOSCA) trial. *First Author: Alberto F. Sobrero, IRCCS A.O.U. San Martino IST, Genoa, Italy*

Background: Six months of oxaliplatin-based treatment has been the standard of care as adjuvant therapy for stage III colon cancer and an accepted option for high-risk stage II. Given the cumulative neurotoxicity associated to oxaliplatin, a shorter duration of therapy, if equally efficacious, would be advantageous for patients and health-care systems. **Methods:** TOSCA was an open-label, phase III, multicenter, non-inferiority trial randomizing patients with high-risk stage II or stage III radically resected colon cancer to receive 3 months or 6 months of FOLFOX4/XELOX. Primary end-point was relapse-free survival. **Results:** From June 2007 to March 2013, 3759 patients were accrued from 130 Italian sites, 64% receiving FOLFOX4 and 36% XELOX in either arm. Two thirds were stage III. At the cut-off time for analysis the median time of follow-up was 62 months and 772 relapses or deaths have been observed. The RFS rate at 8 years is 75%. This analysis was done when 82% of the planned number of events was reached, with a power of 72% instead of 80%. The decision to anticipate the analysis was based on the participation to the IDEA joint collaborative analysis of studies sharing this clinical question. The Hazard Ratio of the 3months vs 6 months for relapse/death was 1.14 (95%CI 0.99-1.31, p for non inferiority = 0.253) and the confidence interval crossed the non inferiority limit of 1.20. **Conclusions:** TOSCA was not able to demonstrate that 3 months of oxaliplatin-based adjuvant treatment is as efficacious as 6 months. Nevertheless , because the absolute difference in RFS between the two treatment durations is small (less than 3 % at 5 years), the decision to complete the whole 6-month program should be individualized based on toxicity and patients' attitude. This study is registered with ClinicalTrials.gov Registration Number: NCT00646607. It was supported by a grant from AIFA (Agenzia Italiana del Farmaco) Grant Code FARM5RWTWZ. Clinical trial information: NCT00646607.

3502 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Final DFS results of the SCOT study: An international phase III randomised (1:1) non-inferiority trial comparing 3 versus 6 months of oxaliplatin based adjuvant chemotherapy for colorectal cancer. *First Author: Timothy Iveson, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom*

Background: Six months of oxaliplatin-based treatment has been the mainstay of adjuvant chemotherapy for colorectal cancer for the last 13 years. Neurotoxicity from oxaliplatin is cumulative, dose limiting, and potentially irreversible. A shorter duration of treatment would save patients significant toxicity/time and substantially reduce the costs of the drug, its administration, and treatment of adverse effects. **Methods:** SCOT is a non-inferiority randomised study designed to determine whether 3 months of adjuvant chemotherapy with OxMdG or Xelox (physician/patient choice) in Stage III/high risk Stage II colorectal cancer is as effective as 6 months treatment. Non-inferiority was determined to be a maximum 2.5% fall in 3-year disease-free survival (DFS) on the 3 month arm (from 78% on the 6 month arm) corresponding to a hazard ratio upper limit of 1.13. The study was designed with 90% power at the 2.5% 1-sided level of statistical significance and aimed to recruit 9500 patients to observe 2,750 DFS events (relapses/deaths/new colorectal cancers). Analysis used a Cox model adjusted for study minimisation factors. **Results:** 6088 patients (60% male, median age 65) with Stage III/high risk Stage II cancers of the colon or rectum were randomised between 27th March 2008 and 29th November 2013. The arms were balanced for clinical and pathological factors. Intended treatment was OxMdG for 1981 and Xelox for 4107 patients. There were 1469 DFS events (734 in 3 month arm and 735 in 6 month arm) giving the study 66% power. 3 year DFS was 76.8% (se = .8%) for the 3 month arm and 77.4% (se = .8%) for the 6 month arm (HR 1.008, 95% CI 0.910-1.117, test for non-inferiority p = 0.014). Non-inferiority appeared stronger for Xelox than OxMdG (test for heterogeneity, p = .059). Results will be shown broken down by stage, site, age, gender and achieved duration of treatment. **Conclusions:** The SCOT study has shown that 3 months adjuvant treatment is not inferior to 6 months treatment. However the SCOT study is part of the IDEA consortium and the results from the 6 studies in the IDEA consortium addressing the same duration question will also be presented at ASCO 2017. Clinical trial information: ISRCTN59757862.

3503 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Primary (1°) tumor location as an independent prognostic marker from molecular features for overall survival (OS) in patients (pts) with metastatic colorectal cancer (mCRC): Analysis of CALGB / SWOG 80405 (Alliance). *First Author: Alan P. Venook, University of California, San Francisco, San Francisco, CA*

Background: 80405 found no OS or Progression Free Survival (PFS) difference when bevacizumab (BV) or cetuximab (Cet) was added to 1st-line FOLFOX or FOLFIRI in All *RAS* wild type (wt) mCRC pts. There was a significant 1° side by biologic interaction (P int: OS = 0.008, PFS = 0.001) favoring pts with left-sided (L) 1°. Analyses of 1° tumors beyond All *RAS* includes Consensus Molecular Subtype (CMS), *BRAF* and MSI. (CMS results - see Lenz et al; *BRAF* -see Innocenti et al) We asked whether 1° tumor location - L vs right (R) - is an independent prognostic marker when these other molecular features are considered. **Methods:** We used a Cox proportional hazard model stratified by prior XRT and +/- adjuvant chemo; adjusted for age, gender, synchronous vs metachronous, CMS, MSI and *BRAF* status. Pts with transverse (T) tumors were excluded in this analysis. **Results:** Sidedness was determined in 782 pts (L - 472; R - 256; T -54). Molecular data from 728 pts (with L - and R-sided 1°s) was available as follows: *KRAS* – 291, *NRAS* -393, *BRAF* - 393, MSI - 378, CMS - 533. L vs R mOS: 32.9 v 19.6 months (mo) (p < 0.0001). See Table for OS results in All *RAS* / *BRAF* wt and *BRAF* mutant (mut) pts. Sidedness (R vs L) is an independent prognostic marker even after adjusting for all these molecular features: HR = 1.392 (1.032, 1.878), p = 0.031. **Conclusions:** Primary tumor location is an independent prognostic factor when adjusted for age, gender, synchronous/metachronous, CMS, MSI and *BRAF* status. We are exploring clinical variables such as tumor burden, metastatic sites and measurability of disease in an attempt to explain the impact of sidedness. *Support: U10CA188021, U10CA180882. Eli Lilly and Co, Genentech/ Roche, Pfizer, Sanofi.* Clinical trial information: NCT002655850.

Population	Median OS (95% CI) L-sided R-sided	Log-rank p-value	Adjusted HR (95%, CI)

3504 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Somatic DNA mutations, MSI status, mutational load (ML): Association with overall survival (OS) in patients (pts) with metastatic colorectal cancer (mCRC) of CALGB/SWOG 80405 (Alliance). *First Author: Federico Innocenti, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: CALGB 80405 was a randomized phase III trial that found no difference in OS in first-line mCRC pts treated with either bevacizumab (Bev) or cetuximab (Cet). Primary tumor DNA from 361 pts, including KRAS mutant (mut) pts, has been profiled for somatic gene mutations/ML/MSI to discover molecular markers of OS. **Methods:** Mutations in 11 genes were determined by PCR, MSI by microsatellite analysis, and ML by next-generation sequencing (FoundationOne). Cox proportional hazard models are used, stratified by prior XRT and +/- adjuvant chemotherapy; adjusted by age, race, gender, synchronous vs. metachronous, liver metastases, sidedness, all RAS. **Results:** BRAF: Mut pts had shorter OS than wild-type (wt) pts (HR 1.92, 95% CI 1.34,2.75; p<0.001); HR 1.65 (1.09,2.50) after adjusting for sidedness (p 0.022). In mut pts longer OS is observed in Bev arm vs. Cet arm (p 0.041); in wt pts no arm difference is observed (p 0.291, table). MSI: OS does not differ between MSI-H and MSI-S pts (HR 0.78 [0.40, 1.52], p 0.450). In MSI-H pts longer OS is observed in Bev arm vs. Cet arm (p 0.002); in MSI-S pts no difference is observed (p 0.305, table). ML: Hypermutated MSI-H pts are excluded. In a subset of 205 pts, pts with ML>5 (N=93) have longer OS than pts with ML≤5 (N=112) (HR 0.65 [0.42,1.00], p 0.048). In Bev arm higher ML confers longer OS than lower ML (HR 0.85 [0.80,0.96], p 0.004); in Cet arm no difference is observed (HR 0.99 [0.90,1.09], p 0.862). **Conclusions:** BRAF is a strong negative prognostic factor in mCRC, even when sidedness is taken into account. ML is a novel marker for further evaluation. The effect of Bev and Cet in either BRAF mut or MSI-H pts should be tested in larger datasets. Updated results from more screened samples will be presented.

3505 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Randomized trial of irinotecan and cetuximab with or without vemurafenib in BRAF-mutant metastatic colorectal cancer (SWOG S1406). *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Metastatic colorectal cancer (mCRC) patients (pts) with *$BRAF^{V600}$* mutations have poor outcomes with standard of care chemotherapy and rarely respond to the BRAF inhibitor vemurafenib. In preclinical models, blockade of $BRAF^{V600}$ by vemurafenib (V) causes feedback upregulation of EGFR, whose signaling activities can be impeded by cetuximab (C) with anti-tumor activity augmented by irinotecan (I). **Methods:** Pts with *$BRAF^{V600}$* mutated and extended *RAS* wild-type mCRC were randomized to irinotecan (180 mg/m^2 IV every 14 days) and cetuximab (500 mg/m^2 IV every 14 days) with or without vemurafenib (960 mg PO twice daily). Eligible pts had ECOG PS ≤1, and had received 1 or 2 prior regimens with no prior anti-EGFR agents. Randomization was stratified for prior irinotecan. Crossover from the control arm (IC) to the experimental arm (VIC) was allowed after documented progression. The primary endpoint was progression-free survival (PFS, investigator assessed), with 90% power to detect a HR of 0.5, with two-sided type 1 error of 5%. **Results:** 106 pts were enrolled (99 eligible, 49 in the experimental arm) from 12/2014 to 4/2016, with median age 62 years, 59% female, and 39% with prior irinotecan therapy. PFS was improved with the addition of vemurafenib (HR 0.42, 95% confidence interval [CI] 0.26 to 0.66, P < 0.001) with median PFS of 4.4 (95% CI 3.6 – 5.7) mos vs 2.0 (95% CI 1.8 – 2.1) months. Response rate was 16% vs 4% (P = 0.08), with disease control rate of 67% vs 22%. In pts with no prior irinotecan, median PFS was 5.7 (95% CI 3.0-6.1) months in the VIC arm vs 1.9 (95% CI 1.7 – 2.1) months in the IC arm. Grade 3/4 adverse events higher in the VIC arm included neutropenia (28% vs 7%), anemia (13% vs 0%), and nausea (15% vs 0%). There was no increase in skin toxicity or fatigue. 23 pts (46%) in the IC arm crossed over at the time of progression, with median PFS from crossover of 6.0 months (95% CI 3.7 – 7.4). Overall survival (OS) data will be mature for ASCO 2017. **Conclusions:** These results demonstrate the clinical benefits of the VIC triplet (vemurafenib, cetuximab, and irinotecan) in pts with treatment-refractory $BRAF^{V600}$ mutated mCRC, and support VIC as a potential new treatment option in this molecular subset. Clinical trial information: NCT02164916.

3506 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

SUNSHINE: Randomized double-blind phase II trial of vitamin D supplementation in patients with previously untreated metastatic colorectal cancer. *First Author: Kimmie Ng, Dana-Farber Cancer Institute, Boston, MA*

Background: In prospective observational studies of mCRC patients, higher plasma levels of 25-hydroxyvitamin D have been associated with improved progression-free (PFS) and overall survival (OS), but the role of vitamin D supplementation in the treatment of mCRC is unknown. **Methods:** SUNSHINE was a multi-center double-blind phase II randomized controlled trial in previously untreated mCRC patients. Patients were eligible if they had histologically confirmed mCRC, no prior therapy for metastatic disease, ECOG PS 0-1, and were not taking vitamin D >2,000 IU/day x 1 year. All subjects received standard treatment with mFOLFOX6 + bevacizumab with 1:1 randomization to concurrent: HiVitD (vitamin D3 po 8,000 IU/d x 2 wks as loading dose followed by 4,000 IU/d) or LowVitD (standard vitamin D3 400 IU/d) until disease progression, intolerable toxicity, or withdrawal of consent. The primary endpoint was PFS, with the sample size designed to provide 80% power to detect a HR of 0.66 for PFS at a 1-sided alpha=0.2. **Results:** From April 2012 to November 2016, 139 patients were randomized. Median age was 54 yrs (range 24-82), 57% were male, 77% were white, and 7% had received prior adjuvant chemo. Baseline characteristics were balanced between arms except ECOG PS = 0 was 42% vs. 60% in HiVitD vs. LowVitD. Median follow-up was 16.1 mos (range 0-45.9) and median compliance with VitD capsules was 98%. Patients randomized to HiVitD experienced longer PFS than those receiving LowVitD (median PFS, 12.4 vs. 10.7 mos, respectively; log rank *P*=0.03). After multivariate adjustment for prognostic variables, HR was 0.66 (95% CI, 0.45-0.99, 2-sided *P*=0.04). Comparing HiVitD vs LowVitD, RR was 58% vs. 63% (*P*=0.54) and disease control rate was 100% vs. 94% (*P*=0.05). The most common grade 3-4 toxicities were as expected for FOLFOX-bevacizumab, and none were related to vitamin D. Currently, 14 patients are still actively receiving treatment, and OS data are not yet mature. **Conclusion:** SUNSHINE met its prespecified primary endpoint, with patients randomized to HiVitD experiencing longer PFS compared to those randomized to LowVitD. A larger confirmatory phase III randomized trial appears warranted. Clinical trial information: NCT01516216.

3507 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Overall survival analysis of the FOXFIRE prospective randomized studies of first-line selective internal radiotherapy (SIRT) in patients with liver metastases from colorectal cancer. *First Author: Ricky A. Sharma, Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom*

Background: The FOXFIRE, SIRFLOX and FOXFIRE-Global (FF-SF-FFG) randomized studies evaluated the efficacy of combining first-line chemotherapy for metastatic colorectal cancer (mCRC) with selective internal radiotherapy (SIRT) using yttrium-90 resin microspheres in patients with liver metastases. The studies were designed for prospective, combined analysis of overall survival (OS). **Methods:** FF-SF-FFG randomized (1:1) chemotherapy-naïve mCRC patients (performance status 0/1) with liver metastases not suitable for curative resection/ablation. Arm A was oxaliplatin-based chemotherapy (mFOLFOX6/ OxMdG) ± investigator-chosen biologically targeted agent. Arm B was the same systemic therapy (oxaliplatin dose modification) + single treatment SIRT with cycle 1/2 of chemotherapy. Primary tumor in situ and/or limited extra-hepatic metastases were permitted. Minimum sample size was 1075 patients (HR 0.8, 80% power, two-sided 5% significance). Secondary outcomes included PFS, liver-specific PFS and response rate. Apart from safety, outcomes were analysed on intention-to-treat population using meta-analytic methods of pooled individual patient data. **Results:** Between 2006 and 2014, 1103 patients were randomized in 14 countries. Median age was 63 years (range 23-89); median follow-up 43.3 months. There were 844 deaths. There was no difference in OS (HR 1.04; 95% CI 0.90-1.19, *p*= 0.609) or PFS (HR 0.90, CI 0.79-1.02, *p*= 0.108) between Arms. Objective response rate (*p*= 0.001) and liver-specific progression (HR 0.51, CI 0.43-0.62, *p*< 0.001) were significantly more favorable in Arm B. Patients in Arm B had higher risk of non-liver progression as first event (HR 1.98, CI 1.53-2.58, *p*< 0.001). Grade 3-5 adverse events were more common in Arm B (74.0%) than A (66.5%), *p*= 0.009. In health status questionnaires, EQ-5D utility scores were not significantly different between Arms at 6, 12 or 24 months. **Conclusion:** Despite higher response rates and improved liver-specific PFS, the addition of SIRT to first-line oxaliplatin-fluorouracil chemotherapy for patients with liver-only and liver-dominant mCRC did not improve OS or PFS. Clinical trial information: 83867919.

3508 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

A randomized, double-blind, placebo-controlled, multi-centered phase 3 trial comparing fruquintinib versus placebo plus best supportive care in Chinese patients with metastatic colorectal cancer (FRESCO). *First Author: Jin Li, Fudan University Shanghai Cancer Center, Shanghai Medical College, Shanghai, China*

Background: Treatment options for third-line metastatic colorectal cancer (mCRC) patients remain limited in China. Fruquintinib, an oral kinase inhibitor selectively targeting vascular endothelial growth factor receptors, in a phase II study was found to significantly improve progression free survival ("PFS") in patients with mCRC as compared to placebo (ESMO abs#2111). Based on these results, a Phase III registration trial, FRESCO, was carried out to confirm fruquintinib's efficacy and safety in third-line mCRC patients (clinicaltrials.gov # NCT02314819). **Methods:** This is a randomized, double-blind, placebo-controlled, multi-center phase III trial. Patients with mCRC who have failed at least 2 lines of systemic chemotherapy were enrolled from 28 centers in China. Patients were stratified based on prior anti-VEGF therapy and K-ras status and randomized to a fruquintinib or placebo arm in a 2:1 ratio. The primary endpoint was overall survival ("OS") which was analyzed in the intent-to-treat population. **Results:** Between December 12, 2014 and May 13, 2016, 416 patients were randomized. Protocol predefined number of OS events for final analysis was reached on January 17, 2017. Fruquintinib significantly improved OS comparing to placebo with a hazard ratio of 0.65 (95% CI: 0.51-0.83; two sided $p<0.001$). Median OS was 9.30 months [95% CI 8.18-10.45] in the fruquintinib group versus 6.57 months [95% CI 5.88-8.11] in the placebo group. Statistically significant benefits were also seen with fruquintinib in all secondary endpoints, such as PFS, objective response rate and disease control rate. The most frequent fruquintinib-related ≥ Grade 3 treatment emerged adverse events included hypertension (21.6%), hand-foot skin reaction (10.8%), proteinuria (3.2%) and diarrhea (3.2%). **Conclusion:** In this phase III confirmatory trial, fruquintinib demonstrated a statistically significant and clinically meaningful OS benefit as compared with placebo in mCRC patients in China. Fruquintinib was well tolerated with a safety profile that is consistent with what was reported previously. Clinical trial information: NCT02314819.

3509 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM

Clinical utility of colon cancer molecular subtypes: Validation of two main colorectal molecular classifications on the PETACC-8 phase III trial cohort. *First Author: Laetitia Marisa, Ligue Nationale Contre le Cancer, Paris, France*

Background: The molecular subtyping of colon cancers (CC) has been the subject of several recent publications, leading to an international consensus. The clinical relevance of these molecular classifications remains to be evaluated on large prospective patient cohorts using a tool that can be widely used on formalin-fixed paraffin-embedded (FFPE) samples. **Methods:** We aimed to evaluate the clinical relevance of two molecular subtyping systems, CMS (Guinney et al. 2015) and CCMST (Marisa et al. 2013), on the PETACC-8 cohort, a randomized phase III trial comparing adjuvant FOLFOX with or without cetuximab in patients with stage III CC. For each of these two classification systems, a predictor tool was developed and adapted to FFPE samples. The NanoString nCounter platform was used to screen 196 genes. Predictors were built from 249 frozen tumor samples previously used to build our classification system and 61 new paired FFPE/frozen samples. Both predictors were then applied to 1781 PETACC-8 FFPE samples. Subtypes associations to clinical and molecular features were analyzed. **Results:** The CMS predictor assigned 297 samples to CMS1 (17%), 585 to CMS2 (34%), 68 to CMS3 (4%) and 770 to CMS4 (45%). CMS were significantly associated with several molecular and clinical features, including MSI status (49% in CMS1, $p < 0.001$), CIMP status (47% in CMS1, $p < 0.001$), KRAS mutation (75% in CMS3, $p < 0.001$), BRAF mutation (34% in CMS1, $p < 0.001$), tumor location (less proximal tumors in CMS2, $p < 0.001$), validating the predictor tool developed. The classification was significantly associated to prognosis in multivariate analysis, CMS4 subtype having a shorter overall survival (hazard ratio = 1.7, $p = 0.021$). A deleterious effect of cetuximab was observed in CMS1 ($p < 0.05$). Similar results were obtained with the CCMST classification. **Conclusions:** We validated molecular CC subtyping predictors for both CMS and CCMST classifications on PETACC-8 FFPE samples. The prognostic value of CMS and CCMST classifications was confirmed, stem-like tumors being associated with a poor prognosis. These results pave the avenue for widely use of the CC molecular classification in clinical routine.

3510 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM

Consensus molecular subgroups (CMS) of colorectal cancer (CRC) and first-line efficacy of FOLFIRI plus cetuximab or bevacizumab in the FIRE3 (AIO KRK-0306) trial. *First Author: Sebastian Stintzing, Department of Hematology and Oncology, Klinikum Grosshadern and Comprehensive Cancer Center, University Hospital Grosshadern, LMU Munich, Munich, Germany*

Background: FIRE-3 compared 1st-line therapy with FOLFIRI plus either cetuximab or bevacizumab in 592 KRAS exon 2 wt mCRC patients. CMS is grouping CRCs according to their gene-signature in 4 different types. Relevance of CMS for the treatment of mCRC remains unclear. **Methods:** Patients were grouped according to tumor CRC-CMSs. Using ALMAC's Xcel tissue array, gene signatures of FIRE-3 tumor samples were analyzed. Survival was compared using Kaplan-Meier estimation and log-rank tests. Hazard ratios (HR) were estimated according to the Cox proportional hazard method. **Results:** CMS classification could be determined in 385 specimens available from the ITT population (n = 592). In this KRAS exon 2 wt population (n = 385), frequencies were: CMS1 (10.4%), CMS2 (36.6%), CMS3 (11.7%), CMS4 (29.1%), non-consensus (12.2%). In RAS wt (n = 315), frequencies were: CMS1 (11.1%), CMS2 (38.1%), CMS3 (9.5%), CMS4 (29.5%), non-consensus (11.7%). Independent of the treatment, CMS was a strong prognosticator for ORR ($p = 0.023$), PFS ($p < 0.001$) and OS ($p < 0.001$). For data on CMS and treatment efficacy in the RAS wt population see the following table. **Conclusions:** CMS classification is prognostic for mCRC. The survival benefit in RAS wt previously observed for FOLFIRI cetuximab vs. FOLFIRI bevacizumab is not significantly different across CMS groups, although there are trends when comparing OS HR between categories with CMS4 showing the best HR.

	Median PFS (months)					Median OS (months)				
	events	All	FOLFIRI Cetuximab	FOLFIRI Bevacizumab	p* HR	events	All	FOLFIRI Cetuximab	FOLFIRI Bevacizumab	p* HR

3511 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM

Impact of consensus molecular subtyping (CMS) on overall survival (OS) and progression free survival (PFS) in patients (pts) with metastatic colorectal cancer (mCRC): Analysis of CALGB/SWOG 80405 (Alliance). *First Author: Heinz-Josef Lenz, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: CALGB 80405 was a randomized Ph3 trial showing no OS or PFS difference in mCRC pts treated with Bevacizumab (BV) or Cetuximab (Cet) in the first line. A Nanostring platform was used to determine the CMS classification of 392 KRAS wt (codon 12 and 13) primary tumors and correlated it with OS and PFS in patients enrolled in 80405. **Methods:** CMS for 392 of 431tumors were defined using a custom CRC Nanostring panel (39 CMS classification not possible). Stratified Cox proportional hazard model was used to evaluate the effect of CMS classification stratified by prior radiation, prior chemotherapy, adjusting for age, sex, race, primary in place, liver met only, and sidedness. **Results:** We found CMS1 (14%), CMS2 (47%), CMS3 (2%), CMS4 (29%), NonConsensus (8%). Results are shown in Table 1. Patients with CMS1 who received BV had significantly longer OS than those who received Cet (HR 0.47, 95% CI [0.24, 0.92]). Patients with CMS2 who received BV tended to have shorter OS than those who received Cet (HR 1.41, CI [0.95, 2.08]). **Conclusions:** Our data suggest that CMS is associated with OS and PFS in first line therapy in mCRC patients. Preliminary data suggest that certain CMS may be associated with efficacy of Bev and Cet based chemotherapy. CMS classification should be explored as a stratification factor in future trials. Support: U10CA180821, U10CA180830, U10CA180882 Clinical trial information: NCT00265850.

3513 Poster Discussion Session; Displayed in Poster Session (Board #136), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

A phase III trial (ZJBIO009): CMAB009 plus irinotecan versus irinotecan alone as second-line treatment after fluoropyrimidine and oxaliplatin failure in wild-type *K-ras* metastatic colorectal cancer patients. *First Author: Yuankai Shi, National Cancer Center /Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing Key Laboratory of Chinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: More efficient second line treatment regimen for mCRC is urgently needed. CMAB009, a recombinant human/mouse chimeric monoclonal antibody, is specifically targeting human epidermal growth factor receptor. This study aimed to determine clinical efficacy and safety of CMAB009 plus irinotecan compared with irinotecan alone in wild-type *K-ras* mCRC patients (pts). **Methods:** This is a open-label, randomized, phase 3 trial. Patients had histologically confirmed wild-type *K-ras* mCRC, who previous failure of 5-fuorouracil plus oxaliplatin more than 1 month of the last-dose enrolled in study. Pts were randomly assigned on a 2:1 to receive CMAB009 (initial 400mg/m^2 on day 1, and then 250 mg/m^2 weekly) plus irinotecan (180mg/m^2, every 2 weeks) (A arm) or irinotecan alone (B arm). B arm pts could switch to CMAB009 sequential treatment (C arm) on diseas progression. The primary end point was overall response rate (ORR). The secondary endpoints were PFS, OS, DCR, and DOR (NCT01550055). **Results:** From May 2009 to December 2012, 512 pts were assigned from 38 sites. Efficacy evaluation could be in 501 pts, ORR were 33.2% (112/337) and 12.8% (21/164) in A arm and B arm ($p < 0.0001$). C arm had 115 pts, DCR was 63.5% (73/115). DOR in A arm and B arm were 210 days and 109 days (p=0.001). In C arm, DOR was 148 days. Median PFS was significantly longer in A arm than B arm (169 days *vs* 95 days; $p < 0.0001$). In C arm, median PFS was 84 days. Median OS was 425 days in A arm and 401 days in B arm (p=0.94). 96.2% (484/503) pts experienced at least one adverse event (AE). 55.3%(187/338) and 37.6%(62/165) patients in A arm and B arm had at least one grade ≥3 AE respectively. The most common AE included diarrhea, emesis, leucopenia, neutropenia and fatigue. Adding CMAB009 to irinotecan increased the risk of rash (66.6% *vs* 5.5%, $p < 0.001$) and paronychia (9.8% *vs* 0,$p < 0.001$). **Conclusions:** CMAB009 plus irinotecan significantly increased ORR and prolonged PFS compared with irinotecan alone. CMAB009 plus Irinotecan were efficient and well tolerated, which could be considered as a standard second-line treatment choice in wild-type *K-ras* mCRC pts. Clinical trial information: NCT01550055.

Tumor sidedness and intrinsic subtypes in patients with stage II/III colon cancer: Analysis of NSABP C-07 (NRG Oncology). *First Author: S. Rim Kim, NSABP/NRG Oncology, Pittsburgh, PA*

Background: The predictive value of tumor sidedness in colorectal cancer is currently of interest especially in metastatic setting for anti-EGFR therapy response. We tested whether intrinsic molecular subtype classification predictive of treatment benefit in stage II/III colon cancer is an independent novel marker in association with tumor sidedness. **Methods:** All available cases included in the NSABP/NRG C-07 trial for which we had both gene expression data and anatomical data (n=1603) were used to determine the molecular subtypes using the following classifiers; the Colorectal Cancer Assigner (CRCA), the Colon Cancer Subtypes (CCS) and the Consensus Molecular Subtypes (CMS). Frequency of tumor sidedness in each subtype and recurrence-free survival were analyzed. **Results:** Intrinsic subtypes were differentially distributed in right- and left-colon tumors with the exception of the stem-like or CMS4 (mesenchymal) subtype (Table 1). Sidedness was not associated with prognosis (p=0.82, HR: 1.022 [CI: 0.851-1.227]) or prediction of patients with greater benefit from oxaliplatin when combined with 5-Fu+LV (interaction p=0.484). **Conclusions:** Although tumor sidedness is associated with distribution of intrinsic subtypes in stage II/III colon cancer, it is not predictive of survival benefit from oxaliplatin in C-07. Association of prognostic value of primary tumor location in stage III colon cancer with RAS and BRAF mutational status. *First Author: Julien Taieb, Hopital Européen Georges Pompidou, Paris, France*

Background: Recent data suggest that the anatomic site of colon primary tumor may be an important factor in the interpretation of molecular markers with clinical outcome in metastatic colon cancer (CC) patients (pts). We assessed here the prognostic value of primary location in fully resected stage III CC pts and its relationship to MSI, *RAS* and *BRAF* mutational status. **Methods:** Pts enrolled in the PETACC-8 trial were analyzed. We categorized tumor site as located proximal (left-sided) or distal (right-sided) to the splenic flexure. The association between tumor location and disease free survival (DFS), survival after relapse (SAR) and overall survival (OS) were assessed by Cox models and adjusted for clinical and pathological features, MSI, *BRAF* and *RAS*mutation status. The outcome of pts receiving FOLFOX or FOLFOX and cetuximab in the adjuvant setting were also determined according to tumor site. **Results:** Among the 1869 pts with full molecular data available, 755 (40%) had a right-sided tumor, 164 (10%) were MSI, 942 (50%) were mutated for *RAS* and 212 (11%) were mutated for *BRAF*. Right-sided tumor was not prognostic for DFS in the whole population but was associated to a shorter SAR (HR: 1.54 [1.23 - 1.93], p = 0.001) and OS (HR: 1.25 [1.02 - 1.54], p = 0.03). Same results were observed for MSS and for MSI pts. However, when looking at pts mutated for *RAS* or *BRAF*(MUT) and those double wild type (DWT) for those mutations, we found that right-sided tumors, when compared to left-sided tumors, was associated with a worst DFS in DWT patients (HR:1.39[1.01-1.92], p = 0.04) and a better DFS in MUT patients (HR:0.77[0.63-0.95], p = 0.01). These results were found independently of the treatment received and no beneficial effect of cetuximab on DFS or OS was observed in left-sided tumors. **Conclusions:** In the whole study population of stage III CC pts, though right-sided tumor location influences OS as previously reported, it does not seem to influence DFS but only SAR, when disease becomes metastatic. Interestingly, sidedness seems to influence DFS when splitting the population in MUT or DWT for *RAS* and *BRAF,* with a worst DFS for right-sided tumors in DWT and a worst DFS for left-sided tumors in *RAS* or *BRAF* mutants. Clinical trial information: 2005-003463-23.

Analysis of serum vitamin D levels and prognosis in stage III colon carcinoma patients treated with adjuvant FOLFOX+/- cetuximab chemotherapy: NCCTG N0147 (Alliance). *First Author: Frank A. Sinicrope, Mayo Clinic Cancer Center, Rochester, MN*

Background: Epidemiological data suggest a protective effect of vitamin D on CC risk. However, association of serum vitamin D level with clinical outcome in pts with surgically resected CC remains unknown. We analyzed total circulating 25-hydroxyvitamin D [25(OH)D)] with clinical outcome in pts with resected stage III CC treated with FOLFOX +/- cetuximab in a phase III trial. **Methods:** Association of pre-treatment level of plasma 25(OH)D with disease-free survival (DFS) and time-to-recurrence (TTR) was analyzed with 25(OH)D as a continuous variable by a relative risk model with splines and as a binary variable (vitamin D deficient [<30 ng/mL]) using multivariable Cox regression. **Results:** Overall, 49% (291/600) of pts were vitamin D deficient. Prevalence of vitamin D deficiency was significantly higher in women vs men (52% vs. 48%, p=0.030) and in blacks vs whites (74% vs. 45%, p=0.0003). The continuous 25(OH)D level and pt sex were associated by the interaction test ($p_{interaction}$=0.044). There were no statistically significant associations with DFS/TTR for either continuous 25(OH)D level (DFS, p=0.22; TTR, p=0.26) nor for vitamin D deficiency (DFS, adjusted hazard ratio [HR_{adj}]=1.01, 95% CI, 0.74-1.38; p_{adj}=0.94; TTR, HR_{adj}=1.00; CI, 0.72-1.38; p_{adj}=0.99. A comparison of the highest vs lowest tertile showed a significant association between the highest 25(OH)D level and better outcomes in men (DFS, $HR_{adj.}$=0.18, CI, 0.04-0.76, p_{adj}=0.020; TTR, $HR_{adj.}$=0.12, CI, 0.02-0.64, p_{adj}=0.014), but not in women (DFS, $p_{interaction}$=0.039; TTR, $p_{interaction}$=0.033). **Conclusions:** Nearly one-half of pts in the clinical trial cohort were vitamin D deficient with lowest 25(OH)D levels found in women and blacks. While vitamin D deficiency was not associated with adverse outcome, high levels of vitamin D in men, but not women, were associated with longer survival. Nut consumption and survival in stage III colon cancer patients: Results from CALGB 89803 (Alliance). *First Author: Temidayo Fadelu, Dana-Farber Cancer Institute, Boston, MA*

Background: Recent prospective cohort studies suggest states of energy excess and hyperinsulinemia, including type 2 diabetes (T2D), obesity, sedentary lifestyle, Western pattern diet, increased dietary glycemic load, high intake of sugar-sweetened beverages, and elevated plasma C-peptide are each associated with an increased risk of colon cancer (CC) recurrence and mortality. Conversely, observational studies indicate that increasing nut intake is associated with lower risk of T2D, metabolic syndrome and insulin resistance. However, the effect of nut intake on CC recurrence and survival is unknown. **Methods:** We conducted a prospective, observational study of 826 patients with stage III CC who reported dietary intake with food frequency questionnaires while enrolled in a randomized adjuvant chemotherapy trial. Using Cox proportional hazards regression, we assessed associations of nut intake with cancer recurrence and mortality. The primary endpoint was disease-free survival (DFS) defined as time from completion of dietary questionnaire following adjuvant therapy to cancer recurrence, death or last follow-up. **Results:** Compared to patients who abstained from nuts, those who consumed ≥ 2 servings of nuts per week had an adjusted hazard ratio (HR) of 0.58 (95% CI, 0.37 to 0.92; $P_{trend} = 0.03$) for DFS and 0.43 (95% CI, 0.25 to 0.74; $P_{trend} = 0.01$) for overall survival (OS). On subgroup analysis, the significant association was confined to tree-nut intake: HR = 0.54 (95% CI, 0.34 to 0.85; $P_{trend} = 0.04$) for DFS and HR = 0.47 (95% CI, 0.27 to 0.82; $P_{trend} = 0.04$) for OS. There was no significant association between intake of peanut or peanut butter and patient outcome. Association of total nut intake with improved outcomes was maintained across other known or suspected predictors of recurrence and mortality, including across common genomic alterations (microsatellite instability, KRAS mutation, BRAF mutation, and PIK3CA mutation). **Conclusions:** Higher consumption of nuts may be associated with significantly reduced cancer recurrence and death in patients with stage III CC. Support: U10CA180821, U10CA180882, Pfizer. Clinical trial information: NCT00003835.

Comparison of long-term survival outcomes between laparoscopic and open surgery for mid or low rectal cancer treated with preoperative chemoradiotherapy: 7-year follow-up of COREAN trial. *First Author: Ji Won Park, Department of Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea*

Background: Laparoscopic surgery for rectal cancer has been used widely. However, recent two randomized trials raised concerns about short-term oncologic safety of laparoscopic surgery for rectal cancer. The aim of this study was to evaluate the long-term oncologic safety of laparoscopic surgery for rectal cancer based on 7-year data from the Comparison of Open versus laparoscopic surgery for mid or low REctal cancer After Neoadjuvant chemoradiotherapy (COREAN) trial. **Methods:** COREAN trial was a non-inferiority, randomized controlled trial. Between April, 2006, and Aug, 2009, eligible participants with mid or low rectal cancer treated with preoperative chemoradiotherapy were randomly assigned (1:1) to laparoscopic (n = 170) or open surgery (n = 170). Seven-year outcomes included overall and disease-free survival, and local recurrence. Log-rank test and stratified Cox regression analysis were used for survival analysis. Analysis was by intention to treat. **Results:** The median follow-up times were 84 months (IQR: 61.5-97.0). No differences were found between laparoscopic and open surgery group in terms of overall and disease-free survival, and local recurrence (7-year overall survival: 83.2% [laparoscopic] vs 77.3% [open], p = 0.48; 7-year disease-free survival: 71.6% [laparoscopic] vs 64.3% [open], p = 0.20; 7-year local recurrence: 3.3% [laparoscopic] vs 7.9% [open], p = 0.08). Stratified Cox regression analysis adjusted for ypT, ypN and tumor regression grade showed no significant difference between groups in terms of overall and disease-free survival, and local recurrence. The hazard ratios for overall survival, disease-free survival and local recurrence (open *vs* laparoscopic surgery) were 0.96 (95% CI = 0.58-1.57), 1.03 (95% CI = 0.70-1.53), and 2.28 (95% CI = 0.82-7.16), respectively. **Conclusions:** The 7-year analysis confirm the long-term oncological safety of laparoscopic surgery for rectal cancer treated with preoperative chemoradiotherapy. The use of laparoscopic surgery does not compromise the long-term survival outcomes in rectal cancer. Clinical trial information: NCT00470951.

Total neoadjuvant chemotherapy to facilitate delivery and tolerance of systemic chemotherapy and response in locally advanced rectal cancer. *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The most common therapy for locally advanced (T3/4 or N+) rectal cancer (LARC) consists of preoperative chemoradiotherapy (chemoRT) followed by surgery and adjuvant chemotherapy. Recently, use of total neoadjuvant therapy (TNT) with preoperative chemotherapy in addition to chemoRT prior to resection has been accepted as an alternative. **Methods:** Of 811 consecutive patients (pts) who presented with LARC at our cancer center in 2009-2015, 320 received chemoRT with planned adjuvant chemotherapy, and 308 received TNT (induction FOLFOX/CAPOX chemotherapy followed by chemoRT). Treatment and outcome data for those two cohorts were compared. **Results:** Pts in the TNT cohort received greater percentages of the planned oxaliplatin and fluorouracil prescribed dose than those in the chemoRT with planned adjuvant chemotherapy cohort ($p < 0{\cdot}005$ and $p < 0{\cdot}001$, respectively). The complete response (CR) rate, which includes pathological CR (pCR) and clinical CR (cCR) at 6 months post-treatment, was 21% in the chemoRT with planned adjuvant chemotherapy cohort and 36% in the TNT cohort. The median follow-up was 40 months in the chemoRT with planned adjuvant chemotherapy cohort and 23 months in the TNT cohort. Fewer distant recurrences were seen in patients who had T downstaging ($p < 0{\cdot}001$), N downstaging ($p < 0{\cdot}005$), a cCR ($p = 0{\cdot}005$), or a pCR ($p < 0{\cdot}005$). There was no statistically significant difference in distant-recurrence-free survival between the two cohorts. **Conclusions:** Our findings provide additional support for the National Comprehensive Cancer Network (NCCN) guidelines for rectal cancer treatment, which categorizes TNT as a viable treatment strategy that facilitates superior compliance and delivery of systemic therapy. Given its high CR rate, TNT may be beneficial as part of a nonoperative treatment strategy aimed at organ preservation.

3520 Poster Discussion Session; Displayed in Poster Session (Board #143), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Colorectal cancer (CRC) patients surveyed by ^{18}FDGPET-CT (PET-CT): An open-label multicenter randomized trial (NCT 00624260). *First Author: Iradj Sobhani, Departement of Gastroenterology and Oncology Hopital Henri Mondor, Creteil, France*

Background: Curative surgery is the best therapy of CRC and recurrences. We assessed whether adding semi-annual PET-CT to the usual surveillance would be cost-effective in high risk recurrent CRC patients. **Methods:** CRC patients (stage II tumor perforated, stages III and IV) in remission after curative surgery were randomly assigned (1:1) to trimester usual surveillance (control) or usual surveillance + semi-annual course PET-CT (intervention) for a 3-yr follow up period. Every 3 months, multidisciplinary committee decided about recurrence by yes/no/doubtful. If yes, curative surgery alone (when relevant), or chemotherapy alone (unresecable recurrence) were conducted; additional exams could be performed if doubtful. Primary composite endpoint (failure) comprised unresectable recurrence & death. The economic assessments according to standards (CHEERS) were performed and costs were compared between groups. Statistical tests for calculation of the relative risk (RR) were used and survival was analyzed using Kaplan-Meier method, Log-Rang test and Cox models. **Results:** Baseline characteristics of 239 patients (120/119) enrolled in 12 centers were balanced. The failure rate was 29.2% (31 unresectable recurrences & 4 deaths) and 23.5% (27 & 1) in Interventional vs Control, respectively with no significant difference (RR = 1.24, 95% CI: 0.81-1.90; $P = .32$). Similar results were observed in multivariate analysis (Cox models) adjusted for stage and tumor differentiation (HR = 1.33, 95% CI: 0.8-2.19, $P = .27$). Period until the unresectable recurrence was significantly shorter in Interventional (median = 7; IQR: 3-20 months) than in Control group (14.3; 7.3-27; $P = 0.016$). This was consistent with lower elevation (median; IQR) of tumour marker in interventional (3.8; 2.8-19) than in control group (10; 5.2-28.6) at the first recurrence time as compared to the baseline (p = 0.007). Overall (mean; SD) cost (euros)/patient was higher in the PET-Scan (9385; 11658) than in the control group (7027; 7656). **Conclusions:** Although recurrences were detected earlier in PET-CT group, the strategy was less effective, more expensive. This exam should not be advised routinely. Clinical trial information: NCT 00624260.

The potential of circulating tumor DNA (ctDNA) to guide adjuvant chemotherapy decision making in locally advanced rectal cancer (LARC). *First Author: Jeanne Tie, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Background: The optimal approach to adjuvant chemotherapy for rectal cancer is keenly debated. Routine practice and clinical guidelines vary widely. After pre-operative chemoradiation (CRT), a pathologic complete response (pCR) or nodal involvement (pN+) are prognostic markers that can guide clinical decision-making, but markers that better define the patients (pts) that are likely or unlikely to benefit from chemotherapy are urgently needed. We investigated the potential role of ctDNA as a biomarker to guide therapy. **Methods:** We conducted a prospective, multi-centre study in pts with LARC (T3/T4 and/or N+) planned for CRT and curative resection. Serial plasma samples were collected pre-CRT, post-CRT, and 4-10 weeks after surgery. Somatic mutations in individual pts' tumor were identified via sequencing of 15 genes commonly mutated in colorectal cancers. We then designed personalized assays to quantify ctDNA in plasma samples. Pts received adjuvant therapy at clinician discretion. **Results:** 200 pts were enrolled between Apr-2012 and Dec-2015. Median age was 62 years (range 28-86), 67% were male and 159 pts had pre-CRT and post-op ctDNA samples available for analysis. Of these, 122 (77%) pts had detectable ctDNA prior to therapy. After surgery, 19 pts had detectable ctDNA and 11 of these 19 (58%) have recurred during a median follow up of 22 months. Recurrence occurred in only 12 of 140 (8.6%) with negative ctDNA (HR 12, $p < 0.001$). One hundred and two (64%) pts received adjuvant chemotherapy. Post-op ctDNA detection was predictive of recurrence irrespective of adjuvant chemotherapy (chemo: HR 10, $p < 0.001$; no chemo: HR 16, $p < 0.001$). Thirty-four pts (21%) achieved a pCR, 43 (27%) had pN+ disease. pCR (vs non-pCR) was associated with a trend for lower recurrence risk (HR 0.31, $p = 0.089$) and pN+ (vs pN0) with a higher recurrence risk (HR 4.2, $p < 0.001$). ctDNA detection remained predictive of recurrence among pts with a pCR (HR 14, $p = 0.014$) or with pN+ disease (HR 11, $p < 0.001$). **Conclusions:** Post-op ctDNA analysis stratifies pts with LARC into very high and low risk groups. ctDNA analysis remains strongly predictive of recurrence among pts with both lower risk (pCR) and higher risk (pN+) disease.

Circulating tumor DNA (ctDNA) utilizing a high-sensitivity panel to detect minimal residual disease post liver hepatectomy and predict disease recurrence. *First Author: Michael J. Overman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Preliminary data suggests that ctDNA can serve as a marker of minimal residual disease following colorectal cancer (CRC) tumor resection. Applicability of current ctDNA testing is limited by the requirement of sequencing known individual tumor mutations. We explored the applicability of a multi-gene panel ctDNA detection technology in CRC. **Methods:** Plasma was prospectively collected from CRC patients (pts) undergoing hepatic resections with curative intent between 1/2013 to 9/2016. In a blinded manner 5ml of preoperative (preop) and immediate post-operative (postop) plasma were tested using a novel 30kb ctDNA digital sequencing panel (Guardant Health) covering SNVs in 21 genes and indels in 9 genes based on the landscape of genomic alterations in ctDNA from over 10,000 advanced cancer pts with a high theoretical sensitivity (96%) for CRC. Median unique molecule coverage for this study is 9000 for cfDNA inputs ranging from 10 – 150 ng (media input preop = 27 ng, median input postop = 49 ng) with 120,000X sequencing depth on an IIlumina HiSeq2500. **Results:** A total of 54 pts underwent liver metastectomies with curative intent with a median follow-up of 33 months. Preop blood was a median of 49 days from last systemic chemotherapy and 3 days prior to surgery; postop blood was a median of 17 days after resection. Tumor mutations from standard of care hotspot multigene panel testing (at MDACC) were identified in 46 of 54 pts (85%). Preop ctDNA mutation detection rate was 80% (43/54) and 44% (24/54) in postop setting, with postop median allele frequency of 0.16% (range 0.01% to 20%). In pts with a minimum of 1 year follow up, sensitivity of postop ctDNA for residual disease was 58% (95%CI; 41%-74%), and specificity was 100% (66%-100%). In 43 patients who underwent successful resection of all visible disease, postop detection of ctDNA significantly correlated with RFS ($P = 0.002$, HR 3.1; 95% CI 1.7-9.1) with 2-year RFS of 0% vs. 47%. Recurrence was detected in ctDNA a median of 5.1 months prior to radiographic recurrence. **Conclusions:** The detection of postop ctDNA using an NGS panel-based approach is feasible and is associated with a very high rate of disease recurrence.

3523 Poster Discussion Session; Displayed in Poster Session (Board #146), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Profiling circulating tumor (ct)DNA mutations after panitumumab treatment in patients with refractory metastatic colorectal cancer (mCRC) from the phase III ASPECCT study. *First Author: Michael Boedigheimer, Amgen Inc., Thousand Oaks, CA*

Background: ASPECCT was a clinical trial performed in the chemotherapy-refractory third-line mCRC setting (N = 1010). This biomarker analysis explores the mutational landscape in panitumumab monotherapy subjects. Analysis of plasma ctDNA at baseline and post-treatment (PT) by next-generation sequencing provides a snapshot of the main changes in key genes before and after therapy. **Methods:** CtDNA collected at baseline and PT was analyzed for mutations using the Plasma*Select*-R™ 63-gene panel (0.1% limit of detection). Gain or loss of mutation was defined at the amino acid level. Net change is the sum of mutations gained minus the sum of mutations lost. A single individual could have both net gain and/or net loss of mutations within a single gene. **Results:** Significant tumor clonal diversification was observed during therapy. In 238 subjects with paired plasma samples,29% of subjects had multiple mutations in the same gene at baseline and 41% of subjects had multiple mutations in the same gene PT. At least 10% of subjects demonstrated an on-therapy acquired mutation in at least one of the following genes: *APC*, *EGFR*, *ALK*, *HER4*, *TP53*, *AR*, *KRAS*, *BRAF*, *PDGFRA*, *STK11, ESR1, FBXWT*, and *KIT* (ordered by frequency). New mutations were noted both inside and outside the EGFR pathway. Unexpectedly, patients with a large decrease in mutant DNA burden after anti-EGFR treatment were also seen. EGFR pathway genes with significant net gain were: *KRAS*, *EGFR*, *NRAS*, *BRAF*, *MAP2K1*, *PIK3CA*, and *AKT1*. Non-EGFR pathway mutations gained included: *APC*, *CDK6*, *SMARCB1*, *FBXW7*, *TERT*, *RB1*, *CTNNB1*, and *IDH1*. **Conclusions:** This 63-gene plasma analysis suggests that there are significant dynamic changes in clonal mutational fraction under anti-EGFR selection. Our analysis reveals that increasing global tumor heterogeneity is associated with poorer overall survival. A subset of patients demonstrated an overall decrease in tumor heterogeneity on panitumumab therapy (28%), indicating that under anti-EGFR selective pressure mutational heterogeneity can also decrease. Clinical trial information: NCT01001377.

3525 Poster Session (Board #148), Sat, 8:00 AM-11:30 AM

Primary tumor location and efficacy of second-line therapy after initial treatment with FOLFIRI in combination with cetuximab or bevacizumab in patients with metastatic colorectal cancer- FIRE-3 (AIOKRK0306). *First Author: Dominik Paul Modest, Department of Hematology and Oncology, Klinikum Grosshadern, University of Munich, Munich, Germany*

Background: FIRE3 compared 1st-line therapy with FOLFIRI plus either cetuximab (arm A) or bevacizumab (arm B) in 592 patients (pts) with KRAS exon 2 wild-type metastatic colorectal cancer (mCRC). Second-line therapies appeared more successful in arm A compared to arm B. The impact of primary tumor location on this observation is unclear. **Methods:** Pts. were stratified for primary tumor site (left- vs. right-sided). Duration of 2nd-line therapy was calculated as time from first to last application. Progression-free survival (PFS2nd) and overall survival (OS2nd) of second-line therapy) were evaluated by Kaplan-Meier method and compared by log rank test as well as Cox regression. All analyses were performed in the RAS wild-type population of the trial and reported according to drug sequences. **Results:** 272 of 400 pts. (68%) received 2nd-line therapy, of those 206 (109 in arm A, 97 in arm B) pts. presented left-sided, whereas 66 (26 in arm A, 40 in arm B) pts. presented right-sided primaries. PFS2nd was markedly longer in pts. with left-sided as compared to right-sided primary tumors (6.0 (95% CI: 5.5-6.7) vs. 3.4 (95% CI: 3.0-5.8) months, hazard ratio (HR): 0.64 (95% CI: 0.47-0.87), $P = 0.005$). Differences in PFS2nd between study-arms were evident in pts. with left-sided primaries (arm A: 7.3 (95% CI: 6.4-7.7) vs. arm B: 5.3 (95% CI: 4.3-5.9) months, HR: 0.61 (95% CI: 0.44-0.84), $P = 0.002$), but not in pts. with right-sided primaries (arm A: 4.0 (95% CI: 3.0-6.3) vs. arm B: 3.3 (95% CI: 2.6-5.8) months, HR: 1.09 (95% CI: 0.62-1.90). Consistent observations were also made for treatment duration and OS2nd. **Conclusions:** This retrospective analysis indicates that treatment duration and efficacy of second-line therapy are associated with primary tumor location. Efficacy of second-line therapy was significantly greater in pts. with left-sided tumors as compared to right sided tumors. This difference was driven by superior activity of second-line regimens of arm A compared to arm B in left-sided tumors. Our observations confirm the strong prognostic value of primary tumor location in mCRC across treatment lines. Clinical trial information: NCT00433927.

3528 Poster Session (Board #151), Sat, 8:00 AM-11:30 AM

Statistical modeling of CALGB 80405 (Alliance) to identify influential factors in metastatic colorectal cancer (CRC) dependent on primary (1o) tumor side. *First Author: Leon Furchtgott, GNS Healthcare, Cambridge, MA*

Background: CALGB 80405 is a phase III clinical trial of FOLFOX and FOLFIRI w/ randomly assigned cetuximab or bevacizumab. Novel machine learning approaches to the study dataset provide valuable insights into CRC prognosis and management of CRC progression. **Methods:** Using a Monte Carlo Bayesian Generalized Linear Model analytical platform, we built an ensemble of models for overall survival (OS). We used 99 baseline and demographic variables, including 1904 patients w/ 1^o side and 949 w/ KRAS wild-type status. Building an ensemble of predictive models reduces risk of overfitting, estimates model uncertainty and identifies key variables by model consensus as measured by ensemble frequency (freq). We fit gender and 1^o side (L vs R) stratum-specific models to examine differences in drivers of disease in those strata. **Results:** 1^o side (avg Cox hazard ratio = 0.89, R side reference), ECOG performance status (1.30, reference level 0), AST concentration (1.01), peripheral neutrophil percentage (1.01) and local primary and abdominal site of disease indicators (1.22; 1.26) were key variables predictive of OS ($>$ 75% freq). In 1^o side stratum-specific models, urine protein level (1.61), treatment intent (0.75, nonpalliative as reference) and hemoglobin concentration (0.85) were more associated w/ L side progression (freq $>$ 85% in L stratum model, $<$ 20% in R), while liver and lung sites of disease (2.3; 1.09) were more associated w/ R side progression (freq $>$ 65% in R stratum model, $<$ 20% in L). Predictors of 1^o left-sidedness included age (avg log odds ratio = 0.02), hemoglobin (0.41), and abdominal (3.79) and liver (0.68) sites of disease. Modest differences in disease prognostic factors existed between genders: women more influenced by metastatic status, age, liver site of disease and creatinine level; men more influenced by urine protein level and prior diabetes. **Conclusions:** 1^o side plays a central role in potentially explaining both variation in OS and differences in drivers of OS. Availability of these measures at baseline enables better sense of disease course at initiation of treatment. Support: U10CA180821, U10CA180882, Eli Lilly & Co., Genentech, Pfizer Clinical trial information: NCT00265850.

3529 Poster Session (Board #152), Sat, 8:00 AM-11:30 AM

Phase 1b/II study of cancer stemness inhibitor napabucasin (BBI-608) in combination with FOLFIRI +/- bevacizumab (bev) in metastatic colorectal cancer (mCRC) patients (pts). *First Author: Johanna C. Bendell, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: Cancer stem cells are considered to be fundamentally important for resistance, recurrence and metastasis. Napabucasin is a first-in-class cancer stemness inhibitor in development identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al, PNAS 112(6):1839, 2015). Preclinically, napabucasin sensitizes cancer cells to chemotherapy and targeted agents. **Methods:** A phase Ib/II multi-center study in mCRC pts was done to confirm the RP2D and signs of anti-cancer activity of napabucasin in combination with FOLFIRI +/- Bev. Pts received napabucasin 240 mg PO BID with bi-weekly FOLFIRI IV +/- Bev 5 mg/kg until disease progression or other discontinuation criterion. **Results:** 82 pretreated mCRC pts were enrolled (ITT); including 32 (39%) previously treated with FOLFIRI +/- bev. Of the 82 pts, 48 received FOLFIRI and 34 FOLFIRI plus bev in combination with napabucasin. There was no dose-limiting or unexpected toxicity or significant PK interactions. Most common adverse events (AEs) included grade 1/2 diarrhea, cramping, nausea, vomiting, fatigue and anorexia with grade 4 diarrhea in 1 pt and 27 pts with grade 3 AEs including: diarrhea (15), fatigue (5), dehydration (1), electrolyte imbalance (4), abdominal pain (1), vomiting (1) and weight loss (1), which resolved with dose reduction and supportive care. Disease control (CR+PR+SD) was observed in 55 of 66 pts who received RECIST evaluation (83%), with 1 CR (1.5%), 13 PR (20%) (33-100% regression) and 27 SD with tumor regression (41%). **Conclusions:** This phase Ib/II study confirmed that napabucasin can be safely combined with FOLFIRI +/- bev, and shows encouraging signs of efficacy in pretreated mCRC pts, including pts previously treated with FOLFIRI +/- bev. Clinical trial information: NCT02024607.

MABp1 to improve clinical outcomes of patients with symptomatic refractory metastatic colorectal cancer patients: Per-protocol population analysis of phase III study (PT026). *First Author: Lucjan Wyrwicz, Maria Sklodowska-Curie Institute of Oncology, Warsaw, Poland*

Background: Refractory metastatic colorectal cancer (mCRC) patients derive minimal benefit from further exposure to toxic agents. MABp1 is an anti-interleukin 1 alpha antibody that is shown to prolong survival (NCT01767857) and improves outcomes when assessed with a primary endpoint based on a constellation of objective and patient self-reported measures (NCT02138422) (Hickish T. et al Lancet Oncology 2017). In the latter study, clinically advanced patients were enrolled (symptomatic, ECOG 1,2), and 18% of patients progressed prior to reaching the endpoint assessments. Here we present the outcomes in per-protocol population (PP), those patients completing week 8 assessments. **Methods:** 309 patients randomized 2:1 to receive MABp1 versus placebo. Patients were ECOG 1-2, with mCRC refractory to chemotherapy, any degree of weight loss, and cancer-associated symptoms. The composite primary endpoint assessed the rate of patients achieving stabilization or improvement in lean body mass (LBM) and two of three symptom measures (pain, fatigue, appetite loss) from screening to the week 8 assessment. The study was designed for placebo cross-over, thus OS analysis for MABp1 vs placebo was not possible. **Results:** 57 patients (38 MABp1 [18%] and 19 placebo [19%]) discontinued study prior to the week 8 assessment due to disease progression, including 17 (8%) and 11 (11%) deaths in MABp1 and placebo respectively. 62% of placebo patients received MABp1 after 8 weeks. 252 patients, 40% in MABp1 (68/169) vs 23% in placebo (19/83) met the primary endpoint ($p = 0.003$). 139 patients were available for PP survival analysis (90 MABp1 vs 49 Placebo). Median OS of those achieving the primary endpoint was 11.7 months vs 5.7 months for those that did not (HR 0.39; $p < 0.0001$). Radiographic stable disease was improved (42% vs 12%; $p < 0.001$) and incidence of SAEs (6% vs 15%; $p = 0.11$) reduced in those achieving the primary endpoint. **Conclusions:** Achieving the primary endpoint was associated with improvement in outcomes, RECIST stabilization, SAEs and survival. Further study should confirm the effect of MABp1 on survival in this population. Clinical trial information: NCT02138422.

3531 Poster Session (Board #154), Sat, 8:00 AM-11:30 AM

Combination of nivolumab (nivo) + ipilimumab (ipi) in the treatment of patients (pts) with deficient DNA mismatch repair (dMMR)/high microsatellite instability (MSI-H) metastatic colorectal cancer (mCRC): CheckMate 142 study. *First Author: Thierry Andre, Hopital Saint Antoine, Paris, France*

Background: Nivo, a fully human anti-PD-1 mAb, provided an ORR of 31%, durable responses (median DOR not reached), and a 12-mo OS rate of 73.8% in pts with dMMR/MSI-H mCRC (Overman M, et al. 2017). Preliminary analysis of nivo + ipi, a humanized anti-CTLA-4 mAb, demonstrated manageable safety and promising efficacy in pts with dMMR/MSI-H mCRC (Overman M, et al. 2016). Here we report interim safety and efficacy of nivo + ipi in this pt population from the Checkmate 142 study (NCT02060188). **Methods:** Pts with dMMR/MSI-H mCRC who progressed on or were intolerant of $\geq$1 prior line of therapy received nivo 3 mg/kg + ipi 1 mg/kg q3w $\times$ 4 doses followed by nivo 3 mg/kg q2w until discontinuation due to disease progression or other reason. Primary endpoint was investigator-reported ORR by RECIST 1.1. Other endpoints included DOR, PFS, OS, safety, and tolerability. **Results:** 27 pts with dMMR/MSI-H mCRC treated with nivo + ipi received the first dose $\geq$6 mo prior to the database lock (DBL; Sept 2016). Of these pts, 93% received $\geq$2 prior lines of therapy. At the time of DBL, 44% of pts remained on treatment, and 14 pts had discontinued therapy due to disease progression (n=8) or TRAEs (n=6). ORR was 41% and disease control rate (DCR) was 78% (Table). The median time to response was 2.7 mo, and 82% of responses (9/11) were ongoing at 6 mo. The medians for DOR, PFS and OS had not been reached. Grade 3–4 TRAEs occurred in 10 pts (37%).TRAEs leading to discontinuation included acute kidney injury, increased transaminases, necrotizing myositis, sarcoidosis, dyspnea, and thrombocytopenia (1 each). No deaths were attributed to therapy. **Conclusions:** Initial analysis ofnivo + ipi in pts with $\geq$6-mo follow-up demonstrated a manageable safety profile and clinical activity characterized by a high DCR and encouraging survival benefit. This study is ongoing, and updated efficacy and biomarker analyses of $\approx$80 pts with $\geq$6-mo follow-up will be presented. Clinical trial information: NCT02060188.

3532 Poster Session (Board #155), Sat, 8:00 AM-11:30 AM

REsect: Blinded assessment of amenability to potentially curative treatment of previously unresectable colorectal cancer liver metastases (CRC LM) after chemotherapy ± RadioEmbolization (SIRT) in the randomized SIRFLOX trial. *First Author: Benjamin Garlipp, Otto-von-Guericke-University Hospital, Magdeburg, Germany*

Background: Secondary resection and radiofrequency ablation (RFA) of primarily unresectable LM from CRC can prolong survival and cure some patients (pts). Effective downsizing treatments are needed but their impact on secondary amenability to surgery/RFA is difficult to evaluate objectively. The added value of SIRT is not well established. **Methods:** Baseline (BL) and follow-up (FU) imaging at best response for CRC pts treated with FOLFOX chemotherapy±bevacizumab (bev) (CT) *vs.* CT+SIRT in the phase III SIRFLOX RCT were reviewed by 3−5 expert HPB surgeons (from a panel of 15) for resectability of LM. Reviewers were blinded to each other and to all clinical information incl. time of imaging (BL/FU). Resectability was defined as ≥60% of reviewers assessing a pt as resectable. For non-resectable cases, surgeons indicated whether a combination of surgery and RFA could completely remove all LM. Lesions deemed suitable for RFA by a surgeon needed to be confirmed by an interventional radiologist. Pts were defined as "clearable" if ≥60% of reviewers assessed them as amenable to complete removal of LM by surgery alone or surgery+RFA. **Results:** 472 pts were evaluable (CT, n = 228; CT+SIRT, n = 244). There was no significant difference in LM resectability at BL (CT, n = 25, 10.96%; CT+SIRT, n = 29, 11.89%; p = 0.77). At FU, significantly more pts in the SIRT arm had resectable LM (CT, n = 66, 28.95%; CT+SIRT, n = 93, 38.11%; p < 0.0001). Of 203 pts in the CT arm and 215 pts in the CT+SIRT arm deemed unresectable at BL, 46 (22.66%) and 67 (31.16%), respectively, were converted to resectability (p < 0.0001). Assessing "clearability" using surgery and RFA, again no difference was noted at BL (CT, n = 31, 13.60%; CT+SIRT, n = 42, 17.21%; p = 0.309). At FU, a trend in favor of CT+SIRT was seen (CT, n = 79, 34.65%; CT+SIRT, n = 102, 41.80%; p = 0.1296). **Conclusions:** The addition of SIRT to FOLFOX(±bev) based CT significantly increased the gain in resectability of primarily unresectable CRC LM compared with CT alone. For amenability to the combination of surgery+RFA, this effect was still seen, albeit attenuated. Subgroup analyses are ongoing. Clinical trial information: NCT00724503.

3533 Poster Session (Board #156), Sat, 8:00 AM-11:30 AM

"CHARTA": FOLFOX/Bevacizumab vs. FOLFOXIRI/Bevacizumab in advanced colorectal cancer—Final results, prognostic and potentially predictive factors from the randomized Phase II trial of the AIO. *First Author: Hans-Joachim Schmoll, Martin Luther University, Division Clinical Oncology, University Hospital, Halle, Germany*

Background: FOLFOXIRI/Bevacizumab (Bev) is superior to FOLFIRI/Bev in the TRIBE trial (F Loupakis, NEJM 2014). The CHARTA trial was developed parallel to TRIBE with the same 4-drug-protocol but vs. FOLFOX/B ev as control arm. **Methods:** From 7/11 to 12/14 250 patients were randomized, including ECOG 0-2, ≥ 1 measurable lesion > 1cm, stratified by ESMO-Group 1,2,3 (HJ Schmoll, Ann Oncol 2012). Induction: 6 months, maintenance Capecitabine+Bev until progression or max.12 months, at P reinduction by investigators decision. 25% dose reduction was allowed in cycle 1 + 2 on the investigator's discretion. Primary EP: significant improvement of PFS-rate @ 9 months (p<0.1, 2-sided Fisher's-exact test); secondary EP: RR, PFS, OS, toxicity. **Results:** 241 pts. (1 not elig., 8 prot. violation) are evaluable after a follow up of 31.4 (0.1-51) months. m/f: 65%/35%, age 61y (21-82), ECOG 0-1/2: 96%/4%. The *Primary Endpoint* was met: PFS @ 9 months 56% vs. 68%, p= 0.086. PFS was improved: 9.8 vs. 12.0 months, HR 0.7 (ns.), identical to TRIBE with 9.7 vs. 12.1 months. Response rate (A/B): CR: 5%/5%, CR/PR 60%/70%, SD 25%/21%, PD 14%/9%. Final OS will be available at the meeting. Toxicity was low to moderate without major differences except ° $^{3}/_{4}$ diarrhea (12%/16%) and neutrophils (14%/20%). Clinical/molecular prognostic or predictive factors are equally distributed (stratification by ESMO groups) (see table). There are major, but mostly not significant differences in RR/ PFS in most subgroups, however, not strong enough to safely identify patients with high potential to benefit from the 4-drug combination. Therefore, a multivariate analysis to model a common prognostic and predictive risk score is ongoing and will be presented at the meeting. **Conclusion:** "CHARTA" supports the superiority of FOLFOXIRI/Bev. A combined prognostic and predictive classification is required to better select those patients with most potential benefit from the 4-drug combination. Clinical trial information: NCT01321957.

3534 Poster Session (Board #157), Sat, 8:00 AM-11:30 AM

Variability in genomic alterations between right- and left-sided microsatellite stable (MSS) metastatic colorectal cancer and impact on survival. *First Author: Rona Yaeger, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Metastatic colorectal cancers (mCRCs) with a right-sided primary site are associated with shorter survival and insensitivity to EGFR inhibitors compared to those originating in the left side of the colon or rectum. **Methods:** We performed targeted gene sequencing of 928 consecutive MSS mCRCs. Primary tumor site was divided into right-sided for cecum to distal transverse colon (n = 242), left-sided for splenic flexure to rectum (n = 673), or unknown colonic location (n = 13). Histologic subtypes were conventional (adenocarcinoma not otherwise specified), conventional with mucinous features (< 50% mucinous), mucinous, signet ring, and poorly differentiated. To evaluate receptor tyrosine kinase (RTK) signaling, we analyzed ligand mRNA expression in TCGA. **Results:** Overall survival from time of metastasis was shorter for right-sided than left-sided primary site (survival at 5 years: 45% v 67%, p < 0.001). Right-sided tumors had more mutations (5.60 v 4.62 per MB, p < 0.001) but fewer copy-number changes (0.18 v 0.22 fraction genome altered, p = 0.001) compared to left-sided tumors. Alterations of KRAS, BRAF, PIK3CA, PTEN, AKT1, RNF43, and SMAD4 were significantly enriched in right-sided tumors, and of APC and TP53 in left-sided tumors. In a multivariate model, APC (HR = 0.7, p = 0.03), BRAF (HR = 3.7, p < 0.001), and KRAS (HR = 1.7, p < 0.01) alterations predicted for survival, but primary site did not (HR = 0.74, p = 0.07). Amphiregulin, epiregulin, neuregulin, and HGF expression was significantly higher in left-sided tumors. We found a higher proportion of conventional histology (83% v 63%) and moderate differentiation (82% v 69%) for left versus right-sided cases. **Conclusions:** We find that within MSS mCRC there are significantly more oncogenic mutations in right-sided tumors, and the difference in survival between right- and left-sided mCRC is primarily driven by differences in mutations. Left-sided tumors more commonly exhibit a "simpler" conventional histology that is lower grade and may rely on native RTK signaling, such as EGFR, for growth, providing a potential mechanism for the differential sensitivity to EGFR inhibitors seen by primary tumor site.

3535 Poster Session (Board #158), Sat, 8:00 AM-11:30 AM

Heterogeneity in early lesion changes on treatment as a marker of poor prognosis in patients (pts) with metastatic colorectal cancer (mCRC) treated with first line systemic chemotherapy ± biologic: Findings from 9,092 pts in the ARCAD database. *First Author: Fang-Shu Ou, Mayo Clinic Cancer Center, Rochester, MN*

Background: CRC is known to be a heterogeneous disease. This study quantifies within pt heterogeneity in early lesion change rate (LCR) in the era of targeted agents compared to chemo alone and its potential impact on survival. **Methods:** Pts with 2-10 lesions measured at baseline were included. For each lesion, the early LCR was defined as the change in size (shrinking or growing) from baseline to 12 weeks on treatment. Within pt heterogeneity in early LCR among lesions was estimated by standard deviation (STD). A larger value of STD indicates larger variation of LCR per pt. Stratified multivariate Cox models were used to assess the associations between LCR STD with overall survival (OS). Adjusted hazard ratios (HR_{adj}) and 95% confidence intervals (CIs) are reported. **Results:** Data were available on 9,092 mCRC pts (median age 61; 60% male, 55% ECOG PS 0; 61% 2+ metastatic sites) enrolled in 16 1st-line randomized trials, with 44%, 42%, and 10% of pts received chemo alone, + a VEGF inhibitor (VEGFi) or an EGFR inhibitor (EGFRi), respectively. LCR heterogeneity is the highest among pts received EGFRi but lowest among pts received VEGFi (Table). Overall, higher heterogeneity is associated with worst OS (HR_{adj}1.22, 95% CI (1.16, 1.27)). The effect is most pronounced in pts received VEGFi (interaction p=0.0012). **Conclusions:** There was heterogeneity observed in lesion size changes within pts. Its magnitude varies across treatment approaches, and was associated with poor survival. This preliminary result reveals the great potentials to define novel response endpoint and refine treatment decision-making by incorporating heterogeneities in lesion changes.

3536 Poster Session (Board #159), Sat, 8:00 AM-11:30 AM

A large multicenter study evaluating prognosis and chemosensitivity of metastatic colorectal cancers with microsatellite instability. *First Author: David Tougeron, Gastroenterology Department, Poitiers University Hospital, Poitiers, France*

Background: Deficient Mismatch Repair (dMMR) in colorectal cancers (CRC) represent 12% of all tumors. In non-metastatic CRC setting, dMMR are associated with good prognosis but also with resistance to adjuvant 5-FU chemotherapy. In metastatic CRC (mCRC) setting, dMMR is found in less than 5% and its influence on prognosis and treatment response is little known. **Methods:** This multicenter retrospective study included all consecutive patients with dMMR mCRC treated between 2005 and 2015 in 17 centers. The Kaplan-Meier method was used to calculate overall survival (OS) and progression-free survival (PFS). Prognostic variables were evaluated in univariate analysis using the Log rank test and in multivariate analysis using the Cox regression model. **Results:** A total of 198 patients with dMMR mCRC were included (median age 64.6 years). dMMR mCRC were mostly diagnosed with synchronous metastases (59%) and frequent peritoneal carcinosis (43%). Lynch syndrome was found in 34% of cases and 36% of tumors had a *BRAF*^{V600E} mutation. Median OS was 20.6 months. A low risk Kohne's prognostic index (HR = 0.40 [0.22-0.72], p = 0.02) and absence of peritoneal carcinosis (HR = 0.51 [0.29-0.90], p = 0.02) were associated with better OS in multivariate analysis. Main first-line regimens were 5FU-based (n = 20), oxaliplatin-based (n = 75) or irinotecan-based (n = 46) chemotherapy. Median PFS on first-line treatment was 5.9 months. The objective response rate (ORR) was 0%, 19% and 36% for 5FU-based, oxaliplatin-based and irinotecan-based chemotherapies, respectively (p = 0.02). A trend for a longer PFS (3.3, 5.5 and 10.2 months, respectively, p = 0.06) and OS (17.7, 21.1 and 34.2 months, respectively, p = 0.05) was also observed for irinotecan-based chemotherapy. The addition of bevacizumab to chemotherapy was associated with a significant increase of ORR (p = 0.01) and PFS (p = 0.04) as compared to the addition of an anti-EGFR therapy. **Conclusions:** This study suggests that dMMR mCRC are associated with poor prognosis and chemoresistance, especially to 5FU-based chemotherapy. Efficacy of irinotecan and bevacizumab should be evaluated in a prospective trial in combination with immune checkpoint inhibitors.

3537 Poster Session (Board #160), Sat, 8:00 AM-11:30 AM

Neoadjuvant radiotherapy vs. surgery alone for stage II/III mid-low rectal cancer with or without high risk factors: A multicenter randomized trial. *First Author: Ziqiang Wang, West China Hospital Sichuan University, Chengdu, China*

Background: Neoadjuvant (chemo)radiotherapy (NRT) is the standard treatment for locally advanced rectal cancer (RC),which reducing local recurrence (LR) without survival benefit. There are also reports claiming similar local control achieved by surgery alone in selected patients, that raising the issue of omitting NRT in low risk patients. The aim of this study was to clarify the benefit of NRT in stage II/III RC with or without high risk factors. **Methods:** Eligible participants with mid-low cT3-4aN$\pm$ RC were included and classified as high risk patients and low risk patients according to the clinical staging. High risk was defined as T3 tumor with extramural spread $>$ 5mm, T4a or lymph node $>$ 8mm. High and low risk patients were both randomized into two groups: high risk radiotherapy (HRR) or high risk surgery (HRS), low risk radiotherapy (LRR) or low risk surgery (LRS) separately. Patients in HRR and LRR received short term NRT (5*5Gy) + TME, while patients in HRS and LRS underwent surgery alone. The primary endpoint was 3-y LR. The secondary endpoints were OS, DFS, quality of surgery and safety. **Results:** From Jun. 2011 to Dec. 2015,401 consecutive patients were analyzed (LRS 99, LRR 97, HRS 102, HRR 103). As for primary endpoint, 3-y LR was obviously lower in low risk patients (3% vs. 9%, p = 0.026), but comparable in LRR vs. LRS (3% vs. 2%, p = 0.32) and HRR vs. HRS (11% vs. 7%, p = 0.42). Concerning secondary endpoints, low risk patients were favorable in 3-y OS ($p < 0.001$), DFS ($p < 0.001$), and distant metastasis (p = 0.001), compared to the high risk. And 3-y OS in HRR was higher than that in HRS (82% vs. 70%, p = 0.032). NRT caused 1.5% grade 3/4°radiation-related complications with a higher rate of late leakage (4.5% vs 0.0%, p = 0.004). Besides, positive CRM was higher in HRS (HRS 14.7% vs. HRR 4.9%, p = 0.017). **Conclusions:** Depth of extramural spread and lymph node status are favorable predictors for LR and survival. NRT may improve OS for high-risk RC. Low-risk RC has very low LR, suggesting against routine use of NRT. Relatively high LR and better OS in high risk patients justify use of NRT or NCR. Short-term radiation is safe for Asian patients, given caution be paid to more late leakage. Clinical trial information: NCT01437514.

3538 Poster Session (Board #161), Sat, 8:00 AM-11:30 AM

Velour trial biomarkers update: Impact of RAS, BRAF, and sidedness on aflibercept activity. *First Author: Pratyaksha Wirapati, Swiss Institute of Bioinformatics, Lausanne, Switzerland*

Background: Addition of (ziv)-aflibercept (A) to FOLFIRI in second-line therapy for metastatic colorectal cancer (CRC) has been shown to be beneficial in phase III VELOUR trial (NCT00561470). A follow-up study (NCT01754272) was undertaken to acquire tumor samples for biomarker analyses and identify subgroups of patients with differential treatment effects. The primary results assessing efficacy according to well-established CRC subgroups defined by RAS, BRAF status and sidedness are reported here. **Methods:** Tissue specimens were collected for 666 patients from 1226 ITT pts. Suitable specimens were assayed for somatic mutation using NGS targeting extended RAS and BRAF genes. NGS assays with no missing values were obtained for 482 pts. Affymetrix gene chip technology was used for whole-transcriptome profiling; sidedness was extracted from available pathological reports. Differences between subgroups were assessed by interaction analysis. **Results:** The treatment effects on overall survival (OS) for the 482 pts is still significant HR=0.80 (CI 0.65-0.99), and similar to the ITT (n=1226) results (HR=0.82, CI 0.71-0.93). Two established ways of defining mutations (traditional KRAS exon 2 and extended RAS using NGS) show a trend for a differential effect across mutation groups.(see table for OS). Interestingly, BRAF mutants (which are all RAS wild type) show a trend for better outcome Same is seen for PFS and RR. Sidedness did not affect efficacy (HR: 0.83 (0.63- 1.1) for left and HR: 0.83 (0.54-1.3) for right. **Conclusions:** None of the mutations subgroup results shows significant interaction, although the ratios of treatment HR favor RAS wild types. Similar trends were observed in published trials with bevacizumab or ramucirumab. *Sanofi supported this ISS.* Clinical trial information: NCT01754272.

3539 Poster Session (Board #162), Sat, 8:00 AM-11:30 AM

Final results of the McCAVE trial: A double-blind, randomized phase 2 study of vanucizumab (VAN) plus FOLFOX vs. bevacizumab (BEV) plus FOLFOX in patients (pts) with previously untreated metastatic colorectal carcinoma (mCRC). *First Author: Johanna C. Bendell, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: VEGF-A and ANG-2 have complementary roles in regulation of tumor angiogenesis. Targeting VEGF-A with BEV in combination chemotherapy (CT) in mCRC has proven to increase PFS and OS. ANG-2 is overexpressed and associated with poor outcome of mCRC pts receiving BEVcontaining treatment. Hence, dual blockade of VEGF-A and ANG-2 by the bispecific mAb VAN with standard CT may improve clinical activity in mCRC. **Methods:** All pts received mFOLFOX-6 and were randomized 1:1 to also receive intravenous VAN 2000 mg every other week (Q2W) (Arm A) or BEV 5 mg/kg Q2W (Arm B). The primary end point was investigator assessed progression-free survival (PFS). Key eligibility criteria included pts with non-resectable mCRC, no prior therapy for advanced disease, PS 0-1, adequate organ functions, and no history of GI fistula/perforation or intraabdominal abscess within the last 6 months. **Results:** 192 pts were randomized (Arms A/B, n = 95/97) by 39 sites in 7 countries, between Oct 2014 and May 2016. Median follow-up was 17.6 months (range 2.8 – 20.7). In the ITT population (n = 189; Arms A/B, n = 94/95), median PFS in Arms A and B was 11.3 and 11.0 months (stratified hazard ratio (HR) 1.00 (95%CI 0.64-1.58; p = 0.985)), respectively. Objective response rate was 52.1% vs 57.9%. Relevant prognostic factors incl. RAS/BRAF status and tumor sidedness were balanced between arms and did not significantly influence outcome. Baseline plasma ANG-2 levels were prognostic in both arms but not predictive for response to VAN. The overall incidence of adverse events (AEs) grade $\geq$ 3 was similar (Arms A/B, 83.9%/82.1%); AEs grade $\geq$ 3 attributed to the mode of action of VAN/BEV included hypertension (37.6%/18.9%), hemorrhage (2.2%/1.1%), thromboembolic events (venous 6.5%/2.1%; arterial 1.1%/3.2%) and GI perforations incl. GI fistula & abdominal abscess (10.6%/8.4%). **Conclusions:** The combination of VAN and FOLFOX did not improve PFS and was associated with a marked increase in hypertension compared with BEV plus FOLFOX. Our results strongly suggest that ANG-2 is not a relevant therapeutic target in the setting of first line mCRC. Clinical trial information: NCT02141295.

3540 Poster Session (Board #163), Sat, 8:00 AM-11:30 AM

Regorafenib (REG) versus trifluridine/tipiracil (TAS-102) as salvage-line in patients with metastatic colorectal cancer refractory to standard chemotherapies (REGOTAS): A propensity score analysis from a JSCCR multicenter observational study. *First Author: Shota Fukuoka, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital, Chiba, Japan*

Background: It is unclear which drug of REG or TAS-102 should be used earlier for the patients with metastatic colorectal cancer (mCRC) who have access to both drugs. This study investigated the comparison of the efficacy between REG and TAS-102 in patients with refractory to standard chemotherapies. **Methods:** The clinical data of patients who were treated with REG or TAS-102 among these drugs naive mCRC patients between Jun 2014 and Sep 2015 were retrospectively delivered from 24 institutions of Japanese Society for Cancer of the Colon and Rectum (JSCCR). The primary endpoint was overall survival (OS). Propensity score (PS) was calculated with a logistic regression, in which using baseline parameters were included. Two methods, adjusted and matched analysis, to take propensity score were used. The clinical outcomes were evaluated with Kaplan-Meier method and Cox models based on PS adjustment and matching. **Results:** Total of 589 patients were enrolled and 550 patients (223 patients in the REG group and 327 patients in the TAS-102 group) met criteria for inclusion in the analysis. The results from PS adjusted analyses showed that OS was similar between the two groups (HR of TAS-102 to REG, 0.96; 95% confidence interval, 0.78–1.18). There were also no statistically significant differences between two groups for progression-free survival (HR 0.94) and time to ECOG Performance status≥2 (HR 1.00), expect for time to treatment failure (HR 0.81; P = 0.025). In the subgroup analysis, REG showed favorable survival compared with TAS-102 in the age of < 65 years patients and unfavorable survival in ≥65 years patients (P for interaction = 0.012). In the PS matched sample (174 patients in each group), the clinical outcomes were similar to the results of the PS adjusted analysis. **Conclusions:** Although REG and TAS-102 showed a similar efficacy in mCRC patients with refractory to standard chemotherapies, the choice of the drug by age might affect the survival. Supported by JSCCR. Clinical trial information: UMIN000020416

3541 Poster Session (Board #164), Sat, 8:00 AM-11:30 AM

A phase II study of pembrolizumab in combination with mFOLFOX6 for patients with advanced colorectal cancer. *First Author: Safi Shahda, Indiana University, Indianapolis, IN*

Background: Pembrolizumab (PEM) has activity in patients with deficient mismatch repair (dMMR) colorectal cancer (CRC). Oxaliplatin (OX) and 5FU lead to immunogenic cell death and increased antigen presentation. We hypothesized that combining mFOLFOX6 and PEM may enhance immunogenic cell death and improve outcome in patients with CRC irrespective of MMR status. **Methods:** Subjects ≥18 years old with untreated, unresectable CRC were assigned to a single arm study. The study had a safety run in cohort of six patients (OX 85 mg/m^2, leucovorin 400 mg/m^2, 5FU 400 mg/m^2, 5FU infusion 2400 mg/m^{2}over 46 hours) and PEM 200 mg Q 3 weeks, followed by a phase II cohort. The primary objective was median progression free survival (mPFS), with secondary objectives: safety and toxicity per CTCAE V4.03, median overall survival, response rate, immune related response, disease control rate, and molecular correlates. **Results:** Between 4/2015 and 9/2016, 30 subjects were enrolled with following characteristics: 11 female, 26 Caucasian, median age: 45 years (25-75), 3 with dMMR, 22 MMR-proficient, and 5 with no available data. During the safety run in, 2 patients had G3 febrile neutropenia (FN) and 1 G4 neutropenia. The data safety monitoring committee recommended dose reduction of mFOLFOX6 to OX 68 mg/m^2, leucovorin 400 mg/m^2, 5FU of 320 mg/m^2, 5FU infusion of 1920 mg/m^{2}over 46 hours and PEM 200 mg Q 3 weeks. At the data cut off (12/29/16), median follow up was 24 weeks (10-66) and 27 patients remained on study. Rate of G3/4 toxicity associated with FOLFOX/PEM and PEM alone was 36.7% and 13.2%, respectively. No further FN was observed. No grade 5 toxicity was seen on study. Best response was recorded as: 1 complete response, 15 partial response (CR +PR = 53%), and 14 stable disease, with 100% DCR at 8 weeks. One patient with dMMR had resection after 2 months of therapy with complete pathologic response. MPFS has not been reached (95% CI: 5.5 months, NR). **Conclusions:** Based on these preliminary results, PEM/mFOLFOX6 has acceptable toxicity though demonstrated a suggestion of increased neutropenia in the initial cohort. Clinical activity was seen in patients with untreated advanced CRC including those with proficient MMR. Clinical trial information: NCT02375672.

3542 Poster Session (Board #165), Sat, 8:00 AM-11:30 AM

Treatments (tx) after progression to first-line FOLFOXIRI plus bevacizumab (bev) in metastatic colorectal cancer (mCRC) patients (pts): A pooled analysis of TRIBE and MOMA studies by GONO group. *First Author: Daniele Rossini, Unit of Medical Oncology 2, Azienda Ospedaliera-Universitaria Pisana, the Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy*

Background: FOLFOXIRI plus bev is regarded by international guidelines as a valuable option in the first-line tx of mCRC pts. One of the major concerns for the adoption of this regimen is the potential limitation of subsequent therapeutic options. The aim of the present analysis was to focus on treatments received after progression in TRIBE (NCT00719797) and MOMA (NCTNCT02271464) studies. **Methods:** We collected data of tx received after progression and their outcome in terms of 2ndPFS (time from 2nd line tx start to disease progression or death) and OS II (time from 2nd line tx start to death). For pts in which the same drugs used in first-line were totally or partially reintroduced, the chemotherapy-free interval (CFI, time from the last administration of irinotecan or oxaliplatin during first-line to disease progression) was calculated. **Results:** Out of 482 pts treated with upfront FOLFOXIRI plus bev, 429 progressed. 303 (70.6%) pts received a 2nd line tx: 93 FOLFOXIRI +/- bev (Group A), 119 FOLFOX/XELOX or FOLFIRI +/- bev (Group B) and 91 other tx (Group C), including an anti-EGFR moAb in 60 cases. No difference was observed among the three groups in terms of 2ndPFS (median 2nd PFS Group A: 5.6 vs Group B: 4.4 vs Group C: 3.9 mos; p = 0.60) or OS II (median OS II Group A: 14.9 vs Group B: 13.8 vs Group C: 11.7 mos; p = 0.49). In the subgroup of pts with a CFI < 6 mos, Group A (n = 52) reported longer 2ndPFS compared to both Group B (n = 58) (median 2ndPFS 5.3 vs 3.0 mos; HR: 0.61,95%CI 0.41-0.89; p = 0.009) and Group C (n = 58) (5.3 vs 3.2 mos; HR: 0.71, 95%CI 0.48-1.05; p = 0.07). Consistent results were achieved in OS II (Group A vs Group B; median OS 13.6 vs 10.8 mos; HR: 0.65, 95%CI 0.42-1.00; p = 0.053; Group A vs Group C 13.6 vs 8.9 mos; HR: 0.60, 95%CI 0.39-0.93; p = 0.002). In the subgroup of pts with a CFI ≥ 6 mos, no significant difference was shown between Group A (n = 41) and Group B (n = 61) or C (n = 33). **Conclusions:** Tx after progression to first-line FOLFOXIRI plus bev are feasible and show expected efficacy results. The reintroduction of the triplet plus bev seems more effective than doublets plus bev or other tx when a more aggressive disease biology is suggested (CFI < 6 mos).

3543 Poster Session (Board #166), Sat, 8:00 AM-11:30 AM

Localization of the primary tumor (LPT) and maintenance strategies after first line oxaliplatin (Ox), fluoropyrimidine (FP), and bevacizumab (Bev) in metastatic colorectal cancer (mCRC): Results from the AIO 0207 trial. *First Author: Anke C. Reinacher-Schick, Ruhr-University Bochum, St. Josef Hospital, Bochum, Germany*

Background: Numerous trials have examined the prognostic and predictive value of the LPT in mCRC, but little is known about the predictive value of LPT on different maintenance strategies. We analyzed progression-free survival (PFS) and overall survival (OS) from start of maintenance according to LPT in patients (pts) from the AIO KRK 0207 trial. **Methods:** Following a 24-week standard induction 471 pts were randomized to FP/Bev, Bev mono or no treatment with 454 pts being evaluable for PFS. Right sided primary tumors were defined as located in the caecum, ascending colon, transverse colon up to the splenic flexure; left colon was defined as splenic flexure, descending and sigmoid colon and rectum. **Results:** Data on LPT was available in 414 pts. for PFS (91%). LPT was left sided (LPTl) in 291 (70%) and right-sided (LPTr) in 123 (30%) of pts, respectively (remaining pts: status was either unknown, n = 37 or LPT was located in both regions, n = 3). Median PFS1 was 3.9 months (mos.) for LPTr and 5.3 mos. for LPTl (p = 0.11; HR 1.19, 95%CI 0.96 - 1.48). Analyses on PFS did not demonstrate a major predictive impact of LPT on the efficacy of the three maintenance strategies. The pairwise comparison of treatment arms showed a better PFS for FP/Bev vs no treatment independent from LPT (left: p < 0.0001; HR = 2.39, 95%CI 1.73-3.31; right: p = 0.011; HR 1.78, 95%CI 1.14-2.80). In addition, Bev mono vs no treatment was superior in LPTl (p = 0.0032; HR 1.54, 95%CI 1.15-2.06) with less difference in LPTr (p = 0.17; HR 1.36, 95%CI 0.87-2.14). Analysis for OS (429 evaluable pts) confirmed the strong prognostic impact of LPT (left vs right: 24.0 vs 16.7 months; p < 0.0001; HR = 1.65, 95%CI 1.32 - 2.06), but without major interaction between LPT and maintenance arms. The impact related to RAS mutational status will be reported. **Conclusions:** The strong prognostic factor of the LPT is confirmed in pts with mCRC undergoing Ox/FP/Bev induction therapy while there seems to be no major predictive impact of LPT on different maintenance strategies. Clinical trial information: EudraCT-Nr: 2008-007974-39.

3544 Poster Session (Board #167), Sat, 8:00 AM-11:30 AM

Impact of FOLFOXIRI and bevacizumab (bev) compared to FOLFOX and bev on health related quality of life (HRQOL) in patients with metastatic colorectal cancer (MCRC): Analysis of the CHARTA-AIO 0209 trial. *First Author: Julia Quidde, Department of Oncology, Hematology and Bone Marrow Transplantation with Section Pneumology, Hubertus Wald-Tumor Zentrum (UCCH), University Hospital Hamburg-Eppendorf (UKE), Hamburg, Germany*

Background: FOLFOXIRI/bev is a highly efficacious first line regimen in MCRC. Despite higher rates of neutropenia, diarrhea and stomatitis, FOLFOXIRI/bev is tolerable and feasible in MCRC patients. To date nothing is known about the impact of this regimen on HRQOL. **Methods:** 250 patients were randomized to FOLFOX/bev (arm A) or FOLFOXIRI/bev (arm B). HRQOL were assessed at baseline, every 8 weeks during induction treatment (6 months) and every 12 weeks during maintenance treatment, using the EORTC QLQ-C30, QLQ-CR29 and QLQ-CIPN20. The mean values of every score were calculated as the average of week 8, 16 and 24 assessment. Test concerning mean values were performed as t-test, with global type I error set at 0.05. HRQOL deterioration and improvement rates were analyzed and compared between treatment groups using chi^2 tests. **Results:** For HRQOL analysis, 237 patients were eligible (arm A: 118; arm B: 119). Compliance rate with the HRQOL questionnaires was 95.4% at baseline, 72.6% at week 8, 59.5 % at week 16 and 43.5% at week 24. Whereas mean global quality of life score (GHS/QOL) was similar between arm A and B (59.8 vs. 58.8; p = 0.726), mean scores for nausea/vomiting (9.4 vs. 16.0; p = 0.015) and diarrhea (23.7 vs. 32.1; p = 0.051) significantly or borderline significantly favored arm A during induction period. Furthermore, at week 8 scores of nausea/vomiting (9.2 versus 17.3, p = 0.006) appetite loss (19.5 vs. 29.4; p = 0.035) and financial problems (18.3 vs. 29.5; p = 0.021) and at the end of treatment physical functioning (75.0 vs. 65.8; p = 0.048) were significantly better for arm A compared to arm B. No significant differences were observed in the remaining EORTC scores. The rates of deterioration and improvement between baseline and week 8 of at least 10 points in the EORTC scores were similar (e.g. deterioration-rate GHS/QOL score 21.5% vs. 26.5% for arm A vs. B; p = 0.461). **Conclusions:** Although no remarkable detriment in HRQOL was noted, the better efficacy of FOLFOXIRI/bev compared to FOLFOX/bev is associated with a decrease in mainly gastrointestinal QOL scores. Further subgroup-analyses will be presented at the meeting. Clinical trial information: NCT01321957.

3545 Poster Session (Board #168), Sat, 8:00 AM-11:30 AM

Phase II trial of the autophagy inhibitor hydroxychloroquine with FOLFOX and bevacizumab in front line treatment of metastatic colorectal cancer. *First Author: Mark H. O'Hara, Abramson Cancer Center, Philadelphia, PA*

Background: Colorectal cancer (CRC) cells can become resistant to chemotherapy and anti-angiogenic therapy through autophagy. The antimalarial agent hydroxychloroquine (HCQ) is a potent inhibitor of autophagy, and *in vivo* studies in CRC cell models show significant decrease tumor volume when these autophagy inhibitors were combined with oxaliplatin and bevacizumab. We previously reported safety with HCQ 600mg BID in combination with standard front-line FOLFOX and bevacizumab in a Phase I study in metastatic CRC patients. We report the results of a single-arm phase II trial of patients with previously untreated stage IV CRC with good performance status and adequate hematologic and biochemical indices. **Methods:** Patients were treated with standard doses of mFOLFOX6 and bevacizumab with HCQ 600mg BID. Imaging was obtained every 2 months. **Results:** 37 patients were enrolled, 62% male, 89% Caucasian, median age 61, 65% ECOG PS 0, and 73% colon primary. Twenty-eight patients were evaluable for response as 2 patients did not start therapy and 7 patients withdrew prior to first response assessment. The ORR was 68% with an 11% CR rate. The median time to response was 3.1 months. Responses were independent of genomic aberrations within tumor tissue, specifically KRAS, TP53, BRAF, and PIK3CA. Median PFS and duration of response were not interpretable given that only 25% of patients came off trial for progression; all other patients withdrew to pursue surgery or liver embolization therapy, to receive therapy elsewhere, or due to toxicity associated with chemotherapy. The 1 year OS rate was 74%, and median OS has not been reached. The most common G3 or higher adverse events included neutropenia (31%), fatigue (11%), thromboembolism (9%), and cardiac events (9%). HCQ-attributable side effects included G1-3 insomnia (26%), G1-3 anxiety (20%), G1 visual disturbances (11%) and G3 allergy (3%). The majority of patients had increase in both LC3 and p62 in peripheral blood mononuclear cells and exhibited an increase in autophagosomes within the cytosol by electron microscopy. **Conclusions:** These data are promising and further evaluation in a randomized controlled trial is planned. Clinical trial information: NCT01206530.

3546 Poster Session (Board #169), Sat, 8:00 AM-11:30 AM

Efficacy of bevacizumab in second-line versus first-line treatment of metastatic colorectal cancer: Results from a new methodological approach based on the ITACa strategy trial. *First Author: Elisabetta Petracci, Biostatistics and Clinical Trials, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: Cancer trials collecting information on subsequent treatment lines offer an invaluable opportunity to gain a deeper understanding of therapeutic strategies. Still in the oncological literature, evidence comes from studies ignoring whole patient history. The few studies that consider more than one line of treatment often analyze data for each line separately. **Methods:** Data from the ITACa strategy trial investigating the role of bevacizumab (B) in first- and second-line of treatment in metastatic colorectal cancer patients (mCRC) were analyzed. The trial consisted of two arms with treatment crossover: chemotherapy (CT) plus B followed by CT alone *vs* CT alone followed by CT+B. The primary end-point was Progression-Free Survival (PFS). Our aim was to evaluate if the efficacy of B was greater or smaller in first- or second-line treatment. Survival analysis for repeated events taking into account of potential selection bias was performed. Indeed, patients starting a second-line treatment are a selected subgroup of patients initially enrolled. **Results:** Of the 370 patients in the intention-to-treat population, 175 (47.3%) received second-line treatment. Considering all available information from randomization to first and eventual second progression and accounting for the potential selection bias, the average effect of B in terms of PFS resulted in an HR = 0.80 [95% CI 0.68-0.95]. When evaluating the differential effect of B in first- and second-line, we found that the addiction of B to CT in first-line provided 10% (95% CI -28%; +12%) risk reduction (HR = 0.90, 95% CI 0.72–1.12) respect to CT alone and the addiction of B to CT in second-line provided 36% (95% CI -51%; -16%) risk reduction (HR = 0.64, 95% CI 0.49-0.84) respect to chemotherapy alone. **Conclusions:** The ITACa trial enabled us to analyze data in a unified framework considering first- and second-line treatment together. Results highlight an advantage of B when administered in combination with second-line chemotherapy, suggesting the best strategy for its administration. Clinical trial information: NCT01878422.

3547 Poster Session (Board #170), Sat, 8:00 AM-11:30 AM

Bevacizumab combined with first-line chemotherapy in elderly patients (≥75 years old) with metastatic colorectal cancer: Final results of the noninterventional CASSIOPEE study. *First Author: Eric Francois, Department of Medical Oncology, Centre Antoine-Lacassagne, Nice, France*

Background: Approximately half of the patients (pts) with metastatic colorectal cancer (mCRC) are elderly (≥65 years). Although few elderly pts are included in clinical studies, results in mCRC have shown similar treatment benefits in terms of progression-free survival and overall survival in young and elderly pts. This study was conducted in pts ≥75 years-old with mCRC treated in real life 1st line bevacizumab + chemotherapy in order to improve the knowledge on this population and to contribute in optimizing treatment strategy. **Methods:** CASSIOPEE is a prospective, multicenter, non-interventional study evaluating 1st line combination of bev + chemotherapy over 24 months in pts aged ≥75 years with mCRC. The primary endpoint was to describe progression-free survival (PFS). Secondary endpoints included the description of pts characteristics, overall survival, bev and chemotherapy regimen, safety and autonomy criteria (Lawton Instrumental Activities of Daily Living Scale; Balducci score). **Results:** A total of 402 pts were included between March 2012 and July 2016. In the efficacy population (n = 358), 52% were men, mean age 81 (±4); 54% were≥ 80 years old and 19% were ECOG ≥2; 80% had primary tumor located in the colon; main metastatic sites: liver (66%) and lung (30%). Bev was mainly combined with Folfox (36%) and Folfiri (29%). Median PFS was 9.1 months [8.3;10.2] in the efficacy population and 9.3 months for pts aged < 80, 9.5 months for pts aged ≥ 80 or ≤ 85 and 8.3 months for pts aged > 85. The PFS rate at 24 months was 11.8%. Median OS was 19.0 months [16.5;21.5] in the efficacy population and 20.6 months for pts aged < 80, 17.8 months for pts aged ≥ 80 or ≤ 85 and 13.0 months for pts aged > 85. The OS rate at 24 months was 42.0%. Autonomy and ECOG status remained stable from baseline to 24 months. In the safety population (n = 383), grade ≥ 3 adverse events occurred in 40% pts including 10% pts with bev related AEs. Overall, 4% pts died of an AE and 0.5% were bev related. **Conclusions:** These results suggest that mCRC patients aged ≥75 years-old, can benefit from 1st line bev plus chemotherapy in daily practice in this population. The safety profile is acceptable. Clinical trial information: NCT01555762.

3548 Poster Session (Board #171), Sat, 8:00 AM-11:30 AM

Concordance of DNA mismatch repair deficient (dMMR)/microsatellite instability (MSI) assessment by local and central testing in patients with metastatic CRC (mCRC) receiving nivolumab (nivo) in CheckMate 142 study. *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: MMR or MSI testing is recommended for mCRC pts and is often done locally by IHC or PCR testing, respectively (NCCN V1.2017) Nivo, a fully human anti-PD-1 mAb, demonstrated durable responses and a 12-mo OS rate of 73.8% in pts with mCRC locally assessed for dMMR/MSI-H status in the CheckMate 142 study (NCT02060188; Overman M, et al. 2017). Here we describe the results of local and central testing with respect to MMR/MSI status and clinical outcomes in the CheckMate 142 study. **Methods:** MMR/MSI status was assessed locally on archival tumor using IHC/PCR at screening and confirmed centrally by PCR (modified Bethesda panel) testing of tumor biopsy at enrollment. dMMR was defined by IHC as a loss of expression in ≥1 mismatch repair proteins. Stable microsatellite (MSS), low MSI (MSI-L), and high MSI (MSI-H), were defined as instability in 0, 1, or ≥2 markers, respectively. Pts with dMMR/MSI-H mCRC who progressed on or were intolerant of ≥1 prior line of therapy received nivo 3 mg/kg Q2W. **Results:** 74 pts were dMMR/MSI-H by local testing. Of these pts, 53 (72%) were centrally confirmed as MSI-H, 7 pts had insufficient tissue sample for PCR testing, and 14 pts had a central test that did not match local test results. Of the 14 pts, 3 pts with a clinical history of LS were identified locally as dMMR but centrally as MSS (Table). INV-reported ORR was 31.1% in 74 pts locally determined as dMMR/MSI-H, 35.8% in 53 pts locally and centrally confirmed as MSI-H, and 21.4% in 14 pts not centrally confirmed as MSI-H. **Conclusions:** The similar clinical activity between pts locally confirmed as MSI-H and pts who were centrally confirmed as MSI-H suggest local testing is appropriate for identifying the dMMR/MSI-H pts who may benefit from nivo monotherapy. Clinical trial information: NCT02060188.

	Local Testing			
Pt	Method	Result	Central Testing	Clinical History of LS
1	IHC	dMMR	MSS	NA
2	IHC	dMMR	MSS	No
3	IHC	dMMR	MSS	Yes
4	IHC	dMMR	MSS	Yes
5	IHC/PCR	dMMR (IHC)/MSI-H (PCR)	MSS	NA
6	IHC	dMMR	MSS	Yes
7	IHC	dMMR	MSS	No
8	PCR	MSI-H	MSS	NA

3549 Poster Session (Board #172), Sat, 8:00 AM-11:30 AM

A randomized phase II study evaluating efficacy and safety of SOX versus mFOLFOX6 as neoadjuvant chemotherapy for patients with resectable rectal cancer (KSCC1301). *First Author: Kenji Katsumata, Department of Gastrointestinal and Pediatric Surgery, Tokyo Medical University, Tokyo, Japan*

Background: Neoadjuvant radiotherapy is the current standard of care for rectal cancer. However, radiation therapy is sometimes associated with short-term severe toxicity and long-term morbidity. Perioperative introduction of new chemotherapy agents without radiotherapy for locally advanced rectal cancer (LARC) may be a promising option. Several studies of combination chemotherapy with oxaliplatin plus S-1 (SOX) have reported promising efficacy and safety in patients with metastatic colorectal cancer, suggesting a potential replacement for mFOLFOX6. **Methods:** A randomized phase II trial was undertaken to compare the efficacy and safety of SOX and mFOLFOX6 as neoadjuvant chemotherapy for patients with LARC. Patients were randomly assigned to receive mFOLFOX6 (every 2 weeks; day 1: 400 mg/m^2 bolus 5-fluorouracil [5-FU]; days 1 and 2: 2,400 mg/m^2 continuous 5-FU; day1: 200mg/m^2 *l*-LV; and day 1: 85 mg/m^2 oxaliplatin) or SOX (every 3 weeks; days 1–14: 80 mg/m^2 oral S-1; and day 1: 130 mg/m^{2}oxaliplatin). The protocol period for neoadjuvant chemotherapy was 3 months. The primary endpoint was the 3-year disease-free survival rate (3y DFS), and the secondary endpoints included pathological effect, R0 resection rate, survival and safety. **Results:** Between September 2013 and October 2015, 110 patients were enrolled and randomized (56 received SOX and 54 received mFOLFOX6). Baseline characteristics were balanced between the two arms. The major adverse events were neutropenia, peripheral neuropathy, loss of appetite, and fatigue. The incidence of grade 3 or higher neutropenia based on the *CTCAE Vers.4.0*was 13.2% in the SOX group and 32.0% in the mFOLFOX6 group. The surgical completion rate was 100% for the SOX group and 96% for the mFOLFOX6 group. The incidence of grade II or more surgical site infection based on Clavien-Dindo classification (CD) was 11.3% and 4.2% for the SOX and mFOLFOX6 groups, respectively. The CD grade III anastomosis-related complications developed in 7 cases in total. **Conclusions:** The KSCC1301 study suggests that neoadjuvant chemotherapy without radiation is active and safe. The results of pathological response will be provided. Clinical trial information: UMIN000011486.

3550 Poster Session (Board #173), Sat, 8:00 AM-11:30 AM

Classic or simplified LV5FU2 regimen: Multivariate analysis from a phase III study in metastatic colorectal cancer in elderly patients. *First Author: Jean-Louis Legoux, Centre Hospitalier Régional Universitaire, Orléans, France*

Background: In the early 2000s, classic LV5FU2 (C) (folinic acid, 5FU bolus, then 5FU infusion on D1 and D2) was replaced with simplified LV5FU2 (S) (folinic acid and 5FU bolus on D1 only), considered as effective and less toxic. No trial proved this assertion. The LV5FU2 companion in the FOLFIRI or FOLFOX regimen was C or S. The FFCD 2001-02 study compared in a 2 x 2 factorial design, in not-pretreated elderly patients (75+) with metastatic colorectal cancer, C or S, with or without irinotecan. No significant differences in PFS and OS were observed in the comparison with or without irinotecan. The median OS was 15.2 months in C versus 11.4 months in S, HR = 0.71 (0.55–0.92) and objective response rate was 37.1% in C vs S 25.6% in S, p = 0.004. The aim of this study was to present the factors associated with these differences. **Methods:** Prognostic factors associated with OS were studied using a Cox model. The multivariate analysis used the significantly different items from the univariate analysis and the differences observed at the inclusion. For each of these items, a subgroup analysis was performed. The second- and third-line treatments were analysed. **Results:** The 282 patients from the intent-to-treat study were included in the model. In OS, the prognostic factors were C versus S, number of metastatic sites, alkaline phosphatases (AP) and CEA. The interaction test in each subgroup for OS was not significant but C was significantly better in the following subgroup: age > 80 years, male, Karnofsky 100%, 1-2 Charlson index, AP ≤ 2N, leucocyte count > 11,000, CEA > 2N, CA 19-9 ≤2N. No differences were observed in the NCI toxicities but 130 serious adverse events in S versus 102 in C. A second-line was used for 55% patients in C, 46% in S, 81% of them with oxaliplatin or irinotecan in C, 76% after S. The third-line administration (20%) and targeted therapy (15%) were similar in C and S. **Conclusions:** C-LV5FU2 was superior both in subgroups with better and lower prognostics and this difference cannot be explained by an imbalance between the populations. The toxicity was not higher and a second-line was more often possible after C. The switch from C to S without scientific proof was perhaps a mistake in our practices. Clinical trial information: NCT00303771.

3551 Poster Session (Board #174), Sat, 8:00 AM-11:30 AM

Hand-foot skin reaction (HFSR) and outcomes in the phase 3 CORRECT trial of regorafenib for metastatic colorectal cancer (mCRC). *First Author: Axel Grothey, Mayo Clinic, Rochester, MN*

Background: Cutaneous toxicity is a known adverse effect of multikinase inhibitors and has been associated with clinical outcomes (Granito 2016). In the phase 3 CORRECT trial (NCT01103323), the multikinase inhibitor regorafenib significantly improved overall survival (OS) vs placebo in patients with mCRC (hazard ratio [HR] 0.77, 95% CI 0.64, 0.94; 1-sided P = 0.0052). This retrospective analysis explored whether HFSR was associated with outcomes in CORRECT. **Methods:** Patients randomized to receive regorafenib 160 mg/day during the first 3 weeks of each 4-week cycle were divided into subgroups based on whether or not they had HFSR. Estimates of OS and progression-free survival (PFS) (95% CI) were calculated using the Kaplan–Meier method. Patients who were randomized, but not treated, were included in the no HFSR group for the analysis of survival. **Results:** Of the 505 randomized patients, 500 received at least one dose of regorafenib. Among the treated patients, 47% (n = 235) had HFSR of any grade and 17% (n = 83) had HFSR grade 3. Of the patients who had HFSR, 69% (n = 162) had their first HFSR event (any grade) during the first treatment cycle. There was some imbalance in baseline characteristics between groups (Table). Survival was improved in patients who had HFSR at any time vs those who did not (Table). The OS benefit was also observed in patients who had the first HFSR event during Cycle 1 vs those who did not (median OS 7.2 vs 5.7 months; HR 0.66, 95% CI 0.51, 0.87). **Conclusions:** This post-hoc exploratory analysis suggests that patients who had HFSR had a greater treatment benefit from regorafenib. Since HFSR and survival are post-baseline assessments, results may be confounded by baseline factors or other unknown factors. Clinical trial information: NCT01103323.

3552 Poster Session (Board #175), Sat, 8:00 AM-11:30 AM

Prolonged (PI) vs short-term irinotecan (STI) administration: The Martha trial—A SICOG (Southern Italy Cooperative Oncology Group) randomized phase III study in the first-line setting of metastatic colorectal cancer (mCRC) patients (pts). *First Author: Vincenzo Formica, Tor Vergata University, Roma, RM, Italy*

Background: FOLFIRI+bevacizuamab(B) is a standard first-line regimen for mCRC pts. It should be delivered until progression, though an early switch to a de-intensified maintenance regimen is often adopted because of toxicity. The MARTHA trial compared FOLOFIRI+B for 6 months(mo) followed by maintenance B monotherapy up to 12mo (PI arm) vs FOLOFIRI+B for 3mo followed by capecitabine+B for further 3mo followed by B monotherapy up to 12mo (STI arm). **Methods:** Chemotherapy-naïve pts with histologically confirmed mCRC and measurable disease were deemed eligible and randomized to PI or STI arm in a 1:1 ratio. Co-primary endopoints were progression free (PFS) and overall survival (OS). The Kaplan-Meier method was used for survival analysis. A novel analysis (the Death Pace Analysis, DPA) was performed to identify pts benefiting more from a specific treatment. A multivariable logistic regression analysis (MLRA) was used to identify clinicopathological predictors of DPA-defined patient subsets. **Results:** 199 pts (100 in PI arm, 99 in STI arm) were enrolled. A non-significant superior OS was observed for STI (HR 0.81, p 0.26), no PFS differences were seen. The DPA demonstrated a 6% of pts identifiable as STI-benefiting pts. According to MLRA including 15 common clinicopathological variables, baseline Hemoglobin (Hb) level was the only independent predictor of the DPA-defined STI-benefit status (OR 2.3, p 0.009, i.e. 2.3-fold increased risk of not being a STI-benefiting patient for 1-point increase in Hb). Indeed, among pts with low baseline Hb ($<$ 13 gr/dL, cutoff determined upon ROC analysis), n = 128, a statistically significant prolonged OS was observed for STI over PI arm (median OS: 21.8 vs 14.4 mo, respectively, HR 0.64, p 0.04).No survival difference was seen between arms in pts with high Hb. **Conclusions:** mCRC pts with low baseline Hb levels are better treated with a STI first-line strategy. Published preclinical data suggest that low Hb may increase the risk of developing early chemo-resistant and aggressive disease with the prolonged use of irinotecan. Clinical trial information: EudraCT 2008-004890-17.

3553 Poster Session (Board #176), Sat, 8:00 AM-11:30 AM

Safety and feasibility of adding tumor debulking to palliative chemotherapy in multi-organ metastatic colorectal cancer: The ORCHESTRA trial. *First Author: Elske C. Gootjes, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: For selected patients with oligometastatic colorectal cancer (mCRC), local treatment of metastases is standard of care based on retrospective reports showing long term survival rates. Local treatment of metastases is technically feasible in an increasing number of patients with multi-organ mCRC. It is unknown if patients with extensive disease will benefit from tumor debulking when added to first line palliative chemotherapy. The ORCHESTRA trial (NCT01792934) was designed to prospectively evaluate overall survival (OS) benefit from tumor debulking in patients with multi-organ mCRC. **Methods:** Patients with multi-organ mCRC were eligible if $>$ 80% tumor debulking was deemed feasible by resection, radiotherapy and/or thermal ablative therapy. All patients received oxaliplatin based chemotherapy $\pm$ bevacizumab. In case of stable disease or response at first evaluation (9 weeks), patients were randomized to continuation of chemotherapy or tumor debulking followed by chemotherapy. Adverse events were reported. If patient withdrawal after randomization was $<$ 10%, the study was deemed feasible. Study continuation was based on the interim report on safety and feasibility after inclusion of 100 (of 478) patients. **Results:** Patients were randomized to the standard (N = 43) or intervention arm (N = 45). No patients withdrew after randomization. In 6.8% of patients debulking was not performed due to progressive disease (N = 5) or death (N = 1) prior to local treatment. Two patients had no lesions left to treat, 37 patients underwent tumor debulking. In 15 patients (40%) 21 serious adverse events related to debulking were reported, 83.7% of patients had no SAEs or recovered within 30 days. Postoperative 90-day mortality was 2.7% (N = 1). Chemotherapy was resumed in 86.5% of patients, median time to restart was 12.7 weeks (SD 5.6) and 78.4% completed $\geq$24 weeks of chemotherapy. **Conclusions:** Tumor debulking is feasible and safe and does not prohibit administration of palliative chemotherapy in the majority of patients with multi-organ mCRC. The ORCHESTRA trial will continue accrual to determine whether the aim of $>$ 6 months OS benefit from tumor debulking will be achieved. Clinical trial information: NCT01792934.

3554 Poster Session (Board #177), Sat, 8:00 AM-11:30 AM

Assessing outcome differences in the second line treatment of metastatic colorectal cancer (mCRC): An ARCAD analysis comparing sequence after first line trials (SAFL) and dedicated second line trials (DSLT). *First Author: Alexis Diane Leal, Mayo Clinic, Rochester, MN*

Background: There is considerable variability in the outcomes between second line (SL) trials in mCRC. The aim of this analysis is to compare the outcomes of patients (pts) with mCRC treated either on SAFL, with protocol defined SL treatment, or DSLT. **Methods:** Individual pt data was available on pts with mCRC enrolled in 1 of 10 trials (7 DSLT, 3 SAFL) in the ARCAD database. Regimens included FOLFIRI, FOLFOX, and irinotecan (IRI), since pts did not receive biologic agents in SL on SAFL. For pts on a SAFL, PFS and OS were defined as time from initiation of SL treatment to second progression (SP)/death and death, respectively. Descriptive statistics and multivariable Cox models were used to assess differences in PFS and OS. **Results:** 5,076 pts were included; 63% were male; median age was 62. See Table for treatment details. Pts treated on SAFL had shorter OS (0.7-1.5 months (mos$>$) shorter) and PFS (0.6-2.6 mos shorter), compared to those treated on DSLT. These findings were statistically significant and differences in OS did not attenuate after adjustment for age, gender, and prior treatment. PFS differences in FOLFOX became insignificant after multivariable adjustment. **Conclusions:** There are modest differences in both PFS and OS between pts with mCRC treated on SAFL and those on DSLT, suggesting differences in these pt populations. Caution is needed when applying these data to pts, as we were unable to control for potential confounders (ECOG PS, number and sites of metastases) at initiation of SL in SAFL, which may impact outcomes.

Second line outcome comparison.

3555 Poster Session (Board #178), Sat, 8:00 AM-11:30 AM

Age as a predictive and prognostic factor for targeted therapy treatment in metastatic chemorefractory colorectal cancer (CRC): An analysis of NCIC CTG CO.17 and CO.20. *First Author: Connor Wells, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: There is minimal data on the efficacy and improvement of quality of life (QoL) of these targeted therapies, like cetuximab, in elderly CRC patients ($\geq$70yo). We analyzed outcomes from two randomized phase III clinical trials from the Canadian Clinical Trials Group, CO.17 and CO.20. **Methods:** CO.17 and CO.20 were retrospectively analyzed. CO.17 compared cetuximab (CETUX) with best supportive care (BSC), CO.20 compared CETUX + brivanib (BRIV) with CETUX + placebo. Key eligibility criteria were similar between each trial. Patients were dichotomized by age ($\geq$70yo/ $<$ 70yo) for comparisons. Outcomes included overall survival (OS), progression free survival (PFS), adverse events (AEs), and QoL deterioration. In CO.17, only patients with wild type *K-RAS* were included in analysis. Multivariate analysis with Cox regression controlled for additional variables. **Results:** 980 patients were included in this analysis. 257 (26.2%) were $\geq$70yo at the time of enrollment. In CO.17, OS and PFS were similar between young and elderly patients treated with CETUX (OS 9.7m vs 8.0m, p = 0.45; HR 0.73 95%CI 0.39-1.37). Compared to the BSC arm, elderly patients treated with CETUX had a non-significant increase in OS (8.0m vs 5.1m, p = 0.11). In patients treated with CETUX, grade 3/4 AEs were similar between age groups, however elderly patients had a faster deterioration in global QoL than younger patients (3.6m vs 5.7m p = 0.046). In CO.20, younger patients had longer OS than elderly (9.2m vs 7.6m, p = 0.02; HR 0.81 95% 0.68-0.97, p = 0.02). AEs in the BRIV+CETUX arm were higher in the elderly than young (88% vs 77%, p = 0.03). Both young and elderly treated with BRIV+CETUX had more rapid decreases in global QoL than the CETUX arm. **Conclusions:** Age was neither prognostic nor predictive of response to targeted therapy in the single agent CO.17 trial. In CO.20, age conferred a worse prognosis. Elderly patients who are eligible for clinical trials may garner similar survival benefits as younger patients with single agent therapy, but may not derive the same improvement in QoL.

3556 Poster Session (Board #179), Sat, 8:00 AM-11:30 AM

A curative intent trimodality approach for advanced isolated abdominal nodal metastasis in metastatic colorectal cancer: Update of a single-institutional experience. *First Author: Benny Johnson, Mayo Clinic Cancer Center, Rochester, MN*

Background: To define and update survival rates and relapse patterns in patients (pts) with isolated advanced abdominal nodal metastasis secondary to colorectal cancer (CRC), treated with curative intent using aggressive trimodality therapy. **Methods:** Fifty-seven pts with isolated advanced abdominal lymph node metastasis (retroperitoneal and mesenteric) secondary to colorectal cancer received trimodality therapy defined as chemotherapy delivered in conjunction with external beam radiotherapy (EBRT) followed by lymphadenectomy and intraoperative radiotherapy (IORT). Infusional 5-FU was the most common radiosensitizer used (66%, 38 pts). The median dose of EBRT was 50 Gy & the median dose of intraoperative radiotherapy was 12.5 Gy. End points included distant metastasis, toxicities, local failure within EBRT field, recurrence within the intraoperative radiotherapy field, and survival. **Results:** 49% of pts were male, median age 50.5 yrs. All patients had ECOG $\leq$ 1. 27 pts had primary right sided colon cancer, 16 left sided colon cancer and 14 rectal primaries. Median time from initial CRC diagnosis to development of abdominal lymph node metastatic disease was 24 months (95% CI, 23.5-45.1 months). 84% (48 pts) had paraaortic nodal metastases, 12% (7 pts) had mesenteric nodal metastases, and 3% (2 pts) had both. With a median follow up of 89.4 months, the median overall survival and 5-year estimated survival rate were 53.2 months (95% CI, 46.4-78.8 months) and 42%, respectively. Median progression free survival was 19.3 months (95% CI, 15.6-32.8 months). 21 (37%) pts never developed distant disease. Outcome was not affected by disease sidedness, rectal primary, or mutational profile. Treatment was well tolerated without any grade 3/4 toxicities. **Conclusions:** The use of trimodality therapy including EBRT with radiosensitizing chemotherapy, lymphadenectomy and IORT produces sustainable long-term survival in selected metastatic CRC pts presenting with isolated retroperitoneal/mesenteric nodal relapse.

3557 Poster Session (Board #180), Sat, 8:00 AM-11:30 AM

A phase I/II trial of combined BRAF and EGFR inhibition in patients (pts) with BRAF V600E mutated (BRAFm) metastatic colorectal (mCRC): The EViCT (Erlotinib and Vemurafenib in Combination Trial) study. *First Author: Jayesh Desai, Royal Melbourne Hospital and Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Pts with BRAFm mCRC have an exceedingly poor prognosis. Unlike melanoma, BRAF inhibitor monotherapy has limited activity in BRAFm mCRC. Preclinically, BRAF inhibition results in rapid feedback activation of EGFR and ongoing tumor proliferation, which can be readily overcome by combining BRAF and EGFR inhibition. EViCT examined the safety and efficacy of combining two oral agents targeting BRAF with Vemurafenib (Vem) and EGFR with Erlotinib (Erl), in BRAFm mCRC pts. Herein, we report safety and preliminary efficacy data. **Methods:** EViCT had 2 parts: a Phase I dose escalation of Erl (cohort 1: 100mg qd; cohort 2: 150mg qd) together with Vem 960mg bd, to determine the maximum tolerated dose (MTD). The Phase II component involved dose expansion at MTD using a Simon 2-stage design to treat 9 pts in stage 1 and 15 pts in stage 2. Cycles were 28 days. Eligible pts had ECOG $<$ 1, $<$ 2 lines of systemic therapy for metastatic disease, and acceptable organ function. Staging CT scans were performed every 2 cycles, response assessed using RECIST 1.1. Primary endoint was clinical benefit rate (CR, PR and SD). A number of pharmacodynamics correlates were assessed including serial ctDNA, FDG-PET and optional tumour biopsies. Pts were treated until disease progression or toxicity requiring discontinuation. **Results:** Between Jul-2014 and Oct-2016, 30 BRAFm mCRC pts were enrolled. The Phase I Lead-in enrolled 4 pts in cohort 1 and 7 pts in cohort 2. There was 1 DLT (grade 3 hand-foot syndrome) in cohort 2. MTD/Recommended Phase 2 Dose was Erl 150mg qd and Vem 960mg bd, the full dose for each agent. The Phase II expansion enrolled 19 pts. Overall, 23 pts are evaluable for this interim analysis. Median age was 61 years, 11 (48%) pts were male. Most pts had 1(50%) or 2 (41%) lines of prior treatment. Overall response rate was 39% (95%CI = [20%, 61%]), including 5 (22%) confirmed PR, 4 (17%) unconfirmed PR, 3 (13%) stable disease and 11 (48%) progressive disease. **Conclusions:** Vem and Erl can both be given safely at their individual full doses when used in combination. In BRAFm mCRC, this combination resulted in clear clinical activity. Clinical trial information: ACTRN12614000486628.

3558 Poster Session (Board #181), Sat, 8:00 AM-11:30 AM

Response to pembrolizumab in patients with mismatch repair deficient (dMMR) colorectal cancer (CRC). *First Author: Alexis Diane Leal, Mayo Clinic, Rochester, MN*

Background: Anti-programmed death-1 (PD-1) antibodies have been shown to be effective in the treatment of dMMR CRC. We describe an updated analysis from a cohort of 19 patients (pts) with dMMR CRC treated with pembrolizumab. **Methods:** Pts were identified through review of the Mayo Clinic electronic medical record (EMR) and chemotherapy administration records from May 2015 through January 2017. All pts with dMMR CRC who received treatment with pembrolizumab were included. The EMR was reviewed to identify demographic, clinical, pathologic and treatment details. Overall survival (OS), progression free survival (PFS) and disease control rate (DCR = CR+PR+SD) are reported. Time to event analysis was calculated using the Kaplan-Meier method. **Results:** Nineteen pts were included in this analysis; median age at diagnosis was 48.6 years (range 25-93); 53% were female. Most primary tumors were right sided (n = 12; 63%), 6 (32%) were left sided and 1 (5%) was a tumor of unknown primary within the bowel. Twelve (63%) pts received $\geq$2 lines of therapy prior to pembrolizumab (range 1-4). Five pts received 2 mg/kg every 3 weeks, 11 received 200 mg/day every 3 weeks and 2 pts received 10 mg/kg (1 every 2 weeks, the other every 3 weeks). The most common alterations identified were loss of MLH1 (11/15) and PMS2 (12/15); 4 pts had germline mutations (mut) identified. KRAS mut was identified in 6/16 pts and 2 pts had BRAF mut. Three pts had MLH1 hypermethylation. Median number of cycles of pembrolizumab was 8 (range 1-35+), with 13 (68%) pts receiving $\geq$6 cycles. DCR at first assessment was 68%, with 5% CR, 47% PR and 16% SD. Median follow-up from diagnosis was 29 months (95% CI 18-42). Median OS was 103 months (95% CI 85-103); 12-month OS was 89%. Median OS from PD-1 therapy was 16.1 months (95% CI 16-NR); 12-month OS from PD-1 therapy was 79%. Median PFS was NR (95% CI 5-NR); 12-month PFS was 54%. At time of analysis, 9 pts remain on PD-1 therapy; 5 pts have died; 3 have received subsequent therapy. **Conclusions:** Anti-PD1 blockade with pembrolizumab can provide long lasting benefit in dMMR mCRC, even in heavily pretreated pts.

3559 Poster Session (Board #182), Sat, 8:00 AM-11:30 AM

An open-label expanded-access study of trifluridine/tipiracil for metastatic colorectal cancer. *First Author: Robert J. Mayer, Dana-Farber Cancer Institute/Partners CancerCare, Boston, MA*

Background: A Phase 3 clinical trial (RECOURSE) showed that trifluridine/tipiracil (FTD/TPI) was effective in the treatment of refractory metastatic colorectal cancer (mCRC) treated with standard chemotherapy and targeted-therapy drugs (Mayer et al. N Engl J Med 2015;372:1909-19). An expanded-access program (EAP) was started to provide access to FTD/TPI for patients with mCRC with similar eligibility and to further assess the safety of FTD/TPI in a "real-world" setting in US patients. **Methods:** Patients aged $\geq$18 years with refractory mCRC resistant to $\geq$2 regimens of standard chemotherapy with appropriate biologics and an Eastern Cooperative Oncology Group performance status of 0 or 1 were enrolled to this open-label EAP. Patients received FTD/TPI 35 mg/m^{2}twice daily for 5 days followed by 2 days' rest repeated twice followed by 14 days' rest over a 28-day treatment cycle until drug discontinuation. Sites reported duration of therapy, discontinuation due to disease progression, and adverse events (AEs) for each patient. **Results:** 549 patients were enrolled; 53.2% were male. Median duration of FTD/TPI therapy was 9.7 weeks, which was similar to US patients from RECOURSE (8.9). 10.2% of patients died during the study period, 9.7% due to disease progression. 76.1% of patients discontinued treatment due to disease progression and 4% discontinued due to AEs. Drug-related clinically significant AEs (all grades) are summarized in the table. **Conclusions:** Patients with refractory mCRC in this EAP had a similar exposure duration to that reported in US patients from RECOURSE, with no unexpected safety concerns. While gastrointestinal toxicity was lower in this population, this may be due to reporting of "significant" events. The clinical profile of FTD/TPI is confirmed in this larger, non-randomized "real-world" experience. *Sponsorship:* Taiho Oncology, Inc. *Editorial Assistance:* Complete HealthVizion. Clinical trial information: NCT02286492.

	Patients (%)

3560 Poster Session (Board #183), Sat, 8:00 AM-11:30 AM

The outcome of patients (pts) with metastatic colorectal cancer (mCRC) based on site of metastases (mets) and the impact of molecular markers and site of primary cancer on metastatic pattern. *First Author: Thiruvarudsothy Prasanna, The Canberra Hospital, Woden, Australia*

Background: Although liver is the commonest site of mets in pts with CRC, pattern of spread is variable and may reflect different biology in different subsets of pts. **Methods:** This is a retrospective analysis to explore the outcome of pts with mCRC based on their site of mets at diagnosis and to identify tumor characteristics which could predict the site of mets. Pts from 2 Australian databases, BioGrid (BG) and South Australian Cancer Registry (SA), from 01/2006 to 12/2015 were grouped into 5 cohorts; lung only, liver only or any pts with brain, bone or peritoneal mets. Overall survival (OS) for each group was compared with the rest of the sample using Kaplan Meier analysis and the log rank test separately in each dataset. Mantel-Haenszel Chi-squared test was performed in pooled data to assess the association between KRAS, BRAF, Micro satellite instability (MSI), site of primary and site of mets. **Results:** 5967 pts were included. In both datasets median OS was significantly higher when mets were limited to lung or liver and shorter for those with brain, bone or peritoneal mets. BRAF, KRAS and MSI data were available for 20%, 37% and 21% of the sample. In the pooled analysis BRAF mutation was associated with brain (Relative Risk=5.2) and peritoneal mets (RR=1.8) with lower incidence of lung (RR=0.3) and liver (RR=0.7) limited mets. KRAS mutation was associated with lung only mets(RR=1.4). Left colon tumors were associated with bone (RR=1.6) and lung only mets (RR=2.3) while peritoneal spread was less frequent compared with right colon tumors(RR=0.6). Rectal cancer was strongly associated with brain, bone and lung mets (RR=1.7, 1.7, 2.0). MSI status was not associated with site of mets though liver only mets was less frequent in MSI high tumors. **Conclusions:** Survival duration with mCRC is related to the site of mets. OS was significantly better when mets were confined to either lung or liver. BRAF mutation and primary rectal cancer were associated with poor prognostic metastatic sites like brain and bone.

Site of mets	SA	BG
	OS months (each group vs overall were significant p≤0.0001)	
Overall	15	25
Liver only	20	30
Lung only	29	39
Brain	6	6
Bone	7	12
Peritoneum	12	17

3561 Poster Session (Board #184), Sat, 8:00 AM-11:30 AM

Early tumor shrinkage (ETS) and depth of response (DpR) in wild-type (WT) RAS tumors from the phase III trial of panitumumab (pmab) plus best supportive care (BSC) versus BSC in chemorefractory metastatic colorectal cancer (mCRC). *First Author: Tae Won Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Activating *RAS* mutation is a negative predictor of anti-EGFR therapy. In the final analysis of 20100007, the first phase 3 study to prospectively evaluate efficacy and safety of WT *RAS* (*KRAS* and *NRAS* exons 2, 3, 4) mCRC, pmab + BSC continued to show improved survival (OS and PFS) and ORR. Recent data suggest that tumor burden reduction and ETS may contribute to improved OS. Previous studies have shown that pmab plus chemotherapy results in ETS, which correlates with OS benefit (Douillard et al, EJC, 2015; Rivera et al, JCO, 2015; Mansmann et al, JCO 2013). Here we report analyses of ETS and DpR and the effect on OS in patients (pts) with WT *RAS* mCRC treated with pmab monotherapy in the '0007 trial. **Methods:** Anti-EGFR naïve pts with WT *KRAS* exon 2 mCRC were randomized 1:1 to pmab + BSC or BSC. Pt tumors were further evaluated for *RAS* status, and DpR (percent tumor shrinkage at nadir or progression) and ETS (≥/< 0% or ≥/< 20% by week 8) were analyzed in WT *RAS* pts. OS and PFS were compared for each ETS group. **Results:** Of 377 pts with WT *KRAS* exon 2 mCRC, 270 were WT *RAS* (142 pmab + BSC, 128 BSC alone). In the pmab + BSC arm, 69.5% and 38.2% of pts had ≥0% and ≥20% ETS, respectively, and median (Q1, Q3) DpR was 16.9% (0%, 37.5%). OS was improved in pts with higher ETS (≥0% or ≥20%) compared with lower ETS (<0% or <20%; Table). **Conclusions:** In this post-hoc analysis, pmab monotherapy provided any ETS benefit (≥0%) in 69.5% of WT *RAS* mCRC pts, and ETS was associated with improved PFS and OS. Pmab should be considered both in combination and as monotherapy for its significant impact on OS and also for its ability for substantial ETS in pts with WT *RAS* mCRC. Validation is necessary to investigate the value and cutoff of ETS in a prospective study. Clinical trial information: NCT01412957.

Primary tumor sidedness associates with prognosis of patients with brain metastases of colorectal cancer. *First Author: Anna Sophie Berghoff, University of Vienna, Vienna, Austria*

Background: Brian metastases (BM) are a rare but devastating complication of colorectal cancer. We aimed to analyse prognostic factors in patients suffering from colorectal cancer (CRC) BM. **Methods:** Patients with histological proven CRC and BM were identified from the brain metastasis database of the Comprehensive Cancer Center Vienna. Clinical characteristics including established prognostic factors were retrieved by chart review. Established clinical prognostic scores for BM patients including the graded prognostic assessment (GPA) and the GPA for gastrointestinal tumours (GI-GPA) were calculated based on clinical characteristics as previously published. **Results:** 215 (male: 125/215 (58.1%); female 90/215 (41.9%)) patients with CRC BM were available for this study. The following established clinical prognostic factors showed a significant association with median overall survival (OS) times from BM diagnosis: number of brain metastases (n = 1: 6 months; n = 2-3: 4 months; n > 3: 3 months; p = 0.001), age at BM diagnosis (< 65 years: 6 months; > 65 years: 4 months; p = 0.047), extracranial disease (present: 4 months; absent: 8 months; p = 0.002) and Karfnofsky performance score (KPS < 70%: 3 months; KPS > 70%: 5 months; p = 0.002), graded prognostic assessment (GPA) class (class I: 15 months; class II: 13 months; class III: 4 months; class IV: 4 months) and the gastro-intestinal disease-specific GI-GPA (class I: 11 months; class II: 6 months; class III: 6 months; class IV: 3 months; p < 0.001). In addition, the location of the primary tumour in the left colon (n = 176 (81.9%); 5 months) was associated with significantly longer median overall survival times from diagnosis of BM than primary tumour location in the right colon (n = 39 (18.1%); 3 months; p = 0.010). Primary tumor sidedness (HR 0.577; 95% CI 0.397-0.841; p = 0.004) remained a strong prognostic factor at multivariate analysis independently of GI-GPA (HR 0.718; 95% CI 0.612-0.842). **Conclusions:** Primary tumor sidedness is an independent prognostic factor in patients with CRC BM and should be included in disease-specific prognostic scores.

3563 Poster Session (Board #186), Sat, 8:00 AM-11:30 AM

Clinical and molecular characterization of patients with metastatic colorectal cancer harbouring DNA mismatch repair deficiency. *First Author: Romain Cohen, Medical Oncology Department, Saint-Antoine Hospital, Paris, France*

Background: Prognosis of patients (pts) with metastatic colorectal cancer (mCRC) harboring microsatellite instability (MSI) is poorly characterized. We aimed to assess the clinical relevance of distinguishing sporadic (SP) from Lynch syndrome (LS)-related mismatch repair deficiency (dMMR). **Methods:** Pts with diagnostic of dMMR and/or MSI mCRC between 1998 and 2016 were retrospectively identified in 6 French hospitals. Tumor samples were systematically collected and screened for *RAS/RAF* mutations and *MLH1* promotor methylation. dMMR and MSI statuses were confirmed using immunohistochemistry and Pentaplex© PCR assay. Sporadic cases were molecularly defined as those displaying MLH1 loss of expression with *BRAF*V600E mutation and/or MLH1 hypermethylation. Clinical data (demographic data, metastatic sites, therapeutic strategies) were recorded. **Results:** 129 pts, of which 48 SP and 81 LS, were included. Compared with LS, SP were associated with female (P < .001), older age at diagnostic (P < .001), proximal colon (P = 0.002), and less liver metastasis (25% vs 47%, P = .02). For initially localized CRC, median disease free survivals (DFS) were 9.1 months (m) for SP (n = 22) and 12.3 m for LS (n = 47) (hazard ratio (HR) = 0.5, 95%CI 0.28-0.90, P = .02). Median overall survivals (OS) from stage IV diagnosis were 43.9 m in the overall population, 23 m for SP and not reached for LS (HR = 0.23, 95%CI 0.10-0.52, P < .001). *BRAF* mutation was harbored by 29 SP tumors (60%) and did not impact OS among SP pts (P = .52). Metastatic disease was less frequently resectable for SP than LS (21% vs 56%, P < .001). Median DFS for pts with resected metastatic disease (n = 55) were respectively 6.7 and 10.5 m (HR = 0.28, 95%CI 0.10-0.73, P = .01). At the data cut-off date, 16 pts (15 LS and 1 SP) were still in complete remission. Median progression free survivals with first-line chemotherapy for pts with unresectable metastasis (n = 61) were 3.9 m for SP and 5.0 m for LS (P = .71). **Conclusions:** This retrospective study suggests a worse prognosis of pts with SP MSI mCRC compared to these with LS-related mCRC.

3564 Poster Session (Board #187), Sat, 8:00 AM-11:30 AM

The impact of cumulative toxicity on physical quality of life in patients with metastatic colorectal cancer receiving first line chemotherapy. *First Author: Claudia Schuurhuizen, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: We have previously suggested that treatment related toxicity has impact on physical quality of life (QOL) scores, as opposed to global QOL. Moreover, the cumulative effect of experienced toxicities, including low-grades AEs, may be of more importance. The purpose of this observational cohort study was to evaluate the association between cumulative toxicity and physical and global QOL in patients with metastatic colorectal cancer (mCRC) receiving chemotherapy. **Methods:** 105 patients with mCRC starting first line chemotherapy were evaluated. All patients completed the EORTC-QLQ-C30 questionnaire at baseline and after 10 weeks. Toxicity, clinical outcomes and demographics were retrieved from patient records. For each patient, we calculated cumulative toxicity in three different ways: i) total number of adverse events (AEs) (all grades), ii) total number of grade 3-4 AEs, and iii) total number of AEs multiplied by their grade. The relation between each cumulative toxicity score and QOL assessed at 10 weeks, was studied. **Results:** The mean age of patients was 64.8 $\pm$ 9.7 years, 70.5% were male, and 83.8% received first line oxaliplatin based combination chemotherapy. AEs occurred in 98.1% of patients, grade 3-4 AEs in 37.1%, and grade 1-2 AEs in 61.0%. The mean number of experienced AEs (all grades) was 5.3 $\pm$ 2.7. The most common toxicities included diarrhea, neuropathy and fatigue. None of the toxicity scores was related to global QOL outcome. A higher total number of all grades AEs (β = - 2.2, 95%CI = -3.7; -6.6) and total number of AEs multiplied by grade (β = -1.3, 95%CI = -2.2; -3.5) were significantly associated with worse physical QOL. **Conclusions:** Cumulative toxicity, defined as the total of all grades AEs, significantly affects physical QOL in patients with mCRC receiving first line chemotherapy. Improvement of treatment related toxicity management by reducing the total number of AEs, may result in relevant improvements in patients' QOL. Our results emphasize that future RCTs should present physical QOL outcomes instead of global QOL, as well as all grades and total number of toxicities for individual patients.

3565 Poster Session (Board #188), Sat, 8:00 AM-11:30 AM

Effect of postoperative morbidity on survival after cytoreductive surgery (CRS) with heated intraperitoneal chemotherapy (HIPEC) for peritoneal metastasis in a series of 700 cases. *First Author: Clarisse Eveno, Hopital Lariboisiere AP-HP, Service de Chirurgie Digestie et Cancérologie, Paris, France*

Background: Major morbidity (MM) after cytoreductive surgery with heated intraperitoneal chemotherapy (CRS/HIPEC) is associated with worsening of disabilities and length of the hospital stay. This study aimed to identify MM prognostic factors and to measure its impact on oncological outcomes. **Methods:** A post-hoc analysis of a prospective cohort of 734 patients with peritoneal metastasis (PM) from 2006 to 2015 was undertaken. Five hundred and two patients who had complete CRS and HIPEC for PM were included. **Results:** Major morbidity was identified in 31% (156/502) of CRS/HIPEC procedures, including 67 hemorrhagic complication (13.3%), 87 anastomotic leaks (17.4%), 121 reoperation (24.1%), and 65 pulmonary complication (12.9%). The multivariate predictors of MM were American Society of Anesthesiologists (ASA) score (ASA 3 vs. 1-2, OR 95%CI: 3.58 [1.54 – 8.34]), origin of PM colorectal adenocarcinoma vs. other, OR 95% CI: 1.62 [1.06 – 2.48]), type of HIPEC drug (oxaliplatin vs. other, OR 95% CI: 2.85 [1.28 – 6.32]), number of anastomosis (no vs. at least 1, HR 95% CI: 1.85 [1.19 – 2.88]), blood transfusion (OR 95%CI: 1.84 [1.05 – 3.23]) and length of surgery longer than the median value (OR 95%CI: 1.88 [1.22 – 2.91]). The in-hospital mortality rate for the entire cohort was 1.7% (9/502). Rate of adjuvant chemotherapy after CRS/HIPEC was comparable between the two groups (70.3% vs. 72.4%, p = 0.64). The median duration of follow-up was 18 months. The MM group had worst OS and DFS comparing non-MM (Hazard ratio and 95% confidence interval at 3.48 [1.90 ; 6.35] and 1.91 [1.43 ; 2.57], respectively). **Conclusions:** Major morbidity after CRS/HIPEC for peritoneal metastasis is a source of significant reoperation and longer hospital and intensive care unit stay; with a decrease in overall survival and disease free survival even after complete CRS. Preoperative ASA score, number of anastomoses, colorectal origin of PM, HIPEC with oxaliplatin, blood transfusion and length of surgery are independent predictors of MM for CRS/HIPEC patients.

3566 Poster Session (Board #189), Sat, 8:00 AM-11:30 AM

Conditional survival analysis of stage IV colorectal cancer patients living >24 months. *First Author: Nadia Dawn Ali, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: The overall survival of patients with stage IV colorectal cancer (both in unresectable and resectable settings) has been increasing over recent decades due to improvements in chemotherapy, liver surgery and other liver-directed therapies. As a result of more patients living longer, there is a need to refine prognostic information to more accurately predict survival to assist multi-disciplinary cancer management teams in treatment decisions but also for patient quality of life. **Methods:** We performed a retrospective analysis of all patients with stage IV colorectal cancer seen at Rutgers Cancer Institute of New Jersey between Jan 1, 2005 to March 10, 2015 by ICD-9 code (N = 318 patients). This included patients who were deemed unresectable and patients who were resected with curative intent. Our study population was patients with documented survival for > 24 months (N = 158). Variables gathered included patient demographics, disease related (primary location, KRAS status, metastasis location, interval to metastases) and treatment related (chemotherapy regimens, radiation and surgery) data. Survival curve estimates are conditional on having survived 24 months. **Results:** Complete data was available for 125 patients (75 were resected for cure and 50 were not). Median overall survival of resected patients was not reached. The median overall survival of non-resected patients was 75.9 months. Univariate and multivariate analysis for surgery and non-surgery groups was performed. No statistically significant covariates were found beyond surgical resectability. The conditional survival probabilities of living 1, 2 or 3 years longer after 24 months of survival are 91.7%, 71.6% and 51.6% respectively in the patients with unresectable disease, and 98.1%, 92.2% and 88.8% in patients who were able to be resected with curative intent. **Conclusions:** These results indicate that patients who survive 24 months with stage IV colorectal cancer have an excellent prognosis. For patients who are unresectable and survive 24 months, this study suggests that they may benefit from resection of remaining metastatic sites if feasible. For resected patients this information may propose a possible benefit from repeat metastasectomy.

3567 Poster Session (Board #190), Sat, 8:00 AM-11:30 AM

Impact of tumor location on outcomes in patients with metastatic colorectal cancer (mCRC) treated with regorafenib (REG): An interim analysis from the prospective, observational CORRELATE study. *First Author: Michel Ducreux, Gustave Roussy Cancer Campus, Villejuif, France*

Background: The anatomical location of the primary tumor has been associated with outcomes in mCRC, with left-sided (L) tumors having a better prognosis than right-sided (R) tumors and location predicting response to treatment. REG significantly improved overall survival (OS) vs placebo in patients with mCRC who progressed on available treatments in 2 randomized, phase 3 trials (CORRECT, CONCUR). This exploratory analysis evaluated outcomes by primary tumor location in patients with mCRC treated with REG in the CORRELATE study. **Methods:** CORRELATE is an observational study designed to characterize the safety and effectiveness of REG in unselected patients for whom the decision to treat with REG has been made by the treating physician according to the local health authority label. Primary L tumors were located in the rectum, splenic flexure, recto-sigmoid, descending, or sigmoid colon; R tumors were in the appendix, hepatic flexure, cecum, or ascending colon. OS was analyzed by the Kaplan–Meier method and comparisons were by a 2-sided log-rank test. **Results:** Primary tumor location was available for 474 patients (L, n = 375 [79%]; R, n = 99 [21%]). Median time from initial diagnosis and from diagnosis of metastatic disease to treatment was slightly longer in L vs R tumors (32 vs 28 months and 25 vs 22 months, respectively). A higher proportion of patients with L vs R tumors, respectively, had prior radiotherapy (34% vs 13%) and a lower proportion had a partial colectomy (40% vs 70%). Best response to prior systemic therapy (partial response + stable disease) was 72% for L tumors and 68% for R tumors with a median duration of treatment of 26 and 22 months, respectively. REG treatment duration was similar in the 2 groups. Median OS (95% CI) was 6.7 months (6.1, 7.7) for L tumors vs 6.3 months (4.9, 8.1) for R tumors (P = 0.3); median progression-free survival (95% CI) was 2.8 months (2.6, 3.0) vs 2.6 months (2.4, 3.0) (P = 0.5), respectively. **Conclusions:** Interim results from this observational study suggest that OS is similar in patients with R and L tumors treated with REG. Clinical trial information: NCT02042144.

3569 Poster Session (Board #192), Sat, 8:00 AM-11:30 AM

Bevacizumab and its impact on survival for patients receiving subsequent anti-EGFR therapy: Updated results from the SA metastatic CRC registry. *First Author: Timothy Jay Price, Queen Elizabeth Hospital and Lyell McEwin Hospital, Adelaide, Australia*

Background: Debate exists as to whether first line bevacizumab effects subsequent sensitivity to anti-EGFR therapy. Authors hypothesize that initial anti-VEGF therapy may induce biological changes that then increase the risk of acquired resistance to subsequent EGFR inhibitors. **Methods:** A retrospective cohort study was performed to compare the characteristics and survival of patients who were treated with an anti-EGFR therapy 2nd line and beyond by two groups defined by the first line therapy; 1. chemotherapy (chemo) plus bevacizumab (bev) and 2. chemo alone. Survival for this analysis is from the time of commencing first line chemotherapy and secondly from anti-EGFR therapy. Pearson chi test analysis was performed to determine whether receiving first line bev was associated with worse overall survival (OS). **Results:** 348 mCRC patients who received chemo with or without bev and then an anti-EGFR therapy were studied. Patient characteristics are summarised in the table below. The significant differences between group 1. Vs. 2. were as follows; median age 63.8 years v 67.9 years ($p = 0.005$), lower use of single agent FU 6.4% v 19.2%, KRAS status not tested (reflecting the practice changes over time) 19.3% v 39.2%, KRAS MT 2% v 4%, and where BRAF MT status was known (11%); BRAF MT rate 23% v 0. Median OS for the 2 groups was 34.2 months, and 28.2 months respectively ($p = 0.12$) from first line therapy. Median OS for patients who underwent single agent anti-EGFR as subsequent therapy was also not significantly different, 31.1 months group 1 ($n = 60$) versus 27.7 months group 2 ($n = 85$), $p = 0.52$. Results based on commencement of anti-EGFR therapy are under way. **Conclusions:** Survival was not significantly different between the two groups, and the trend was towards higher OS with chemo plus bev suggesting that in our registry population, bev administration in first line therapy with chemo did not lead to a worse outcome overall for those patients subsequently receiving anti-EGFR therapy, either with chemotherapy or as a single agent. Updated results from commencement of anti-EGFR therapy will give further insights and will be presented at the meeting.

3570 Poster Session (Board #193), Sat, 8:00 AM-11:30 AM

Upfront short course radiotherapy (SCRT) in metastatic rectal cancer (mRC): A way forward. *First Author: Shanu Jain, Tata Memorial Hospital, Mumbai, India*

Background: To evaluate the feasibility and efficacy of SCRT followed by chemotherapy (CT) in locally advanced metastatic rectal cancer (LAmRC). **Methods:** Between May 2012 and August 2015, 70 patients having LAmRC with or without circumferential resection margin (CRM) positive disease treated with SCRT (25Gy/5#) followed by 3-6 cycles of capecitabine/5-FU, oxaliplatin or irinotecan based CT were assessed. **Results:** Fifty one had single site metastases (23 liver, 16 lung, 10 retroperitoneal lymph nodes and 2 peritoneum), 9 had combined lung and liver metastases and 10 had combined nodal and organ metastases. Sixty five (93%) patients could complete planned SCRT and 3-6 cycles of chemotherapy (starting 7-10 days after RT completion) with dose reduction in 21 (32%) patients owing to CT induced toxicities. Local tumor down-staging was achieved in 43 (61.4%) patients and the rest had a stable primary disease. Radiologically, CRM was free in 25 (46.3%) patients out of 54 initially involved. Surgery of the primary was planned in 38 (58%). R0 resection in 26 (40%), R1 in 7 (pCRM positive). Five refused surgery in spite of being resectable. Rest of the 27 (41%) received palliative CT due to progression of distant disease. Metastatectomy along with primary surgery was done in 16 (25%) patients. Median follow up was 29 months. Overall survival (OS) of entire cohort at 2 years was 40%. Median progression free survival (PFS) and OS of patients with resected primary was 17 (10-24) and 37 (28-45) months, respectively, which is significantly better than those who were not resected ($p = < 0.001$). Of these 33 resected patients, 13 (39.4%) are disease free and 20 have progressed (16 distant, 2 loco-regional and 2 local and systemic). **Conclusions:** Upfront SCRT followed by systemic CT in an unresectable group of metastatic rectal cancer patients is safe and feasible and is having encouraging results in terms of downstaging and resectability of the primary.

Patient group	PFS in months	OS in months
Whole cohort (n = 70)	10 (7-13)	16 (8-24)
Operated for Primary (n = 33: 47%)	17 (10-23.6)	37 (28-46)

3571 Poster Session (Board #194), Sat, 8:00 AM-11:30 AM

PEGylated human IL-10 (AM0010) monotherapy in refractory metastatic colorectal cancer. *First Author: Jeffrey R. Infante, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: Colorectal Cancer (CRC) has been refractory to immune therapies. The clinical benefit of immunotherapy is thought to depend on the expansion of activated, intratumoral, tumor specific cytotoxic CD8+ T cells which are low in most CRCs. AM0010 stimulates the survival, expansion and cytotoxicity of intratumoral CD8+ T cells. Patients with CRC who have progressed on SOC first and second line of therapy have a reported 7.1 months OS with TAS-102 (Meyer et al. NEJM372;20, 2015). In this Phase 1 study the efficacy of AM0010 was studied in refractory metastatic CRC patients. **Methods:** CRC pts progressing on a median of 4 prior therapies (range 2-7) were treated daily with AM0010 in doses of 1 ug/kg SQ daily to 40 ug/kg in a dose escalation design. Tumor responses were assessed using irRC. Serum cytokines, activation of blood derived T cells and peripheral T cell clonality were analyzed. Pretreatment archival tissue samples were evaluated by IHC for tumor infiltration by CD8+T cells. **Results:** AM0010 was tolerated with reversible TrAEs. 10 pts (of 27) had a G3/4 TrAE. There were no objective responses. 11 patients were treated in dose escalation cohorts (1-10 ug/kg) and 16 pts were treated at or above RP2D (20 ug/kg or 40 ug/kg). Seven of 25 pts with at least one radiographic response evaluation had stable disease at 8 weeks. One patient had SD for 19.4 months. The mPFS (ITT n = 27 pts) was 1.6 months, mOS was 11.7 (range 2.4 – 32+) months. The median follow-up is 25.2 months (range 13-35). AM0010 increased Th1 cytokines IL-18 and IFNg in the serum of patients, while decreasing mediators of chronic, tumor promoting inflammation (Th17 cytokines) and TGFb. Tumor infiltrating granzyme B+ CD8+ T cells increased during the treatment. AM0010 induced de-novo oligoclonal expansion of T cell clones in patients. **Conclusions:** AM0010 is well tolerated in patients with refractory CRC. Although objective tumor responses were not seen in this very advanced CRC population, the observed immune activation including clonal T cell expansion, prolonged stable disease, and the mOS of 11.7 months is encouraging in this advanced CRC population. Future study of AM0010 in combination with FOLFOX in a second – line of therapy colorectal cancer patients is being planned. Clinical trial information: NCT02009449.

3572 Poster Session (Board #195), Sat, 8:00 AM-11:30 AM

Results of the Quad wild type arm of the AGITG ICECREAM study: A randomised phase II study of cetuximab alone or in combination with irinotecan in patients with refractory metastatic colorectal cancer with no mutations in *KRAS, NRAS, BRAF* or *PIK3CA*. *First Author: Jeremy David Shapiro, Department of Medical Oncology, Cabrini Hospital, Melbourne, Australia*

Background: Cetuximab (cet) increases survival in *RAS* wild-type (WT) metastatic colorectal cancer (mCRC) in first-line and chemorefractory patients (pts). Adding irinotecan (iri) to cet in refractory pts who had progressed on iri increased response and delayed progression in the BOND trial, which was conducted prior to recognition that *RAS* mutations are predictive of EGFR-inhibitor (EGFR-I) resistance. Subsequent trials in chemorefractory pts used single agent EGFR-I as standard. In the era of biomarker selection, the benefit of continuing iri versus single agent EGFR-I had not been resolved. **Methods:** ICECREAM is a randomised phase II trial evaluating cet v cet + iri in chemotherapy-refractory mCRC, stratified for *KRAS* G13D mutation (previously reported) or no mutations in *KRAS*, *NRAS*, *BRAF* and *PI3KCA (*Quad WT*)*. EGFR-I naïve, ECOG PS 0-1 pts, progressing within 6 months of iri and refractory (or intolerant) to fluoropyrimidine and oxaliplatin were randomised to cet 400mg/m^2 IV loading then 250mg/m^2 weekly +/- iri 180mg/m^{2}q2 wks. The primary endpoint was progression-free survival at 6 months (6m PFS); secondary endpoints were response rate (RR), overall survival (OS), toxicity and quality of life (QOL). **Results:** From Nov 2012 to June 2016, 48 Quad WT pts were recruited: 2 ineligible (not iri-refractory, *BRAF* mutation) wre not included for analyses and a further 2 not evaluable for response. Characteristics were balanced between cet ($n = 21$) v cet-iri ($n = 25$), except for sex (male 62 v 72%) and primary site (left 95 v 68%). 6m PFS rate was 14% v 41%; HR 0.39 (95% CI: 0.20–0.78, $p = 0.008$). RR was 10% (2 PR) v 36% (1 CR, 8 PR); $p = 0.04$. Toxicities were higher with cet-iri; at least one grade 3/4 adverse event in 50 v 23%. No differences in global or specific QOL were seen. **Conclusions:** The AGITG ICECREAM trial confirms a significant synergy for the addition of iri to cet and improved PFS in Quad WT chemorefractory mCRC, echoing data in molecularly unselected pts. Clinical trial information: ACTRN12612000901808.

3573 Poster Session (Board #196), Sat, 8:00 AM-11:30 AM

Rapid in vitro evaluation of immune responses to tumor-derived organoids as an adjunct to immunotherapy trials. *First Author: Robert George Ramsay, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Cancer immunotherapy has made rapid advances with the development of agents that subvert the negative arm of the immune system. This has been important because patients can mount anti-tumor immune responses. In the case of colorectal cancer (CRC), the presence of tumour infiltrating lymphocytes (TILs) appears to have predictive power regarding outcome. Nevertheless, assays that directly evaluate the quality, phenotype and anti-tumor activity of TILs are lacking. Here a novel immune assay platform is presented that measures the kinetics of TIL killing which correlates with pathological tumour response after treatment. **Methods:** Treatment naïve fresh cancer biopsies were processed to generate organoids and TILs from patients (n = 12) with pathological complete response (pCR) verses non-responding tumours (NRT). These were co-cultured with TILs to organoid ratios of 1:1, 5:1 and 10:1 for 48 hs and TILs function were measured by cytokine release and mean fluorescence intensity (MFI) based upon activated caspase activity. Additionally, TILs from patients with metastatic CRC (n = 20) have also been evaluated. **Results:** Ten thousand+ organoids are routinely cultured while millions of TILs are retrieved and expanded from biopsies. TIL-mediated killing of patient-matched tumor organoid confirm CD8+ve specific killing. At 24hrs MFI was significantly higher in pCR organoid indicative of immune-mediated cell death compared to NRT organoids at a ratio of 1:1. The efficiency of TIL killing was further enhanced as the ratio increased to 5:1 and 10:1. Gamma interferon production by cytotoxic (CD8+) T-cell is a robust measure of TIL activation state and was also significantly higher by pCR TILs compared to NRT TILs. Substantive differences in TIL subsets were also found in mCRC-derived samples compared to primary CRC. **Conclusions:** This is a novel functional immune assay and the first of its kind that successfully demonstrated the differences in patient-matched TIL killing between non-responding and responding CRC. This assay can be performed within in two weeks and thus it has translational potential that may change clinical management in the future and immunotherapy strategy design.

3574 Poster Session (Board #197), Sat, 8:00 AM-11:30 AM

Prognostic implications of TAMs in colorectal cancer hepatic metastases. *First Author: Matthew Reilley, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A limited understanding of the immune microenvironment of mismatch repair-proficient metastatic colorectal cancer (mCRC) impedes efforts to develop effective immunotherapy treatments for the majority of CRC patients. Liver metastatic disease is common and associated with poor outcomes. While T-cell infiltration of liver metastases positively correlates with survival, most mCRC patients do not benefit from checkpoint-blockade therapy. Tissue associated macrophages (TAMs) have been associated with an immune suppressive environment, but their prognostic role in mCRC is largely unknown. **Methods:** Comprehensive analysis of gene expression and immunohistochemistry (IHC) in 25 microsatellite stable (MSS) untreated liver metastatectomy (LM) specimens was performed. Clinical outcomes including recurrence, immunologic data, and tumor microsatellite status were evaluated and correlated. **Results:** Principal component analysis of immune and cancer pathway related genes were performed and compared with recurrence status. All samples were confirmed MSS. There were distinct differences in gene expression between patients who remained disease free and those who recurred. Among immune related genes CXCL5, IRF4, IL6R, TNF, CTLA4, ICOS, and ARG1 were relatively over-expressed in non-recurrent tumors, while PPARG, AIRE, and EPCAM were over-expressed in recurrent tumors (FDR 0.2, $p < 0.05$). Cibersort analysis predicts a significantly higher number of M2 versus M1 macrophages regardless of recurrence status ($p < 0.05$), with an approximate M1:M2 ratio of 1:2 and a higher total number of M1/M2 macrophages in tumors that recur. On IHC, an average of 29% of cells per sample expressed macrophage marker CD68. Relatively fewer CD3, CD4, and CD8 T cells were observed with average infiltration rates of 7.4%, 3.6%, and 2.6% respectively. **Conclusions:** CRC liver metastases demonstrate evidence of a large TAM population with significant M2 component and a smaller T cell population. A greater number of TAMs appear to correlate with recurrence, while a more immunogenic phenotype correlates with lower recurrence risk.

3575 Poster Session (Board #198), Sat, 8:00 AM-11:30 AM

Robotic procedure versus open surgery for simultaneous resection of colorectal cancer with liver metastases: Short-term outcomes of a randomized controlled study. *First Author: Jianmin Xu, Institute of General Surgery, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: The simultaneous resecting both colorectal cancer and liver metastases is a safety and efficacy surgical procedure for treating colorectal cancer patients with liver metastases (CRCLM).The safety and efficacy of robot-assisted simultaneous resection of CRCLM is unclear. Furthermore, what kind of selective CRCLM patients would obtain benefits from robotic procedure need identify. The aim of this study was designed to compare robotic procedure with open surgery, and establish robotic surgery indications to identify benefit population of CRCLM. **Methods:** CRCLM patients were evaluated and confirmed with surgical indication by multidisciplinary team (MDT), and randomized to two groups, robotic arm (n = 58) and open arm (n = 57). The primary endpoint is 3-year DFS, the second endpoints include short-term surgical outcomes, complications and safety. **Results:** A total of 115 patients were randomized between September 2013 and September 2016. Despite longer operating time, patients assigned to robot-assisted surgery had less blood loss (100ml vs. 150ml, $P < 0.001$), a shorter time to pass first flatus (3 d vs. 4 d, $P < 0.001$) and return to diet (3 d vs. 5 d, $P = 0.002$), shorter hospital stay with improved sexual function. Furthermore, followed benefits were observed in robotic arm versus open arm: lower serum C reactive protein (CRP) level on postoperative day 1 (POD1) (16 mg/L vs. 37 mg/L,$P < 0.001$), and POD3 (112 mg/L vs. 160 mg/L, $P < 0.001$), lower level of liver transaminase on POD5, and lower liver-related complication morbidity(10.3% vs 28.1%, $p = 0.016$). In addition, we identified and recommended selective CRCLM patients with the number of liver metastases < 3, maximal tumor size < 5cm, tumor not located in segment I to accept robotic procedure. **Conclusions:** We identified and recommended selective CRCLM patients to accept robotic surgery for treating liver metastases. Robotic surgery result in similar safety as open procedure, with shorter recovery time, decreased morbidity, and improved sexual function. Clinical trial information: NCT02642978.

3576 Poster Session (Board #199), Sat, 8:00 AM-11:30 AM

Comparison of 5-FU vs capecitabine in combination with mitomycin or cisplatin in the treatment of anal cancer. *First Author: Irene Yu, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: The patterns of capecitabine use as an alternative form of fluoropyrimidine to infusional 5-FU in the non-operative management of anal cancer in the real world are poorly described. Our objectives were to determine the frequency of capecitabine use, compare the observed outcomes between oral and intravenous fluoropyrimidines, and examine for variations in treatment-related adverse events between the two agents. **Methods:** All anal cancer patients who received either capecitabine or infusional 5-FU as part of their chemoradiation treatment from 2004 to 2013 at any 1 of 6 cancer centers in British Columbia were included. Chi-square and Wilcoxon-Mann tests were used to assess for associations between treatment groups and clinical characteristics and outcomes. **Results:** A total of 486 patients were identified: median age was 59 (IQR 53-67) years, 175 (36%) were men, 418 (86%) had ECOG 0/1, and 30 (6%) were HIV positive. Median total radiation dose was 54 cGy (IQR 50-54) and 47 (10%) underwent a colostomy prior to chemoradiation. Baseline characteristics were balanced between the two groups with respect to age, gender, ECOG, and HIV status (all $p > 0.05$). Prior to 2010, only 5-FU was utilized. From 2010 to 2013, 155 and 82 patients (65% vs 35%) received capecitabine vs 5-FU, respectively. Overall (68% vs 67%, $p = 0.831$) and disease-free survival rates (59% vs 59%, $p = 0.926$) at 3 years were similar in the capecitabine vs 5-FU groups. Rates of subsequent abdomino-perineal resection were also similar (10% vs 14%, $p = 0.164$). Patients who received 5-FU were more likely to report adverse effects (76% vs 57%, $p < 0.01$). The capecitabine group had a lower incidence of stomatitis (7% vs 43%, $p < 0.01$) whereas the 5-FU cohort reported less frequent hand-foot syndrome (1% vs 7%, $p < 0.01$). The rates of myelosuppression, nausea/vomiting, diarrhea, and rash were similar between the two groups (all $p > 0.05$). **Conclusions:** This represents one of the largest population-based studies to demonstrate a preference for capecitabine in place of 5-FU in the management of anal cancer. Survival outcomes were similar between the two treatment groups, but capecitabine may be better tolerated in the real world.

3577 Poster Session (Board #200), Sat, 8:00 AM-11:30 AM

Prospective study of biomarkers in squamous cell carcinoma of the anal canal (SCCAC) and their influence on treatment outcomes: Final results. *First Author: Camila Motta Venchiarutti Moniz, Instituto Do Câncer Do Estado De São Paulo, São Paulo, Brazil*

Background: While chemoradiation (CRT) is a curative treatment for SCCAC, many patients (pts) present primary resistance. As a rare tumor, the predictors of response in this setting remain unknown. **Methods:** Prospective cohort study aimed to evaluate predictive biomarkers (Ki-67, PD-L1, Human papillomavirus (HPV), HIV status and mutations in tumoral DNA) associated with complete response (CR) following standard CRT for localized SCCAC. Eligible pts had T2-4/N0-3/M0 disease and were candidates to standard CRT. CR at 6 months (m) measured by RECIST 1.1 was the primary endpoint. DNA mutations were analyzed by next-generation (NGS) TruSight Tumor26 panel. HPV positivity was tested by PapilloCheck Test. KI-67 and PD-L1 were evaluated by immunohistochemistry. **Results:** 78 pts were recruited from Jan/2011 to Dec/2015. 75 were evaluable for response. Median age 57 years; 49 (65%) were stage III, and 9 (12%) were HIV+. At 6m 47 (62.7%) had CR, 18 (24%) partial response (PR) and 10 (13.3%) disease progression. HPV was evaluated in 67 and found in 47 (70.1%), the majority HPV16. PD-L1 was tested in 61, 10 (16.4%) had $>$ 1% positive expression. Ki-67 was performed in 65, a median was 50% (1-90%) per patient. Clinical stage, HIV status, median KI-67, HPV and PD-L1 positivity, and treatment interruption were tested as predictive factors of CR in 6m by logistic regression. On multivariable analyses, ECII patients were 4.7 more likely to achieve CR than ECIII (OR 4.70 CI95%1.36-16.30; p = 0.015). HIV was borderline significant (OR 2.53 CI95% 0.9-7.1; p = 0.079). Analyzing the patients with PR and CR HIV+ was significantly associated with poor response. Patients HIV- were 5.7 more likely to achieve CR or PR (OR 5.72 CI95%2.5-13.0; p $<$ 0.001). 25 patients had tumor samples proper for NGS, 17 had at least one pathogenic mutation. The most common mutated genes were PIK3CA and MET in 6. There was no differences in CR rates according to MET (50% vs 47.3%, p = 1) or PIK3CA (33.3% vs 47.3%, p = 0.6) mutation status. TP53 codon 72 polymorphism was present in 72% (n = 18) and was not associated with CR (44% VS 57%, p = 0.6). **Conclusions:** Our study suggests that HIV+ pts are less responsive to CRT.

3578 Poster Session (Board #201), Sat, 8:00 AM-11:30 AM

Colorectal cancer: Impact of primary tumor location on genetic alterations. *First Author: Mohamed E. Salem, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Recent data show that patients with left sided colon tumors (LT) have better survival and respond differently to biologics compared to patients with right-sided tumors (RT), likely due to molecular differences. We sought to examine these differences. **Methods:** Primary colorectal tumors (n = 1730) with origins clearly defined as RT (cecum to hepatic flexure; n = 273), LT (splenic flexure to sigmoid colon; n = 585), or rectal (RC; n = 872) were examined by NextGen sequencing, protein expression and gene amplification. Tumor mutational load (TML) was calculated in 1001 of these tumors using only somatic nonsynonymous missense mutations. Chi-square was used for comparison. **Results:** When compared to LT, RT carried a significantly higher rate of BRAF (25% vs 7%; p $<$ 0.0001), PTEN (5.4% vs 1.3%; p = 0.008), and ATM (4% vs 1%; p = 0.04) mutations. RT were likely to have more MSI-high tumors (22% vs 5%; p $<$ 0.0001) and PD-1 overexpression (58% vs 44%; p = 0.01). There were no differences in the rate of KRAS (50% vs 42%; p = 0.07) or NRAS mutations (2.2% vs 3.4%; p = 0.4). When compared to RC, RT had a higher rate of BRAF (25% vs 3%; p = $7E^{-07}$), PIK3CA (22% vs 11%; p = 0.001), CTNNB1 (3% vs 0.3%; p = 0.02); ATM (3% vs 1%; p = 0.04), PTEN (5% vs 1%; p = 0.004), and BRCA1 mutations (4% vs 0%; p = 0.02), and a lower rate of TP53 (56% vs 71%; p = 0.001) and APC (53% vs 66%; p = 0.003) mutations. When compared to RC, LT showed higher rates of BRAF (6.7% vs 3.2%; p = 0.04) and CTNNB1 (2.1% vs 0.3%; p = 0.04) mutations, and a higher rate of MSI-high tumors (4.6% vs 0.7%; p = 0.04), whereas RC had a higher rate of KRAS mutation (50% vs 42%; p = 0.04). There were no differences between RT, LT, and RC for the frequency of PD-L1 (2%, 2%, and 1%) or Her-2 (1%, 2%, and 3%) overexpression, although Her-2 amplification was significantly different (1%, 3%, and 5%, RT vs RC; p = 0.03). Mean TML was 12, 11, and 8 mutations/megabase for RT, LT, and RC, respectively (RT vs RC; p = 0.01). There was a correlation between TML and PD-L1 (p = 0.04) and PD-1 (p = 0.01). **Conclusions:** Tumors arising in the right colon carry genetic alterations that are different from LT as well as RC. However, it appears that CRCs carry a continuum of molecular alterations from the right to the left side, rather than displaying sharp, clear-cut differences.

3579 Poster Session (Board #202), Sat, 8:00 AM-11:30 AM

Association of immune markers and Immunoscore with survival of stage III colon carcinoma (CC) patients (pts) treated with adjuvant FOLFOX: NCCTG N0147 (Alliance). *First Author: Frank A. Sinicrope, Mayo Clinic, Rochester, MN*

Background: Tumor infiltrating lymphocytes (TIL) indicate a host immune response that may influence survival. Immunoscore was developed using $CD3^+$ and $CD8^+$density and location in primary CC pts with pooled stages, varying treatment and follow-up. We determined if individual immune markers and/or Immunoscore are prognostic in resected stage III CC pts (N=600). **Methods:** $CD3^+$ and $CD8^+$ T-cell or $CD20^+$ B lymphocyte density in central tumor (CT) and invasive margin (IM) was evaluated by immunostaining and quantified by image analysis. Immunoscore was calculated on a scale of I0 to I4 with high densities of $CD3^+$ and $CD8^+$in both CT and IM scored as I4; low densities scored as I0. Associations with disease-free survival (DFS) were evaluated by multivariable Cox regression adjusting for covariates. **Results:** Data for $CD3^+$, $CD8^+$ and $CD20^+$ were generated (N=595). Higher density of $CD3^+$ CT, $CD3^+$ IM and $CD8^+$ IM were associated with longer DFS adjusting for covariates (Table). $CD3^+$ IM had the strongest association with DFS, and was stronger in left-sided ($HR_{adj.}$=0.81, 95% CI, 0.70-0.94, $p_{adj.}$= 0.0049) vs right-sided ($HR_{adj.}$=0.93, 95% CI, 0.85-1.0 $p_{adj.}$=0.52) tumors ($p_{interaction}$=0.039). Higher density of $CD3^+$ IM was associated with older age (p=0.034), $T_{1/2}$ (p$<$.0001), N_1 (p=0.017), right-sided (p=0.013), high TILs (p=0.0008), and deficient MMR (p=0.0003). Using a prior Immunoscore risk stratification, higher scores were associated with better DFS ($HR_{.}$=0.62, CI, 0.44-0.87, p=0.006) (Table). **Conclusions:** Densities of $CD3^+$ and $CD8^+$, especially at IM, are individually prognostic in FOLFOX-treated pts. Association of $CD3^+$IM with prognosis differed by primary CC site. Immunoscore was strongly prognostic, and this result provides validation in a clinical trial cohort.

Immune marker	HR_{adj} (95% CI)	P_{adj}
$CD3^+$ CT	.89 (.79, .99)	.033
$CD3^+$ IM	.89 (.83, .96)	.0018
$CD8^+$ IM	.79 (.65, .95)	.013
Immunoscore		
I2-I4 vs I0-I1 (ref)	.64 (.45, .92)	.015

3580 Poster Session (Board #203), Sat, 8:00 AM-11:30 AM

Identification of a novel predictive genomic biomarker for response to combination bevacizumab in metastatic colorectal cancer (mCRC). *First Author: Annette T. Byrne, Department of Physiology and Medical Physics, Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: Somatic copy number alterations (SCNA) are genomic alterations evident in cancers including mCRC. These alterations support biomarker discovery, allowing identification of variants that can be used to predict response to therapy. Herein, we studied the impact of SCNAs on mCRC patient response to bevacizumab (BVZ). **Methods:** SCNA data was assembled from mCRC tumors in the TCGA cohort (n = 676), from the CAIRO 2 study [n = 143] and from the ANGIOPREDICT cohort (n = 258) [Betge et al. Digestion 2016 94(3):129-137]. GISTIC v2.0 was used to identify the most frequent and overrepresented chromosomal aberrations. A region was considered deleted if the logR value was $<$ 0.1 and amplified when the logR was $>$ 0.1. A cutoff q-value of 0.25 was used to select significantly overrepresented SCNAs. To further explore the impact of new ANGIOPREDICT clusters and consensus molecular subtypes (CMS), [Guinney J et al Nat Med. 2015 21(11):1350-6], a panel of seven xenografts representing each CMS subtype was treated with FOLFOX (40mg/kg 5-FU, 13.4mg/kg folinic acid & 2.4mg/kg oxaliplatin) + B20 antibody (mouse avastin, 10mg/kg) for 4 weeks. **Results:** Unsupervised hierarchical clustering classified all 1077 tumors into 3 consensus SCNA subgroups termed 'ANGIOPREDICT' clusters 1-3. Concordance between CMS and ANGIOPREDICT clusters was evident: CMS1 - Cluster 1 78%, CMS3 - Cluster 1 50%. CMS2 - Cluster 2/3 92% and CMS4 - Cluster 2/3 84%. Tumors with intermediate or high copy number instability (ANGIOPREDICT cluster 2 & 3) showed improved progression free survival (PFS): 369d *vs.* 227d p = $1.36e^{-7}$) whereas tumors with low copy number alterations displayed a poor response to BVZ therapy (PFS: 147d *vs* 152d p = 0.906). Xenografts corresponding to CMS 2&4/ ANGIOPREDICT cluster 2-3 showed improved response to FOLFOX + B20 therapy and increased PFS (p $<$ 0.001) *vs.* CMS1&3/ ANGIOPREDICT cluster 1. **Conclusions:** For the first time, in a large test and validation cohort including retrospectively collected and randomized controlled trial patient samples, we have identified a predictive genomic biomarker for BVZ therapy in mCRC. We have further demonstrated the utility of CMS subtyping to stratify patients to BVZ .

3581 Poster Session (Board #204), Sat, 8:00 AM-11:30 AM

Extraordinary survivorship after colorectal liver metastasis resection to identify a distinct molecular profile associated with survival in an independent cohort of 965 patients. *First Author: Jesse Joshua Smith, Colorectal Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Half of patients diagnosed with colorectal cancer (CRC) develop metastases and most are CRC liver metastasis (CRLM). A mere 20% of these patients undergo complete resection of their liver disease and 5-year overall survival (OS) is only 50%. We hypothesized that we could identify a specific molecular profile associated with extraordinary survivorship in CRLM patients that would more precisely inform underlying tumor biology beyond standard clinical and pathologic features. **Methods:** Tumor samples were identified from patients who underwent curative resection. Patients with disease-specific survival (DSS) ≥10 years following resection were compared to those with ≤2-year survival (10yr vs. 2yr). Evaluable DNA was obtained from 36 cases (2yr, n = 17; 10yr, n = 19) then sequenced and analyzed with MSK-IMPACT (MSK-I), a hybridization capture, next generation sequencing platform. Differentially altered genes in 10yr vs. 2yr cohorts were identified (Fisher's exact). Findings in the extraordinary survivors group were validated using MSK-I in an independent cohort of 965 metastatic CRCs (metCRCs). Kaplan-Meier estimates and log-rank test were used. **Results:** In the 2yr group, we noted higher clinical risk scores and more complex chemotherapy regimens vs. the 10yr group. Molecularly, mutually exclusive KRAS and TP53 mutations were noted in the 10yr group, whereas significant co-occurrence of KRAS and TP53 mutations was seen in the 2yr group. Further, we noted significant enrichment of VEGF copy number gains in the 2yr group vs. the 10yr group. APC mutation was equally common. In the validation cohort, $KRAS^{mut}/TP53^{wt}$ and $TP53^{mut}/KRAS^{wt}$ patients (median OS of 10 and 15 years respectively) had significantly better OS than the co-occurring $KRAS^{mut}$ / $TP53^{mut}$patients (median OS of 4.9 years; (P = 0.0001)). **Conclusions:** Single mutation of either KRAS or TP53 is associated with better outcomes than co-occurring KRAS/TP53 mutations in metCRC. These data demonstrate use of an extraordinary survivor cohort to identify a molecular profile associated with significant survival differences in an independent cohort of metCRC patients.

3582 Poster Session (Board #205), Sat, 8:00 AM-11:30 AM

Impact of overall severity of adverse events (AEs) on long-term outcomes in metastatic colorectal cancer (mCRC) patients (pts) treated with first line systemic chemotherapy: Findings from 3,971 pts in the ARCAD database. *First Author: John Raymond Zalcberg, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: The prognostic importance of the incidence, severity, type and duration of AEs pts experience during chemotherapy varies between tumor types, and the available evidence across the board is often conflicting. Here we investigated the impact of the overall severity of AEs among pts with mCRC receiving first-line oxaliplatin (Oxa)- and/or irinotecan(Iri)-based regimens. **Methods:** The overall severity of AE data (i.e., max grade (G) of all AEs) were available on 3,971 pts (median age 61; 60% male, 47% ECOG PS 1+; 57% 2+ metastatic sites) enrolled onto 6 1st-line randomized trials. Around 46%, 45%, and 9% of pts had received Oxa-, Iri-, and Oxa+Iri-based regimens, respectively. Pts receiving biologic agents were excluded. Stratified multivariate Cox models were used to assess the associations with overall survival (OS) and progression-free survival (PFS); adjusted hazard ratios (HR_{adj}) and 95% confidence intervals (CIs) are reported. **Results:** Pts who only received Oxa-based treatment reported the lowest rate of G3+ AEs ($p < .0001$) compared to pts treated with Iri- or Oxa+Iri-based regimens. Older age, female gender, and PS 1 or 2+ were associated with higher grade AEs (all $p < .0001$). Considering AEs experienced within 6w after randomization, 10% and 61% of pts experienced G4+ and G2-3 AEs, respectively. G3+ AEs were associated with a shorter OS for both pts receiving Oxa- (HR_{adj}= 1.2, 95% CI, 1.1-1.3, $p_{adj} < .0001$) and Iri-based regimens (HR_{adj}= 1.4, 95% CI, 1.2-1.5, $p_{adj} < .0001$). For the entire treatment course, 19% and 72% of pts experienced G4+ and G2-3 AEs, respectively. For Oxa-based regimens, pts with G3+ AEs had a longer OS (HR_{adj}= 0.86, 95% CI, 0.78-0.94, $p_{adj} = .0016$), whereas G3+ AEs were associated with a shorter OS (HR_{adj}= 1.2, 95% CI, 1.1-1.4, $p_{adj} = .0004$) for pts treated with Iri-based regimens. Similar patterns were seen for PFS. **Conclusions:** Pts who reported higher grade AEs during initial treatment (≤6w) have significantly worse outcome than those who do not. Further analyses with treatment exposure/detailed dose-AE profile and its impact on survival are warranted.

3583 Poster Session (Board #206), Sat, 8:00 AM-11:30 AM

Targeted therapy for HER2 driven colorectal cancer. *First Author: Jeffrey S. Ross, Albany Medical College, Albany, NY*

Background: *ERBB2* (*HER2*) genomic alterations (GA) are evolving therapy taregets in metastatc coorectal cancer (mCRC). **Methods:** Hybrid capture based comprehensive genomic profiling (CGP) was performed on 8874 (9.6%) mCRC including both colonic adenocarcinomas (7587 cases; 85%) and rectal adenocarcinomas (1287 cases, 15%) Tumor mutational burden (TMB) was calculated from a minimum of 1.2 Mb of sequenced DNA. **Results:** *ERBB2* amplifications or a short variant (SV) alterations or both were found in 433 (4.9%) of the total mCRC. 195 (45%) of the *ERBB2* positive mCRC were female and 238 (55%) were male. Median age was 54 years (range 22 to 88 years). The most frequently co-altered genes were SV GA in *TP53* (82%), *APC* (70%), *KRAS* (26%), *SMAD4* (15%) and *PIK3CA* (13%). Clinically relevant GA significantly under-represented in *ERBB2*-altered CRC included significantly reduced GA in *KRAS* at 26% (p = 0.001) and *BRAF* at 4% (p = 0.003) as well as other kinases at 1% including *EGFR*, *KIT*, *MET* and *RET*. The frequency of TMB at > 10 mut/Mb ($p < 0.0001$), but at > 20 mut/Mb mCRC cases demonstrated virtually the same results regardless to *ERBB2* status at a frequency of x%. The overall *ERBB2* GA frequency at 5.3% in rectal mCRC is slightly higher than that seen in colonic mCRC at 4.9%, (p = 0.36). The frequency of TMB > 10 mut/Mb in *ERBB2* WT mCRC is greater in the colonic mCRC than the rectal mCRC ($p < 0.0001$ for both comparisons). When > 20 mut/Mb is used as the cut-off, the greater frequency of TMB in colonic mCRC versus rectal mCRC remains significant ($p < 0.0001$). When the *ERBB2*altered mCRC cases are evaluated, the greater frequency of TMB > 10 mu/Mb in colonic mCRC versus rectal mCRC remains significant (p = 0.009), but the greater frequency in colonic verses rectal mCRC at the > 20 mut/Mb is not significant (p = 0.37). **Conclusions:** Although lower than observed in breast and upper gastrointestinal carcinomas where anti-HER2 therapies are approved indications, the frequency of *ERBB2* GA in CRC at 4.9% is significant. Importantly, nearly half of CRC *ERBB2* alterations are SVs, not detectable by routine IHC and FISH testing. However, the success of anti-HER2 therapies shown here and progress in on-going clinical trials indicates that targeting *ERBB2* has potential to become an approved advance in precision therapy for mCRC patients.

3584 Poster Session (Board #207), Sat, 8:00 AM-11:30 AM

Clinical outcomes and emergent circulating tumor (ct)DNA *RAS* mutations and allele fraction for patients with metastatic colorectal cancer (mCRC) treated with panitumumab from the ASPECCT study. *First Author: Timothy Jay Price, The Queen Elizabeth Hospital and University of Adelaide, Woodville, Australia*

Background: ASPECCT was a phase III clinical trial performed in the chemotherapy-refractory third-line mCRC setting (N = 1010). This analysis explores the relationship between circulating levels of mutations and clinical outcomes for panitumumab-treated subjects using univariate and multivariate models that treat total mutational load as a continuous measure. **Methods:** 238 subjects treated with panitumumab had paired plasma samples at baseline and post-treatment (PT). Samples were analyzed for mutations using the Plasma*Select*-R™ 63-gene panel (0.1% limit of detection). The fraction of mutant *RAS* reads was evaluated for association with tumor response (by RECIST) and overall survival using univariate and multivariate Cox proportional hazards models. **Results:** 52% of the subjects who were *RAS* wild-type by plasma at baseline never developed a *RAS* mutation. For those with mutant *RAS* ctDNA (*KRAS*+*NRAS*) detected at baseline or PT, there was an overall increase in *RAS* mutant DNA fraction at PT compared to baseline. By non-parametric analysis, there was no difference in the distribution of baseline mutant *RAS* fraction between those who achieved stable disease (SD) or those with progression ($P = 0.09$). There was also no difference in the increase in mutant *RAS* fraction on therapy between subjects with SD or progressive disease (PD). In addition, *RAS* mutation was not required for progression: 48% of subjects with PD had no *RAS* mutant DNA detected. **Conclusions:** In this exploratory analysis, baseline plasma mutant *RAS* fraction is an unreliable predictor of subsequent tumor response. Subjects with objective response or SD may have stable or rising levels of mutant *RAS* DNA. Subjects without any detectable *RAS* mutation still experience PD. These findings suggest that detectable plasma ctDNA *RAS* mutations do not necessarily predict response to panitumumab and should be interpreted with caution. Further work is needed to establish clinically relevant and validated thresholds. Clinical trial information: NCT01001377.

3585 Poster Session (Board #208), Sat, 8:00 AM-11:30 AM

Association of genetic variations in genes implicated in the axis with outcome in patients (pts) with metastatic colorectal cancer (mCRC) treated with cetuximab plus chemotherapy. *First Author: Yuji Miyamoto, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Accumulating evidence suggests that right- and left-sided CRCs have different prognoses and different sensitivities to *EGFR* inhibitors in several phase3 trials. These differences might be related to different embryological origins, which are reflected in different molecular profiles of tumors. *LEFTY*, *Nodal* and *ACVR2B*, which are *TGF-beta*superfamily, are key regulators of left-right axis during embryogenesis; these expressions control sidedness. Our aim was to evaluate whether SNPs in these genes are associated with clinical outcomes in mCRC pts enrolled in the FIRE3 trial. **Methods:** Genomic DNA was obtained from mCRC pts receiving cetuximab plus FOLFIRI as first-line treatment and analyzed by using PCR-based direct sequencing. Four functional SNPs in 4 genes (*LEFTY1*, *LEFTY2*, *Nodal*, and *ACVR2B*) were tested in 305 pts in FIRE3 trial cetuximab cohort (NCT00433927). Main characteristics were the following: male/female = 207/98; median age = 64; RAS-wildtype/mutant = 195/95; median PFS = 9.6 months; median OS = 26.5 months, median follow-up time = 41.8 months. **Results:** In patients with left sided tumor (*N*= 237), *LEFTY2* rs3007716 G/G variants (*N*= 14) showed shorter PFS than any A variants (*N*= 222) in univariate (8.0 months (M) vs. 10.3 M, HR = 2.24, 95% CI = 1.27-3.94, P < 0.01) and multivariate analyses (HR = 2.12, 95%CI = 1.20-3.75, P < 0.01). *Nodal* rs1904589 T/T (*N*= 36) showed longer OS than any C variants (*N*= 196) in univariate analysis (50.1 m vs. 29.8 M, HR = 0.61, 95% = 0.37-1.01, P = 0.048) and multivariate analyses (HR = 0.59, 95%CI = 0.35-0.99, P = 0.046). In patients with right sided tumors (*N*= 58), *ACVR2B* rs2268753 C/C (*N*= 12) showed shorter PFS than any T variants (*N*= 43) in univariate analysis (3.7 m vs. 7.7 M, HR = 1.93, 95% = 0.99-3.77, P = 0.038) and multivariate analysis (HR = 2.24, 95%CI = 1.12-4.51, P = 0.023). **Conclusions:** Our study showed for the first time that genetic variations in sidedness related genes are associated with PFS and OS in patients receiving cetuximab based chemotherapy, which may dependent on location.

3586 Poster Session (Board #209), Sat, 8:00 AM-11:30 AM

Right-sided colorectal cancer (RC): Response to first-line chemotherapy in FIRE-3 (AIO KRK-0306) with focus on early tumor shrinkage (ETS) and depth of response (DpR). *First Author: Julian Walter Holch, Department of Medical Oncology, Comprehensive Cancer Center Munich, University Hospital Grosshadern, Ludwig-Maximilians- University Munich, Munich, Germany*

Background: Recent evidence suggests that benefit from anti-EGFR treatment is restricted to RAS wild-type left-sided colorectal cancer (LC) (Holch JW et al. Eur J Cancer 2017). However, these results are preliminary. We therefore investigated patients with RC enrolled in the FIRE-3 trial, which evaluated the efficacy of first-line FOLFIRI plus either cetuximab (cet) or bevacizumab (bev) in RAS wildtype mCRC. New metrics of tumor dynamics were used to characterize the patients. **Methods:** The splenic flexure was used to differentiate LC from RC. Survival analysis was done using Kaplan-Meier estimation and differences were expressed using Log-Rank test, hazard ratios (HR) and corresponding 95% confidence intervals. Central independent radiological data was used to calculate early tumor shrinkage ≥20% (ETS) and depth of response (DpR). **Results:** In total, 330 patients were assessable for central radiological evaluation. In patients with LC (n = 257), treatment with FOLFIRI + cet led to longer overall survival (OS) compared to FOLFIRI + bev (HR = 0.68, p = 0.016). In patients with RC (n = 68), OS was comparable between treatment arms (HR = 1.11, p = 0.715). In patients with RC and ETS < 20%, OS was inferior in patients treated with FOLFIRI + cet. In patients who reached ETS ≥20%, a comparable OS was evident between treatment arms (for further details of efficacy in patients with RC see table). **Conclusions:** Patients with RC do not represent a uniform population. ETS ≥20% defines a subgroup of patients where comparable treatment efficacy was observed with regard to OS, ORR and DpR by addition of cetuximab vs. bevacizumab to FOLFIRI.

	ETS ≥20%			ETS < 20%		
FOLFIRI plus	cet	bev	HR (P-Value)	cet	bev	HR (P-Value)
number of patients	17	16	-	13	22	-

3587 Poster Session (Board #210), Sat, 8:00 AM-11:30 AM

Factors contributing to the black/white colorectal cancer survival disparity in nonelderly patients. *First Author: Helmneh M. Sineshaw, American Cancer Society, Atlanta, GA*

Background: Previous studies reported that black/white survival disparities among elderly colorectal cancer (CRC) patients largely reflect differences in tumor presentation rather than differences in treatment. We sought to determine the contribution of differences in tumor presentation and receipt of treatment to the black/white survival disparity among nonelderly CRC patients. **Methods:** We selected non-Hispanic black (black) and Non-Hispanic white (white) patients aged 18-64 years, and diagnosed between 2004-2012 with single or first primary invasive stage I-IV CRC in the National Cancer Data Base. Blacks were sequentially matched with three white comparison cohorts, using propensity score and greedy matching algorithm, by demographics (age, sex, diagnosis year, region), tumor presentation (stage, grade, margin, tumor location, node status, comorbidity score), and treatment (surgery, chemotherapy, radiotherapy, metastatectomy) characteristics. We used Kaplan-Meier method to estimate 5-year survival for blacks compared with whites in the entire cohort and in the three sequentially matched cohorts. **Results:** In the entire cohort, 5-year survival was 9.2% lower in nonelderly blacks than whites (57.3% vs 66.5%). The survival difference remained unchanged after demographic matching, but it decreased to 3.3% (5.9% absolute and 64% relative reductions) after tumor presentation matching, and to 2.6% (0.7% absolute and 7.6% relative reductions) after treatment matching. By anatomic subsite, treatment matching reduced the black/white 5-year survival difference by 26% (3%/11.5%) for rectal cancer, only by 5.6% (0.5%/9%) for left colon cancer, and no change for right colon cancer. **Conclusions:** Differences in tumor presentation characteristics explained about two-thirds of the black/white survival disparity in nonelderly CRC patients, while treatment explained less than ten percent of the disparity. Future research should explore the biological mechanisms underlying these observed differences in tumor presentation and implications for treatment.

3588 Poster Session (Board #211), Sat, 8:00 AM-11:30 AM

Prognostic signatures of oligometastasis in colorectal cancer liver metastasis. *First Author: Sajid A. Khan, Yale School of Medicine, New Haven, CT*

Background: Knowledge of molecular differences between limited metastasis (oligometastasis) and widespread metastases may provide biomarkers for selection of patients who will benefit from curative metastasis resection and provide useful prognostic information. In this study, we detect messenger RNA expressional patterns in patients with colorectal cancer liver metastasis (CRCLM) and identify networks of coding and noncoding RNAs corresponding to oligometastatic phenotype. **Methods:** RNA was prepared from frozen tumor tissue of 55 patients with CRCLM patients treated with liver resection and/or biopsy of their metastatic tumors with greater than 15 years of follow-up. Survival was calculated and stratified according to risk of recurrence. Cases were subject to RNA-Sequencing experiments with paired end sequencing. **Results:** RNA analysis with TopHat and Cuffdiff found significant differences in transcript expression according to recurrence for 667 genes (P < 0.05). Of these transcripts, 166 had a greater than 2-fold gene expression between groups when comparing mean Fragments Per Kilobase of transcript per Million mapped reads (FPKM) (P < 0.05). Unsupervised hierarchical clustering revealed distinct genomic patterns based on clinical outcome. A supervised gene expression analysis revealed a differential expression of genes in the Homeobox (*HOX*) family (P < 0.05). Overexpression of individual members of the *HOX* gene family are associated with prognosis. Upregulation of the *HOXD11* gene was associated with cure in 60% of cases while downregulation was associated with 5-year overall survivals of 16% (P = 0.023). Furthermore, when clusters of *HOX* family members were compared, we found that expression correlated with survival, underlining the importance of this gene family in oligometastasis biology. A high ratio of the *HOXD* cluster to *HOXA* cluster was associated with a long recurrence free survival (P = 0.002). **Conclusions:** Common genomic signatures characterize patients with liver oligometastasis from primary colorectal cancer. The *HOX* gene family strongly correlates with prognosis and represents a unique molecular subtype of patients. Further mechanistic studies of the *HOX* gene family in metastases are underway.

3589 Poster Session (Board #212), Sat, 8:00 AM-11:30 AM

Not all *RAS* mutations created equal: Functional and clinical characterization of 80 different *KRAS* and *NRAS* mutations. *First Author: Jonathan M. Loree, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutations (mts) in *RAS* predict lack of response to anti-EGFR therapy in colorectal cancer. Outside the "typical *RAS*" mts (*KRAS/NRAS* Codons 12, 13, 59, 61, 117, 146) cited in guidelines and anti-EGFR labeling, clinical impact of other "atypical *RAS*" mts is uncertain. **Methods:** Available literature and databases were surveyed to identify 80 *KRAS/NRAS* mts. We used the NovellusDx Functional Annotation for Cancer Treatment (FACT) to transfect these *RAS* mts (repeated a mean of 5.5 times/mt) in a cell-based assay that quantifies nuclear ERK localization as a measure of MAPK pathway activation, and normalized to wild type (WT) transfection. In 963 metastatic colorectal cancer patients (pts) with *BRAF* WT/*KRAS* mutant tumors, overall survival (OS) was evaluated by level of *RAS* signaling activity. **Results:** Of the surveyed mutations,96% (45/47) of typical mts and 39% (13/33) of atypical mts increased MAPK pathway activation above WT (range: 107%-211% of WT activity). Within the typical RAS mts, mts in *NRAS* or exon 3, 4 of *KRAS* had higher activity than mts in exon 2 (codons 12/13) of *KRAS*, reaffirming the biologic relevance of expanded *RAS* testing (median activity of 130% vs 178%, $P < 0.001$). The median activity of atypical *RAS* mts was lower than typical *RAS* mts (110% vs 159%, $P < 0.001$). Several notable exceptions in atypical *RAS* mts with high activity levels were *KRAS* V14I, Q22K, D33E, N116S, and F156L (all > 165% of WT activity). Conversely, within the typical *RAS* mts in the guidelines, *KRAS* G13C and K117R were not shown to increase activity significantly above WT. Pts with any *RAS* mt with MAPK activity above the median of typical mts had a worse OS compared to pts below the median in univariate (HR 1.45, 95% CI 1.04-2.32, P = 0.033) and multivariate models (HR 1.96, 95% CI 1.13-3.42, P = 0.017) that controlled for age, gender, sidedness, and synchronous vs metachronous presentation. **Conclusions:** Functional characterization confirmed activity of *RAS* mts in the current guidelines, but also suggested that a subset of atypical *RAS* mutations have similar levels of activation of the MAPK pathway. Within the subset of pts with *RAS* mts, those mts resulting in high MAPK activity are associated with notably shorter OS.

3590 Poster Session (Board #213), Sat, 8:00 AM-11:30 AM

Arginine methylation of EGFR in circulating tumor cells: A new biomarker for predicting resistance to anti-EGFR agents. *First Author: Krittiya Korphaisarn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Arginine methylation of the epidermal growth factor receptor (meEGFR) increases binding affinity of EGF and other EGFR ligands, reduces the efficacy of anti-EGFR agents *in vivo*, and is reported to have a role in predicting response to anti-EGFR agents. This study aimed to investigate the predictive impact of meEGFR in metastatic colorectal cancer (mCRC) patients (pts) treated with anti-EGFR agents using blood-based testing. **Methods:** 15 mL of blood were collected from mCRC pts with documented disease progression following anti-EGFR treatment (Rx). Circulating tumor cells (CTCs) were isolated using antibody (ab)-independent micro-fluidic cassette-based technology (Parsortix system), which separates CTCs on the basis of size and deformability. CTCs were identified based on negative staining for CD45ab and positive staining for EpCAMab. meEGFR was identified based on positive staining for me-R198/200ab on CTCs. Associations between meEGFR-CTCs and total CTCs with progression free survival (PFS) were determined by Kaplan-Meier method and compared by the log-rank test. **Results:** A total of 47 mCRC pts were prospectively included in this study. CTCs were identified in 30 out of 47 cases (64%). Of those 30, meEGFR-CTCs were identified in 19 cases (63%). Mean total CTCs and meEGFR-CTCs counts were 3.6 (range 0-52) and 2.3 (range 0-30) cells per 7.5ml, respectively. There was no association between meEGFR-CTCs and clinic-pathological features (age, sex, tumor site & grade), line of anti-EGFR Rx, previous irinotecan used, or *NRAS, BRAF, PIK3CA*, and MSI status. However, in $RAS^{wt}/BRAF^{wt}$mCRC pts, high levels of meEGFR ratio (defined as > 0.25 meEGFR-CTCs per total CTCs) was associated with significantly inferior PFS with anti-EGFR Rx (median PFS 5.4 mo vs. 8 mo, HR 3.4, 95% CI of 1.5-7.9, P = 0.004). By contrast, high levels of total CTCs (> 3 cells/per 7.5 ml) had no impact on PFS with anti-EGFR Rx. **Conclusions:** We have successfully isolated CTCs from mCRC pts' blood using Parsortix system. Elevated levels of arginine methylated EGFR is associated with a shorter PFS with anti-EGFR-based Rx. Assessment of meEGFR-CTCs may provide a "liquid biopsy" biomarker for reduced efficacy from anti-EGFR Rx.

3591 Poster Session (Board #214), Sat, 8:00 AM-11:30 AM

Early prediction of clinical outcomes in resected stage II and III colorectal cancer (CRC) through deep sequencing of circulating tumor DNA (ctDNA). *First Author: Maximilian Diehn, Stanford University Medical Center, Stanford, CA*

Background: Adjuvant chemotherapy is offered to most pts with Stage III CRC, and to a subset with Stage II disease deemed at high-risk for recurrence. Nevertheless, risk stratification strategies remain suboptimal. Detection of minimal residual disease (MRD) through ctDNA analysis has been shown to identify pts at high recurrence risk in Stage II CRC, but not Stage III disease. **Methods:** The next-generation sequencing based AVENIO ctDNA Surveillance Kit (Research Use Only) was used to identify single nucleotide variants (SNVs) in tumor tissue within a cohort of 145 Stage II and III CRC pts following R0 surgical resection (n = 86 and 59 respectively; median follow-up = 32.1 mo). The same assay was used to monitor ctDNA with a single post-operative blood sample (mean surgery-to-phlebotomy time: 10 days). Regions from 197 genes recurrently mutated in CRC were interrogated, and pts were classified as ctDNA positive (+) or negative (-) in plasma based on the detection of SNVs previously identified in tumor tissue. **Results:** Variants were identified in 99% of tumors (n = 144) with a median of 4 SNVs/sample (range 1-24) and all post-operative plasma samples were successfully profiled. Pts with detectable ctDNA (n = 12) displayed a significantly shorter 2-year relapse-free survival (RFS; 17% vs 88%; HR 10.3; 95% CI 2.3-46.9; $p < 0.00001$), time to recurrence (TTR; HR 20.6; 95% CI 3.1-139.0; $p < 0.00001$) and overall survival (OS; HR 3.4; 95% CI 0.5-25.8; p = 0.041) than ctDNA- pts (n = 132). 11 (92%) of ctDNA+ pts developed recurrence compared to 9 (7%) of ctDNA- pts. Monitoring multiple variants doubled sensitivity of MRD detection compared to tracking a single driver mutation. TTR was shorter in ctDNA+ vs ctDNA- Stage II (HR 23.1, 95% CI 0.28-1900.4; $p < 0.00001$) and stage III pts (HR 17.9; 95% CI 2.7-117.3, $p < 0.00001$). TTR of Stage II and III ctDNA- pts was similar (p = 0.7). **Conclusions:** Our results indicate that ctDNA analysis can detect MRD within days after complete resection of CRC and accurately identifies pts at high risk of recurrence in both Stage II and III CRC. MRD detection via ctDNA sequencing may allow personalization of adjuvant treatment strategies.

3592 Poster Session (Board #215), Sat, 8:00 AM-11:30 AM

Impact of patient age on molecular alterations in left-sided colorectal tumors. *First Author: Benjamin Adam Weinberg, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: The incidence of colorectal cancer (CRC) in younger patients (pts) is rising. This increase is most pronounced in tumors arising from the distal colon and rectum. Since tumor sidedness has emerged as an important prognostic and predictive biomarker in CRC, we aim to explore the impact of age on the tumor biology of left-sided colon cancer (LCC). Herein, we compare profiles of LCC from younger (≤ 45 years) and older pts (≥ 65 years). **Methods:** LCCs (splenic flexure to rectum; n = 1,602) were examined by NextGen sequencing, protein expression, gene amplification, and microsatellite instability fragment analyses. Tumor mutational load (TML) was calculated using only somatic nonsynonymous missense mutations. Chi-square tests were used for comparisons. **Results:** LCCs from younger (median age 40, range 22-45 years, n = 229) and older (median age 71, range 65-89, n = 503) pts were studied. The most frequently mutated genes included *APC*, *TP53*, *KRAS*, *PIK3CA*, *ARID1A, FBXW7*, *SMAD4*, *ATM*, *BRAF*, and *NRAS*. Comparing younger v. older pts, there were no significant differences in the rates of *APC* (75.3% v. 82.9%, P = 0.139), *TP53* (79.5% v. 73.1%, P = 0.261), *KRAS* (37.6% v. 43.0%, P = 0.403), *PIK3CA* (9.4% v. 14.6%, P = 0.234), *ARID1A* (14.3% v. 13.2%, P = 0.884), *FBXW7* (11.4% v. 10.5%, P = 0.830), *SMAD4* (13.1% v. 7.4%, P = 0.129), *BRAF* (4.8% v. 5.7%, P = 0.762), or *NRAS* (3.5% v. 2.6%, P = 0.680) mutations. Additionally there were no significant differences in protein overexpression. However, there was a trend towards increased HER2 amplification in younger pts (5.7% v. 2.1%, P = 0.05). *MSH6* (4.8% v. 0.5%, P = 0.015), *MSH2* (2.4% v. 0%, P = 0.032), *POLE* (2.4% v. 0%, P = 0.032), and *NF1* (7.9% v. 0%, $P < 0.001$) mutations were observed at higher rates in younger pts. High TML (≥ 17 mutations per megabase) was seen more frequently in younger pts (8.2% v. 2.6%, P = 0.02). **Conclusions:** The molecular differences between LCC in younger and older pts are mostly due to mutations in mismatch repair genes. Higher TML may predict a higher response rate to checkpoint inhibitors in younger pts with LCC. The differences in tumor biology observed here warrant further study and may eventually be used to tailor therapy.

3593 Poster Session (Board #216), Sat, 8:00 AM-11:30 AM

Monitoring the effect of first-line treatment in RAS/RAF mutated metastatic colorectal cancer by serial analysis of tumor specific DNA in plasma. *First Author: Caroline Brenner Thomsen, Danish Colorectal Cancer Center South, Vejle, Denmark*

Background: Personalized medicine calls for an early indicator of treatment failure. Circulating tumor DNA (ctDNA) is a promising marker in this setting and our prospective study explored the association between disease control and change of ctDNA during first line chemotherapy in patients with RAS/RAF mutated metastatic colorectal cancer (mCRC). **Methods:** The present study included 138 mCRC patients receiving standard first line combination chemotherapy. In patients with a RAS/RAF mutated tumor the same mutation was quantified in the plasma using droplet digital PCR (ddPCR). The fractional abundance of ctDNA (ctDNA level) was assessed in plasma before treatment start and at every treatment cycle until radiologically defined progressive disease (PD). **Results:** RAS/RAF mutations were detected in the plasma from 77 patients (94% of patients with a tumor mutation). Twenty patients progressed on treatment and 57 stopped treatment without progression. The presence of a RAS/RAF mutation in plasma correlated to overall survival (OS) with a median of 24.2 months for patients with a wild-type tumor compared to 12.7 months for patients with a mution in plasma. A substantial increase in ctDNA level was highly associated with progression on treatment (risk ratio = 4.58, 95%CI = 1.99-10.51, $p < 0.0001$). Furthermore, with a stable ctDNA level the chance of non-progression was 88.2% (range 76.1-95.6%). The first substantial increase in ctDNA level occurred at a median of 51 days (range 14-133 days) before radiologically confirmed PD. **Conclusions:** The results indicate that ctDNA level may be predictive of treatment effect in patients with mCRC. An increase was observed to correlate with high risk of progression with a relevant lead time, whereas an unchanging ctDNA level related to stable disease.

3594 Poster Session (Board #217), Sat, 8:00 AM-11:30 AM

Genetic polymorphisms of CCL5 and CCR5 to predict efficacy of cetuximab-based treatment in metastatic colorectal cancer patients depending on primary tumor location. *First Author: Mitsukuni Suenaga, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: EGFR signaling blockade increases CCL5 expression, which attracts with tumor-infiltrating leukocytes regulating either the host-derived anti-tumor immunity or tumor progression. We tested whether genetic polymorphisms in the CCL5/CCR5 axis could predict efficacy of cetuximab (CET)-based first-line treatment in metastatic colorectal cancer (mCRC) patients (pts). **Methods:** Genomic DNA was extracted from 491 samples of two different cohorts with *KRAS* wild-type mCRC in the FIRE-3 study: an evaluation cohort of 244 pts receiving CET plus FOLFIRI (median age 64 yrs; median follow-up 34.1 mos); and a control cohort of 247 pts receiving bevacizumab plus FOLFIRI (median age 65 yrs; median follow-up 39.4 mos); Single nucleotide polymorphisms (SNPs) of *CCL5* and *CCR5* genes were analyzed by PCR-based direct sequencing. **Results:** Pts in the evaluation cohort with any *CCL5* rs2280789 G allele had shorter OS compared to those with the A/A variant (19.9 vs. 33.4 mos, HR 1.56, 95%CI: 1.05–2.30, $P = 0.024$), which was confirmed in multivariable analysis (HR 1.64, $P = 0.015$). Pts carrying any *CCR5* rs1799988 T allele had a trend lower response rate than those with the C/C variant (68 vs. 81%, $P = 0.078$). Statistically significant differences in efficacy were shown between the groups consisting SNPs and tumor location (Table). The findings were not confirmed in the control cohort. **Conclusions:** Genetic variants of *CCL5* and *CCR5* SNPs may predict outcomes in mCRC pts receiving CET-based first-line treatment depending on tumor location.

3595 Poster Session (Board #218), Sat, 8:00 AM-11:30 AM

Association of high microsatellite instability (MSI-H) with a high immunoscore (IS) compared to PD-L1 expression and increased survival in patients (pts) with metastatic colorectal cancer (mCRC) treated with oxaliplatin (Ox) and fluoropyrimidine (FP): A pooled analysis of the AIO KRK 0207 and RO91 trials. *First Author: Stefanie Noepel-Duennebacke, Ruhr-University Bochum, St. Josef Hospital, Bochum, Germany*

Background: MSI-H is an established prognostic marker in early colon cancer. Moreover, MSI-H, tumor immune cell infiltration and PD-L1 expression are also discussed as potential predictive biomarkers for immunotherapy. However, little is known about the prognostic value of these biomarkers and their association among each other in mCRC. **Methods:** We analyzed samples from pts. with mCRC uniformly treated with a FP and Ox within two randomized AIO trials (KRK 0207 and RO91). MS status was assessed by immunohistochemistry (IHC) of mismatch repair proteins and subsequent fragment length analysis in case of protein loss or incoherent results. PD-L1 expression was determined by IHC (1% expression threshold). Tumor lymphocytic infiltration (CD8 and CD45RO) was scored according to the immunoscore (IS) concept by Galon et al (J Transl Med 2016). **Results:** 41/550 cases (7.5%) displayed MSI-H. The mean IS of the total population was 0.57 (SD 0.97), the IS of MSI-H pts. was significantly higher (mean of 2.4; SD 1.4; $p \leq 0.0001$). 17 cases were PD-L1 positive (pos.) (3 %), only four of these were MSI-H. MSI-H status was significantly correlated with a higher IS, but not with PD-L1 expression (table 1). There was no difference in median overall survival (mOS) between MSI-H and MS stable (MSS) pts. (mOS MSI-H/MSS: 17.6/22.5 months (mos.), log rank: p=0.85), PD-L1 negative (neg.) and pos. pts. (mOS PD-L1 neg./pos.: 22.1/28.9 mos., log rank: p=0.49) and IS high or low pts. (mOS IS high/low: 21.1/22.1mo., log rank: p=0.25). **Conclusions:** In contrast to early stage colon cancer, none of these parameters was prognostic in mCRC patients. Panel-sequencing with a total of 35 genes including RAS, BRAF and POL-E on cases with PD-L1 expression, high IS or MSI-H status to further characterize these cases will be reported. Clinical trial information: AIO-R091, AIO-KRK-0207: EudraCT-Nr: 2008-007974-39.

Correlation of PD-L1 expression, immunoscore (IS) and MS status.

	All	MSI-H (%)	MSS (%)
	550	41 (7.5)	509 (92.5)
PD-L1 neg.	533	37 (6.9)	496 (93.1)
PD-L1 pos.	17	4 (23.5)	13 (76.5)
IS low	503	15 (3)	488 (97)
IS high	47	26 (55.3)	21 (44.7)

3596 Poster Session (Board #219), Sat, 8:00 AM-11:30 AM

Surgeon and hospital variation in adjuvant chemotherapy delivery to patients with stage III colon cancer. *First Author: Zhaomin Xu, University of Rochester Medical Center, Rochester, NY*

Background: It is well established that age and comorbidities have significant impact on adjuvant chemotherapy delivery to stage III colon cancer patients. This study examines differences in the hospital and surgeon-specific probabilities of adjuvant therapy delivery to stage III colon cancer patients by comorbidity burden and age. **Methods:** Patients who underwent surgery for stage III colon cancer from 2004-2013 were included from the New York State Cancer Registry and the Statewide Planning and Research Cooperative System. Comorbidity burden was defined with the Charlson Comorbidity Index (CCI). Multilevel logistic regressions characterized variation in adjuvant chemotherapy delivery among individual hospitals and surgeons by CCI and age. **Results:** 11575 patients met inclusion criteria, of which 59% received adjuvant therapy. Younger age, lower CCI, and high volume surgeons/hospitals were associated with delivery of adjuvant therapy ($p < 0.01$). Median time to chemotherapy was 43 days among CCI = 0 vs 48 among CCI≥2. The risk adjusted hospital and surgeon-specific probabilities of adjuvant delivery decreased with increasing CCI and age. The proportion of variation attributable to surgeons, vs hospitals, increased with CCI and age. Hospital variation between the highest and lowest hospitals increased from a 6-fold difference among CCI = 0 to an 11 fold difference among CCI≥2. Surgeon variation increased from a 14-fold difference among CCI = 0 to a 40 fold difference among CCI≥2. **Conclusions:** Variation in adjuvant chemotherapy delivery to stage III colon cancer patients increased with higher comorbidity burden and age. While a larger proportion of variation is attributable to surgeons among patients with the highest CCI and the most elderly, the vast majority of the variation is related to hospital factors. Even taking into account that some patients may be unfit for adjuvant therapy, this variation in treatment is alarmingly high.

Variation in probability of adjuvant delivery (%).

	CCI = 0	CCI≥2	Age < 60	Age≥80
Hospital Specific (Med, Range)	69 (14-82)	38 (7-71)	83 (72-91)	18 (6-27)
Surgeon Specific (Med, Range)	71 (7-93)	41 (2-89)	84 (33-93)	18 (3-46)
Proportion of Total Variation Attributable to Surgeon	12	39	19	27

3597 Poster Session (Board #220), Sat, 8:00 AM-11:30 AM

Circulating tumor DNA analysis before and after resection for colorectal cancer. *First Author: Erin L. Symonds, Bowel Health Service, Repatriation General Hospital, Daw Park, Australia*

Background: Detection of circulating tumor DNA (ctDNA) has broad clinical utility including disease monitoring, prognostication and response to chemotherapy. ctDNA is commonly detected by targeting tumor-specific features including mutations, insertions, deletions or hypermethylation. The two genes, *BCAT1* and *IKZF1,* are methylated with high frequency in colorectal cancer (CRC). This study aimed to analyze the impact of tumor resection on ctDNA levels by assaying pre- and postoperative blood samples for methylated *BCAT1* and *IKZF1*. **Methods:** 91 people (age 32-86 years, 53% male) with invasive CRC, but without neoadjuvant therapy, had blood collected prior to surgery and within 12 months (1-12 months) after resection. Cancers were clinicopathologically staged. DNA extracted from plasma was assayed for methylated *BCAT1/IKZF1* and detection of either marker was deemed positive for ctDNA. **Results:** 47 (52%) of the 91 CRC patients were ctDNA positive before resection, including 5/30 (17%) stage I, 17/28 (61%) stage II, 23/31 (74%) stage III and 2/2 (100%) stage IV. After resection 75% (35/47) became ctDNA negative (median 2 months after resection), and all had apparent tumour clearance. Of the 35 postoperative ctDNA negative cases 22 had further surveillance CT scans within study timeframe. 86% (20/22) showed no recurrent CRC but 2 of these developed a new cancer (metachronous CRC, prostate). The remaining 2 tested ctDNA positive 14 and 25 months later and recurrence was confirmed. Of the 12 postoperative ctDNA positive cases, two were found to not have complete tumour clearance at surgery (residual disease). Follow-up CT scans were available for a further 8 patients which revealed that 4 later presented with cancer (3 recurrence, 1 thyroid) at a median 15 months after resection. The remaining 4 postoperative positive cases were negative at subsequent blood testing (median 8 months later). **Conclusions:** Methylated *BCAT1/IKZF1* DNA in preoperative blood is dependent on tumor stage, but informs the completeness of resection given the high rate (74.5%) of ctDNA disappearance post-surgery. If cases persistently test ctDNA positive after surgery or become ctDNA positive later, residual or recurrent disease should be suspected, respectively.

3598 Poster Session (Board #221), Sat, 8:00 AM-11:30 AM

Emergence of *KRAS* mutations and acquisition of resistance to EGFR blockade. *First Author: Takeshi Yamada, Department of Digestive Surgery, Nippon Medical School, Tokyo, Japan*

Background: Epidermal growth factor receptor (EGFR) blockade can effectively shrink tumors in patients with metastatic colorectal cancer (CRC). However, most patients who benefit from EGFR blockade acquire resistance. Although *RAS* mutation is established as a main cause of primary resistance, the mechanisms of this acquired resistance remain unclear. Here, we aimed to identify the mechanisms underlying acquired resistance to EGFR blockade by using circulating cell-free (ccf)DNA to track emerging *KRAS, BRAF* and *S492R* mutations during chemotherapy. **Methods:** We enrolled 33 patients with metastatic CRC and no *RAS* mutations in their primary tumors. Patients were treated with first-line systemic chemotherapy that included EGFR blockade. We obtained ccfDNA from each patient before they started chemotherapy, and every 2–3 months during chemotherapy until disease progression. We detected *KRAS* (codons 12, 13, 61, and 146), *BRAF* (V600E) and *S492R* mutations using digital polymerase chain reaction. **Results:** *KRAS* mutations were detected in the ccfDNA of 4 of the 33 patients (12%) before chemotherapy. The response rate was 88% (29/33); all four non-responders had *KRAS* mutations in their ccfDNA and one of the four had both *KRAS* and *BRAF* mutations before starting chemotherapy. A response was detected in all patients (29/29) with no *KRAS* or *BRAF* mutations in their ccfDNA before chemotherapy. Of the 29 initial responders, 14 (48%) acquired resistance. Emerging *KRAS* mutations were detected in the ccfDNA of 13 of these 14 patients (93%); eight of these patients had multiple mutations (e.g. G12D and G12V; G13D and Q61H). *BRAF* mutations were also detected in six patients (43%); none of the patients had solo *BRAF* mutations. Six patients (43%) had *S492R* mutations; none of the patients had solo *S492R* mutations. Only one patient had no *KRAS*, *BRAF* or *S492R* mutations. **Conclusions:** Emergence of *KRAS, BRAF* or *S492R* mutations that were undetectable before the start of chemotherapy may be a mechanism underlying acquisition of resistance to EGFR blockade. Notably, emerging *KRAS* mutations were detected in most of the patients (93%) who acquired resistance. This indicates that *KRAS* mutation emergence may play a major role in the acquisition of resistance to EGFR blockade.

3599 Poster Session (Board #222), Sat, 8:00 AM-11:30 AM

Association of T-cell infiltration assessed in pretherapeutic biopsies (PTB) of patients with locally advanced rectal adenocarcinoma (LARC) with tumor response and relapse after chemoradiotherapy (CRT) and rectal surgery. *First Author: Marc Van Den Eynde, Institut Roi Albert II, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium*

Background: Pre-operative CRT followed by total mesorectal excision (TME) is nowadays the standard of care for patient with LARC (cT3-T4N0 or cTxN+). Currently, pathologic complete response occurs in +/- 15% after CRT. Colorectal cancer T-cell infiltration is a strong prognostic factor for survival after primary tumor resection. Our aim was to determine whether T-cell infiltration in PTB could be predictive of tumor response and relapse after CRT + TME. **Methods:** Between 1999 and 2012, patients with LARC who underwent CRT + TME and with available clinical follow-up and PTB (with sufficient tumor cells density) were identified at the Cliniques universitaires St-Luc. The density of CD3 (T cells) and CD8 (cytotoxic) was quantified on immunostained PTB slides and analyzed with a dedicated image analysis software on whole-slide imaging. Comparisons were made using the Wilcoxon-Mann-Whitney test. Cumulative disease-free survival (DFS) was performed using the Kaplan-Meier estimator and compared by log-rank tests. Cox regression we used for uni- and multi-variate analysis. P value of less than 0.05 was considered statistically significant. **Results:** 154 patients (sex ratio M/F 1.8; mean age 65 years-old; upper (20%), mid (29%) and low rectum (51%), synchronous metastases (11%)) were analyzed. High CD3 and CD8 PTB densities were significantly associated with a higher pathological response (Dworak 3-4) and lower ypTNM stage after CRT +TME ($p < 0,05$). Higher CD3 and CD8 PTB densities were associated with higher patient DFS (CD3: HR = 2,30 (CI95%:1,15-4,59) p = 0,02; CD8: HR = 1,95 (CI95%: 1,01-3,75) p = 0,04). These results were confirmed in uni and multivariate analysis. CD3 and CD8 PTB densities added to pathological response (ypTNM/Dworak) but also clinical response (ycTNM) after CRT + TME increases significantly the accuracy prediction of tumor relapse. **Conclusions:** Pretherapeutic T-cell infiltration of LARC is predictive of tumor response and relapse after CRT +TME. This biomarker could be helpful for patient treatment decision. It must be validated in larger patient cohorts.

3600 Poster Session (Board #223), Sat, 8:00 AM-11:30 AM

Cetuximab (Cet) clearance and survival in patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Di Maria Jiang, The Ottawa Hospital, Ottawa, ON, Canada*

Background: Cet, a monoclonal antibody against EGFR, is a standard therapy for RAS wild-type (WT) mCRC. Limited data suggest a correlation between Cet clearance and progression-free survival (PFS). We performed a population pharmacokinetic (pop-pK) analysis of Cet in pts with KRAS WT mCRC who participated in the randomized phase III NCIC CO.20 trial. **Methods:** Standard Cet doses ± brivanib (Briv) were administered. Intermittent blood samples were obtained, and analyzed by ELISA for Cet. Pop-pK analysis was conducted to estimate Cet clearance. Pts were divided into quartiles according to clearance parameters to evaluate exposure-outcome with overall survival (OS), PFS, response rate (RR), and toxicity. **Results:** Blood samples were available from 703 pts. Cet clearance was best described as a one-compartment model with a saturable elimination (defined by V_{max} and K_m). Mean values (± standard deviation) were 5.6 ± 1.4 L for V, 10.5 ± 2.8 mg/h for V_{max}, and 403.1 ± 2.0 mg/L for K_m. V_{max} and K_m were significantly associated with OS, but not PFS or RR. Median OS for pts in the highest quartile of V_{max} was 7.8 versus (vs.) 11.6 ms for pts in the lowest V_{max} quartile (HR 1.12, 95% confidence interval (CI) 1.05-1.20, $p< 0.001$). In the highest K_m quartile, median OS was 11.6 vs. 7.6 ms in the lowest K_m quartile (HR 0.89, 95% CI 0.83-0.96, $p= 0.001$). Pts with the lowest clearance parameters (lowest V_{max} and highest K_m) had significantly longer OS (11.6 ms) compared to pts with the highest clearance (highest V_{max} and lowest K_m) (7.6 ms) (HR 0.67, 95% CI 0.53-0.83, $p< 0.001$). Overall incidences of grade 3/4 toxicity were not associated with Cet clearance. However, pts with the lowest clearance parameters had more frequent grade 3 diarrhea (OR 0.23, $p= 0.005$). **Conclusions:** For KRAS WT mCRC, standard Cet dosing is not optimal for all pts. Pts with lower Cet clearance have significantly improved OS and increased likelihood of grade 3 diarrhea. Further studies are needed to identify individual patient factors associated with Cet clearance, and to optimize Cet dosing based on individual pk assessments.

3601 Poster Session (Board #224), Sat, 8:00 AM-11:30 AM

Survival prediction in patients treated by FOLFIRI and bevacizumab for metastatic colorectal cancer (PRODIGE 9) using contrast-enhanced CT texture analysis (SPECTRA). *First Author: Anthony Dohan, Lariboisière Hospital, Viscéral and Vascular Radiology Department, INSERM U965, Paris, France*

Background: Quantitative assessment of tumor architecture changes may help to early identify non-responder patients and propose a tailored treatment strategy. Our objective was to build and validate a radiomics signature able to predict early the lack of response to chemotherapy including FOLFIFRI and bevacizumab using baseline and first evaluation CT and to compare it to the RECIST and morphological criteria. **Methods:** For 230 patients of PRODIGE 9 study and treated by FOLFIRI and bevacizumab, a computed analysis (CA) was performed on the dominant liver lesion (DLL) at baseline and 2 months post-chemotherapy. RECIST evaluation was performed at 2 and 6 months. The sum of the target liver lesions (STL), the density of the DLL, CA parameters and their changes rates were correlated with the 2-year survival status. A radiomics signature combining 3 parameters was built in one arm and validated in the second arm. Survival was estimated with the Kaplan-Meier method and compared with log-rank test. **Results:** The strongest predictive factors for 2-year survival status were decrease in STL(AUC = .69±.05[95%CI:.60-.77]), change rate in kurtosis (ssf = 0) (AUC = .66±.05[95%CI:.57-.74]), and the baseline density of the DLL (AUC = .68±.05[95%CI:.59-.77]). Using multivariate analysis, predictive factors of 2-year survival status were the decrease in STL $>$ 15% (HR = 1.92, P= .002), the increase in kurtosis value(ssf = 0) $>$ 93% (HR = 2.16, P= .001), and baseline DLL $>$ 64.3UH (HR = 1.70, P= .02). Then, the SPECTRA-score was built by according 1 point for each of the 3 criteria. Patients with a SPECTRA-score $>$ 1 had a lower overall survival in the training (P= .001) and in the validation cohort (P= .002). Non-response according to RECIST at 6 months had the same prognostic value as SPECTRA-score$>$1 at 2 months. **Conclusions:** A radiomics signature combining STL, density and CA on baseline and first evaluation CT is be able to predict which patient will have a poor outcome with same performances than standard evaluation with RECIST1.1 at 6 months in mCRC patients. Clinical trial information: NCT00952029.

3602 Poster Session (Board #225), Sat, 8:00 AM-11:30 AM

Differences in systemic and surgical therapy between right (R) and left (L) sided metastatic colorectal cancer (mCRC). *First Author: Hagen F. Kennecke, Department of Medical Oncology, BC Cancer Agency, Vancouver, BC, Canada*

Background: Patients (pts) with L sided primary tumors and mCRC have a significantly longer overall survival (mOS) than R sided tumors. Reasons for this remain unclear. The objective of this study was to compare systemic and surgical therapy received by tumor side and correlate this with mOS. **Methods:** Sequential pts with mCRC referred to the British Columbia Cancer Agency in 4 treatment eras were included. Pts with unresected primary tumors were excluded to ensure accurate ascertainment of tumor location. Receipt of systemic therapy includes Òall 3 drugsÓ (irinotecan, oxaliplatin, fluouracil), bevacizumab and epidermal growth factor receptor inhibitors (EGFRi). Cox-regression survival analysis for sidedness was performed controlling for age, sex, tumor grade, lymphovascular/perineural invasion, nodes removed and metastatectomy. **Results:** Among 3242 pts, a progressive improvement in mOS is documented in both L and R sided tumors since 1995. L and R tumors received Òall 3 drugsÓ, bevacizumab and EGFRi therapy with similar frequency which plateaued after the introduction of EGFRiÕs in 2009. Patients with L sided tumors were significantly more likely to have a hepatic or pulmonary resection. In Cox regression analysis, the mOS difference between L and R sided tumors was more pronounced in more recent eras. **Conclusions:** Patients with R sided tumors receive similar systemic therapy compared to L sided tumors, but are significantly less likely to undergo resection of distant disease. Resection of distant metastases may be an important consideration to understand the survival differences between R vs L mCRC.

3603 Poster Session (Board #226), Sat, 8:00 AM-11:30 AM

Robotic vs. laparoscopic vs. open abdominoperineal resection for low rectal cancer: Short-term outcomes of a single-center prospective randomized controlled trial. *First Author: Ye Wei, Institute of General Surgery, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Currently, robotic surgery for rectal cancer using da Vinci System is common. However, there is almost no clinical trial reported. This randomized controlled trial aims to compare the safety and efficacy of robotic, laparoscopic and open abdominoperineal resection (APR) for low rectal cancer. **Methods:** From September 2013 to August 2016, patients aged from 18 to 75 years, with low rectal cancer within 5 cm from anal verge, clinical T1 to T3, no distant metastases, were randomly assigned to receive either robotic procedures (RAP), laparoscopic procedures (LAP) or open surgery (OS) for APR in 1:1:1 ratio. The primary endpoint was postoperative complication rate. This study is registered with ClinicalTrials.gov (NCT01985698). **Results:** Totally 406 patients were randomly assigned. Actually, 135 finished RAP, 131 finished LAP, and 137 finished OS (including 4 convert from LAP to OS). RAP had significantly lower postoperative complication rate (11.1%) than both LAP (21.4%, P = 0.023) and OS (27.7%, P = 0.001). Also, RAP reduced intraoperative hemorrhage (median [interquartile range], 100 [90-110] ml) than LAP (130 [100-150] ml, P $<$ 0.001) and OS (150 [120-260] ml, P $<$ 0.001). And RAP promoted postoperative recovery, with shorter days to first flatus (1.0 [1.0-2.0] day) than LAP (2.0 [2.0-3.0] day, P $<$ 0.001) and OS (3.0 [2.0-4.0] day, P $<$ 0.001), shorter days to first automatic urination (2.0 [2.0-3.0] day) than LAP (3.0 [2.0-4.0] day, P $<$ 0.001) and OS (3.0 [2.0-4.0] day, P $<$ 0.001), and shorter days to discharge (5.0 [5.0-6.0] days) than LAP (6.0 [5.0-7.0] days, P $<$ 0.001) and OS (6.0 [5.0-7.0] day, P = 0.005). There was no significant difference in open conversion rate, resection margin involvement (including circumferential resection margin), number of lymph node harvested and pathological tumor stage. **Conclusions:** Robotic APR was safer, and reproduce equivalent surgical quality of conventional laparoscopic and open surgery. Also, it provided less injury and faster functional recovery. Clinical trial information: NCT01985698.

3604 Poster Session (Board #227), Sat, 8:00 AM-11:30 AM

Genetic correlates of therapeutic toxicities of stage III colon carcinoma patients treated with adjuvant FOLFOX+/-cetuximab (NCCTG N0147, Alliance). *First Author: Polly A. Newcomb, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Limited research has investigated the role of variation in the host genome as a determinant of colon carcinoma (CC) outcomes, including toxicity due to therapeutic agents. We examined the relationship between germline genetic factors and treatment-associated serious adverse events (SAEs) in a population of CC patients in which treatment was standardized and follow-up for outcomes was uniformly conducted. **Methods:** Using existing biospecimens from CC patients with resected stage III disease in a phase III randomized trial of FOLFOX adjuvant chemotherapy with and without cetuximab (NCCTG N0147), genome-wide genotyping arrays were conducted for 2200 patients for a total of ~20 million single nucleotide polymorphisms (SNPs). Using logistic regression models we assessed SNP-specific associations with SAEs, utilizing a discovery-based approach to search the genome in an unbiased manner. Detailed information on SAEs was collected using the Common Toxicity Criteria for Adverse Events (CTCAE, v3.0). Analyses evaluating associations with specific classes of common grade ≥3 SAEs were performed, including gastrointestinal toxicities, neutropenia, and paresthesias. A threshold of $P < 5x10^{-8}$was used to denote genome-wide significance. **Results:** Among patients who received FOLFOX, several SNPs on chr 15 near the ANP32A gene and on chr 2 near the CD207 gene were statistically significantly associated with grade ≥3 neuropathy. The strongest SNP-specific associations in these regions were in the range of odds ratio (OR) = 1.3, $P = 2.8\times10^{-10}$ and OR = 1.5, $P = 2.7\times10^{-10}$, respectively. **Conclusions:** Findings from this genome-wide analysis demonstrate the potential importance of germline genetic variation in influencing CC patients' experience of specific toxicities to FOLFOX regimens. These results highlight two genomic regions of potential interest for understanding the biological mechanism for such toxicities, although further evaluation and replication is needed. Support: U10CA180821, U10CA180882, U10CA180820, U10CA180863, U10CA180888, CCSRI 021039, R01CA176272, Eli Lilly & Co, Pfizer, Sanofi. Clinical trial information: NCT00079274.

3605 Poster Session (Board #228), Sat, 8:00 AM-11:30 AM

Association between timing and duration of adjuvant chemotherapy and survival for colorectal cancer in korea, 2011-2014: A nationwide study based on the database of quality assessment and the health insurance. *First Author: In Gyu Hwang, Department of Internal Medicine, Chung-Ang University Hospital, Chung-Ang University College of Medicine, Seoul, Republic of Korea*

Background: Few population-based analyses on treatment outcomes of colorectal cancer (CRC) have been conducted in Asian countries. We conducted a nationwide study to assess relationship between timing and duration of adjuvant chemotherapy (AC) and survival for patients with CRC in South Korea. **Methods:** Data from the Health Insurance Review and Assessment Service Database (HIRA) were analyzed for demographics, tumor characteristics, adjuvant chemotherapy, and survival of patients who underwent curative-intent surgical resection for CRC from 2011 to 2014. **Results:** From the HIRA data, a total of 61315 patients were identified: 15620 (25.5%) in stage I, 20525 (33.5%) in Stage II, and 25170 (41.0%) in stage III. Chemotherapy regimens were consisted: 11332 (18.5%) in 5-fluorouracil and leucovorin/capecitabine (FL/CAP), 13183 (21.5%) in FL/CAP plus oxaliplatin (FOLFOX/CAPOX), 357 (0.6%) in uracil and tegafur/doxifluridine (UFT/D) and 36443 (59.4%) in surgery alone. For patients with stage II and III CRC, the initiation of AC $\geq$ 8 weeks after surgery was associated with a significant decrease in overall survival (OS) (FL/CAP: HR, 1.82; 95% CI, 1.53 to 2.17, and FOLFOX/CAPOX: HR, 2.92; 2.47 to 3.45, respectively), however UFT/D regimens were not statistically significant. For patients with stage II and III colon cancer, receiving AC $<$ 3 months had lower OS (FL/CAP: HR, 3.72; 95% CI, 2.80 to 4.94, FOLFOX/CAPOX: HR, 2.15; 1.87 to 2.47, and UFT/D: HR, 1.74; 0.56 to 5.41, respectively). For patients with stage II and III rectal cancer, receiving AC $<$ 3 months regardless of chemotherapy regimens had a significant lower survival (FL/CAP: HR, 1.91; 1.66 to 2.20, FOLFOX/CAPOX: HR, 2.20; 1.75 to 2.77, and UFT/D: HR, 3.71; 1.45 to 9.44, respectively). **Conclusions:** Time to initiation and duration of AC after surgery were associated with survival. Based on our results, starting within 8 weeks and receiving more than 3 months of AC are needed to have an overall survival benefit.

3606 Poster Session (Board #229), Sat, 8:00 AM-11:30 AM

A randomized phase II trial of consolidation chemotherapy after preoperative chemoradiation (preop CRT) versus CRT alone for locally advanced rectal cancer (LARC). *First Author: Sun Young Kim, Center for Colorectal Cancer, Research Institute and Hospital, National Cancer Center, Goyang, Republic of Korea*

Background: In LARC, preop CRT followed by total mesorectal excision (TME) is a standard of care. Recently consolidation chemotherapy after CRT was shown to be safe and to improve pathologic complete response (pCR) rate in LARC. We aimed to evaluate downstaging (DS) rate (the proportion of ypT0-2N0M0) of CRT followed by consolidation chemotherapy (capecitabine and oxaliplatin: CapOx) compared to that of CRT alone. **Methods:** Patients (pts) with adenocarcinoma of rectum($\leq$ 12cm from anal verge), ECOG PS 0 or 1, and cT3-4NxM0 were enrolled. CRT (50-50.4Gy/25-28fx) with Cap (825mg/m^2/day for 5 days per week throughout CRT) followed by TME was planned in Arm A (control arm). In Arm B, 2 cycles of CapOx was given a week after completion of CRT before TME (Cap 850mg/m^2/day from day 1 to day 14; Ox 100mg/m^{2}on day 1; q 3w). 110 pts (55 per arm) were needed to show improvement of DS rate in per-protocol population (PP set) from 30% to 50% in arm B with one-sided α = 0.15, 1- β = 0.85, and follow-up loss in 5%. **Results:** From 9/2014 Sep to 2/2016, 110 (56 in arm A; 54 in arm B) were enrolled; 108 (55 in arm A; 53 in arm B) were randomized and started study treatment. Median age was 56 years; male/ECOG PS 1/cT4 was 76%/70%/18%. 100 pts (54 in arm A; 46 in arm B) completed CRT $\pm$ CapOx and surgery (R0 or R1 resection), while 8 (1 in arm A, 7 in arm B) dropped out mainly due to consent withdrawal. 2 of each arm underwent non-TME; that leaves 96 (52 in arm A and 44 in arm B) in PP set. Relative dose intensity of CapOx was 96% (Cap) and 95% (Ox). The main treatment outcome is described in table. The mean interval days between completion of CRT and surgery was significantly longer in arm B (52.9 vs 61.3, p $<$ 0.0001). **Conclusions:** 2 cycles of CapOx after completion of CRT was feasible and safe, and it showed improvement in DS rate, even with high dropout rates (13%). Clinical trial information: NCT01952951.

	arm A	arm B	p value

3607 Poster Session (Board #230), Sat, 8:00 AM-11:30 AM

Neoadjuvant chemotherapy with mFOLFOXIRI alone for cT4 and fixed cT3 rectal cancer: Results from a single arm phase II study (FORTUNE). *First Author: Jianwei Zhang, Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Although neoadjuvant chemoradiotherapy achieves low local recurrence rates in locally advanced rectal cancer (LARC), it delays administration of systemic chemotherapy. About 30% of patients still developed distant metastases, which is the main obstacle for improving survival of LARC. Besides, preoperative radiation causes lots of concerns about anal and sexual functions. We aimed to explore the efficacy of preoperative chemotherapy with mFOLFOXIRI in LARC rather than consistent use of chemoradiotherapy. **Methods:** Patients with fixed cT3 or cT4 rectal cancer evaluated by pelvic MRI participated in this trial. All candidates were to receive 4-6 cycles of mFOLFOXIRI. MRI will be performed to assess clinical responses. Patients with stable/progressive disease were to have radiation before surgery, whereas responders were to have immediate total mesorectal excision (TME). Postoperative radiation was planned if R0 resection was not achieved. Postoperative FOLFOX was recommended. The primary endpoint is the ratio of tumor downstaging to $ypT_{0\text{-}2}N_0M_0$.The secondary endpoint included pathologic complete response rate, 3-year disease free survival rate and safety. **Results:** Between August 2014 and September 2016, 83 patients were enrolled and 80 participants had received TME. Three refused surgery after chemotherapy, because the tumor location is too low to perform sphincter-preserving operation. Of 80 patients completing at least 4 cycles of preoperative chemotherapy, two received short-term radiation before TME, and 10 patients underwent long-term chemoradiotherapy after MRI evaluation. The pCR rate of the whole group was 15 of 80 (18.8%) and the tumor downstaging rate was 43.8%. Among patients without chemoradiotherapy, the pCR rate and tumor downstaging were 14.3% and 41.4%, respectively. And the chemo-related toxicity was all tolerable. **Conclusions:** Neoadjuvant chemotherapy with mFOLFOXIRI and selective radiation does not seem to compromise outcomes in LARC. The result was promising and further phase III study is warranted to validate this experience. Clinical trial information: NCT02217020.

3608 Poster Session (Board #231), Sat, 8:00 AM-11:30 AM

Pathologic complete response rate after neoadjuvant chemoradiation in patients with locally advanced rectal cancer affects survival in patients with prolonged radiation-surgery interval. *First Author: Benjamin Mitchell Motz, Levine Cancer Institute, Charlotte, NC*

Background: The current standard of care in locally advanced rectal cancer is neoadjuvant chemoradiation and R0 resection. An optimal radiation-surgery interval (RSI) has not been established. A small institutional dataset showed RSI $>$ 49 days improved pathologic complete response (pCR) rates and disease free survival. However, in a national dataset, RSI greater than 60 days was associated with increased rates of positive margins and impaired overall survival. Because pCR is associated with improved survival, we used a national database to evaluate the relationship between RSI, pCR and survival after neoadjuvant therapy for rectal cancer. **Methods:** The NCDB was queried for cases 2004-2013 of AJCC stage II or III rectal adenocarcinoma that underwent neoadjuvant radiation followed by radical resection. We excluded patients with missing and outlier RSI. pCR was defined as ypT0N0M0. Chi-square, univariate, multivariable Cox model, and Cochran-Armitage time trend analyses were performed. **Results:** 23475 patients were identified. 7901 (33.7%) had RSI $\geq$60 days. pCR occurred in 1766 (11.3%) of the $<$ 60 group and 1174 (14.9%) of the $\geq$60 group (p $<$ 0.001). RSI $\geq$60 days has increased over time, from 22.1% in 2004 to 45.4% in 2013 (p $<$ 0.001), as have pCR rates, from 8.4% in 2004 to 14.2% in 2013 (p $<$ 0.001). Multivariable Cox model of the total cohort showed that RSI $\geq$60 days (HR = 1.11, 95% CI = 1.04-1.19) and residual disease (HR = 2.04, 95% CI = 1.78-2.34) were associated with increased mortality. Subgroup analysis of patients with pCR showed RSI $\geq$60 days was not associated with worse survival (HR = 1.07, 95% CI = 0.82-1.41). However, analysis of patients with residual disease showed RSI $\geq$60 days was associated with worse survival (HR = 1.13, 95% CI = 1.06-1.21). **Conclusions:** In a large national database, RSI $\geq$60 days worsens survival in patients who have residual disease after neoadjuvant therapy for locally advanced rectal cancer, while there is no difference in those with pCR. Emphasis should be placed on identifying patients who are unlikely to have pCR and to prioritize resection in these patients within 60 days of completion of chemoradiation.

3609 Poster Session (Board #232), Sat, 8:00 AM-11:30 AM

Prognostic impact of tumor budding in stage II colon cancer: A prospective study (SACURA trial). *First Author: Hideki Ueno, National Defense Medical College, Department of Surgery, Saitama, Japan*

Background: Growing number of studies indicate tumor budding is a significant prognostic factor in colorectal cancer (van Wyk, et al. Cancer Treat Rev 2015), but this has been shown only in retrospective studies. We prospectively evaluated prognostic factors in stage II colon cancer to determine their prognostic value in a multi-institutional phase III study (SACURA trial, ASCO2016 abst#3617). **Methods:** A total of 991 patients with curatively resected stage II colon cancer (2006–2010; 136 institutions) were included in the study. Tumor budding was defined as an isolated cancer cell or a cluster composed of fewer than five cells in the invasive frontal region, and was graded based on its number within a microscopic field of a 20x objective lens (0.785 mm^2) in the hotspot. Tumors with < 5, 5–9, and ≥ 10 budding foci were classified as grades G1, G2, and G3, respectively. All clinical and pathological data including the grade of budding were prospectively recorded and prognostic analyses were performed at 5 years after the completion of registration. **Results:** According to budding grading, 376, 331 and 284 tumors were classified as G1, G2, and G3, and 5-year relapse-free survival (RFS) rate was 90.9%, 85.1%, and 74.4%, respectively ($P < 0.0001$). Budding grade was significantly associated with the incidence of recurrence in the liver, lung, lymph node, and peritoneum ($P < 0.0001$–0.01). Among conventional factors, T stage and the serum CEA levels were associated with RFS, however, tumor grade, lymphatic and venous invasions, and the number of lymph node examined were not significant factors. Multivariate analysis for RFS showed budding, along with T stage, exerted an independent influence on prognostic outcome. Budding grade surpassed T stage and tumor grade in the ability to stratify patients by RFS (Harrell's c-index, 0.63, 0.59, and 0.54, respectively). **Conclusions:** Our prospective study indicates that the grade of tumor budding is more informative for prognostic prediction than conventional prognostic factors in stage II colon cancer. The role of this prognostic factor should be highlighted in the adjuvant treatment setting, and conversely, some of prognostic factors adopted in clinical guidelines may need to be reconsidered. Clinical trial information: NCT00392899.

3610 Poster Session (Board #233), Sat, 8:00 AM-11:30 AM

The feasibility and efficiency of wait and see policy for patients with complete clinical response following neoadjuvant therapy in rectal cancer: A prospective cohort study from China. *First Author: Jin Gu, Peking University Cancer Hospital, Beijing, China*

Background: It has been reported that non-operative treatment (wait and see) is feasible for the selected rectal cancer cases with a complete clinical response (cCR) following neoadjuvant therapy (NT). The aim of this study is to determine whether "wait and see" policy is efficient for the cCR patients in China. **Methods:** We designed a prospective cohort study in China (ChiCTR-TRC-12002488). From Jul 2012 to August 2016, totally 45 patients with locally advanced rectal cancer who were cCR following NT were enrolled in the study; within whom, 32 patients were assigned to wait and see group, and the remaining 13 patients were assigned to surgery group (intent-to-treat grouping). **Results:** The median follow-up time was 24 months (range: 3-51). Of the patients who were followed up more than 12 months (n=37), 8 patients developed tumor progression (7 in wait and see group and 1 in surgery group, respectively). In the wait and see group, the local regrowth took an account of 23.1% (6/26), while the distant metastasis rate was 3.8% (1/26). In the surgery group, there were 23.1% (3/13) of patients who has residual cancer confirmed by postoperative pathological assessment. All the patients with tumor regrowth underwent radical surgery and no body died of cancer. **Conclusions:** Wait and see policy has an acceptable safety and efficiency, it may become an alternative treatment for the patients who were cCR following NT. Clinical trial information: ChiCTR-TRC-12002488.

The criteria of complete clinical response.

Examinations	Presentation
Digital rectal examination	Absence of residual palpable lesion
Colonoscopy	No residual tumor or only a small residual scar, usually accompanied by whitening of the mucosa, and the presence of telangiectasia
Biopsy	No cancer cell
Serum CEA, CA199	Normal
MRI/CT	No massive lesion and suspicious lymph node, normal bowel or diffused edema or fibrosis of bowel wall
Others	No distant metastasis

3611 Poster Session (Board #234), Sat, 8:00 AM-11:30 AM

Recurrence risk factors and outcome stratification in stage II colon cancer patients: A subanalysis of the SACURA trial. *First Author: Megumi Ishiguro, Tokyo Medical and Dental University, Department of Translational Oncology, Tokyo, Japan*

Background: Efficacy of adjuvant chemotherapy for stage II colon cancer is still controversial. We conducted the SACURA trial, a phase III study which evaluated the superiority of 1-year adjuvant treatment with oral tegafur-uracil (UFT) to surgery alone in stage II colon cancer. However, survival benefit of 1-year UFT to surgery alone was not demonstrated (ASCO2016 abst#3617). We herein aimed to identify risk factors for recurrence in the stage II patients "without adjuvant chemotherapy", and to stratify the prognosis by using these factors. **Methods:** Among a total of 982 patients without adjuvant chemotherapy enrolled to the SACURA trial, we extracted the factors correlated to recurrence using a univariate and multivariate Cox proportional hazard model. 943 and 935 patients in the surgery alone group and UFT group were divided to subgroups according to the number of risk factors, and the recurrence rate in each subgroup was evaluated. **Results:** Among the conventional clinicopathological characteristics, the multivariate analysis identified pT4, elevated CEA, and examined lymph nodes less than 12 as significant risk factors for recurrence. The rate of patients with 0, 1, 2, and 3 risk factors were 45.0%, 42.4%, 11.5%, and 1.1%, respectively. The recurrence rate for each subgroup was shown in the table: the recurrence rate increased with number of risk factors, while 10.2% of patients without any risk factors developed recurrence. Difference in the recurrence rate between the treatment groups was significant in patients without risk factor, marginal in patients with 1 risk factor, and none in patients with >1 factors. **Conclusions:** pT4, elevated CEA, and examined lymph nodes less than 12 were identified as risk factors for recurrence in stage II colon cancer patients. The recurrence rate was divided by the number of these risk factors, but we could not extract the very-low risk group in whom adjuvant therapy is unnecessary. Induction of novel risk factors other than conventional clinicopathological characteristics is recommended. Clinical trial information: NCT00392899.

Recurrence rate.

No. of risk factors	Surgery alone group	UFT group	HR (95%CI)
0	10.2%	6.2%	0.60 (0.73-0.98)
1	13.1%	10.3%	0.76 (0.50-1.15)
2-3	27.9%	26.6%	1.00 (0.61-1.63)

3612 Poster Session (Board #235), Sat, 8:00 AM-11:30 AM

Phase I study of trametinib with neoadjuvant chemoradiation (CRT) in patients with locally advanced rectal cancers (LARC). *First Author: Christina Sing-Ying Wu, Emory University, Atlanta, GA*

Background: The RAS/RAF/MEK signal transduction pathway is critical to the development of colorectal cancer, and tumors harboring KRAS, NRAS, and BRAF mutations were shown to be resistant to radiation. Thus, we conducted a phase I study of trametinib, a potent MEK1/2 inhibitor, in combination with CRT in patients with LARC. **Methods:** Phase I trial for patients with Stage II/III rectal cancers with a 3+3 design, and an expansion cohort of 12 patients at the maximum tolerated dose (MTD). Trametinib is given orally at 3 dose levels: 0.5mg, 1mg, and 2mg (Mon-Fri). CRT regimen is infusional 5-flourouracil (5FU) 225mg/m^2/day (Mon-Fri) and daily fractions of 1.8 Gy (total 50.4Gy). There is a 5-day trametinib lead-in followed by trametinib and CRT. Six to 10 weeks after completion of CRT, patients then proceed to their surgery and adjuvant therapy. The primary endpoint is to identify the MTD and recommended phase 2 dose of trametinib with CRT. Immunohistochemistry staining for phosphorylated –ERK (pERK) and genomic profiling is performed on the tumor samples. **Results:** Enrollment is complete at all dose levels with18 patients, and 15 patients evaluable for toxicity and response as of Feb 6. One dose-limiting toxicity of diarrhea was observed at the 2mg dose. Grade 3 and most common toxicities are shown in Table 1. No grade 4/5 toxicities have been observed. At 2mg dose level, 3/9 (33%) patients had pathological complete response (pCR) and 2/9 (22%) had a near pCR. Correlative studies confirm decrease in pERK levels with increasing doses of trametinib. Correlation of genomic mutational status with toxicity, response, and outcomes is being analyzed. **Conclusions:** The combination of trametinib with 5FU CRT is tolerable with promising preliminary activity. Final results will be presented at the meeting. Toxicities. Clinical trial information: NCT01740648.

3613 Poster Session (Board #236), Sat, 8:00 AM-11:30 AM

Impact of adjuvant treatment in elderly patients with locally advanced rectal cancer: A population-based retrospective study. *First Author: Shiru Lucy Liu, Department of Medicine, Dalhousie University, Halifax, NS, Canada*

Background: Little is known about the benefit and use of adjuvant chemotherapy (ADJ) in the elderly population (age ≥ 65) with locally advanced rectal cancer (LARC). We undertook a provincial review of LARC patients to evaluate the potential benefits, including survival and time to relapse (TTR), of ADJ in elderly patients. **Methods:** We performed a retrospective analysis of 286 LARC patients (stage 2 and 3) diagnosed between January 2010 and December 2013 from Nova Scotia, Canada, who underwent curative-intent surgery. Baseline patient, tumor and treatment characteristics were collected. Survival and TTR analysis were performed using Kaplan-Meier and Cox-regression statistics. **Results:** 152 patients were age ≥65, and 92 age ≥70. Median follow-up was 46 months. 178 patients (62%) received neoadjuvant chemo-radiation (NEOADJ). While 109 patients (81%) age < 65 received ADJ, only 68 patients (45%) age ≥ 65 received ADJ. Kaplan-Meier analysis revealed a significant survival and TTR advantage for ADJ irrespective of age (table). In cox-regression multivariate analysis, ECOG status, T stage, and ADJ were significant predictors of survival ($p < 0.04$), while age was not. Similarly, N stage, NEOADJ, and ADJ were significant predictors of TTR ($p < 0.007$). Poor ECOG status was the most common cause of ADJ omission. There was a significantly higher amount of grade≥ 1 chemotherapy-related toxicity experienced by patients age ≥ 65 treated with ADJ compared to no ADJ (77% vs 32%, $p < 0.0001$), which consisted mostly of diarrhea and mucositis. Toxicity was the main reason for non-completion of ADJ in the elderly. **Conclusions:** Elderly patients with LARC have significantly improved overall survival with ADJ, but the use of ADJ is lower than in patients age < 65. However, elderly patients experience more chemotherapy-related toxicities, leading to higher rates of early treatment discontinuation.

3614 Poster Session (Board #237), Sat, 8:00 AM-11:30 AM

Comparison of two different neoadjuvant chemoradiatiotherapy regimens for locally advanced rectal cancer: Results of a phase II, multicenter, randomized trial. *First Author: Ji Zhu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The aim of this study is to compare clinical outcomes between two groups of different chemoradiation Regimens. **Methods:** Eligible patients were randomly assigned to Patients received either IMRT to the pelvis of 50 Gy/25Fxs concurrent with oxaliplatin 50 mg/m2 weekly and capecitabine 625 mg/m2 bid d1–5 weekly (Arm A), or IMRT to the pelvis of 50 Gy/25Fxs and a concomitant boost of 5 Gy to the primary tumor in 25 fractions, followed by a cycle of XELOX two weeks after the completion of chemoradiotherapy (Arm B). Surgery was scheduled eight weeks after the completion of CRT. All patients were recommended to receive adjuvant CT regardless of pathological stages. A total of six cycles of XELOX chemotherapy was recommended including neoadjuvant and adjuvant period. The primary end point was pCR. **Results:** From February 2010 to December 2011, a total of 120 patients were randomly assigned to Arm A (n = 60) or Arm B (n = 60). One hundred and ten patients (Arm A = 53, Arm B = 57) underwent surgery, the other 10 patients didn't receive surgery because of unresectable disease. Eight and 14 cases were evaluated as pCR in two groups respectively (p= .157). Tumor response was further classified into good response and poor response, the former was defined as ypT0N0, ypT1-2N0 and ypT0N1a. The rate of good responses were 30.0% and 55% (p= .006). No significant differences were found in grade 3 or 4 acute adverse events during the treatment between the two groups. However, number of patients who had delayed incision healing was 13 and 3 patients (p= .007). There were no statistical differences in OS (p= .553), DFS (p= .349) and local-regional control (p= .856) between the two groups. In the univariate analysis, N stage, MRF involvement and tumor response had significant impacts on OS, DFS and LC. In the multivariate analysis, MRF involvement had significant impacts on OS (p= .02), DFS (p= .01) and LC (p= .01). **Conclusions:** A dose-intensified radiotherapy in neoadjuvant chemoradiotherapy demonstrated contribution to tumor regression with acceptable toxicity, but led delayed incision healing after surgery. The impact of MRF involvement on survival merits further investigation. Clinical trial information: NCT01064999.

3615 Poster Session (Board #238), Sat, 8:00 AM-11:30 AM

Microbiota as a new indicator of colorectal cancer (CRC) heterogeneity. *First Author: Iradj Sobhani, Departement of Gastroenterology and Oncology Hopital Henri Mondor, Creteil, France*

Background: Location and somatic gene signature of CRCs may impact prognosis and therapy response. The aim was to characterize colon Microbiota in CRC patients regarding location, gene markers and outcome. **Methods:** Patients (N = 173) signed consent for whole metagenome (shot gun sequencing on Illumina HiSeq2500) analysis of stool DNA: 72 CRC (53 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families. "MOCAT" pipeline was used, library sorted (Phred quality score ¡20 Alientrimmer v0.4.0) after exclusion of < 35 nt, human genes or phage sequences. Quality sequences were aligned (REFMG.V13) and most abundant genes constructed (MBMA program v0.1). The Shaman program (shaman.c3bi.pasteur.fr) was used. The number of bacteria was estimated (REFMG program). The linear model (GLM) was implemented in the DESeq2 R kit. Dfferences between Control (N = 87) and CRCs (N = 69), between L (N = 19) and S CRCs (N = 50), and between LCRC (N = 19) and Healthy Lynch relatives were obtained after interaction of age, BMI and gender was considered (GLM model). The $P < 0.1$ value was retained after correction (Benjamini and Hochberg). The specific taxonomic composition of the control and CRC groups was subjected to random analysis (Caret's R package) with two optimization parameters (precision and kappa) in the model. **Results:** There was no difference for gender, age ($p = 0.08$) and BMI ($p = 0.187$) in the L and S CRCs. Significant differences were observed between Normal and CRCs, C-CRC and L-CRC, L-CRC and first degree relatives based on the common component (similarity of sequences): 13 species differentiated Normal and CCRs, two were more prevalent in L-CRCs. The panels of bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging: I (N = 17, 2L and 15S), II (N = 12, 5L and 7S), III (N = 20, 10L, 10S), IV (N = 22.1L, 21S). DFS might be dysbiosis dependent. **Conclusions:** CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through therapies impact the prognosis. Microbiota signature should be taken in consideration in trials.

3616 Poster Session (Board #239), Sat, 8:00 AM-11:30 AM

Clonal evolution in locally advanced rectal cancers in response to neoadjuvant chemoradiotherapy. *First Author: Sinead Toomey, Department of Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: Locally advanced rectal cancer, LARC (T3/4 and/or N+) is currently treated with neoadjuvant chemoradiotherapy (NACRT), however clinicopathological response is variable. Monitoring clonal evolution in response to NACRT may identify mutations driving therapeutic resistance or tumor growth after treatment. **Methods:** Fresh-frozen pre- and post-NACRT tumor and matched normal tissue from LARC patients were stratified into good (RCPath A), intermediate (RCPath B) and poor (RCPath C) responders. Following histological review, targeted exome capture was performed using an Agilent SureSelect Human all Exome V3 kit. Samples were sequenced to a minimum of 100X coverage on an Illumina HiSeq2000, and clonal evolution was assessed in matched pre- and post-NACRT tumor samples. **Results:** The median somatic mutation burden in pre-treatment samples was 114 (IQR 19-207). Two tumors were microsatellite (MSI) unstable and had elevated mutational burdens. The least evolution occurred in the poor responders, where there was little change in clonal composition after treatment, and driver mutations in genes including TP53 and APC were retained. On average 79% of pre-treatment mutations were retained post-treatment in poor responders and 33% of mutations were retained in intermediate responders. Many of the intermediate responders had loss of driver mutations including TP53 from the pre-treatment sample, but also shared a number of mutations in genes including PIK3CA and BRAF between pre- and post-treatment samples. There was also increased frequency in the post-treatment samples of clones that were not present in the pre-treatment samples. In one intermediate responder, all 47 mutations that were present in the pre-treatment sample including the driver mutations TP53 and APC were absent in the post-treatment sample, while 10 completely new mutations were identified. **Conclusions:** Dynamic mutational processes occur in LARC following selective pressures of exposure to NACRT, including changes in somatic mutation presence or frequency after treatment, owing to persistence or loss of sub-clones. As NACRT can profoundly affect the LARC genome, monitoring molecular changes during treatment may be clinically useful.

TPS3618 **Poster Session (Board #241a), Sat, 8:00 AM-11:30 AM**

Phase 3, open-label, randomized study of first-line pembrolizumab (pembro) vs investigator-choice chemotherapy for mismatch repair-deficient (dMMR) or microsatellite instability-high (MSI-H) metastatic colorectal carcinoma (mCRC): KEYNOTE-177. *First Author: Luis A. Diaz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: About 5% of mCRCs are dMMR, leading to high levels of MSI. CRCs with MSI-H have abundant lymphocyte infiltrates and strong expression of immune checkpoints. In the phase 2 KEYNOTE-016 study, the anti-programmed death 1 (PD-1) antibody pembro provided an ORR of 40% in patients (pts) with progressive dMMR mCRC vs 0% in pts with MMR-proficient mCRC. KEYNOTE-177 (ClinicalTrials.gov, NCT02563002) is an international, randomized, open-label, phase 3 study designed to evaluate the efficacy and safety of pembro vs standard-of-care (SOC) chemotherapy in the first-line setting for dMMR or MSI-H mCRC. **Methods:** Key eligibility criteria include age $\geq$ 18 years, locally confirmed dMMR or MSI-H stage IV CRC, measurable disease per RECIST v1.1 by local site assessment, ECOG performance status 0-1, no active autoimmune disease or brain metastases, and no prior therapy for mCRC. Pts are to be randomized 1:1 to receive either pembro 200 mg Q3W or investigator's choice of SOC chemotherapy, which must be chosen prior to randomization; options include mFOLFOX6 or FOLFIRI alone or in combination with bevacizumab or cetuximab. Treatment is to continue until disease progression, unacceptable toxicity, pt/investigator decision, or completion of 35 cycles (pembro only). Response is to be evaluated Q9W per RECIST v1.1 by central imaging vendor review and per RECIST adapted for immunotherapy response patterns. Pts in the SOC arm who have disease progression and meet crossover criteria may be eligible to receive pembro for up to 17 treatment cycles. Eligible pts may continue pembro beyond initial RECIST-defined progression. AEs are to be assessed throughout treatment and for 30 days thereafter (90 days for serious AEs) and graded per NCI CTCAE v4.0. Pts are to be followed for survival Q9W. Primary end point is PFS per RECIST v1.1 by central imaging vendor review. Secondary end points include ORR per RECIST v1.1 by central imaging vendor review, OS, and safety and tolerability. Other end points include DOR and HRQoL. Planned enrollment in KEYNOTE-177 is 270 pts across 21 countries. Clinical trial information: NCT02563002.

TPS3619 **Poster Session (Board #241b), Sat, 8:00 AM-11:30 AM**

CanStem303C trial: A phase III study of napabucasin (BBI-608) in combination with 5-fluorouracil (5-FU), leucovorin, irinotecan (FOLFIRI) in adult patients with previously treated metastatic colorectal cancer (mCRC). *First Author: Axel Grothey, Mayo Clinic Cancer Center, Rochester, MN*

Background: Cancer stem cells are considered to be fundamentally important for resistance to therapy, recurrence and metastasis. Napabucasin is a first-in-class cancer stemness inhibitor in development identified by its ability to inhibit STAT3-driven gene transcription and spherogenesis of cancer stem cells (Li et al, PNAS 112(6):1839, 2015). Preclinically, napabucasin sensitizes cancer cells to chemotherapeutics, including 5-FU and irinotecan. Encouraging anticancer activity in advanced CRC was observed in a phase Ib/II (Bendell et al, GI ASCO 2017) study of 63 pts with disease control rate (DCR) of 93% (28/30) and overall response rate (ORR) of 33% (10/30) in FOLFIRI-naïve pts who have had an on-study RECIST evaluation. On the basis of these data, a phase III trial is being conducted in North America, Europe, Australia, and Asia. **Methods:** This study (ClinicalTrials.gov NCT02753127) will assess the efficacy of napabucasin+FOLFIRI *vs* FOLFIRI in pts with mCRC (n = 1250). Addition of bevacizumab (bev) is permissible per investigator choice. Pts must have failed 1 prior line of therapy with oxaliplatin and a fluoropyrimidine +/- bev for metastatic disease. Pts are randomized 1:1 to receive napabucasin 240 mg PO BID plus FOLFIRI bi-weekly, or FOLFIRI bi-weekly (bev may be added to FOLFIRI by investigator choice) and stratified by geography, time to progression on 1st-line therapy, RAS mutation status, bev as part of study treatment and primary tumor location. Treatment will continue until disease progression, or another discontinuation criterion. Primary endpoint is overall survival (OS) in the general study population (ITT) (HR 0.80 for OS improvement from 12.54 to 15.68 months); secondary endpoints include OS in the biomarker positive (biomarker+) population, progression free survival (PFS) in the ITT population, PFS in biomarker+ population, ORR and DCR in the ITT and in biomarker+ populations, safety and quality of life. Also, blood and tumor archival tissue will be assessed for PK and biomarker analyses. Global enrollment is underway. Clinical trial information: NCT02753127.

TPS3620 **Poster Session (Board #242a), Sat, 8:00 AM-11:30 AM**

Avelumab and cetuximab in combination with FOLFOX in patients with previously untreated metastatic colorectal cancer (MCRC): The phase II AVETUX-CRC trial (AIO KRK 0216). *First Author: Alexander Stein, Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*

Background: Inhibition of the PD-1/L1 axis has shown to improve survival as single agent in a variety of tumor types. The efficacy of single agent PD-1/L1 inhibition in patients with treatment refractory MCRC seems to be limited to hypermutated tumors characterized by mismatch repair deficiency. 1st line chemotherapy (e.g. FOLFOX) with cetuximab for patients with RAS/BRAF wildtype MCRC result in objective response rates of about 60%, thus substantial antigen release will likely occur triggering immune control. Furthermore, the induction of immunogenic cell death has been recently shown for cetuximab-based regimen. Thus, the evaluation of FOLFOX and cetuximab in combination with avelumab in 1st line MCRC is of particular interest. **Methods:** AVETUX is a single arm exploratory phase II investigator initiated trial. Patients with RAS/BRAF wildtype MCRC will be included independent of mismatch repair status to receive mFOLFOX6 and cetuximab in combination with avelumab (10mg/kg from day 1 of cycle 2 onwards). Treatment with avelumab is limited to a maximum of 18 months. Primary endpoint is 12month progression-free survival rate, which should be increased from 40% to 57%, with type I error of 10% and 80% power, leading to a sample size of 43 patients. An early stopping rule will be applied in case of an increase in toxicity after the first 15 patients received at least two months of treatment. The trial is flanked by a large translational program including immunoprofiling to determine and correlate the respective immune response signatures with clonal dynamics (RAS/EGFR). Recruitment will start in 11 German sites early 2017. Clinical trial information: EudraCT No 2016-004434-26. **Conclusion:** The AVETUX trial will determine the feasibility and early efficacy of FOLFOX and cetuximab combined with avelumab in 1st line MCRC. The translational research program will shed light on the potential mode of action of this novel combination. Clinical trial information: 2016-004434-26.

TPS3621 **Poster Session (Board #242b), Sat, 8:00 AM-11:30 AM**

The CCTG CO.26 trial: A phase II randomized study of durvalumab plustremelimumab and best supportive care (BSC) vs BSC alone in patients with advanced colorectal carcinoma (CRC) refractory to standard therapies. *First Author: Eric Xueyu Chen, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Durvalumab (D) is a human monoclonal antibody (mAb) that inhibits binding of programmed cell death ligand 1 (PD-L1) to its receptor (PD-1) thereby preventing reduction in the number and efficacy of activated T-cells. Tremelimumab is a mAb directed against the cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) thereby resulting in enhanced T-cell activation and anti-tumour activity. Monotherapy with the anti-PD-1 agent pembrolizumab has demonstrated significant activity in CRC pts with tumours demonstrating microsatellite instability (MSI-H). Inhibiting PD-1/PD-L1 alone is likely of limited benefit in advanced CRC as only 5% of pts are MSI-H. Targeting both PD-L1 and CTLA-4 may have additive or synergistic activity as the mechanisms of action of CTLA-4 and PD-L1 inhibition are non-redundant. This study is designed to evaluate whether combining PD-L1 and CTLA-4 inhibition will lead to improved patient survival *vs* BSC alone in advanced CRC, regardless of MSI status. **Methods:** This randomized phase II study (ClinicalTrials.gov NCT02870920) will assess the efficacy and safety of D+T *vs* BSC in pts with metastatic or advanced, unresectable, refractory CRC (n = 180). Pts have failed standard chemotherapy based regimens containing a fluoropyrimidine, irinotecan and oxaliplatin (and an EGFR inhibitor, if *Ras* wild type) and no other therapeutic options. Pts are randomized in a 2:1 ratio to receive D (1500 mg) D1 q 28 days and T (75 mg) D1 for first 4 cycles. Treatment will continue until disease progression, death, intolerable toxicity, or patient/investigator decision to stop. Primary endpoint is overall survival; secondary endpoints include progression free survival, safety, overall response rate and quality of life. Analysis will be according to randomized group stratified by ECOG PS (0 *vs* 1) and site of tumour (right *vs* transverse *vs* left vs rectum). In addition, blood, plasma, and archival tissue will be collected and assessed for potential prognostic and predictive biomarkers, including tumour MSI status. As of February 1 2017, 20 pts have been randomized and recruitment is ongoing. Clinical trial information: NCT02870920.

TPS3622 **Poster Session (Board #243a), Sat, 8:00 AM-11:30 AM**

BEACON CRC (binimetinib [BINI], encorafenib [ENCO], and cetuximab [CTX] combined to treat *BRAF*-mutant metastatic colorectal cancer [mCRC]): A multicenter, randomized, open-label, three-arm phase III study of ENCO plus CTX plus or minus BINI vs irinotecan (IRI)/CTX or infusional 5-fluorouracil/folinic acid/IRI (FOLFIRI)/CTX with a safety lead-in of ENCO + BINI + CTX in patients (Pts) with *BRAF*^{V600E} mCRC. *First Author: Sanne Huijberts, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: *BRAF* mutations are found in ≈10% of mCRC cases. Pts with *BRAF*^{V600E} mCRC have a poor prognosis, with shorter progression-free survival (PFS) and overall survival (OS) than pts with *BRAF*^{wt} mCRC (Van Cutsem et al 2011; Modest et al 2012; Sorbye et al 2015). The benefits of combined BRAF + EGFR inhibition in mCRC have been demonstrated in vitro (Corcoran et al 2012; Prahallad et al 2012; Yang et al 2012), and preclinical evidence suggests that adding MEK signaling inhibition improves antitumor activity. Early clinical data indicate that BRAF + EGFR + MEK inhibition has greater activity than BRAF + EGFR inhibition in pts with *BRAF*^{V600E} mCRC (Van Cutsem et al 2016). Our study will examine the combination of BINI (a MEK inhibitor) + ENCO (a selective BRAF kinase inhibitor) + CTX (an anti-EGFR antibody) and of ENCO + CTX in pts with *BRAF*^{V600E} mCRC. **Methods:** BEACON CRC (NCT02928224) is enrolling pts with *BRAF*^{V600E} mCRC whose disease has progressed after 1 or 2 prior regimens in the metastatic setting. A safety lead-in phase (≈30 pts) will determine the safety and tolerability of oral ENCO 300 mg QD + oral BINI 45 mg BID + intravenous CTX 400 mg/m^2 followed by 250 mg/m^2 QW. In the phase 3 portion, ≈615 pts will be randomized 1:1:1 to triplet (ENCO + BINI + CTX), doublet (ENCO + CTX), or control (investigator's choice of IRI/CTX or FOLFIRI/CTX) arms. Pts will be treated in 28-day cycles until disease progression, unacceptable toxicity, withdrawal of consent, initiation of subsequent anticancer therapy, or death. The primary endpoint is OS (triplet vs control). Secondary endpoints include OS (doublet vs control), confirmed investigator-assessed objective response rate according to RECIST version 1.1 (triplet or doublet vs control; triplet vs doublet), PFS (triplet or doublet vs control), duration of response, time to response, pharmacokinetics, and pt-reported outcomes. Safety will be summarized using standard adverse event reporting. Clinical trial information: NCT02928224.

TPS3623 **Poster Session (Board #243b), Sat, 8:00 AM-11:30 AM**

Multicenter phase I/II trial of BBI608 and pembrolizumab combination in patients with metastatic colorectal cancer (SCOOP Study): EPOC1503. *First Author: Yasutoshi Kuboki, Department of Gastrointestinal Oncology, National Cancer Center Hospital, Chiba, Japan*

Background: Immune checkpoint inhibitor (ICI) was reported to show durable responses in patients with MSI-H (Microsatellite Instability-High) metastatic colorectal cancer (mCRC). On the other hand, for patients with MSS (Microsatellite Stable) mCRC, ICI monotherapy achieved no response. Recently, WNT/β-catenin signaling has been reported to be involved in the elimination of tumor-infiltrating lymphocytes and the resistance of anti-PD-L1 antibodies. CRC is representative cancer with WNT/β-catenin pathway activation. Furthermore, STAT3 has also been reported to be a key driver of this immune evasion. Considering these rationales, the blocking of these signaling pathways with ICI may enhance antitumor immune response. Therefore, we initiated phase I/II study to assess efficacy and safety for the combination of BBI608, which blocks STAT3 and WNT/β-catenin signaling, with pembrolizumab in patients with mCRC. **Methods:** The eligibility criteria were patients with gastrointestinal cancer not responded to or intolerant of standard chemotherapies (SOC) for phase I part, and MSS mCRC refractory or intolerant to fluoropyrimidine, irinotecan, oxaliplatin, and anti-EGFR antibody (if wild-type *RAS*) for Cohort B in phase II part. For Cohort A, MSI-H mCRC refractory or intolerant to the SOC, irrespective of anti-EGFR antibody are investigated. Phase I part was designed to determine the recommended phase II dose in a "3+3" cohort-based dose escalation design of BBI608 (240mg BID every day on level 1 and 480mg BID every day on level 2) with pembrolizumab (200mg/body q3w). Primary endpoint of the phase II part is Immune-related objective response rate (irORR) determined by their Response Evaluation Criteria In Solid Tumors (irRECIST). A null hypothesis and alternative hypothesis for cohort B are irORR = 5% and 20%, respectively. Required sample size for Cohort B was 40 with a one-sided alpha of 5% and power of 90%. Required sample size for Cohort A (10 patients) was determined in an exploratory manner. We also investigate biomarker study using paired samples of both tumor biopsy and blood. The enrollment to phase I part began in November 2016. Clinical trial information: NCT02851004. Clinical trial information: NCT02851004.

TPS3624 **Poster Session (Board #244a), Sat, 8:00 AM-11:30 AM**

A phase II, open label study of tucatinib (ONT-380) combined with trastuzumab in patients with HER2+ metastatic colorectal cancer (mCRC)(MOUNTAINEER). *First Author: John H. Strickler, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: To improve survival for patients with mCRC, efforts are needed to identify and treat actionable genomic alterations. *HER2* is amplified in approximately 5-8% of patients with *KRAS* and *NRAS (RAS)* wild-type mCRC. *HER2* functions as an oncogenic driver and a mediator of EGFR antibody (Ab) resistance. Although prior studies have shown that anti-HER2 therapies are active in patients with HER2+ (HER2 IHC 3+ or *HER2* amplified) mCRC, there are no HER2-directed therapies approved for these patients. Tucatinib is a potent and highly selective oral small molecule tyrosine kinase inhibitor of HER2, currently being developed to treat metastatic breast cancer. In HER2+ CRC patient derived xenograft models, tucatinib has substantial anti-tumor activity. The addition of the anti-HER2 monoclonal Ab trastuzumab augments tumor growth inhibition. **Methods:** This single-arm phase II study will test the combination of tucatinib and trastuzumab in patients with HER2+ mCRC. Eligible patients include those with RAS wild-type mCRC who have been previously treated with 5-FU, oxaliplatin, irinotecan, and an anti-VEGF monoclonal Ab. Patients must have HER2+ disease by IHC, FISH, or NGS. Prior treatment with anti-HER2 targeting therapy is excluded. The primary objective is to assess the objective response rate for the combination. Secondary objectives are to evaluate the efficacy (PFS, OS, clinical benefit rate), safety, and tolerability of the combination. Correlation between tissue and blood-based biomarkers and clinical outcomes will be explored. Blood will be collected at baseline and each restaging to determine if the combination eliminates *HER2* amplified circulating tumor DNA. Subjects will receive tucatinib at a dose of 300mg by mouth daily, and trastuzumab will be administered every 3 weeks (8 mg/kg IV day 1 of cycle 1, then 6 mg/kg IV Q3 weeks). Response will be assessed every 3 cycles (9 weeks) per RECIST version 1.1. Both agents will be provided by the study. This study was initiated in February 2017. Recruitment is ongoing at 8 sites in the Academic and Community Cancer Research United (ACCRU) network. Clinical trial information: NCT03043313.

TPS3625 **Poster Session (Board #244b), Sat, 8:00 AM-11:30 AM**

LUNA: A randomized phase II trial of liver resection plus chemotherapy or chemotherapy alone in patients with unresectable lung and resectable liver metastases from colorectal adenocarcinoma. *First Author: Yun Shin Chun, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Liver resection for metastatic colorectal cancer is associated with 5-year overall survival (OS) of 58% and accepted as standard of care. However, the role of liver resection with unresectable low-volume lung metastases is unknown. A recent retrospective study showed that resection of liver metastases was associated with statistically improved OS compared to a matched group of patients treated with systemic therapy alone for lung and liver metastases (3-year OS 43% vs. 14%; Mise Y, Ann Surg Oncol 2015). LUNA is a single-institution phase 2 randomized trial designed to determine the overall survival benefit of liver resection in patients with unresectable lung metastases and to integrate biological surrogates to risk stratify patients and optimize patient selection for hepatectomy. **Methods:** Eligibility criteria include resectable liver metastases, defined as sufficient liver remnant volume, adequate vascular inflow and outflow, and preservation of 2 contiguous liver segments. Low-volume lung metastases are defined as solid pulmonary nodules $<$ 2 cm in size and $<$ 15 in number. Chest computed tomography is reviewed by an attending thoracic surgeon, and lung metastases are deemed unresectable due to anatomic location, distribution, or patients' comorbidities. Previous treatment with systemic chemotherapy and/or biologic agents is permitted. After stratification by *KRAS* status and primary tumor location in the colon vs. rectum, patients are randomized 1:1 to liver resection plus chemotherapy or no liver resection with chemotherapy at the discretion of the treating oncologist as routine standard of care. Patients are restaged every 3–6 months until 3 years after randomization or death. The primary endpoint is OS. Secondary endpoints include quality of life and identification of biological surrogates in blood and resected liver tissue associated with response to chemotherapy, time to tumor progression, and survival. Targeting an effect size of extending median OS from 17 to 34 months will provide 80% power with 0.05 one-sided alpha with a sample size of 80 patients. Clinical trial information: NCT02738606.

TPS3626 **Poster Session (Board #245a), Sat, 8:00 AM-11:30 AM**

A phase I dose-escalation of trifluridine/tipiracil in combination with oxaliplatin in metastatic colorectal cancer. *First Author: Antoine Hollebecque, Drug Development Department (DITEP), Gustave Roussy, Villejuif, France*

Background: Trifluridine/tipiracil, also known as TAS-102, is a combination of an antineoplastic thymidine-based nucleoside analogue (trifluridine) and a thymidine phosphorylase inhibitor (tipiracil hydrochloride). The antitumor activity of combined trifluridine/tipiracil and oxaliplatin has been studied in gastrointestinal tumor xenografts, including a 5-FU resistant subline, using a nude mouse model. This study demonstrated increased antitumor activity for the combination compared to trifluridine/tipiracil or oxaliplatin alone ($p < 0.001$) (Nukatsuka et al., Anticancer Res 2015). These data support the rationale for clinical use of the combination. We describe a phase 1, international, dose-escalation study of the combination in metastatic colorectal cancer (mCRC). **Methods:** This trial includes mCRC patients pretreated with at least one line of standard chemotherapy. The 14-day administration schedule of trifluridine/tipiracil differs from current clinical practice to avoid overlapping toxicity, notably decreased neutrophils due to oxaliplatin or trifluridine/tipiracil. Trifluridine/tipiracil is administered orally (cohort 1: 25 mg/m^2 bid; cohort 2: 30 mg/m^2 bid; cohort 3: 35 mg/m^2 bid) from day 1 to 5; and oxaliplatin at 85 mg/m^2 (with a possibility to reduce to 65 mg/m^2) on day 1. The primary objective is to determine the maximum tolerated dose (MTD) through a 3+3 design. Secondary objectives include safety, pharmacokinetics, and preliminary efficacy (overall survival, progression-free survival, overall response rate and biomarkers). As of December 2016, no dose-limiting toxicities had been reported in cohorts 1 or 2. The MTD has not yet been reached and dose-escalation continues with enrollment in cohort 3 at full dose for both drugs (trifluridine/tipiracil 35 mg/m^2 bid and oxaliplatin 85 mg/m^2). Once established, the MTD will be confirmed in 6 additional patients to define the recommended dose to be used in the expansion part of the study planned in the same patient population. The results of the dose-escalation part are expected in 2017. (NCT02848443). Clinical trial information: NCT02848443.

TPS3627 **Poster Session (Board #245b), Sat, 8:00 AM-11:30 AM**

A phase Ib study combining irinotecan with AZD1775, a selective WEE 1 kinase inhibitor, in RAS/RAF mutated metastatic colorectal cancer patients who progressed on first line therapy. *First Author: Deirdre Jill Cohen, Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: Mutant KRAS tumors show a dependency on WT-H/N-Ras for activation of ATR/Chk1-mediated G2 DNA damage response (Grabocka, Cell, 2015). We have shown in vitro that the Wee1 kinase inhibitor AZD1775, which acts to abrogate the G2 DNA damage checkpoint and induces replication stress during S-phase, selectively sensitizes RAS/RAF mutant cells to the DNA damaging agent irinotecan. Up to 65% of metastatic colorectal cancers harbor RAS or BRAF mutations and these patients have limited treatment options following first line therapy. **Methods:** This is an open label, single-arm, phase Ib study using a modified 3+3 dose-escalation schedule with expansion cohort. Primary objective is to determine the MTD of AZD1775 in combination with irinotecan as 2nd-line therapy in patients with metastatic KRAS, NRAS or BRAF mutated colorectal cancer. Up to 18 patients will be enrolled in the dose escalation portion. Standard dose irinotecan is given on day 1 of every 2 week cycle. AZD1775 is administered PO twice daily for 3 to 5 days of each cycle, starting cycle 2. The maximum tolerated dose (MTD) is defined as the highest dose level at which $\leq$1 of 6 patients experience a dose limiting toxicity. Once the MTD is reached and/or recommended dose for expansion is determined, a dose expansion cohort of 14 patients will be enrolled. Secondary endpoints include characterizing the safety profile at the MTD, obtaining a preliminary estimate of efficacy for the combination (measured by overall response rate, progression-free and overall survival rates), and obtaining pharmacokinetic parameters. Pre- and on-treatment biopsies will be collected from the expansion cohort to determine: adequate target engagement of Wee1, changes in markers of DNA damage, TP53 mutation status, and changes in gene expression profiles in order to identify potential biomarkers of response. At February 2017, 2 patients have been enrolled on this study. Clinical trial information: NCT02906059.

Dose escalation schema.

Dose Level	AZD1775 (q2w)	Irinotecan (q2w)
-1	125 mg bid x 3 days	150mg/m^2
1 (starting dose)	125 mg bid x 3 days	180mg/m^2
2A	150 mg bid x 3 days	180mg/m^2
2B	125 mg bid x 5 days	180mg/m^2
3	150 mg bid x 5 days	180mg/m^2

TPS3628 **Poster Session (Board #246a), Sat, 8:00 AM-11:30 AM**

PRODIGE 34 ADAGE: Adjuvant chemotherapy in elderly patients with resected stage III colon cancer—A randomized phase III trial. *First Author: Thomas Aparicio, Department of Gastroenterology, Saint Louis Hospital, Paris, France*

Background: Colon cancer (CC) occurs in around 50% of the patients after 70 years. Adjuvant chemotherapy (CT) has demonstrated a benefit on disease-free survival (DFS) and overall survival after a stage III CC resection. Nevertheless, adjuvant CT is poorly used in elderly patients. There is still concern about the efficacy of doublet CT with oxaliplatin in fit elderly patients and the usefulness of fluoropyrimidine monotherapy in unfit elderly patients. The selection of patients that should be treated remains a challenge. Geriatric evaluation and tumor biology should be explored to help for patient selection. **Methods:** ADAGE is a multicenter, randomized phase III study comparing 3-years DFS of 2 therapeutic strategies in 2 groups of patients aged over 70 with completely resected stage III CC. Patients are included in one of the 2 groups after a multidisciplinary team evaluation; Group 1 (arm A and B) is defined as "able" to be treated with doublet CT; Group 2 (arm C and D) is defined as "unable" to be treated with doublet CT. In each group, patients are randomized according to a 1:1 ratio. Randomization is stratified according to center, gender, stage (IIIA *vs* IIIB *vs* IIIC), occlusion and/or perforation (yes *vs* no) and independent activity of daily living score (IADL: normal *vs* abnormal). Arm A and D receive LV5FU2 or capecitabine, arm B FOLFOX4 or XELOX and arm C is an observation arm. The treatment is planned for 6 months. Adjuvant CT should start within 12 weeks after surgery. Geriatric questionnaires and Lee score must be completed before randomization. Radiological assessment is performed every 6 months for 3 years after randomization and then annually for 2 years. Hypotheses (α two-sided = 5%, power = 80%) are to improve 3-years DFS from 65% (arm A) to 72% (arm B) in group 1 (756 patients required) and from 40% (arm C) to 55% (arm D) in group 2 (226 patients required). Safety is evaluated based on laboratory and clinical tests before each cycle. Exploratory analysis are planned to determine geriatric prognostic factors for DFS. A biological ancillary study is planned to allow prognostic evaluation of mismatch repair status and other molecular signatures. At the 1stof February 2017 the accrual was 246 patients. Clinical trial information: NCT02355379.

TPS3629 **Poster Session (Board #246b), Sat, 8:00 AM-11:30 AM**

NRG-GI002: A phase II clinical trial platform for total neoadjuvant therapy (TNT) in rectal cancer. *First Author: Thomas J. George, NSABP/NRG Oncology, and The University of Florida, Pittsburgh, PA*

Background: Improvements in outcomes for locally advanced rectal cancer (LARC) have plateaued due to an inability to consistently deliver adjuvant therapy (tx) and thus far ineffective novel therapies. Systematic testing of new chemotherapy and radiation sensitizers are needed to advance treatment outcomes. This randomized phase II modular clinical trial platform utilizes Total Neoadjuvant Therapy (TNT) with parallel experimental arms in LARC. The experimental arms are not intended for direct comparison, but to test a variety of sensitizers or hypotheses in a consistent and relatively homogenous high-risk patient (pt) population with correlative biomarkers. Success of any given experimental arm will be determined by achievement of pathologic endpoints compared to a control arm. **Methods:** This NCTN multi-arm randomized phase II trial serves as a modular platform to assess novel sensitizers to neoadjuvant chemotherapy and/or chemoradiotherapy (chemoRT) in LARC. Eligibility includes LARC as defined by any ONE of the following criteria: distal location (cT3-4 $\leq$5cm from the anal verge, any N); bulky (any cT4 or tumor within 3mm of the mesorectal fascia); high risk for metastatic disease (cN2); or not a candidate for sphincter-sparing surgical resection. After randomization, pts receive neoadjuvant FOLFOX x 4mo $\rightarrow$ chemoRT (capecitabine with 50.4Gy) $\rightarrow$ surgical resection 8-12 wks later. Based on promising phase I results, the first experimental arm will assess the activity of veliparib added to standard chemoRT (capecitabine + RT). Primary endpoint is to demonstrate improvement in Neoadjuvant Rectal Cancer (NAR) score for the experimental arm vs control representing 20% relative risk reduction in DFS HR and 3-4% absolute OS improvement. Secondary endpoints include comparisons of OS, DFS, toxicity, pCR, cCR, tx completion, negative surgical margins, sphincter preservation, sphincter function including quality of life, and exploratory assessments of molecular and radiographic predictors of response and distant failure. Target accrual is 79 evaluable pts per arm with additional arms added through rolling protocol amendments. NCT02921256. Support: U10 CA-180868, -20, 21, -22; UG-189867; AbbVie. Clinical trial information: NCT02921256.

TPS3630 Poster Session (Board #247a), Sat, 8:00 AM-11:30 AM

Randomized trial of FOLFOX alone or combined with atezolizumab as adjuvant therapy for patients with stage III colon cancer and deficient DNA mismatch repair or microsatellite instability (ATOMIC, Alliance A021502). *First Author: Frank A. Sinicrope, Mayo Clinic Cancer Center, Rochester, MN*

Background: In metastatic colorectal cancer with deficient DNA mismatch repair (MMR), anti-PD-1 antibody monotherapy produced high tumor response rates and extended progression-free survival compared to lack of benefit for proficient MMR tumors (Le, M, et al, NEJM 2016). We propose a phase III randomized trial to determine if the addition of the anti-PD-L1 antibody, atezolizumab (Genentech™), to adjuvant FOLFOX can improve patient disease-free survival (DFS) vs FOLFOX alone in patients with stage III colon cancers with dMMR or microsatellite instability (MSI). By blocking the PD-1/PD-L1 interaction, atezolizumab may activate T cells, thereby, restoring their ability to detect and attack tumor cells. Limited data suggest that FOLFOX may increase intratumoral cytotoxic CD8+ T cells that may serve as 'immune priming.' **Methods:** Patients with curatively resected stage III colon carcinomas with evidence of dMMR or MSI will be randomized to modified FOLFOX6 for 6 months (12 cycles) alone or combined with atezolizumab (840 mg IV q2 wk) continued as monotherapy for an additional 6 months (total duration of 12 months). Patients will be stratified by T, N stage and tumor sidedness. Local testing for MSI or MMR proteins is allowed. Atezolizumab must begin by/with cycle 2. The targeted accrual goal of 700 patients provides 90% power to detect an effect size expressed as hazard ratio of 0.6 for the primary endpoint DFS at two-sided alpha of 0.05. Interim analyses are planned at 50% and 75% of events. Secondary endpoints include overall survival, treatment tolerability, and quality of life. This study will be conducted by the Alliance for Clinical Trials in Oncology. The protocol has been approved by NCI CTEP and is expected to be activated in mid 2017. Clinical trial information: NCT02912559.

TPS3631 Poster Session (Board #247b), Sat, 8:00 AM-11:30 AM

Transanal versus laparoscopic total mesorectal excision for low rectal cancer: A multicenter randomized phase III clinical trial (TaLaR trial) protocol. *First Author: Shuangling Luo, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Since 1982, Total Mesorectum Excision (TME) was regarded as a golden standard for radical resection of rectal cancer. Current evidences have proved that both open and laparoscopic TME could achieve the comparative oncological safety. However, for low rectal cancer, it remains a challenge to achieve complete TME with safe resections margin by the conventional transabdominal approach, especially in cases such as bulky mesorectum, enlarged prostate, narrow pelvic floor, etc. Transanal TME (TaTME) is a new approach for rectal cancer. Several retrospective studies have showed its advantage of providing better resection quality for low rectal cancer compared with transabdominal approach, but its long-term effect still needs to be explored. **Methods:** TaLaR trial is an open-label multicenter randomized controlled phase III trial with a non-inferiority design, aiming to compare the short and long term effect between TaTME and laparoscopic TME (lapTME) for low rectal cancer. Patients diagnosed with clinical stage no more than T3N0 or ycT3N2 rectal cancer, inferior border of the tumor from anal verge less than 7cm, are eligible for the present study. A total of 1114 patients (557 per group) will be randomized to either TaTME or lapTME. The primary end-points are 3-year disease-free survival (DFS) and 5-year overall survival (OS). The secondary endpoints include resection quality, postoperative morbidity and mortality, pelvic function and quality of life. Clinical trial information: NCT 02966483.

TPS3632 Poster Session (Board #248a), Sat, 8:00 AM-11:30 AM

A randomized phase III trial of capecitabine with or without irinotecan driven by UGT1A1 in neoadjuvant chemoradiation of locally advanced rectal cancer (CinClare). *First Author: Ji Zhu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Irinotecan is an effective drug for rectal cancer. Early small sample size trials have assessed the addition of irinotecan to standard CRT with fluoropyrimidines in neoadjuvant phase of locally advanced rectal cancer, in which pCR rates varied from 13.7 to 37%. ARISTOTLE trial, a multicentre UK-based phase III trial, will complete recruitment in autumn 2016. However, all patients in case group were prescribed with weekly irinotecan dose of 60mg/m^2 guided by UGT1A1*28 6/6 and 6/7 genetypes in neoadjuvant chemoradiation. Therefore, this phase III trial was designed to confirm the potential improvement in outcomes seen with the addition of irinotecan to CRT. **Methods:** Eligible patients are randomly allocated to either radiotherapy 50 Gy with concurrent capecitabine, followed by a cycle of capecitabine and oxaliplatin two weeks after the end of CRT (Control arm) or radiotherapy 50 Gy with concurrent capecitabine and irinotecan, followed by a cycle of capecitabine and irinotecan (Case arm). Capecitabine is prescribed with 825mg/m^2 The primary end point is ypCR. The hypothesis is to increase ypCR from 12% in the control group to 25% in the case group. To detect such a difference, with alpha = 0.05 (two-tailed) and belta = 0.15, 360 randomly assigned patients are required. Secondary end points are toxicities, surgical complications, local control, progression-free survival and overall survival. Clinical trial information: NCT02605265.

TPS3633 Poster Session (Board #248b), Sat, 8:00 AM-11:30 AM

EORTC1527/JCOG1609INT: Diffusion-weighted MRI (DW-MRI) assessment of liver metastasis to improve surgical planning (DREAM). *First Author: Kozo Kataoka, EORTC, Brussels, Belgium*

Background: For patients with initially unresectable colorectal liver metastases (CRLM) with good clinical response to chemotherapy, the presence of disappearing liver metastases (DLMs) diagnosed by CT is a major independent prognostic factor. DW-MRI as well as contrast enhanced (CE)-MRI is recommended to detect and characterize CRLM. However, the correlation between radiological and pathological complete response has not been fully investigated using these latest imaging and pathology techniques. Our main aim is to demonstrate the added value of DW-MRI, CE-MRI to that of CT alone to provide precise assessment of the viability of DLMs. In addition, we aim to optimize the therapeutic management of CRLM patients. No prospective study has been conducted to determine the predictive value of DW-MRI combined with CE-MRI in confirming sites of DLMs and assessing their true status. **Methods:** This is the first collaborative study between EORTC, ESSO and JCOG with an integrated quality assurance program for imaging, surgery and pathology. Patients with unresectable CRLM will receive standard systemic chemotherapy and liver resection if resectable. Both CT and MRI (DW-MRI, CE-MRI and T1/T2) will be used to identify confirmed DLMs (cDLMs). cDLMs will be either resected or, if resection is not possible, followed-up without resection until 2 years after surgery to evaluate the true status of the cDLMs. The primary endpoint is negative predictive value (NPV) of DW-MRI, CE-MRI, T1/T2 and CT in confirming the status of cDLMs using as reference either the histopathological complete response or the absence of a local recurrence at the site of cDLMs during the follow up period of 2 years. The study aims at excluding a NPV$\leq$0.85 and is powered under the alternative that the NPV$\geq$0.95. The planned sample size is 92 evaluable (resected or left behind) cDLMs, with a 1-sided alpha of 5% and a power of 90% adjusting for within-patient correlation between cDLMs of 0.2 and an average number of 2 cDLMs per patient. Approximately 400 patients will be registered from European, Japanese and US sites over 3 years. As of February 2017, 2 patients have been enrolled. Clinical trial information: NCT02781935.

4000 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Second-line tivantinib (ARQ 197) vs placebo in patients (Pts) with MET-high hepatocellular carcinoma (HCC): Results of the METIV-HCC phase III trial. *First Author: Lorenza Rimassa, Humanitas Cancer Center, Humanitas Clinical and Research Center, Rozzano, Italy*

Background: Tivantinib (T), a selective, oral MET inhibitor, improved overall survival (OS) and progression-free survival (PFS) versus placebo (P) in a phase II study in MET-High HCC pts. **Methods:** This randomized, placebo-controlled phase III trial (NCT01755767) enrolled pts with: advanced HCC; Child Pugh A; ECOG PS ≤1; adequate bone marrow, liver, kidney functions; no liver transplant; radiographic disease progression (PD) after or intolerance to sorafenib; tumor MET-High (MET ≥2+ in ≥50% of tumor cells) by centralized immunohistochemistry. Pts were randomly assigned 2:1 to oral T or P, stratified by vascular invasion (VI), extrahepatic spread (ES), AFP (< / > 200ng/mL), treated until PD or unacceptable toxicity. Response (RECIST 1.1) was evaluated by CT / MRI every 8 weeks. Primary endpoint of OS and secondary endpoints including PFS and safety were assessed in the intent-to-treat (ITT) population. **Results:** From Dec 2012 to Dec 2015, 1209 pts were consented in Australia, the Americas, Europe, New Zealand: 589 MET-High, 43 initially randomized at the dose of 240mg BID, then reduced due to high neutropenia rate, 340 randomized at 120mg BID: 226 to T, 114 to P (ITT population). Characteristics of pts were balanced between arms: 306 (90%) male; median age: 67; PS 0: 207 (61%); VI: 117 (34%); ES: 197 (58%); AFP ≤200: 195 (57%); radiographic PD on sorafenib: 275 (81%). Median OS (95% CI) was 8.4 months (m) (6.8-10.0) in T, 9.1 m (7.3-10.4) in P, HR = 0.97 (0.75-1.25), $P = 0.81$. Median PFS (95% CI) was 2.1 m (1.9-3.0) in T, 2.0 m (1.9-3.6) in P, HR = 0.96 (0.75-1.22), $P = 0.72$. No OS difference was seen in pts with VI (HR 1.19, 0.79-1.79), ES (HR 1.09, 0.78-1.52), AFP > 200ng/mL (HR 1.00, 0.71-1.41). Grade (G) > 3 AEs were 55.6% in T, 55.3% in P. In T, most common G > 3 AEs were ascites (7.1%), general deterioration (5.8%), anemia (4.9%); most common serious AE was general deterioration (4.9%). Deaths within 30 days of last dose were 22.1% on T vs 15.8% on P (most common causes: general deterioration 3.5%, hepatic failure 2.6%). **Conclusion:** Tivantinib at the 120mg BID dose did not improve OS or PFS over placebo in patients with advanced MET-High HCC who failed previous treatment with sorafenib. Clinical trial information: NCT01755767.

4001 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase III trial of lenvatinib (LEN) vs sorafenib (SOR) in first-line treatment of patients (pts) with unresectable hepatocellular carcinoma (uHCC). *First Author: Ann-Lii Cheng, National Taiwan University Hospital, Taipei, Taiwan*

Background: SOR is the only approved agent in uHCC and new options are needed. LEN, an inhibitor of vascular endothelial growth factor receptors 1–3, fibroblast growth factor receptors 1–4, platelet derived growth factor receptor α, RET, and KIT, showed activity in uHCC in a phase II trial. We report a phase III trial of LEN vs SOR as first-line therapy for uHCC. **Methods:** In this randomized, open-label, noninferiority (NI) study, pts had uHCC, ≥ 1 measurable target lesion, Barcelona Clinic Liver Cancer stage B or C, Child-Pugh class A, ECOG PS ≤ 1, and no prior systemic therapy. Pts were randomized 1:1 to LEN (body weight ≥ 60 kg: 12 mg/day; < 60 kg: 8 mg/day) or SOR 400 mg twice daily. The primary endpoint was overall survival (OS). The OS hazard ratio (HR) and its 95% CI were estimated with a stratified Cox proportional hazard model. The predefined NI margin was 1.08. Secondary efficacy endpoints were progression-free survival (PFS), time to progression (TTP) and objective response rate (ORR) by modified RECIST. Type I error rates for secondary efficacy endpoints were controlled with a fixed sequence procedure at 2-sided α = 0.05 after OS NI was claimed. **Results:** 954 Pts enrolled (LEN: 478; SOR: 476). Efficacy outcomes are shown in the table. A similar number of pts in both arms had treatment-emergent adverse events (TEAEs). Most common LEN TEAEs were hypertension (42%), diarrhea (39%), decreased appetite (34%), decreased weight (31%), and fatigue (30%). Median (range) treatment duration was 5.7 mos (0−35.0) for LEN and 3.7 mos (0.1−38.7) for SOR. 13% Of LEN-treated and 9% of SOR-treated pts discontinued due to adverse events. 33% Of LEN-treated and 39% of SOR-treated pts received second-line therapy. **Conclusions:** LEN is noninferior in OS, and achieves statistically significant and clinically meaningful improvements in PFS, TTP, and ORR, as first line therapy for uHCC. TEAEs were consistent with the known LEN safety profile. Clinical trial information: NCT01761266.

Outcomes	LEN	SOR	HR
Median OS, mos (95% CI)	13.6 (12.1−14.9)	12.3 (10.4−13.9)	0.92 (0.79−1.06)
Median PFS, mos (95% CI)*	7.4 (6.9−8.8)	3.7 (3.6−4.6)	0.66 (0.57−0.77)
Median TTP, mos (95% CI)*	8.9 (7.4−9.2)	3.7 (3.6−5.4)	0.63 (0.53−0.73)
ORR, n (%)*	115 (24)	44 (9)

4002 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase III multi-centre open-label randomized controlled trial of selective internal radiation therapy (SIRT) versus sorafenib in locally advanced hepatocellular carcinoma: The SIRveNIB study. *First Author: Pierce H. W. Chow, National Cancer Center Singapore, Singapore, Singapore*

Background: The optimal therapeutic regime for locally advanced hepatocellular carcinoma (HCC) with and without vascular invasion remains unclear. This study evaluates the efficacy of Selective Internal Radiation Therapy using SIR-Spheres yttrium-90 microspheres (Y90) versus sorafenib in Asian Barcelona Clinic Liver Cancer (BCLC) stage B and C patients without extra-hepatic metastasis. **Methods:** This investigator-initiated multi-center trial randomized eligible patients with locally advanced inoperable HCC to single injection of Y90 or sorafenib (oral 400mg BD) till progressive disease or unacceptable toxicity. The sample size, assuming type I error (two-sided) of 0.05 and power of 90% was 360 patients. Final analysis was planned at 266 reported deaths. **Results:** 360 patients (182 Y90, 178 sorafenib) were enrolled from 27 centers in 11 Asian countries. BCLC C patients without extra-hepatic metastasis comprised 41.4% of patients, 30.6% had portal vein thrombosis (PVT), 88.6% were Child-Pugh A, 57.2% were hepatitis B and 15.0% were hepatitis C. Altogether 28.6% and 9.0% of patients in the Y90 and sorafenib arms respectively failed to receive planned therapy. Intention-to-treat analysis was carried out with the overall survival (OS) in the Y90 and sorafenib arms being 8.54 and 10.58 months respectively (Hazard ratio (HR) 1.17, p =0.203). Tumour response rate (TRR) was 16.5% and 1.7% ($p < 0.001$) respectively. Time-to-tumor -progression (TTP) was 5.88 vs 5.36 (overall) (HR 0.93) and 6.08 vs 5.39 (liver-specific) (HR 0.91) months for Y90 and sorafenib respectively. Progression-free-survival (PFS) was 5.29 vs 5.06 (overall) (HR 0.94) and 5.85 vs 5.06 (liver-specific) (HR 0.92) months respectively. At least one severe adverse event was found in 27.7% and 50.6% of patients in the Y90 and sorafenib arms respectively. **Conclusions:** Asian patients with locally advanced HCC without extra-hepatic metastasis treated with Y90 have statistically significant better TRR, and fewer SAEs when compared with those treated with sorafenib. There were no statistically significant differences in OS between Y90 and sorafenib. Clinical trial information: NCT01135056.

4003 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

KEYNOTE-059 cohort 1: Efficacy and safety of pembrolizumab (pembro) monotherapy in patients with previously treated advanced gastric cancer. *First Author: Charles S. Fuchs, Yale Cancer Center, New Haven, CT*

Background: Pembro has shown promising antitumor activity and manageable safety in a phase 1 study of pts with previously treated advanced gastric cancer. We conducted a global, multicohort, phase 2 study of pembro in pts with advanced gastric or gastroesophageal junction (G/GEJ) cancer (KEYNOTE-059;NCT02335411). **Methods:** Cohort 1 enrolled 259 pts, aged ≥18 y with measurable recurrent or metastatic G/GEJ adenocarcinoma who had progressed on ≥2 prior chemotherapy regimens and had ECOG PS 0-1. Pts received pembro 200 mg Q3W up to 2 y or up to disease progression, investigator/pt decision to withdrawal, or unacceptable toxicity. PD-L1$^+$pts had expression in ≥1% tumor or stromal cells using IHC (22C3 antibody). Primary end points: ORR (RECIST 1.1, by central review), safety, and tolerability. **Results:** Of 259 pts in cohort 1, 76.4% were men; median age was 62.0 y. 51.7% and 48.3% received pembro as 3rd-line (3L) and 4L+ therapy, respectively. 57.1% had PD-L1$^+$ tumors. At data cutoff (Oct 19, 2016), median duration of follow-up was 5.4 mo (range, 0.5 to 18.7). Overall ORR (CR + PR) was 11.2% (95% CI, 7.6-15.7); 1.9% of pts (95% CI, 0.6-4.4) had CR, 9.3% had PR (95% CI, 6.0-13.5), 17% (95% CI, 12.6-22.1) had SD, and 55.6% (95% CI, 49.3-61.7) had PD. Median DOR was 8.1 mo (range, 1.4+ to 15.1+). ORR was 14.9% (95% CI, 9.4-22.1) in 3L pts and 7.2% (95% CI, 3.3-13.2) in 4L+. In PD-L1$^+$ pts, ORR was 15.5% (95% CI, 10.1-22.4) with 2.0% (95% CI, 0.4-5.8) CR and 13.5% (95% CI, 8.5-20.1) PR; in PD-L1$^-$ pts, ORR was 5.5% (95% CI, 2.0-11.6), with 1.8% (95% CI, 0.2-6.5) CR and 3.7% (95% CI, 1.0-9.1) PR. In 3L pts with PD-L1$^+$ tumors, ORR was 21.3% (95% CI, 12.7-32.3), with 4.0% (95% CI, 0.8-11.2) CR; in 3L pts with PD-L1$^-$ tumors, ORR was 6.9% (95% CI, 1.9-16.7), with 3.4% (95% CI, 0.4-11.9) CR. Grade 3-5 treatment-related AEs (TRAEs) occurred in 43 pts (16.6%). TRAEs led to discontinuation in 2 pts (abnormal LFT, bile duct stenosis) and were fatal in 2 pts (acute kidney injury, pleural effusion). **Conclusions:** Pembro showed encouraging efficacy and manageable safety after ≥2 prior lines of therapy in pts with advanced G/GEJ cancer in this large phase 2 trial. Survival and additional biomarker data, including MSI status, will be presented. Clinical trial information: NCT02335411.

4004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Perioperative chemotherapy with docetaxel, oxaliplatin, and fluorouracil/leucovorin (FLOT) versus epirubicin, cisplatin, and fluorouracil or capecitabine (ECF/ECX) for resectable gastric or gastroesophageal junction (GEJ) adenocarcinoma (FLOT4-AIO): A multicenter, randomized phase 3 trial. *First Author: Salah-Eddin Al-Batran, Institute of Clinical Cancer Research (IKF) at Krankenhaus Nordwest, UCT-University Cancer Center, Frankfurt, Germany*

Background: The MAGIC trial established perioperative (periop) epirubicin, cisplatin, and 5-FU (ECF) as a standard treatment for patients (pts) with operable esophagogastric cancer, but survival continues to remain poor. FLOT4 (NCT01216644) is a multicenter, randomized, investigator-initiated, phase 3 trial. It compares the docetaxel-based triplet FLOT with the anthracycline-based triplet ECF/ECX as a periop treatment for pts with resectable gastric or GEJ adenocarcinoma. **Methods:** Eligible pts of stage ≥cT2 and/or cN+ were randomized to either 3 preoperative and 3 post-operative 3-week cycles of ECF/ECX (epirubicin 50 mg/m2, cisplatin 60 mg/m², both d1, and 5-FU 200 mg/m² as continuous infusion or capecitabine 1250 mg/m2 orally d1-21) or 4 pre-operative and 4 post-operative 2-week cycles of FLOT (docetaxel 50 mg/m2, oxaliplatin 85 mg/m², leucovorin 200 mg/m², and 5-FU 2600 mg/m² as 24-hour infusion, all d1). The primary endpoint was overall survival (OS; 80% power; HR of 0.76; 2-sided log-rank test at 5% type I error). **Results:** Between Aug 2010 and Feb 2015, 716 pts (360 ECF/ECX; 356 FLOT) were randomly allocated. Baseline characteristics were similar between arms (overall, male 74%; median age 62; cT3/T4 81%; cN+ 80%; GEJ 56%). 91% and 37% of pts with ECF/ECX and 90% and 50% with FLOT completed planned pre-operative and post-operative cycles, respectively. Median follow-up was 43 mon. 369 pts died (203 ECF/ECX; 166 FLOT). FLOT improved OS (mOS, 35 mon with ECX/ECF vs. 50 mon with FLOT; HR 0.77 [0.63 - 0.94]; p = 0.012). 3y OS rate was 48% with ECF/ECX and 57% with FLOT. FLOT also improved PFS (mPFS, 18 mon with ECX/ECF vs. 30 mon with FLOT; HR 0.75 [0.62 - 0.91]; p = 0.004). Periop complications were 50% with ECF/ECX and 51% with FLOT. 30- and 90-day mortality was 3% and 8% with ECF/ECX and 2% and 5% with FLOT. There was more G3/4 nausea and vomiting with ECF/ECX and more G3/4 neutropenia with FLOT. **Conclusion:** Periop FLOT improved outcome in patients with resectable gastric and GEJ cancer compared to periop ECF/ECX. Clinical trial information: NCT01216644.

4006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Adjuvant capecitabine for biliary tract cancer: The BILCAP randomized study. *First Author: John Neil Primrose, University of Southampton, Southampton, United Kingdom*

Background: Despite improvements in multidisciplinary management, BTC has a poor outcome. Approximately 20% of cases are suitable for surgical resection with a 5 year survival of < 10%. BILCAP aimed to determine whether capecitabine (Cape) improves overall survival (OS) compared to observation (Obs) following radical surgery. **Methods:** Patients with completely-resected cholangiocarcinoma (CCA) or gallbladder cancer (including liver and pancreatic resection, as appropriate), with adequate biliary drainage, no ongoing infection, adequate renal, haematological and liver function, and ECOG PS ≤2, were randomized 1:1 to Cape (1250 mg/m^2 D1-14 every 21 days, for 8 cycles) or Obs. Randomization was minimized on tumor site, resection status, ECOG PS and surgical center. The primary outcome was OS in the intention to treat (ITT) population. 410 patients were needed to detect a hazard ratio (HR) of 0.69 (2-sided $\alpha = 0.05$ and 80% power). HR was estimated by Cox survival model with adjustment for the minimization factors. Primary analysis performed with at least 24 months (m) follow-up. **Results:** 447 participants were randomized to Cape (n = 223) or Obs (n = 224) from 44 UK sites between 2006-2014. Median age was 63y (IQR 55, 69) and 201 (45%), 232 (52%), and 14 (3%) patients were ECOG PS 0, 1 and 2 respectively. Primary site: 84 (19%) intrahepatic, 128 (28%) hilar, 156 (35%) extrahepatic CCA and 79 (18%) muscle-invasive gallbladder cancers. Resection margins: R0 in 279 (62%) and R1 in 168 (38%); 207 (46%) were node-negative. Follow up was at least 36m in > 80% of surviving patients. By ITT analysis (n = 447), median OS was 51m (95%CI 35, 59) for Cape and 36m (95%CI 30, 45) for Obs, HR 0.80 (95% CI 0.63, 1.04; p = 0.097). Sensitivity analyses with adjustment for nodal status, grade of disease and gender indicated HR 0.71 (95%CI 0.55, 0.92 p < 0.01). In the per-protocol analysis (Cape n = 210, Obs n = 220) median OS was 53m (95%CI 40, NR) for Cape and 36m (95%CI 30, 44) for Obs, HR 0.75 (95%CI 0.58, 0.97; p = 0.028). Median RFS (ITT) was 25m (95%CI 19, 37) for Cape and 18m (95%CI 13, 28) for Obs. Grade 3-4 toxicity was less than anticipated. **Conclusions:** Cape improves OS in BTC when used as adjuvant and should become standard of care. Clinical trial information: ISRCTN72785446.

4007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Results of the randomized phase II portion of NRG Oncology/RTOG 0848 evaluating the addition of erlotinib to adjuvant gemcitabine for patients with resected pancreatic head adenocarcinoma. *First Author: Howard Safran, Rhode Island Hospital, Providence, RI*

Background: NRG/RTOG 0848 is a 2-step study designed to determine whether erlotinib (E) added to gemcitabine (G) (randomized Ph II) &/or adjuvant radiation with concurrent 5-FU or capecitabine following 6 months of systemic chemotherapy (Ph III), improve survival in patients (pts) with resected pancreatic head adenocarcinoma. The erlotinib results are reported here. **Methods:** Eligible pts include those with resected pancreatic head adenocarcinoma, pathologic stage T1-T3, N0-1, M0; PS 0-1, & CA19-9 ≤ 180 IU/L. Pts in Arms 1 & 2 received G 1 gm/m^2 weekly for 3 weeks in a 28-day cycle for 6 cycles. Pts in Arm 2 also received E 100 mg/day. The primary hypothesis for the E portion was that G+E would increase overall survival (OS) compared to G alone. With a 1-sided alpha of 0.15, 200 OS events provide 80%/90% power to detect a signal for an increase in median OS from 22 to 28.8/30.6 months (mos). OS was estimated by the Kaplan-Meier method & arms compared using the log rank test. The Cox proportional hazards model was used to analyze treatment effect. **Results:** 336 pts were randomized from 11/17/2009 to 2/28/2014, with 163 pts evaluable for G and 159 for G+E. Median age was 63 years (39-86). Most pts had pathologic T3 disease (78%) & CA19-9 ≤ 90 (93%). There are 32 pts (20%) with grade 4 adverse events (AEs) & 2 pts (1%) with grade 5 AEs on G and 27 (17%) & 3 (2%) on G+E arm, respectively. There are fewer grade ≥ 3 GI AEs on the G arm (22%) as compared to the G+E arm (28%), and 110 (69.2%) & 93 (59.6%) pts received at least 85% of planned G dose for the G & G+E arms, respectively. 58% of E pts received at least 85% of planned E dose. The median follow-up for alive pts is 42.5 mos (min-max: < 1-75). With 203 deaths, median & 3-yr OS (95% CI) are 29.9 mos (21.7-33.4) & 39% (30, 45) for G and 28.1 mos (20.7-30.9) & 39% (31, 47) for G+E; log-rank p = 0.62. The hazard ratio (95% CI) comparing OS of G+E to G is 1.04 (0.79- 1.38). **Conclusions:** The addition of adjuvant E to G did not provide a signal for increased OS in pts with resected pancreatic head cancer compared to G alone. Accrual to the trial is continuing to answer the Ph III radiation question. Clinical trial information: NCT01013649.

4008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Randomized phase II study of PEGPH20 plus nab-paclitaxel/gemcitabine (PAG) vs AG in patients (Pts) with untreated, metastatic pancreatic ductal adenocarcinoma (mPDA). *First Author: Sunil R. Hingorani, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Hyaluronan (HA) accumulation in the tumor microenvironment produces elevated tumor pressure, vascular compression, and reduced drug delivery. PEGPH20 degrades HA, increasing the access and therapeutic index of anticancer agents. **Methods:** In Stage 1 of this phase II study, pts with untreated mPDA were randomized 1:1 to PAG (P; 3 μg/kg IV 2x/wk x 3 wks in C1, then 1x/wk x 3 wks in C2+, plus AG) vs AG every 28 days. An imbalance in thromboembolic (TE) events in the PAG arm led to a clinical hold (~40% of pts discontinued PEGPH20), exclusion of pts at high risk for TE events and enoxaparin prophylaxis in both study arms. In Stage 2, randomization was 2:1 to PAG vs AG. Tumor HA was tested using a novel assay (VENTANA HA RxDx). Primary endpoints were PFS (evaluable pts) and TE event rate (Stage 2). Secondary endpoints were PFS by HA level and ORR. **Results:** 279 pts were randomized; 231 are evaluable for efficacy. Of 246 pts with HA data, 84 (34%) were HA-High. As of December 16, 2016, the primary PFS endpoint was statistically significant for PAG vs AG (HR 0.73, 95% CI 0.53-1.00; p = 0.048) (Table). PFS in HA-High pts was also statistically significant in the PAG vs AG arm (HR 0.51; 95% CI 0.26-1.00; p = 0.048). ORR in HA-High pts was 46% (PAG) vs 34% (AG). Overall survival in HA-High pts (exploratory) was 11.5 months (mo) (PAG) and 8.5 mo (AG) (HR 0.96, 95% CI 0.57-1.61). TE events were similar (PAG 14% vs AG 10%) following enoxaparin initiation. All grade treatment-related AE included peripheral edema (PAG 63% vs AG 26%), muscle spasms (56% vs 3%), neutropenia (34% vs 19%), and myalgia (26% vs 7%). **Conclusions:** Randomized Phase II study met both primary endpoints (PFS and TE event rate), with the largest improvement in the secondary endpoint of PFS in HA-High pts. These data support HA as a potential predictive biomarker for patient selection of PEGPH20, currently investigated in the ongoing global Phase III HALO 301 study with PFS and OS as co-primary endpoints. Clinical trial information: NCT01839487.

	Events/Total, n Median PFS, months		HR	
Population	PAG	AG	(95% CI)	P value
Efficacy Evaluable (n = 231)	100/139; 6.0	65/92; 5.3	0.73 (0.53, 1.00)	0.048
HA-High (n = 84)	24/49; 9.2	19/35; 5.2	0.51 (0.26-1.00)	0.048

A randomized phase II pilot study prospectively evaluating treatment for patients based on ERCC1 for advanced/ metastatic esophageal, gastric, or gastroesophageal junction cancer: SWOG S1201. *First Author: Syma Iqbal, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Platinum based treatment (tx) is standard in HER2 negative patients (pts) with advanced esophagogastric cancer (AEGC). Retrospective data suggest intratumoral ERCC1 levels may determine platinum sensitivity. A randomized phase II study was performed in pts with AEGC to explore whether the efficacy of a platinum 5-FU/LV/Oxaliplatin (FOLFOX) vs. non-platinum containing regimen irinotecan/taxotere (IT) differed according to ERCC1 levels. **Methods:** 203 untreated pts with AEGC, Her2 -, Zubrod PS 0-1, were randomized to FOLFOX vs. IT, stratified by intratumoral ERCC1 low (<1.7) vs. high (≥1.7). Objectives were to assess PFS and OS in all pts treated with FOLFOX compared with IT, and in those pts with low and high ERCC1 levels and to assess for interactive effects between ERCC1 expression and tx arm. **Results:** 86% of pts had ERCC1 values <1.7. Thus, evaluation of ERCC1 pts in the high subgroup was not feasible. Tx groups were well matched by age, sex, race, ERCC1 level, and site. A series of K-M plots were used to explore whether tx arm differences in PFS varied based on ERCC1 levels; little evidence of such was noted. Grade ≥ 3 anemia, dehydration, diarrhea and fatigue were greater in pts with IT. Grade ≥ 3 neuropathy and decreased neutrophils were greater in pts with FOLFOX. **Conclusions:** In all pts, FOLFOX had a statistically superior PFS and RR, when compared with IT. In pts with ERCC1 <1.7 receiving FOLFOX, PFS and RR was statistically superior, with no difference in OS. There was no significant evidence of differential treatment effect on PFS across ERCC1 levels. Clinical trial information: NCT01498289.

All Patients	FOLFOX (n=99)	IT (n=104)	
ERCC1 <1.7	87%	86%	
ERCC1 ≥1.7	13%	14%	
mPFS	5.7 mos (95% CI 4.4-7.1)	2.9 mos (95% CI 1.9-4.1)	HR 0.70 (95% CI 0.52-0.93, p=0.01)
mOS	11.4 mos (95% CI 9.9-13.3)	8.7 months (95% CI 6.2-10.0)	HR 0.82 (95% CI 0.61-1.10, p=0.19)
RR	33/80 (41%, 95% CI 30-52%)	23/86 (27%, 95% CI 17-36%)	p=0.05
ERCC1<1.7	n=86	n=89

ABSOLUTE: A phase 3 trial of nanoparticle albumin-bound paclitaxel (*nab*-PTX) versus solvent-based paclitaxel (*sb*-PTX) in patients with pre-treated advanced gastric cancer (AGC)—Efficacy and QOL results. *First Author: Keisuke Koeda, Department of Surgery, Iwate Medical University School of Medicine, Morioka, Japan*

Background: *Sb*-PTX is a standard second-line treatment for patients (pts) with AGC. *Nab*-PTX was developed to avoid the toxicities with use of solvents in *sb*-PTX and potentially improve efficacy. Based on ABSOLUTE trial, we conducted the additional analysis to evaluate the efficacy and QOL of *nab*-PTX and *sb*-PTX. **Methods:** Pts who were refractory to a fluoropyrimidine-containing first-line treatment were randomly assigned (1:1:1) to receive intravenous q3w *nab*-PTX (260 mg/m^2) on day 1 of a 21-day cycle, and q1w *nab*-PTX (100 mg/m^2) or q1w *sb*-PTX (80 mg/m^2) on days 1, 8, and 15 of a 28-day cycle. The primary objective was to evaluate whether q3w *nab*-PTX and q1w *nab*-PTX were non-inferior to q1w *sb*-PTX in terms of overall survival (OS). Tumor shrinkage at 8 weeks and at the time of the best response were also investigated. For the QOL analysis, EQ-5D score were collected at baseline and every 8 weeks during the first 24 weeks, and thereafter at every 24 weeks. Time to deterioration of EQ-5D score was compared between each arm as a minimally important difference of 0.05. **Results:** 741 pts were randomly assigned to q3w *nab*-PTX, q1w *nab*-PTX, or q1w *sb*-PTX. Median OS (months) were 10.3, 11.1, and 10.9, respectively. Q1w *nab*-PTX was non-inferior to q1w *sb*-PTX (hazard ratio 0.97, 97.5% CI 0.76-1.23; non-inferiority one-sided p = 0.0085), whereas q3w *nab*-PTX was not non-inferior to q1w *sb*-PTX (1.06, 95% CI 0.87-1.31; non-inferiority one-sided p = 0.062).The response rate of target lesions at 8 weeks and at the time of the best response (%) were 22.1 and 27.7 for q3w *nab*-PTX, 28.2 and 34.9 for q1w *nab*-PTX, and 18.0 and 25.6 for q1w *sb*-PTX. Median time to deterioration of EQ-5D score (months) were 2.1 in q3w *nab*-PTX, 3.8 in q1w *nab*-PTX, and 3.7 in q1w *sb*-PTX. **Conclusions:** Q1w *nab*-PTX was non-inferior to q1w *sb*-PTX in terms of OS. In addition, q1w *nab*-PTX showed favorable effect in comparison with q1w *sb*-PTX in terms of response rate of target lesions and time at best response. QOL was similar between q1w *nab*-PTX and q1w *sb*-PTX. These results suggest that q1w *nab*-PTX is a useful second-line treatment for pts with AGC. Clinical trial information: 132059.

4011 Poster Discussion Session; Displayed in Poster Session (Board #3), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Cisplatin/5-FU (CF) +/- panitumumab (P) for patients (pts) with non-resectable, advanced, or metastatic esophageal squamous cell cancer (ESCC): An open-label, randomized AIO/TTD/BDGO/EORTC phase III trial (POWER). *First Author: Markus H. Moehler, University Medical Center Mainz, Mainz, Germany*

Background: Most ESCC pts have advanced disease at time of diagnosis. Chemotherapy (CTX) is used to improve quality of life (QoL) and overall survival (OS), but still with limited impact. Prior studies suggested increased efficacy of EGFR antibodies (AB) combined with CF (Lorenzen, *Ann Oncol* 2009). **Methods:** This open-label, randomized (1:1), multicenter, multinational phase III included pts with non-resectable, advanced or metastatic ESCC (RECIST1.1), not radiochemotherapy (RCTX) eligible and ECOG 0-1. Previous CTX in metastatic setting, concurrent RCTX and exposure to EGFR-AB were excluded. Pts received CF (C 100 mg/m² d1 + F 1000 mg/m²/d, d1-4) or CFP (9 mg/kg d1) q3 weeks until disease progression. Due to more Gr3-4 SAEs in the first 60 Pts with CFP, C was reduced to 80mg/m²d1 Tumor assessment was performed q9 weeks. Primary objective was OS: superiority of CFP (9 months [mo]) over CF (6 mo) with 300 pts (90% power). **Results:** Between 6.2012-5.2015, 146/155 pts were randomized. After interim analysis for futility, the trial was stopped. 60(83%) of CFP and 55 (79%) of CF pts had any AE, mostly diarrhea, hypokalemia, hypomagnesaemia, rash, and hand-foot syndrome. Main Gr≥3 AEs were low neutrophils 21/ 24% and anemia 13/16 % for CFP vs CF, respectively. Gr 3-4 skin reactions and rash were higher in CFP (10%) vs CF (0%). Overall, 51/72 (71%) of CFP and 36/70 (51%) of CF had SAE. Main SAE were dysphagia, acute kidney injury, diarrhea, fevers and febrile neutropenia in 6/6%, 7/4%, 7/3%, 3/6% and 6/1% for CFP vs CF, respectively. For all CFP vs CF pts, median OS was 9.4 vs. 10.2 mo (hazard ratio (HR) 1.17, 95%CI 0.79-1.75; P=0.43). For 56 pts treated with cisplatin 100mg/m²d1, OS was 9.4 vs. 12.9 mo (HR 1.83, 95 % CI 0.98-3.42; P=0.06). After C was reduced (80mg/m²), OS (85 pts) favored CFP vs CF, with 9.8 vs. 8.3 mo (HR 0.84, 95%CI 0.49-1.43; P=0.51). Median PFS for all CFP vs CF pts, was 5.3 vs. 5.8 mo. (HR 1.21, 95%CI 0.85-1.73; P=0.29) respectively. **Conclusions:** Addition of Panitumumab to CF provided no additional benefit to chemotherapy alone as first-line treatment of ESCC. Biomarker program is going on for further analyses. Clinical trial information: NCT1627379.

4012 Poster Discussion Session; Displayed in Poster Session (Board #4), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

KEYNOTE-059 cohort 2: Safety and efficacy of pembrolizumab (pembro) plus 5-fluorouracil (5-FU) and cisplatin for first-line (1L) treatment of advanced gastric cancer. *First Author: Yung-Jue Bang, Seoul National University Hospital, Seoul, Republic of Korea*

Background: Preliminary analyses from the global, multicohort, phase 2 KEYNOTE-059 (NCT02335411) study suggested that safety of pembro + 5-FU + cisplatin is manageable as 1L therapy in pts with advanced gastric or gastroesophageal junction (G/GEJ) cancer (cohort 2). We present efficacy and updated safety data from KEYNOTE-059 cohort 2. **Methods:** Cohort 2 enrolled pts ≥18 y with HER2$^-$ recurrent or metastatic G/GEJ adenocarcinoma, measurable disease, no prior therapy for metastatic/advanced disease, and ECOG PS 0-1. Pts received pembro 200 mg on day 1 of each 21-day cycle + cisplatin 80 mg/m^2 for 6 cycles + 5-FU 800 mg/m^2 (or capecitabine 1000 mg/m^2 in Japan) Q3W for up to 2 y or until disease progression, investigator/pt decision to withdrawal, or unacceptable toxicity. PD-L1$^+$pts had expression in ≥1% tumor or stromal cells using IHC (22C3 antibody). End points were safety and tolerability (primary), ORR (RECIST v1.1, by central review), DOR, PFS, and OS (secondary). **Results:** Of 25 enrolled pts, 64% were men, 68% were Asian, and 64% had PD-L1$^+$ tumors. Median age was 64 y. At data cutoff (Oct 19, 2016), median duration of follow-up was 12.2 mo (range, 1.8 to 19.6) and 84% of pts had discontinued treatment, mainly owing to clinical or radiologic disease progression (64%). ORR (CR + PR) was 60% (95% CI, 38.7-78.9) in all pts. Overall, 32% of pts had SD (95% CI, 14.9-53.5), 4% had PD (95% CI, 0.1-20.4), and 4% were not evaluable (95% CI, 0.1-20.4). ORR was 68.8% (95% CI, 41.3-89.0) in PD-L1$^+$ pts and 37.5% (95% CI, 8.5-75.5) in PD-L1$^-$ pts. Median DOR (range) was 4.6 mo (2.6 to 14.4+) in all pts, 4.6 mo (3.2 to 14.4+) in PD-L1$^+$ pts, and 5.4 mo (2.8 to 8.3+) in PD-L1$^-$pts. Median PFS was 6.6 mo (95% CI, 5.9-10.6); median OS was 13.8 mo (95% CI, 7.3-not estimable). Grade 3-4 treatment-related adverse events (TRAEs) occurred in 76% of pts. TRAEs led to discontinuation in 3 pts (grade 3 stomatitis, grade 2 hypoacusis, and grade 1 creatinine increase). No TRAEs were fatal. **Conclusions:** Pembro + 5-FU + cisplatin showed manageable safety and encouraging antitumor activity as 1L therapy for pts with advanced G/GEJ cancer. Further exploration of pembro + 5-FU + cisplatin in this setting is warranted. Clinical trial information: NCT02335411.

Nivolumab (nivo) in sorafenib (sor)-naive and -experienced pts with advanced hepatocellular carcinoma (HCC): CheckMate 040 study. *First Author: Todd S. Crocenzi, Providence Cancer Center, Portland, OR*

Background: Many pts with advanced HCC progress on SOC therapy. Nivo is a fully human anti–PD-1 IgG4 mAb that demonstrated durable responses (20% ORR with a median DOR of 9.9 mo; 9-mo OS rate was 74%) in pts with advanced HCC in the dose-expansion (EXP) phase of the CheckMate 040 study (NCT01658878; Melero et al. 2017). Here we present survival and durability of response data in both sor-naive and -experienced pts with advanced HCC in CheckMate 040. **Methods:** Pts naive to or previously treated with sor received nivo in phase 1/2 dose-escalation (ESC; 0.1–10 mg/kg) and -EXP (3 mg/kg) cohorts Q2W regardless of PD-L1 status. Primary endpoints were safety/tolerability (ESC) and ORR (EXP; ORR by investigator [INV] and blinded independent central review [BICR]) using RECIST v1.1. Secondary endpoints included DOR, DCR, and OS. Biomarkers were assessed using pre-treatment tumor samples. **Results:** Overall, pts (N=262) had a median follow-up of 12.9 mo, and 98% had Child-Pugh scores 5–6. In sor-naive pts (n=80), the ORR (INV) was 23%, with 44% of responses (8/18) ongoing (Table). The DCR was 63%; 40% of pts had stable disease ≥6 mo. In sor-experienced pts (n=182; 91% progressed on sor), the ORRs (INV) were 16%–19%. Overall, responses occurred regardless of etiology or tumor cell PD-L1 expression. Nivo had a manageable safety profile consistent with that reported in other tumor types. Updated data with additional 4 mo of follow-up will be presented. **Conclusions:** Nivo demonstrated durable responses with long-term survival and favorable safety in both sor-naive and -experienced pts with advanced HCC. Clinical trial information: NCT01658878.

4014 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Nivolumab ± ipilimumab in pts with advanced (adv)/metastatic chemotherapy-refractory (CTx-R) gastric (G), esophageal (E), or gastroesophageal junction (GEJ) cancer: CheckMate 032 study. *First Author: Yelena Yuriy Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the phase 3 ONO-12 study, 3rd- or later-line nivolumab (N) monotherapy prolonged OS vs placebo in Asian pts with adv G/GEJ cancer (median OS, 5.3 vs 4.1 mo; HR, 0.63; $P < 0.0001$; ASCO-GI 2017, Kang YK et al. *J Clin Oncol.* 2017;35 (suppl 4S) [abstract 2]). The phase 1/2 CheckMate 032 study showed favorable clinical activity of N ± ipilimumab (I) in Western pts with adv CTx-R G/E/GEJ cancer (NCT01928394). We report updated long-term follow-up data of G/E/GEJ pts in CheckMate 032. **Methods:** Pts received N 3 mg/kg Q2W (N3), N 1 mg/kg + I 3 mg/kg Q3W (N1+I3), or N 3 mg/kg + I 1 mg/kg Q3W (N3+I1). Primary endpoint was ORR. Secondary endpoints included DOR, OS, PFS, and safety. Efficacy in pts by PD-L1 status was assessed. **Results:** 160 heavily pretreated pts (79% had ≥ 2 prior Tx) were enrolled (N3, n = 59; N1+I3, n = 49; N3+I1, n = 52); 24% had PD-L1$^+$ (≥ 1%) tumors. ORR was 12% in N3, 24% in N1+I3, and 8% in N3+I1. In pts with PD-L1 ≥ 1%, ORR was 19% (3/16) in N3, 40% (4/10) in N1+I3, and 23% (3/13) in N3+I1; in pts with PD-L1 < 1%, ORR was 12% (3/26), 22% (7/32), and 0% (0/30), respectively. Median DOR was 7.1 mo in N3, 7.9 mo in N1+I3, and NA in N3+I1. OS in all pts and in pts with PD-L1 ≥ 1% is in the Table. Grade 3–4 treatment-related AEs reported in ≥ 10% of pts in any treatment arm were diarrhea (N3, 2%; N1+I3, 14%; N3+I1, 2%), ALT increased (N3, 3%; N1+I3, 14%; N3+I1, 4%), and AST increased (N3, 5%; N1+I3, 10%; N3+I1, 2%). **Conclusions:** N ± I led to durable responses and long-term OS in heavily pretreated Western pts with adv G/E/GEJ cancer, which is consistent with the clinical activity observed in Asian pts in the ONO-12 study. Safety was consistent with prior reports. These data support ongoing investigation of N ± I in pts with adv G/E/GEJ cancer. Clinical trial information: NCT01928394.

OS in all pts and pts with PD-L1 ≥ 1%.

Phase I study of AG-120, an IDH1 mutant enzyme inhibitor: Results from the cholangiocarcinoma dose escalation and expansion cohorts. *First Author: Maeve Aine Lowery, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: Mutations in the metabolic enzyme isocitrate dehydrogenase 1 (mIDH1) occur in patients (pts) with cholangiocarcinoma (CC) and are detected in up to 25% of intrahepatic CC. mIDH1 produce the oncometabolite, D-2-hydroxyglutarate (2-HG), resulting in epigenetic and genetic dysregulation and oncogenesis. AG-120 is a first-in-class, potent, oral inhibitor of mIDH1 tested in this phase I study in mIDH1 solid tumors, including CC. **Methods:** AG-120 was escalated in a 3+3 design from 100 mg twice daily to 1200 mg once daily (QD) in 28-day cycles (N = 60, mIDH1 advanced solid tumors). Key eligibility for CC: recurrence of progressive mIDH1 CC following standard therapy (dose escalation) or at least a prior gemcitabine-based regimen (expansion cohort). Response (RECIST 1.1) was assessed every 8 weeks. Plasma and tumor tissue were collected for exploratory analyses. **Results:** Based on the safety, pharmacokinetic, and pharmacodynamic data from dose escalation, the 500 mg QD dose was selected for expansion in mIDH1 CC and other mIDH1 solid tumors. As of Dec 16, 2016, 73 pts with mIDH1 CC had been dosed in the dose escalation (n = 24) and expansion (n = 49) cohorts. Demographics: M/F = 24/49, median number of prior therapies = 2 (range 1–5), ECOG 0–1 = 26/47. There were no dose-limiting toxicities. Treatment-related adverse events (AEs) in ≥5% pts: fatigue (21%), nausea (18%), vomiting (12%), diarrhea (10%), decreased appetite (8%), dysgeusia (5%), QT prolongation (5%). Two (3%) pts experienced related grade 3 AEs: fatigue and low phosphorus. There were no AG-120-related AEs leading to discontinuation. Among the 72 efficacy evaluable (≥1 post baseline response assessment or discontinued prematurely) mIDH1 CC pts (24 in escalation and 48 in expansion cohort), 6% (n = 4) had a confirmed partial response and 56% (n = 40) experienced stable disease. The progression-free survival rate at 6 months was 40%, and 8 pts have been treated with AG-120 for ≥1 year. **Conclusions:** In this pretreated mIDH1 CC population, AG-120 was associated with a favorable safety profile and prolonged stable disease. A global, phase III, randomized, placebo-controlled study of AG-120 in mIDH1 CC has been initiated (ClarIDHy). Clinical trial information: NCT02073994.

SWOG S1310: Randomized phase II trial of single agent MEK inhibitor trametinib vs. 5-fluorouracil or capecitabine in refractory advanced biliary cancer. *First Author: Richard D. Kim, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: No standard treatment options are available for patients with advanced BC who fail gemcitabine/platinum therapy. The rationale for evaluation of trametinib was based on the presence of MAPK alterations and on earlier promising results with other MEK inhibitors in BC. **Methods:** Pts with histologically proven BC who progressed on gemcitabine/platinum were randomized to trametinib (2mg qd) (Arm A) vs infusional 5FU at 2400 mg/m2 over 46 hours or capecitabine (1000 mg/m^{2}PO days 1-14 BID) (Arm B). Patients were stratified by planned chemotherapy 5FU/LV vs capecitabine; and disease site: cholangiocarcinoma vs gallbladder. The primary endpoint was overall survival (OS). Secondary endpoints included progression-free survival (PFS) and response rate (RR). 80 eligible patients (40 for each arm) were needed to detect an improvement in median OS from 5 months to 8.25 months (1.65 HR). A planned interim futility analysis of objective response was performed on the first 14 pts registered to the trametinib arm. **Results:** The study was stopped early based on the lack of measurable response in the trametinib arm. 53 pts were randomized (27 pts in Arm A vs 26 pts in Arm B). Median age was 62 years and the primary sites of tumor were cholangiocarcinoma (77%) and gallbladder (23%). Median OS was 4.3 months (95% CI 3.1-5.1) for Arm A, and 8.0 months (95% CI 3.2-14.6) for Arm B with a HR of 2.02 (95% CI 1.01-4.03, p=0.05). The median PFS was 1.3 months (95% CI 1.2-1.5) for arm A and 2.8 months (95% CI 1.4-6.9) for arm B with a HR of 2.95 (95% CI 1.38-6.30, p=0.01). Overall RR was 8% (95% CI 0%, 19%) in Arm A vs 10% (95% CI 0%, 23%) in Arm B (p>0.99), and 8% vs 45% had stable disease. Eight pts in Arm A experienced treatment-related ≥ grade 3 toxicities, including one death due to vomiting/dehydration. Seven pts in Arm B experienced treatment-related grade 3 toxicities; no higher grade toxicities were reported. **Conclusions:** To our knowledge, this is the first prospective randomized study of a targeted agent versus chemotherapy for the second line treatment of BC. In this unselected population, the lack of response to trametinib resulted in early closure. The PFS and OS for trametinib were inferior to 5FU. Clinical trial information: 02042443.

ARQ 087, an oral pan-fibroblast growth factor receptor (FGFR) inhibitor, in patients (pts) with advanced intrahepatic cholangiocarcinoma (iCCA) with FGFR2 genetic aberrations. *First Author: Vincenzo Mazzaferro, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: FGFR genetic aberrations have been implicated in the development and progression of a number of solid tumor types, including iCCA. Pts with unresectable advanced iCCA who relapse after first-line chemotherapy have limited treatment options with poor prognosis. Recently, FGFR2 fusions, observed in up to 20% of pts, have been recognized as a potential therapeutic target. ARQ 087 is a multi-kinase inhibitor with a potent pan-FGFR activity. **Methods:** 119 cancer pts were enrolled in the phase 1/2, open-label study of ARQ 087. Study design and results of the phase 1were reported previously. Assessments included response by RECIST v1.1 every 8 wks, safety (physical examination, vital signs, ECOG PS, laboratory tests), plasma concentrations of phosphate and FGF19, 21 and 23 (potential biomarkers). **Results:** As of 1Feb17, 35 iCCA pts with FGFR2 genetic aberrations were treated with ARQ 087 300 (n = 33) or 400 mg (n = 2) daily. FGFR2 status was identified by FISH or NGS, 29/35 pts were FGFR2 fusion positive (FISH n = 15/18; NGS n = 14/17). Pts were all white, female (60%) with ECOG PS 0 (69%) and median age 58 yrs (31-82). Median number of prior systemic therapies was 1(0-6). Drug-related AEs (all grades) were reported in 89% of pts; the most common (≥10%) included nausea (37%), dry mouth (29%), asthenia (26%), fatigue, vomiting (23%, each), abnormal LFTs, dysgeusia (20%, each), alopecia, diarrhea, vision blurred (14%, each), and conjunctivitis (11%). Grade 3/4 AEs occurring in ≥2 pts were asthenia and abnormal LFTs (6%, each). AEs were mostly (71%) of mild to moderate intensity, manageable and reversible. Median time on treatment was 183 days (95%CI: 166-289). 19 pts were on treatment for > 16 wks, nine are ongoing. 30 pts had at least one post-treatment radiographic assessment: 6 (20%) had PR (32-47% tumor reduction, all FGFR2 fusion positive), 17 SD (7 had tumor reduction between 10 to 25%), and 7 had PD. One pt died prior to scheduled assessment and assessment in 4 pts is pending. **Conclusions:** ARQ 087 demonstrated encouraging antitumor activity and manageable safety profile. Updated data, including safety, efficacy and biomarkers will be presented. Clinical trial information: NCT01752920.

A phase II trial of gemcitabine (G), cisplatin (C), and nab-paclitaxel (N) in advanced biliary tract cancers (aBTCs). *First Author: Rachna T. Shroff, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BTCs are often diagnosed at an advanced stage and have a poor prognosis. The standard therapy for aBTCs is the combination of GC. However, the median overall survival (mOS) is dismal at 11.7 months (mos) with a median progression free survival (mPFS) of 8 mos. **Methods:** A single arm, phase II study was conducted at MD Anderson and Mayo Clinic Arizona. Patients (pts) with aBTC were treated at initial dose level of G/C/N (in mg/m^2) at 1000/25/125 (n = 27) which was reduced to lower doses due to grade 3/4 hematological (heme) toxicity (tox) - G/C/N: 800/25/100 (n = 33). Cycles were q21 days with restaging q3 cycles until progression. PFS was the primary endpoint (endpt). Using a Bayesian hypothesis test-based design, we assumed mPFS of 8 mos under the null hypothesis (H0), 10 mos under the alternative (H1). Secondary endpts included mOS, RECIST v1.1 response rate (RR), safety and CA19-9 response. **Results:** 60 pts were enrolled with data on 51 available as of the time of this abstract (age: median 60 yrs [range 31-77], ECOG PS 0/1 (17/34), M/F (30/21), intrahepatic cholangiocarcinoma/extrahepatic/gallbladder (32/8/11). Median follow-up was 11.5 mos and median number of treatment (trmt) cycles = 5. Pts at initial dose level had significant grade 3/4 heme tox: neutropenia, febrile neutropenia, anemia, and thrombocytopenia leading to trmt discontinuation in 6/27 pts. After dose reduction to G/C/N (in mg/m^2) at 800/25/100, trmt was better tolerated with only 4 pts experiencing grade 4 heme tox. Non-heme tox were grade 3 in 10 pts: nausea/vomiting, diarrhea, thromboembolic event/CVA, hypokalemia, constipation, cystitis, LFT elevations. In the initial 51 pts, mPFS = 11.4 mos (95% CI: 6.1, not reached) and mOS not reached (estimated > 20 mos, 1-year survival rate 66.7%; 95%CI: 65.9-92.2%). 34 pts evaluable for response: disease control rate (PR+CR+SD)-82.3% and RR-32.3%. 3 unresectable cases were operated post trmt with 1 pathologic CR. **Conclusions:** The combination of GCN was well tolerated at adjusted doses and demonstrates encouraging preliminary efficacy having met its mPFS endpt and a 1-year survival rate higher than historical control. These results merit evaluating GC +/-N in a randomized controlled study. Clinical trial information: NCT02392637.

Intergroup phase III trial of neo-adjuvant chemotherapy, followed by chemoradiation and surgery with and without cetuximab in locally advanced esophageal carcinoma: First results from the SAKK 75/08 trial. *First Author: Thomas Ruhstaller, Kantonsspital, St. Gallen, Switzerland*

Background: We compared chemoradiotherapy followed by surgery with the addition of neoadjuvant and adjuvant cetuximab (cetux) in patients with esophageal carcinoma. **Methods:** Pts with resectable esophageal cancer (T2N1-3;T3-4aNx) received two cycles of induction chemotherapy (docetaxel 75mg/m2, cisplatin 75mg/m2) followed by chemoradiation (45 Gy, docetaxel 20mg/m2 and cisplatin 25mg/m2 weekly) and surgery or the same treatment with addition of neoadjuvant cetux 250mg/m^2 weekly and adjuvant cetux 500mg/m2 bi-weekly for three months. Primary endpoint was progression-free survival (PFS). After a median follow-up of 4y 166 of the planned 180 events occurred (plateau reached). **Results:** 300 pts were treated between 2010-13: 88% male, median age 61y, 63% adenocarcinoma, 85% cT3/4a, 90% cN+. 84% completed neoadjuvant therapy, 87% were operated (cetux: 89%, control: 86%), 67% started and 50% completed adjuvant cetux-therapy. The R0 resection rate was 95% in the cetux-arm and 97% in the control-arm, there were 10 and 14 treatment-related deaths and 9 and 4 postoperative in-hospital deaths, respectively. Major differences in adverse events (grade >2) with addition of cetux were higher rate of allergic reactions and hypomagnesemia, but lower rate of dysphagia (-15%) and esophagitis (-4%) during chemoradiation. **Conclusions:** The addition of cetuximab to a multimodal therapy showed a statistically significant reduction of loco-regional recurrences which led to a statistically non-significant, but clinically relevant improvement of PFS and OS. Clinical trial information: NCT01107639.

	Control-arm	Cetux-arm	Log-rank test p-value	Hazard ratio (HR)
Progression-Free Survival				
Median PFS (mo)	24 (18 – 34)	35 (24 – nr)	p = 0.13	HR = 0.79 (0.58 - 1.07)

A randomized phase III trial on the role of esophagectomy in complete responders to preoperative chemoradiotherapy (CRT) for esophageal squamous cell carcinoma (ESCC). *First Author: Sook Ryun Park, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea*

Background: To investigate the role of esophagectomy in pts who achieved clinical complete response (cCR) with CRT for locally advanced ESCC. **Methods:** Pts with resectable cT3-T4a anyN M0 or anyT N+ M0 thoracic ESCC, 20-75 yrs, and ECOG PS ≤2 received 2 cycles of induction XP (capecitabine 1000 mg/m^2 bid D1-14 + cisplatin 60 mg/m^2 D1 q3w) followed by CRT (50.4 Gy/28 fx, X 800 mg/m^2 bid x 5 d/w and P 30 mg/m^2 weekly). Pts with cCR were randomized to surgery (S) or observation (O). The primary endpoint was disease-free survival (DFS). **Results:** From Nov 2012 to March 2016, 86 pts (17.7% of the target number) were enrolled. The slow accrual caused early closure of the study. 81 pts completed CRT, and 38 pts (44.2%) achieved cCR among whom 37 pts were randomized to S (n=19) or O (n=18). The compliance rates differed between the allocated arms (68.4% in the S arm vs 100% in the O arm; *P*=0.020). In both Intent-to-treat (ITT) and as-treated analysis, there were no significant differences in DFS, PFS, TTP, and OS in both arms although the S arm tended to have better DFS, PFS and TTP than the O arm (Table 1). In the as-treated analysis, the relapse rate was 23.1% (3/13) in the S arm and 45.8% (11/24) in the O arm (*P*=0.288). All 10 locoregional only relapse in the O arm were considered resectable, of whom 8 pts underwent surgery (n=7) or endoscopic dissection (n=1). In the as-treated analysis, the S arm had a higher R0 resection rate (92.3% vs 42.9%; *P*=0.031) and lower pTNM stages (*P*=0.0005) than the O arm. **Conclusions:** Watchful waiting might be a valuable option in pts with thoracic ESCC who have cCR to CRT. Further large-scale studies are necessary to confirm our results and to optimize treatment decision in the individual pt. Clinical trial information: NCT01740375.

Survival outcomes between the surgery and observation arms.

	ITT Analysis			As-Treated Analysis		
	S (n=19)	O (n=18)	P	S (n=13)	O (n=24)	P

4021 Poster Session (Board #13), Sat, 8:00 AM-11:30 AM

Phase III study of individualized intraperitoneal/intravenous/oral chemotherapy compared with standard intravenous/oral chemotherapy in patients with advanced gastric cancer. *First Author: Yang Yang, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University and Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: Tumor mRNA expression levels may have a promising role as potential predictive biomarkers for chemotherapy. Intraperitoneal (IP) chemotherapy provides sustained high local concentrations, and its efficacy has been shown in ovarian cancer and gastric cancer patients with peritoneal metastasis. We developed a regimen combining IP/intravenous(IV)/oral chemotherapy for the treatment of advanced gastric cancer patients with individualized chemotherapeutics according to mRNA expression. This multicenter phase III study evaluated the efficacy of individualized multi-route chemotherapy compared to standard systemic chemotherapy. **Methods:** Eligibility criteria included pathologically confirmed advanced gastric adenocarcinoma, and no prior chemotherapy. Patients were randomized 3:1 to an individualized arm (IN) and standard arm (ST). Randomization was stratified by center. Patients in individualized arm first underwent mRNA expression (BRCA1/TOPO1/TS) to choose sensltive chemotherapeutics from oxaliplatin/cisplatin/docetaxel/irinotecan/S-1 and then received individualized IP/IV/oral chemotherapy. The primary endpoint was overall survival (OS). Secondary endpoints were response rate, progression-free survival (PFS), and safety. **Results:** Between April 2013 and December 2015, 231 patients were enrolled, and 218 patients were included in the efficacy analysis. Baseline patient characteristics were balanced between the two arms. The median OS for IN and ST were 16.3 and 14.1 months, respectively (adjusted hazard ratio [aHR] 0.77, 95% confidence interval [CI] 0.61-0.98, $p < 0.05$). The overall response rate was 44.0% in the IN arm, and 33.9% in the ST arm ($p < 0.05$). Both regimens were tolerable. **Conclusions:** The primary analysis showed the statistical superiority of the individualized multi-route regimen. It suggested clinical efficacy of this regimen in patients with advanced gastric cancer. Clinical trial information: ChiCTR-IPR-15006201.

4022 Poster Session (Board #14), Sat, 8:00 AM-11:30 AM

Clinical impact of microsatellite instability in patients with stage II and III gastric cancer: Results from the CLASSIC trial. *First Author: Yoon Young Choi, Yonsei University Health System, Seoul, Republic of Korea*

Background: The clinical implications of microsatellite instability (MSI) in gastric cancer are unclear. We investigated the usefulness of MSI status as a predictor of prognosis and responsiveness to adjuvant chemotherapy in patients with stage II and III gastric cancer. **Methods:** Tumor specimens and clinical information were collected from patients enrolled in the CLASSIC trial, a randomized controlled study of capecitabine plus oxaliplatin-based adjuvant chemotherapy. Five mononucleotide markers were used to assess tumor MSI status. **Results:** Of 592 specimens, 36 (6.1%) were MSI-high (MSI-H), whereas others were MSI-low or microsatellite-stable (MSS). Among 286 patients not treated with adjuvant therapy, those with MSI-H tumors had a better 5-year disease-free survival rate than did those with MSI-low/MSS tumors (hazard ratio adjusted by age, sex, tumor grade, disease stage, tumor location: 0.244 [95% confidence interval, 0.069–0.867]; $p = 0.0292$). Among 306 patients who received adjuvant chemotherapy, MSI-H status did not correlate with better disease-free survival (adjusted hazard ratio: 0.561 [95% confidence interval, 0.190–1.654]; $p = 0.2946$). Benefits from adjuvant chemotherapy differed by MSI status; although adjuvant chemotherapy improved disease-free survival among patients with MSI-low/MSS (adjusted hazard ratio: 0.634 [95% confidence interval, 0.485–0.828]; $p = 0.0008$), no benefit was observed in the MSI-H group (adjusted hazard ratio: 1.877 [95% confidence interval, 0.284–12.390]; $p = 0.5130$). **Conclusions:** Among patients with stage II and III gastric cancer, a MSI-H status correlated with a favorable prognosis, and adjuvant chemotherapy benefited those with MSI-L/MSS tumors but not those with MSI-H tumors.

4023 Poster Session (Board #15), Sat, 8:00 AM-11:30 AM

PD-L1 expression and response to neo-adjuvant chemotherapy in esophageal adenocarcinoma. *First Author: Eileen E. Parkes, Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom*
